
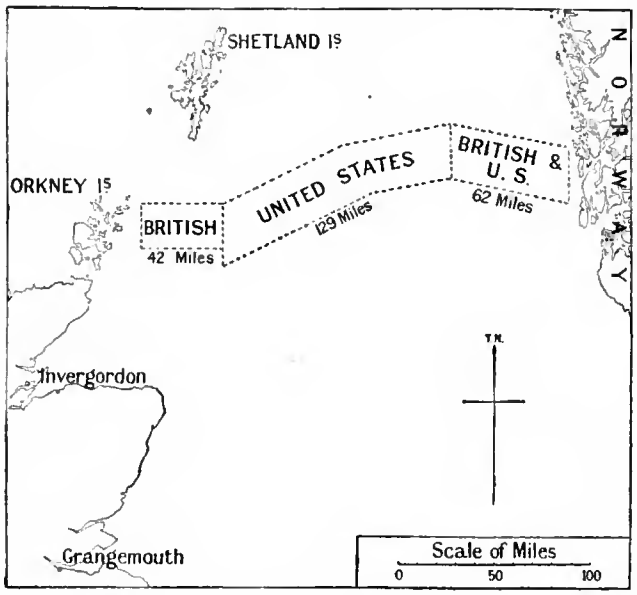

FIG. 1.—Plan of the great northern mine barrage, consisting of 63,117 mines. Laid in 1918 by British and U.S. submarines.

the Straits of Dover; but the mines dragged and had to be swept up. It was, however, relaid by the end of July 1917. In Jan. 1917 it became essential to encircle the Heligoland Bight and thus to surround all exits from German ports; but the shortage of mines at the time caused the operation to be postponed, nor was the British mine considered suitable for it. However, towards the end of 1917 the "Abdiel" and five minelaying submarines had laid nearly 16,000 mines in the German Bight; and these accounted for a certain number of German destroyers and minesweepers. The mine used in the later stages of this operation was the new British H2, which, except for its method of taking depth, was similar in principle to the German Carbonit mine.

The German method of depth-taking was for the mine, attached to the sinker, to drop to the bottom, where, after a short interval for the purpose of safety, the mine released itself from the sinker and rose to the depth for which it was set. In the British method the mine did not go to the bottom; it did not, in fact, go below the depth for which it was set. The sinker regulated the depth while the mine was still on the surface; then, in sinking, pulled the mine down to its required position. An advantage of the British system was that heavy water pressure on the mine-case was obviated; but, on the other hand, it did not obtain the exceptional accuracy in depth-taking which was noticeable in the German method. In due course the new H2 mine was delivered in sufficient quantity for the long-delayed defensive minefields to be begun by the British, and an extensive new barrage in the English Channel was then completed. Between Folkestone and Cape Gris Nez 9,500 mines were laid in 20 parallel lines, the shoals of the Varne and the Ridge dividing the area into three sections. This barrage effectively closed the Channel exit to the German submarines, nine of which were lost in attempts to pass it.

Minelaying by the United States.—The entry of the United States into the War admitted of a large augmentation in mines and in minelayers; and an attempt was made to close the northern exit from the North Sea by a mine barrage between the Orkneys and the Norwegian coast (see fig. 1). This operation was undertaken by both British and U.S. minelayers. The latter formed a base at Inverness, and supplied ten large minelayers with a total carrying capacity of over 5,500 mines. The United States used a mine of a novel type. It carried the usual charge of 300 lb. of tri-nitro-toluene, but from each mine there extended antennae for a distance of 35 ft. which, if touched by a metal ship, exploded the mine. The result was that the danger zone was largely increased.

The vast area covered by mines can best be appreciated by a reference to the plan, which gives an idea of the work carried out by the U.S. minelayers. Difficulties were encountered as the operation proceeded. A proportion of the American mines exploded prematurely; while a number of British mines took up a shallower depth than intended, and had to be swept up and relaid. The complete operation, however, was finished by June 1918. It must not be supposed that the whole water available for a submarine was effectively covered by this minefield; but the dangerous area was greatly increased and an effect on the morale of the Germans quickly produced. In July German submarines began to creep past in Norwegian waters; but the Norwegians closed this coastal lane to both belligerents by minefields of their own. Of the mines laid in the Northern Barrage 56,571 were American and 13,546 British. All this time the encircling of the Bight had been going steadily on, and some 21,000 mines were in place by the date of the Armistice. During the period of the War, approximately 160,000 mines were dropped in the North Sea and Channel by the British and American minelayers, the very great majority of which were laid during the last 18 months of the War.

II. MINESWEEPING

Before the outbreak of War in 1914 the British Navy had, to some extent, realised the possibility of a mining offensive on the part of their enemies; and, largely due to the foresight of the late Admiral Lord Charles Beresford, trawlers had been tested and had proved efficient minesweepers as early as 1907. A trawler reserve purely for minesweeping was instituted shortly afterwards. Thus, by Aug. 8 1914, 96 hired trawlers had put to sea to sweep up enemy mines, and within a fortnight another 100 trawlers had been requisitioned and were fitting out. The trawler minesweeper, however, did not entirely cover the requirements, as it was too slow to sweep the water ahead of a moving fleet; and this had been realised, and to some slight extent, catered for, by training a flotilla of eight old torpedo-gunboats. These ships were capable of towing the sweep at 12 knots, which was double the speed at which the majority of the trawlers could operate. This gunboat flotilla moved north from Dover on July 31 1914, and, with sweeps out, actually covered the track over which the Grand Fleet passed. They were necessarily much overworked in the first six months of the War, as, whenever practicable, they swept the waters through which the fleet moved, and were also constantly required to search areas where mines were expected to be laid. Fortunately no mines were laid near the bases of the fleet until much later, when this small flotilla had been considerably augmented.

Methods of Sweeping.—At the outbreak of War, the British system of minesweeping was for two vessels to tow a stout wire between them, the wire being kept at the required depth by means of water-kites. The towed wire, termed the sweep, thus came into violent contact with the mooring-rope of a mine, which it generally broke, causing the mine to come to the surface, when it could be sunk by rifle-fire. In some cases, however, the sweep would strike a horn of the mine, and explode it. This occasionally led to the parting of the sweep and consequent delay while a new wire was passed. The most serious drawback was

if the sweep failed to break the mine wire, when the mine would be towed along, more often than not unknown to the sweepers. This latter trouble caused many of the early minefields to be scattered far beyond the limits in which they were laid, and constituted a serious danger. The eventual safeguard was to heave the sweep slowly in, and to sight the whole wire and water-kites on the surface before slipping it, when a mine holding to the wire would be seen and reswept afterwards. The innovation of a serrated form of sweep wire eventually reduced the difficulty to a considerable extent. This simple method of minesweeping stood the test of the whole War, and its simplicity had the great advantage of reducing the training period which would have been necessary had a more complicated apparatus been used.

The French towed from a single vessel two sweeps, one on either side, each kept out by an otter similar to the usual otter used in trawling, but regulated for depth by attachment to a large torpedo-shaped float, the depth at the other end being regulated by a water-kite. Along each wire was distributed a series of small mechanical and explosive wire-cutters. The "shooting" of these sweeps caused trouble unless the crews were adept, and the speed at which the apparatus could be towed was limited to six to seven knots. The spread of the British system was 400 to 500 yd. per pair according to the type of minesweeper, that of the French system not more than 200 yards. In the latter part of the War the Americans adopted the French method, which had by then been somewhat simplified.

The German system was akin to the British, excepting that, in order to cover the route of their fleet more quickly, they instituted a very light form of sweep which could be towed at 20 knots. Directly this apparatus met with an obstacle it was automatically slipped, thus giving notice of the obstruction, whereupon the slower type of sweepers were hastened to the spot to clear it. In practice this system constantly led the fast sweepers to report mines when they had only encountered wrecks or some other harmless obstruction, and little confidence was therefore placed in the reports of mines by this fast flotilla.

Under ordinary cruising conditions, searches by sweepers were made whereby only a small percentage of the water was covered—sufficient, however, to allow a strong probability of the presence of mines being discovered in good time. The introduction of the "paravane," which protected the ship herself, very much reduced the mine danger; but men-of-war were not fitted with this device until 1917, nor by the end of the War was it general in merchant ships. The paravane is an apparatus which, for assured efficiency, requires skilled handling. There are situations where its use is impracticable, and it has not replaced the necessity for the minesweeper.

Early Difficulties.—The War was only a day old when the first mining operation was undertaken by the Germans. An armed merchant ship, the "Königin Louise," laid a large minefield off Southwold, at a distance well outside British territorial waters. The "Königin Louise" was sunk, but H.M.S. "Amphion" struck a mine after the action. This minefield caused considerable loss to merchant ships, many of which were neutrals. It also led to early losses of minesweeping trawlers, in which the mortality was heavy. Throughout the War, an average of half of the crew of a trawler was lost when one was mined. For the first two months of the War, for every two mines swept one trawler was lost. Improved method and greater experience later minimised the losses, until an average of one loss for every 80 mines was achieved in 1918; but the effect on shipping in the early days was such that any form of flotsam was reported as a mine.

The outcry for minesweepers became universal, and more trawlers were requisitioned. In Great Britain there was no lack of volunteers from the fishermen, nor of officers from the Naval and Naval Volunteer Reserves; but all of these were untrained in minesweeping, efficiency in which was proving so essential. By Sept. 1 1914 little had been done with the Southwold-Aldeburgh minefield, other minefields were suspected, insurance rates were rising, and the situation had become grave. A rear-admiral was appointed as Admiral of Minesweeping on the East Coast. The immediate situation was dealt with by the institution of a channel close to the coast, buoyed adequately and swept continuously. Merchant shipping was instructed to pass close to the line of buoys; but the organisation requisite to insure this information reaching all the ships, and the difficulties of enforcing obedience, were not overcome for a considerable time. The losses were reduced to a slight extent, however; and when this channel was extended from Dover to the Firth of Forth, and the organisation was perfected, losses by mine were the exception. Against the British Fleet no mines were laid during the first year of War; but the situation in mined localities had emphasised the necessity for a larger Fleet Sweeping Flotilla, and a number of special vessels, termed sloops, were laid down.

Details of Minefields.—The actual minefields laid by the Germans between Aug. 5 1914 and Aug. 5 1915 were as follows:—

1914	Aug. 5	Aldeburgh-Southwold . . .	180 mines
1914	Aug. 26	off Humber	200 mines
		Tyne	194 mines
1914	Oct. 26	Tory I. (Ireland)	200 mines
1914	Nov. 3	Smith's Knoll	130 mines
1914	Dec. 16	Scarborough	100 mines
1915	April 4	Swarte and Indefatigable Banks .	360 mines
1915	May 16	E. Dogger Banks	480 mines

These mines were all laid by surface vessels, and accounted for a heavy toll in merchant vessels and minesweepers.

At the entrance to the Dardanelles minesweeping had to be carried out under heavy shellfire. At first only slow trawlers were available, and night clearing was never a practicable operation.

Growth of the British Minesweeping Force.—In British home waters the augmentation of the minesweeping force was less difficult than abroad. Light-draft excursion (paddlers) were requisitioned in addition to the newly built craft already mentioned, and by April 1915, over 150 vessels purely for minesweeping were distributed as follows: Grand Fleet—6 gunboats, one new sloop and 10 trawlers. Scotland—47 trawlers. Humber—6 paddlers, 30 trawlers. Lowestoft—47 trawlers. Harwich—33 trawlers. Dover—12 trawlers. South Coast—24 trawlers. West Coast—4 trawlers. Clyde—6 paddlers. In the Dardanelles 8 cross-channel steamers had augmented the trawler force, and destroyers had been fitted for minesweeping.

The Submarine Minelayer.—Up to June 1915 all minefields had been laid by surface vessels; but in this month came the first effort of the submarine. A small type, termed U.C. boats, working from Zeebrugge, with Bruges as a mine-depôt, commenced laying batches of 12 mines held in vertical shoots, at first between Dover and Harwich, and later over a wider area. During 1915 54 cargoes (648 mines) were laid in this manner. The effect was a serious increase in British losses by mine, which comprised 5 supply ships, one hospital ship, 2 Trinity House vessels, 34 British steamers, 24 neutrals, 10 fishing boats, and 15 minesweepers, a total of 100 vessels. A useful form of night-sweep came into use against this menace, consisting of a light wire, a depth float kite and explosive grapnel. It was to some extent similar to the German high-speed sweep, and prone to the errors of the latter. No fully efficient minesweep for use in the dark hours was evolved in the War, although this light wire served for searching purposes on several occasions when shipping was forced to arrive at a port at daybreak. In June 1915 the Germans had also extended their minelaying to Archangel, where a unit of six British trawlers was dispatched to assist the Russians. They destroyed 150 mines in this locality under severe conditions of service.

Mining Against the Grand Fleet.—The first mining offensive against the Grand Fleet occurred in Aug. 1915, when 380 mines were laid in the entrance to the Moray Firth, distributed over lines which totalled nearly 70 miles. A large portion of the fleet was at Invergordon at the time. The results were negligible, the losses being confined to minesweepers and one destroyer. A channel was found to be clear on the northern side of the Firth, which was at once used as an exit for the fleet. On the southern side, however, a channel was cleared, but an area of mines was purposely left to form a defensive barrier and so limit the water necessary for patrol and minesweeping. On Jan. 1 1916 the

area west of Scapa Flow was mined by the "Moewe" on her passage into the Atlantic. In this field 252 mines were laid, endangering an area of 40 sq. m., which resulted in the loss of H.M.S. "King Edward VII." before the presence of mines was realised. Once located, this area was treated in the same way as the Moray Firth.

Progress in 1916.—By the beginning of 1916, 14 sloops had joined the Grand Fleet, and 35 hired paddlers were in action. The success of this latter type led to 24 being laid down by the Admiralty, and also a new type of twin-screw sweeper, known as the "Hunt" class. The value of these ships lay in their sea-keeping qualities and shallow draught. The paravane also passed its test in 1916, and by the end of the year had been supplied to 180 of H.M. ships. Shaped like a torpedo, it contained mechanism for accurate depth keeping at any appreciable speed, and was capable of carrying a heavy wire cutter on the nose, or, when used against a submarine, an explosive charge. As a mine-protection it was towed from a sliding "shoe" which worked up and down the stem of the vessel. The paravane automatically ran out from a ship under way, stretching the wire rigidly at an angle of about 50 degrees to the fore and aft line of the ship. Towed from the point of greatest draught, the wire protected the whole of the ship from a mine; for, on coming in contact with a mine mooring, this wire deflected the mooring until it entered the cutter on the paravane, which instantly functioned. The mine then came to the surface clear of the ship. A modified form of this apparatus was fitted in merchant vessels; and, by the end of the War, 2,740 merchant ships had been fitted. Paravanes in H.M. ships cut 55 mine moorings, but the number cut by merchant ships was less.

The number of German submarine minelayers increased in 1916, and there were larger boats operating over a still wider area. These carried 18 mines. As further construction improved, the number of mines carried rose to 24, and in 1917, to 36. The larger boats worked from the Elbe, and the smaller from Flanders. On May 29 1916, U75 laid her 18 mines close to Marwick Head, off the northwest coast of Orkney. The operation was part of the pre-Jutland submarine actions of the enemy. It is understood that a mining operation on the western exit from Scapa was intended, with a view to crippling the Fleet should it use that exit. The contour of the coast near Marwick and that off the western entrance to Scapa, a few miles to the southward, are very similar, and a mistake in the landmarks was possibly made by the submarine commander. In view of the time elapsing between the laying of the mines and the sailing of H.M.S. "Hampshire" from Scapa Flow for Russia, it would seem obvious that the position chosen is not susceptible of a tactical explanation. Sixteen mines from this batch were swept up directly afterwards in this position, and one was recovered set for a depth of seven metres. (It transpired, after the War, that all these mines were set for this depth.) The tide was appreciable, causing sufficient "mine dip" to insure the mines at this depth being innocuous even to a heavy-draught ship, except at low slack water, and with considerable motion on that ship. The period of slack water was extremely limited. The "Hampshire," proceeding in a sudden gale, and hugging the shore to obtain less sea, struck one of the mines at low-slack water. By this curious conjunction of all these factors, the career of Lord Kitchener was brought to a tragic close. Except for a determined offensive by the Flanders submarines against the Channel Ports, the mine was not extensively used in the latter part of 1916. It would appear that the Germans were then husbanding their resources for unrestricted submarine and mine warfare.

Changes in the British Service.—The reorganisation of the British naval staff in May and June 1917 led to considerable changes in the minesweeping service. The rear-admiral, who had throughout 1916 been very fully employed in concentrating on the paravane and other improvements of minesweeping material, now took over the Dept. of Torpedoes and Mines, which included the technique of minesweeping devices. The control of operations was therefore entirely separated and delegated to a captain on the naval staff, who, in Oct. 1917, became Director of the Minesweeping Div. under the assistant chief of the naval staff. The whole of the minesweeping, then so greatly extending in area, was thus co-ordinated under a central control at the Admiralty.

The intensity of minelaying and expansion of areas in the first half of 1917 was difficult to meet with the minesweepers available; and the climax was reached in April, with a loss of one minesweeper per diem for the greater part of that month. Probably no other service had a more severe strain placed on its personnel during this month and those immediately following. Every available and suitable paddle steamer and motor fishing boat had to be requisitioned; and those incapable of towing a heavy sweep were fitted with a light one, and used for search. Aircraft and motor launches were also used for low-water searches for mines, in order to reduce losses of sweepers; and improvements in traffic organisation and still closer co-operation between adjacent areas were gradually effected. Further protective minefields were laid in certain suitable positions, but the opening of new areas was constantly necessary; and, by the end of 1917, the coastal waters of Great Britain and Ireland, over 1,000 m. in extent, were being swept every day for mines. The war channel was also extended to the Firth of Forth, and merchant ships only released from a night shelter when they could proceed in freshly swept water. One hundred new vessels of the "Hunt" class were laid down, and 300 new drifters put out to contract, so as gradually to replace and release trawlers for patrol and anti-submarine work.

Synchronous mining of adjacent British ports was resorted to by the Germans, which raised many sudden problems in traffic control. The convoy system had now been introduced, and the sweeping of convoys into certain ports often became essential. Particular difficulties arose in regard to Liverpool owing to the shallowness of the channel and narrow entrance; mines swept up, and sunk without exploding, causing serious danger to heavy draught ships by their proximity to the ship when resting on the bottom.

The south coast of Ireland was seriously and continuously mined, and even the bays on the west coast of Ireland did not escape. The year closed with a total of 3,089 German moored mines swept up in home waters, at a cost of 170 Allied and neutral merchant ships sunk and 28 damaged. This total of mines for the year exceeded the combined totals for the previous years of the War. Nevertheless, the outlook was more hopeful. Although the intensity of minelaying had become so much greater, the losses had only been increased by nine ships over those of the previous year: and progressive success in the destruction of submarines and their personnel made it evident that the same intensity and efficiency of the minelayers could not be continued much longer. New construction and greatly improved material for minesweeping had already made their mark. The only fear was that the minesweep would be defeated by some innovation of the enemy. This fear, however, never materialised; although a delayed action (intentional or otherwise) for releasing the mine from its sinker some hours after it was laid was observed on several occasions.

While minelaying had, in home and Mediterranean waters, now been confined to submarines, the "Wolf," a surface raider with 458 mines, succeeded in breaking through the patrols into the Atlantic. Her voyage lasted 15 months. Rounding the Cape of Good Hope, she cruised in the Indian Ocean, then proceeded south of Australia to New Zealand and Fiji; and returning by New Guinea, the Dutch East Indies and the Cape, she reached the Cattegat again in safety. Her mines were distributed all over the globe; and, although the losses caused by them were comparatively light, it was very difficult to obtain suitable sweepers in the various areas to locate and destroy them. It was, in fact, not until the Armistice that all the localities were defined.

End of the Mining Offensive.—The beginning of 1918 saw the defeat of the great mining offensive completed; and by the end of hostilities no more than a dozen efficient German minelaying submarines existed. Their losses had by then completely outstripped new construction, and a well-trained or experienced personnel was entirely lacking. Of the many factors which, taken

together, finally killed the minelayer, the most important were: (1) the great efficiency of relaid Dover barrage; (2) the deep minefields in localities regularly used by minelayers; (3) improvements in anti-submarine methods of hunting; (4) co-operation between the Intelligence and Minesweeping divisions; and (5) the distribution of information. In 1918 the average time elapsing from the receipt of the news of a new minefield to its distribution to every base, and to all vessels within the area of wireless communication, was 75 minutes. As a result of these improvements, the total losses by mine during 1918 in home waters were reduced to an average of just two over Allied or neutral merchant ships per month.

Early in 1918, an appreciation of failure led the Germans to concentrate their efforts in minelaying in two directions only. The first was a grandiose scheme, which, commencing in January, was only concluded in late September. It consisted of batches of 36 mines, laid at regular intervals of 10 m. apart on a semicircle 45 from. m the Bell Rock, the result being a complete ring round the entrance to the Firth of Forth. This operation fulfilled a two-fold purpose. It menaced the exit and entry of Norwegian convoys, which were then working from Methil in the Firth of Forth; it also menaced every possible course taken by the Grand Fleet when leaving or entering its base at Rosyth. The scheme, however, was barren of results to the Germans, although methodically carried out in every detail. It was appreciated and countered after the third batch of these mines was discovered, the result being that each of the successive groups of mines was located and cleared immediately; and this was done without the Germans realising that any of these groups had been removed. The other concentration took the form of a field of 400 mines, also laid gradually by submarines. It was directed against the Dutch convoys, and was laid close to the Dutch coast to cover the approaches to the Maas and Ijmuiden. This position was such that any attempts at clearance exposed the minesweepers to a flank attack from enemy vessels. There were some losses by mine, particularly to destroyers escorting the convoys; but the convoys sailed as before, and the losses, on the whole, were very trivial.

Minesweeping after the Armistice.—When the hour of the Armistice struck, a minesweeping force was waiting at the gate of the Dardanelles; and, within 24 hours, 600 British and enemy mines had been removed to clear the way for the fleet to Constantinople. For one year after the War, mineclearing was continuous in every area where British or German mines had been laid. Under the difficult conditions which immediately followed the War, a special minesweeping force had to be enrolled. It consisted of some 600 officers and 15,000 men. Over 23,000 Allied mines and some 70 German mines were cleared from the sea by British minesweepers. No loss of a merchant ship by mine occurred during that period; and exactly one year to the day from the institution of this force the seas round Britain, her colonies and in the Mediterranean were reported clear. A fine performance in this respect was the clearing by the Americans of the mines laid between Orkney and the Norwegian coast. The Germans also commenced to clear the heavily mined areas in the Heligoland Bight, and later in the Baltic; but this work of clearance was not completed until 1923. Other nations concerned cleared their own coastal waters.

MINERALOGY (*see* 18.500).—During the war period of 1914–8 much attention was given in all countries to the development of home resources of various minerals of economic value, and to meet new circumstances new sources of supply were developed. Further, there was an increased demand for certain kinds of minerals, for example those which yield the rarer metals used in the hardening of steel. Much of the mineralogical literature of the period was therefore of an economic character, and many recent text-books gave prominence to the practical uses of minerals. Fortunately, however, pure science was not altogether neglected. Many new facts have been recorded, and new methods of investigation have been devised.

X-Ray Examination of Minerals.—The X-ray method of investigating the internal structure of crystals has been applied with much success to the study of minerals (*see* CRYSTALLOGRAPHY). The material for examination has usually been prepared as definitely orientated crystal plates, but it is found that the results can be obtained with a fine powder, *i.e.*, an aggregate of minute crystals or fragments of crystals with all possible orientations. The method can therefore be used for the purpose of distinguishing between the crystalline and the amorphous or colloidal states. Since each crystallised mineral gives a more or less characteristic series of bands on the photographic film, the powder method may also be used for the recognition of the minerals present in intimate mixtures, such as fine-grained rocks, ores, clays and soils.

X-rays have also been employed in a method of spectrum-analysis for detecting the presence of the various chemical elements present in minerals. For example, hafnium has been detected, and the amount approximately estimated, in many zirconium minerals.

Microscopical Examination of Opaque Minerals.—A method for the investigation of opaque minerals borrowed from metallography (*q.v.*), in which polished sections are examined under the microscope in reflected light, has proved to be especially useful for the study of metallic ores. It consequently finds an economic application in the valuation of ore deposits. The several mineral species of which the ore is composed can be distinguished, and their relations to one another determined; *e.g.*, the order of their deposition, and whether they are of primary or secondary origin.[1]

The process of grinding and polishing the sections presents certain difficulties owing to the extreme differences of hardness of the several minerals that may be present. The prepared section is illuminated vertically by means of a right-angle prism placed in the tube of the microscope above the objective. Details of structure can be brought out by etching the section with various chemical reagents. The several characters (colour, hardness, relief) of the minerals, together with their behaviour towards reagents, help in their determination. But in many cases ordinary simple tests made on fragments detached from the polished surface are more reliable. Electrical tests can be made with quite simple apparatus: for example, the electrical conductivity can be determined with a dry cell and voltmeter using needles as terminals on the polished surface. Certain optical determinations can also be made in reflected polarized light.

One result of this study of opaque minerals is to draw attention to the extremely intimate association and intergrowth of many of the ore-minerals; this is well shown in the numerous photo-micrographs published by American workers in economic geology. What to all appearances by ordinary methods is a homogeneous mineral may be found by the new method to be really heterogeneous; and, in fact, several supposed mineral species have been proved to be mixtures, and well-developed crystals have in certain cases been found to contain enclosures of other minerals. The method is thus of use for ascertaining the degree of purity of material collected for exact chemical analysis when the formula of a species is to be established. The long-debated question as to how silver exists in argentiferous galena (lead-ore) has been studied by this method. Galena containing 0·10 to 0·35% of silver shows definite spots of tetrahedrite and argentite, whilst specimens containing more silver show evidence of later addition of proustite or pyrargyrite in the form of veinlets.

Mineral Transformations.—In synthetical mineralogy a large amount of experimental work has been done, especially in the Geophysical Laboratory of the Carnegie Institution at Washington. Many minerals and allied compounds have been prepared artificially in silicate and salt fusions. The conditions necessary for their formation and their ranges of stability—either when alone or when in the presence of other compounds—have been studied in detail. One important result obtained by experimenting over wide ranges of temperature has been to show that practically all compounds known as minerals exist in several polymorphous forms.

[1] The technique of the subject (called mineralography or mineragraphy) is dealt with in the text-books: J. Murdoch, *Microscopical Determination of Opaque Minerals* (New York, 1916) and W. M. Davy and C. M. Farnham, *Microscopic Examination of the Ore Minerals* (New York, 1920.)

The work has shown that silica (SiO_2) undergoes a remarkable series of changes in its crystalline structure and physical characters when it is submitted to different degrees of temperature. The changes with increasing temperature are:—

α-quartz (rhombohedral trapezohedral), passing at 575° C. into
β-quartz (hexagonal trapezohedral), passing at 870° C. into
β-tridymite (hexagonal holohedral), passing at 1,470° C. into
β-cristobalite (cubic) melting at 1,625° C.

These transformations are reversible, but with falling temperature they take place very slowly. Molten silica unless cooled very slowly solidifies as a glass. β-tridymite when quickly cooled undergoes a change at 163° C. (β_2-tridymite to β_1-tridymite), and at 117° C. passes over into α-tridymite, which is optically biaxial and probably orthorhombic in crystallisation, being identical with the naturally occurring tridymite. Similarly, β-cristobalite when quickly cooled changes at about 180°–270° C. into α-cristobalite, which is optically biaxial (pseudo-cubic) and identical with the cristobalite occasionally found in volcanic rocks.

Now these and many other similar changes give information as to the conditions of temperature under which various minerals were formed in nature, thus providing a "geological thermometer." For example, the presence of tridymite, or of pseudomorphs of the more stable quartz after tridymite, establishes that the rock in which they occur must have been formed at a temperature between 870° and 1,470° C. The quartz of certain veins and that of granite present differences in structure which indicate that the former was formed below 575° C. and the latter above this temperature. Or again, the presence of orthorhombic copper-glance (β-Cu_2S) as a pseudomorph after cubic α-Cu_2S proves that the ore-deposit in which it occurs was formed at a temperature higher than 91° C.

Chemical Composition.—The chemical composition of many minerals is still imperfectly understood, and even for some quite common species there are doubts as to the correct empirical formulae, especially as to the silicates, a satisfactory classification of which is still wanting. Many attempts have within recent years been made to gain some idea as to the constitution of the silicates; there has been much experimental work and plenty of speculation, but with no very definite results. In certain groups, *e.g.*, the feldspars and the garnets, the composition can be satisfactorily expressed on the assumption of the isomorphous mixing of different chemical molecules. But attempts to extend this principle to all silicates often lead to highly complex hypothetical molecules, the existence of which can only be regarded as doubtful. Alternative suggestions have been put forward, such as the "mass effect" of large molecules and the "solid solution" of certain other substances in the main mass of the crystal. Experiments with silicate fusions show that various substances can be taken up, or dissolved, in certain amounts, giving on solidification apparently homogeneous crystals.

Radioactivity.—The strong radioactivity (*q.v.*) of uranium minerals affords a ready means of recognising these valuable ores in the search for them by prospectors. The mineral may be wrapped up with a photographic plate, which is afterwards developed; but a simpler and quicker test is that with a quite simple (home-made) gold-leaf electroscope. A piece of the mineral to be tested is placed on the cap of the electroscope, which is then charged with electricity, readily developed by rubbing with glass or vulcanite (say the mouthpiece of a tobacco-pipe): if the mineral contains uranium (and consequently radium), the gold leaves will soon come together. It is always well to make a comparative test, timing the rate of collapse, with a piece of ordinary stone.

Determinations of the ratio of the amount of uranium to the amounts of the various products of its decay (radium, helium, lead, etc.) present in various radioactive minerals give (knowing the rate of the decay) some idea of the period of time during which these products have been accumulating. In this way estimates have been made of the age in years of these minerals and even of the age of the earth; but, of course, many unknown factors must have been omitted from such calculations. Lead of radioactive origin, or isotropic lead—the final product of uranium decay—is found to vary slightly in its atomic weight (*q.v.*) according to the uranium mineral from which it is extracted.

To radioactivity is ascribed the well-known "pleochroic haloes"—tiny spots or borders of deeper colour surrounding microscopic inclusions—long ago observed in certain rock-forming minerals (cordierite, andalusite, mica, etc.) when microsections of rock are examined in polarised light. The long and continued emission of X-rays from zircon or other mineral grains has caused a change in colour of the surrounding mineral for distances varying from 0·002 to 0·4 millimetre. A study of these has again given some information as to the age of the minerals. In this connection it may be mentioned that much experimental work on the coloration of minerals has been done within recent years by exposing the minerals to the action of radiations of various kinds, including ultra-violet rays, cathode rays, X-rays and the rays emitted by radium salts. For example, some diamonds acquire a green colour and fluorspar becomes blue when placed in contact with radium bromide.

Some New Minerals.—In descriptive mineralogy a considerable number of new minerals have been named, but unfortunately in many cases not completely determined and described. A few of the more prominent and well-established of these are:—

Carnotite.—Hydrated vanadate of uranium and potassium, $K_2O{\cdot}2UO_3{\cdot}V_2O_5{\cdot}nH_2O$, occurring as a canary-yellow crystalline powder impregnating sandstones over a wide area in western Colorado and the adjoining portions of Utah and New Mexico. In Colorado it has been collected on a large scale for the extraction of vanadium, uranium and radium. It has also been found in South Australia and in Pennsylvania; and an allied mineral (tyuyamunite, containing calcium in place of potassium) is known from Tyuya-Muyun in Russian Turkestan.

Germanite.—A sulphide ore mineral containing copper, iron and the rare elements germanium (5–8%) and gallium ($\frac{1}{2}$–$\frac{3}{4}$%). As a massive, reddish-grey mineral intermixed with tennantite it is found in some quantity at Tsumeb in South West Africa.

Kasolite.—A hydrated silicate of uranium and lead, $PbO{\cdot}UO_3{\cdot}SiO_2{\cdot}H_2O$, forming radiating groups of small, ochre-yellow, monoclinic crystals. Together with several other new but imperfectly defined minerals, it occurs as an alteration product of pitchblend at Kasolo in Katanga, Belgian Congo.

Lorandite.—Sulpharsenite of thallium, $TlAsS_2$, forming transparent, monoclinic crystals with a carmine-red colour and adamantine lustre. It is found with realgar at Allchar in Macedonia, and is one of the few minerals that contain the rare element thallium as an essential constituent (Tl 59·5%).

Mullite.—Recent experiments have shown that the only aluminium silicate that can be prepared artificially is the compound $3Al_2O_3{\cdot}2SiO_2$, and not $Al_2O_3{\cdot}SiO_2 = Al_2SiO_5$ (fibrolite) as formerly supposed. The same compound, as minute orthorhombic crystals, has been found in slates fused by igneous rocks in the Island of Mull, Scotland, and has been named mullite.

Patronite.—Vanadium sulphide, VS_4, forming dark greenish-black compact masses. It occurs abundantly at Minasragra, Cerro de Pasco, Peru, where it is a valuable ore of vanadium. It weathers very readily with the production of various highly coloured vanadium compounds; even on material kept in collections there is a slow growth of blue and green efflorescences.

Spencerite.—Hydrated basic zinc phosphate, $Zn_3(PO_4)_2{\cdot}Zn(OH)_2{\cdot}3H_2O$, forming pearly white, scaly cleavage masses and small monoclinic crystals. It has been found in some abundance forming large stalactites in a cavern near Salmo, British Columbia.

Tarbuttite.—Basic zinc phosphate, $Zn_3(PO_4)_2{\cdot}Zn(OH)_2$, forming colourless, or faintly coloured green or red, anorthic crystals, with a perfect cleavage in one direction. It has been found in considerable quantity at the Rhodesia Broken Hill Mine in Northern Rhodesia.

Thortveitite.—Silicate of scandium, yttrium, etc., $(Sc, Y)_2O_3{\cdot}2SiO_2$, occurring as large orthorhombic crystals of prismatic habit in pegmatite in southern Norway and Madagascar. This is the only mineral known to contain the rare element scandium in large amount.

BIBLIOGRAPHY.—Details of descriptive mineralogy are collected in Appendices 1–3 of Dana's *System of Mineralogy* (New York, 1899–1915); and numerical data respecting the constants of minerals are tabulated in the international *Tables annuelles de constantes et données numériques*, 6 vol. (Paris, 1912 etc.). A work of comprehensive character is C. Doelter, *Handbuch der Mineralchemie*, 4 vol. (Dresden and Leipzig, 1912 etc.). An advanced textbook on new lines is P. Niggli, *Lehrbuch der Mineralogie* (Berlin, 1924, with two more volumes to follow). A number of elementary textbooks have been published, *e.g.*, G. A. J. Cole, *Outlines of Mineralogy for Geological Students* (London, 1912); A. F. Rogers, *Introduction to the Study of Minerals* (New York, 1912); E. H. Kraus and W. F. Hunt, *Mineralogy, an Introduction to the Study of Minerals and Crystals* (New York, 1920); H. Buttgenbach, *Les minéraux et les roches* (Paris and Liége, 1924). A popular book with coloured plates is L. J. Spencer, *The World's Minerals* (London, 1911, 2nd ed., New York, 1916). Books of an economic character are H. Ries, *Economic Geology* (5th ed., New York, 1925); T. Crook, *Economic Mineralogy, a Practical Guide to the Study of Useful Minerals* (London, 1921); B. Dammer and O. Tietze, *Die nutzbaren Mineralien* (2 vol., Stuttgart, 1913–4). *Special Reports on the Mineral Resources of Great Britain* have been issued by the Geological Survey, London, since

1915; and a long series of pamphlets, *The Mineral Industry of the British Empire and Foreign Countries* by the Imperial Mineral Resources Bureau, London, since 1920. New journals are *Fortschritte der Mineralogie, Kristallographie und Petrographie*, issued by the German Mineralogical Society, Jena, since 1911; *Beiträge zur Kristallographie und Mineralogie*, ed. by V. Goldschmidt (Heidelberg, since 1914); *Schweizerische Mineralogische und Petrographische Mitteilungen*, Zürich, since 1921. A review of the recent scientific literature is given in the Mineralogical Society's series of *Mineralogical Abstracts*. (L. J. S.)

MINERS' PHTHISIS (*see* 18.541b).—Almost any dust inhaled in sufficient quantity may cause chest trouble of some kind or another, but certain dusts are related to the occupational disease variously known as miners' phthisis, pneumonokoniosis, grinders' rot, potters' rot, stonecutters' rot, etc.

Phthisis-producing Dusts.—Dusts with this association are often referred to as phthisis-producing dusts because pulmonary tuberculosis plays a more or less important part in this disease and is always associated with a fatal termination and usually with disablement. Prof. E. L. Collis has shown that the phthisis-producing dust of far the greatest importance in industry is dust of free silica (SiO_2) and the disease is often known as "Silicosis." For a dust to be phthisis-producing it must be comparatively insoluble and inert and the particles must be minute, say from five microns downwards, or about the size of the common pathogenic micro-organisms. Owing to their minute size these particles may be present in air in dangerous concentration without being visible to the eye or in any other way noticeable to the senses, so in a phthisis-producing industry it is expedient to sample the air for dust as one samples for gas in a "gassy" mine.

The Lungs and Dust.—The lungs have a very considerable power of ridding themselves of inhaled particles, and some dusts, like coal-dust, are much more readily got rid of than others while, in the case of a phthisis-producing dust, accumulation readily gets ahead of elimination, so quite small quantities of air-borne dust may be dangerous. It is owing to this cumulative factor that duration and continuity of exposure are of importance as well as concentration in the air. While the average incidence of miners' phthisis on the gold-mines of the Witwatersrand is under 3% per annum of the underground population the incidence rises as high as 10% per annum in the case of miners of 13 years' service and over.

Dust Cells.—A certain proportion of the fine dust inhaled runs the gauntlet of the upper respiratory passages and gets right down into their minute blind extremities, the alveoli. In silicosis as in pulmonary tuberculosis "lesion means arrest" and the dust particles are arrested by being taken up by certain cells known as dust cells. The dust cells are a variety of the phagocytes of Metchnikoff and, when dust-laden, they aggregate together forming small masses or pseudo-tubercles. These pseudo-tubercles may be found on the alveolar walls, under the pleura and in the lymphatic channels which they obstruct. The dust-containing cells forming the pseudo-tubercles tend to degenerate and become fibrous tissue thus forming the fibroid nodules characteristic of the early stage of silicosis.

Prevention.—It is the fine dust that matters and, in mines where a phthisis-producing rock is dealt with, the chief sources of fine dust are blasting and rock-cutting with machines. From the point of view of prevention, in industries where blasting is practised, the workers should not return to the working-place until after all dust and fume have been blown away. Ventilation with good currents of dust-free air is the great safeguard because, by treating the air-borne dust as a gas, it can be diluted down towards a safe level. What is a safe level? When one has to deal with daily exposure over many years, perhaps about one milligramme of dust per cu. metre of air. The fine dust is only a small proportion by weight of the total air-borne particles, but includes the majority of particles by enumeration. A sample of air-borne dust of 2 milligrammes per cu. metre as determined by the method in use on the Witwatersrand corresponds to about 350 particles of fine dust per cu. cm. of air (counted by Kitze koniometer). The other great safeguard is "working wet" and the chief source of the dust associated with machine drilling is "sludging" with air. When it is practicable to sludge with water only, machines raise much less dust. Water-sprays should be in continuous use and the roof, walls and floor of the working-place kept wet. All broken rock should be thoroughly wetted before moving (*see* MINING).

A machine may be in good order for rock-cutting and in bad order for dust-control and should be inspected from the latter point of view as well as the former. A hand-drill is more difficult to keep in order for dust-control than is the larger machine and it is doubtful if it is possible to secure safe conditions if hand-drills are used dry when cutting phthisis-producing rock. In all phthisis-producing industries, apart from working wet, it is wise to think of the fine air-borne dust as a gas and make every possible use of exhaust-hoods and abstractors; while sources of dust escaping to the air should, as far as possible, be located and enclosed.

There are two important factors in the severe forms of miners' phthisis:—

(1) The phthisis-producing dust.

(2) The tubercle bacillus.

Carriers.—The modern view of pulmonary tuberculosis as met with in the adult population of civilised countries is that it is related to re-infection by the obvious route of inhalation. Under experimental conditions the presence of dust in the air, together with the tubercle bacillus, renders the susceptible animal much more liable to infection by inhalation. It is on account of this association that, in a phthisis-producing industry, one must strive not only to eliminate dust but also to eliminate the tubercle bacillus. The only practicable step towards the latter ideal is to detect and remove the "carrier," *i.e.*, the sufferer from open tuberculosis. For the sake of others as well as for their own, sufferers from tuberculosis should not be allowed to work at a phthisis-producing industry. Tuberculosis, of course, is not a compensatible occupational disease, but it might well be so regarded in a phthisis-producing industry for, although pulmonary tuberculosis is not miners' phthisis, practically all grave miners' phthisis is associated with pulmonary tuberculosis.

Collis, *Industrial Pneumonoconioses*, Milroy Lectures, 1915 (1919); *Annual Reports of Miners' Phthisis Board* and *Miners' Phthisis Medical Bureau*, Department of Mines and Industries, Union of South Africa; *Publications of United States Bureau of Mines*, B132, T.P. 372, etc. (A. MAY.)

MINING (*see* 18.528).—Since 1910 there has not been much change or development in the methods of working as applied to the extraction of mineral ores and other substances from veins and stratified deposits. This is, perhaps, more particularly the case in regard to coal and stratified deposits than of metalliferous ores occurring in veins. The development in respect of the former lies chiefly in the direction of the machinery used in the mines and its application, more particularly at the working face, and especially that used in the getting and transporting the coal at the faces.

In the working of metalliferous veins, while the standard methods of extracting the ore by overhand or underhand stoping have changed little, a more definite classification than existed formerly has grown up respecting the application of these methods to given local conditions. Comparatively thin veins, with a steep pitch (dip), are developed by a series of drifts (levels), and above each of these overhand stopes are opened for extracting the ore, the working being advanced upward. The broken ore is run through chutes (mills or passes) to the level below, in which it is conveyed in trams by hand or mechanical power to the shaft or through an adit (tunnel) to the surface. For thicker veins, especially those with a steep dip, underhand stoping is occasionally employed, the advance being forward and downward toward the haulage level. In the case of flat veins or of bedded deposits breast-stoping is used, the details of which much resemble those of underhand stoping. In all of these methods, the roof of the deposit (hanging wall) is supported by pillars of ore, by props, balks of timber (stulls), by "square-set" timbering or by masses of waste ore and rock (filling) carried by stulls. Sometimes stopes are completely filled with waste.

Shrinkage Stopes.—There are a variety of overhand stopes which have been more widely employed than formerly for both narrow and wide steeply dipping veins. In these stopes the broken ore accumulates until the stope is complete, thus making artificial support for the walls of the stope unnecessary. Since rock when broken increases in bulk, from 25 to 40% of the ore is drawn from the stope as it advances to leave room at the top for the miners, who stand on the broken ore while drilling. This method is applicable only to those cases where the inclination and width of the vein are great enough to allow of the broken ore sliding down freely to the stope floor (footwall). Finally, after all the ore has been drawn off, the stope is allowed to cave in or is filled with waste. In principle, the shrinkage stope is identical with the "battery-breast," commonly used in fairly thick coal seams, when the pitch exceeds about 35° to the horizontal.

Caving Systems.—The prototype of these, long employed in certain British iron mines, is known in the haematite iron ore mines of Lancashire and Cumberland as the caving system. In the United States caving was first used for the soft iron ores of northern Michigan. More recently, it has been extensively applied to the iron deposits of the Mesabi district, Minnesota, and to some large copper deposits in the south-west of the United States. The chief requisites for the successful application of caving methods are: (1) massive deposits of relatively cheap minerals; (2) ore-bodies of large horizontal dimensions, overlaid by a capping varying in character from earthy soil or glacial drift to firm rock; (3) large-scale work. There are three distinct methods: top-slicing, block-caving and sub-level caving. The salient features of all are: (*a*) horizontal subdivision of the ore-body into floors; (*b*) subdivision of each floor into small slices or blocks which are mined separately; (*c*) delivery of the broken ore through chutes to the haulage-ways below and thence to the shafts; (*d*) as the ore is removed, the overlying capping must gradually cave in and settle.

The period 1910–25 was marked by a wider application of the slicing and caving methods, especially for large low-grade deposits of disseminated copper ore. More deposits of this type have been developed and worked in recent years than ever before, many variations in details being introduced to suit the dimensions of the ore-body, its depth below the surface and the character of ore and of the super-incumbent strata or capping. All this has brought a more definite understanding of the applicability and limitations of the caving systems, as determined by existing local conditions.

Some prominent examples of the newer mines, in which different forms of slicing and caving have been adopted, follow.

Inspiration Mine, Arizona.—The ore-body is a massive deposit of disseminated sulphide of copper (calcopyrite), containing about 100,000,000 tons of low-grade ore, and overlaid by a valueless capping, 30 to 350 ft. thick. A variation of the caving system is used, known as "block-caving." The ore-body is intersected at vertical intervals of 150 ft. by main haulage levels, connecting with the

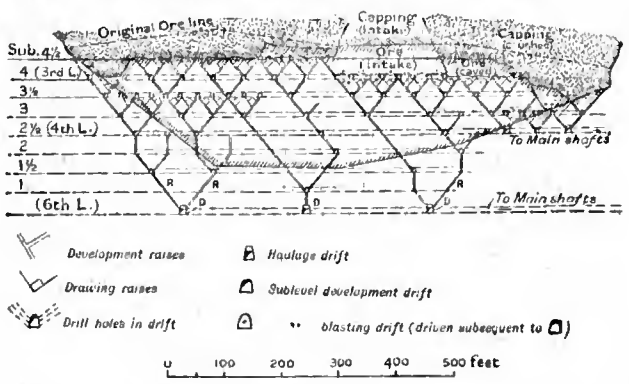

FIG. 1.

winding shafts (fig. 1). Above the haulage levels are long chute-raises, inclined at 50° to the horizontal, from which numerous short secondary raises ("finger-raises") are driven to a system of sub-level drifts, 35 ft. apart vertically and 50 ft. horizontally. The ore developed by the sub-level drifts is thus divided into small "blocks," which are undercut and broken up by blasting out the supporting pillars between the drifts. The broken ore is drawn down through the branching finger-raises underneath, into the main raises and thence to the haulage levels, the flow being controlled by gates. As the upper part of the ore-body is thus removed, the capping caves in on top of the solid unmined ore below. (For full details, see *Trans. Amer. Inst. Mining Eng.*, vol. 55, p. 218: vol. 59, pp. 299, 305; vol. 66, p. 127.) Block-caving, similar to that of the Inspiration mine, is also used by the Ohio Copper Co., Bingham, Utah, and the Nevada Consolidated Copper Co., Ely, Nev.

Arizona Copper Co.—A top-slicing method (fig. 2) is applied to large bodies of soft ore, carrying 2 to 4% copper. A main haulage

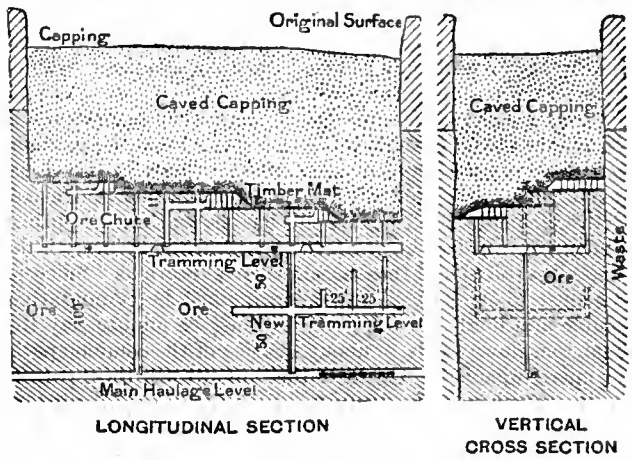

FIG. 2.

road is driven near the bottom of the ore-body, and above it are intermediate working levels, 50 to 60 ft. apart vertically. These comprise a rectangular system of tramming drifts and cross-cuts, from which chute-raises are made into the ore above at 25 to 30 ft. intervals. Starting from the tops of these raises, horizontal slices of ore, 7 to 15 ft. thick, are blasted out and the broken ore is run down through the raises to the tramming level. Thence it is conveyed to the nearest main raise, connecting with the haulage road below. (For details of the slicing operations and the manner in which the overlying capping caves in as the successive slices are removed, *see* 18,532.)

These modifications of top-slicing consist chiefly in making raises from the intermediate tramming levels at short intervals, to minimise the labour cost of handling the ore mined in the slices. In one of the Arizona Copper Co.'s mines a further saving has been effected by omitting the tramming levels and the small raises from them. A main drift is driven longitudinally through the axis of the ore-body, just below the roof or capping, and from it, at right angles, cross-cuts, 40 ft. apart, to the walls. The panels or blocks of ore between the cross-cuts are sliced back from the walls of the ore-body towards the main drift. On each side of the latter a pillar is left, which is finally sliced back from its end, in completing a floor. While one floor is being mined, the next, 11 ft. below, is in preparation. This method of panel slicing has recently been adopted successfully in the Herman gold mine, California. The vein dips 45° to 60°, and the panels are laid out at an inclination of 52°, across the ore-body. Top-slicing is also used in many massive deposits of low-grade copper ore; for example: Cumberland-Ely, Nev.; Cananea, Mexico; Miami, Ariz.; Bingham, Utah; and mines of the Calumet & Arizona Mining Co., Arizona. At the last-named property, the older caving method has been replaced by a modification called the Mitchell top-slicing system, found economical in reducing the shovelling required.

Other Variations.—In a number of important mines working large ore-bodies, special conditions have been dealt with by combining two or more of the methods referred to above. Examples are to be found in the mines of the Braden Copper Co., Chile; New Jersey Zinc Co., Franklin, N. J.; Utah Copper Co. (Boston mine); Ray Consol. Copper Co., Ariz.; Homestake Gold-Mining Co., S.D., and the De Beers Mining Co., South Africa. In most cases, operations begin by shrinkage stoping, after which the intervening pillars are mined by top-slicing, block-caving or sub-level caving, the object aimed at being the getting of as high a toral tonnage extraction as possible, that is, obviating loss occasioned by leaving ore in permanent pillars or through mixture with waste material.

Stripping Superficial Ore Deposits.—This old mode of attacking shallow deposits of large horizontal area was oftener resorted to in the period 1910–25 than previously, and was applied to deeper ore-bodies than formerly were considered capable of being mined by stripping.

Standard Methods.—Standardisation of methods of working when practicable probably promotes efficiency and economy of

operation. Seams of coal and some regular bedded deposits of the base metals, owing to their comparative uniformity of geological occurrence, can be worked to a greater degree by standardised methods than most metalliferous deposits, which vary greatly in their physical characteristics. A notable instance (to the contrary is perhaps that of the Banket deposits of the Rand, Transvaal, which are in the nature of highly inclined beds of conglomerate. (See the useful discussion by C. A. Mitke, "Mining Methods of the United Verde Extension Mining Company, Arizona," *Trans. Amer. Inst. Mining Engs.*, vol. 61, p. 188.) In the three years 1922–5 a "Committee of One Hundred" of the Amer. Inst. Mining Engs. (comprising 13 sub-committees) collected and published descriptions of the mining methods in the principal districts of the United States. It was planned to classify these data, with a view still further to standardise mining practice for the different kinds and shapes of ore deposit.

In many mining operations there is a stronger tendency toward standardisation of details. Thus, some mining companies have adopted standard "rounds" of holes for shaft-sinking, drifting, cross-cutting, raising and stoping. The foremen are furnished with instruction sheets which specify the position, depth and charge of explosive for each hole. The miners are required to follow these instructions instead of doing their work in accordance with their own individual ideas. The adoption of such methods has been assisted by the greater attention now given to what may be termed efficiency engineering. Many large mines have "efficiency engineers," who study in detail the performance of both men and machinery, thus improving the quality and amount of work done. In Great Britain too, quite lately, attention is being directed in some enlightened quarters to the psychological side of mining with a view to ensuring greater efficiency.

Directed toward this end also are the movements inaugurated by several mining companies to instruct their employees in the best methods of doing their work. Thus, an education department is maintained by the Phelps-Dodge Corp., of New York, which operates a number of mines in the southwest of the United States. Lectures are delivered to the miners on practical mining topics, followed by examinations. The North Butte Mining Co., of Montana, has also standardised the details of many underground operations. The cost of these education departments is considerable, but is amply justified by the results. A wholesome spirit of rivalry is encouraged amongst the miners and their ambition is aroused; hence, better work is done, the *morale* of the whole force is raised, and better relations are established between the employees and the mine management. The principles of standardisation have also been increasingly applied to the design of mining appliances and machines.

Blasting.—Explosives for blasting rock and ores underwent considerable change in composition during 1915–25, and tests have supplied valuable data respecting the disruptive and propulsive forces and the sensitiveness of the types and grades of dynamite, leading to a better understanding of their suitability for different kinds of service. Explosives for coal-mines, especially those in which dangerous gases occur or which are dry and dusty, must be so constituted that ordinary charges will not produce a flame of sufficient intensity and duration to ignite explosive mixtures of gas and air. These comprise the tested "permitted explosives," lists of which are published in coal-mining countries and revised from time to time, to keep them up to date. In Europe their use under certain conditions—conditions which exist in the majority of the coal mines—is required by law. In the United States the lists appear in publications of the Bureau of Mines. The bureau can only recommend them, though legal requirements exist in some of the states.

"Permitted explosives" have certain characteristic ingredients: (*a*) ammonium nitrate; (*b*) salts containing water of crystallisation, which, being liberated and vaporised by the heat of explosion, reduces the flame temperature; (*c*) organic nitrates other than nitro-glycerine, *e.g.*, nitro-starch; (*d*) nitro-glycerine, mixed with free water or an excess of carbon. It was formerly assumed that nitro-glycerine compounds and other detonating explosives were not suitable for collieries, because, due to market requirements, excessive shattering of coal is undesirable (except for coke-making); but low-strength, "short-flame" dynamites are now being satisfactorily used. While no explosive can be absolutely safe in gassy mines, those in the "permitted" lists are relatively safe. The standard tests vary as between countries; that of the United States, which is now given, is less drastic than that operative in Great Britain. In the U.S.A. an explosive is accepted for the list when a charge of 680 gm. (1½ lb.) does not ignite gas or coal-dust; it is not accepted if a charge of 250 gm. does cause ignition. In 1912 the permitted list of the U.S. Bureau of Mines comprised 96 kinds and grades of safety explosive; in Jan. 1924 the number had increased to 158, many being almost identical in composition. The United States is the largest user of "permitted explosives" in the world, the quantity consumed having more than doubled in 1912–25.

Blasting methods in the United States have been improved by the introduction of "delay action" electrical fuses. In work like tunnelling (cross measure or stone drifting) and shaft-sinking, where rounds of charged holes are best fired in volleys, these special fuses save time, as the miners need not return to the working place after each volley to prepare for the next. The entire round is wired, as if all the holes were to be fired simultaneously, and there is but one application of the current. The groups of holes explode successively, in the desired order and at intervals of about one second, by using "no-delay" fuses for the first group and "first-delay" and "second-delay" fuses for the following groups. In British coal-mining, volley firing of charges is not permitted by the laws regulating the industry.

Construction of Delay Fuses.—The platinum bridge in the cap shell, between the terminals of fuse wires, is not embedded in the fulminating charge itself, so as to explode it directly, but ignites a short piece of slow-burning ordinary fuse, which in turn explodes the fulminate. The delay interval depends on the length of ordinary fuse used. Another new device for the same purpose is the electric fuse-igniter. A special electric cap contains a small charge of fine-grain black powder, beyond which is a piece of ordinary fuse, with a cap on the end to be placed in the dynamite cartridge. For blasting with black powder, no cap is put on the ordinary fuse.

Mine Hygiene.—Improvements made in the years 1910–25 were chiefly in five directions: (1) better ventilation of mine workings; (2) enforcement of dust-prevention regulations and of regulations requiring the adulteration of coal-dust in the mine by the admixture therewith of inert dust; (3) introduction of new types of blasting explosives, so constituted as to minimise the quantity of deleterious gases evolved; (4) adoption of precautions with the object of producing more perfect combustion of explosives, and the consequent reduction or prevention of the formation of the poisonous carbon monoxide; (5) study and better understanding of special miners' diseases and their treatment. (*See* INDUSTRIAL WELFARE.)

Ventilation.—Formerly, artificial ventilation by fans or blowers was provided only for collieries, to dilute and sweep out gases emanating from the coal and surrounding strata. In recent years, mechanical ventilators have been increasingly applied in the ventilation of metalliferous mines also.

About the year 1902 the high mortality amongst the miners of some districts, especially on the Rand, South Africa, began to attract attention. Investigation showed that acute lung trouble ("miner's phthisis" or silicosis) is caused by inhaling dust from drilling in dry silicious rock or ore. In 1903 a Government Commission was appointed to study the conditions in the Transvaal gold-mines. Their report led to a demand for better ventilation of the mine workings, and the adoption of water-spraying devices to allay the dust arising from the operation of drilling. Revised and more stringent regulations were enacted in 1913. Other governmental investigations were made in Cornwall and the ganister mines of the Midlands, England, Australia and New Zealand, and in the United States by the Bureau of Mines. In 1911 one of the large gold-mining companies in the Transvaal, the Rand Mines (Ltd.), established a department of sanitation, to deal in general with miners' living and working conditions and diseases. The department's activities now cover a large number of the mines of the district, employing between 55,000 and 65,000 men, and marked benefits have resulted from this important movement, which is gaining in strength.

Tests of the gases from blasting explosives have revealed the extent to which they may vitiate mine air. One pound of

standard dynamite produces about 10 cu. ft. of gas, which, due to incomplete detonation, often contains 25 to 30% of carbon monoxide. Since, for safety, this actively poisonous gas should be diluted to about 0·01 of 1%, it is evident that natural ventilation cannot always be relied upon, and mechanical ventilators have been installed for many metalliferous mines. Several new types of high explosives have recently been introduced, so compounded that they produce much less carbon monoxide (CO) and methane (CH_4) than the standard ("straight") dynamites. They are therefore particularly useful in poorly ventilated mine workings, as headings where, in order to secure ventilation (in coal mines), bratticing or air pipes are necessary. Furthermore, there has been increased insistence on the use of high-strength caps or detonators, since imperfectly detonated explosives of all kinds produce an excessive amount of carbon monoxide.

Explosions in Coal Mines.—Advances have taken place in the appliances for fighting mine fires, in the modes of preventing and dealing with gas and dust explosions in collieries and in the design of safety lamps. Coal dust explosions are generally much more serious in bituminous than in anthracite mines. Most explosions in anthracite mines are of gas, sometimes aided by presence of dust. Many investigations of coal-dust explosions have been made in Europe since 1880, but some of the phenomena attending their initiation and propagation have long been imperfectly understood.

Since Professor Galloway (afterwards Sir William Galloway) first drew attention, about 1880, to the dangers arising from coal dust and the brothers Atkinson (Inspectors of Mines) wrote their book on colliery explosives, Sir William Garforth, after the Altofts explosion in Yorkshire, described the arresting effects of stone-dust on the explosive blast, and thereafter the Mining Association of Great Britain established a plant near Altofts for carrying out large scale experiments and did excellent work. Eventually the Home Office took over the plant and, transporting it to Eskmeals in Cumberland, added to it and extended the scale of the experiments.

The results of the elaborate work of the Home Office committees, extending over the period 1910–4, was published before the World War, and after the War a comprehensive set of regulations was established by the British Govt. for the purpose of reducing the accumulations of coal-dust in the mine and rendering such dust as remains uninflammable by reason of the admixture of inert and innocuous dust in stated proportions and of a specified fineness. Experiments were also carried out at the Liévin testing station in France, commencing in 1907, and later in Belgium and in Germany, and by the U.S.A. Bureau of Mines at their testing plant and Brunton experimental mine, near Pittsburgh (since 1909). Amongst the facts demonstrated are:—

(*a*) The blasting of a single hole, charged with long-flame explosive (gunpowder or high explosive), may cause the ignition of coal-dust; (*b*) respecting the initiation of an explosion, if enough dry coal-dust is present, it is immaterial whether the air at the point of origin is quiescent or moving in either direction; (*c*) quantities of dust as small as ⅓ oz. per cu. ft. of space (or 1 lb. per linear ft. of an ordinary roadway in the mine) will propagate an explosion; (*d*) in presence of sufficient dust, an explosion may be produced at will in a roadway, even when the roof, sides and floor are wet to the touch owing to the presence of dry dust on the timbers, etc.; (*e*) the force of a coal-dust explosion usually increases in violence as it is propagated through a mine working and may reach its maximum after travelling 500 to 800 ft. from the place of origin; (*f*) pressures as high as 120 lb. per sq. in. have been measured at right angles to the direction of movement of an explosion, the pressure in the line of advance being doubtless much greater.

Stone-dust Barriers.—Stone-dust barriers, for checking or preventing the propagation of coal-dust explosions, were devised by J. Taffanel and modified by G. S. Rice, of the U.S. Bureau of Mines, but constitute a doubtful safeguard. They consist of series of wide shelves, set across the mine gangway near the roof, each loaded with rock-dust. The shelves are tripped mechanically by the advance force waves of an explosion, being set to operate at certain air velocities produced by the explosion. From two to three tons of rock-dust are thus discharged in a dense cloud, in front of the advancing explosion wave, and, mixing with the coal-dust-laden atmosphere of the gangway, prevent propagation of the explosion.

It would appear that the only really safe precaution to take is the thorough admixture with the coal-dust of the fine stone-dust. It was until quite recently considered that the presence of 30% of inert dust secured safety, but the most recent experiments of Professor Wheeler, of the British Mines Department of Safety of the Mines' Research Board, shows that this may prove insufficient with coal-dust of high volatile content, and that as much as 50% or more may be necessary in some cases. Great interest in "stone dusting" is now being manifested in mining circles. See the publications issued by the British Mines Department and the U.S. Bureau of Mines, *Bull.* No. 225 (1924).

Gas Helmets, etc.—Gas helmets and oxygen breathing-apparatus, long used in mine rescue work, have undergone considerable improvement in point of construction, though no new principle can be said to have been evolved.

Winding Engines.—Power plants (frequently hydroelectric except in the case of Great Britain) have been established in many mining districts, and supply electric current at cheaper rates than are possible for equivalent steam power. Electric-driven winding engines are consequently used in much greater numbers than formerly and in Great Britain, though electricity is seldom obtainable from water power, electric hoists have increased in use at collieries which have in some instances established large power plants, *e.g.*, at Powell Duffryn Colliery in South Wales. The control mechanism of electric winders is so perfected that these engines are as manageable as the best steam winding engines. The large variations in load, unavoidable in winding operations, and very disadvantageous for electric transmission of power, are successfully dealt with by the "equalising systems" of winding or hoisting, the first of which, the Siemens-Ilgner, was introduced just previous to 1906. Modifications of it, based chiefly on the mode of control, are the Westinghouse and the Ward-Leonard. The design and operation of all of these devices are based on the principle that, when a motor receives electric current, it will deliver mechanical power; conversely, when driven by mechanical power, the motor becomes in effect a generator and furnishes electric current. The alternating current usually supplied to a mine is first reduced to about 500 volts and then goes to a motor-generator set, comprising a shunt or induction motor, which drives a direct-current generator and a heavy fly-wheel, all on a common shaft. This set is in constant motion, though not at constant speed. From the generator the current goes to a winding engine motor, which drives a pair of drums on the drum shaft.

At the beginning of a winding cycle, the winding engine motor receives current from the motor-generator set; but, after the descending cage has reached a point where the trip can be completed by the weight of the rope, the winding engine motor is driven by the drum, and therefore supplies current to the generator of the motor-generator set. Thus, part of the recovered power is stored in the fly-wheel, while the remainder is expended in driving the induction motor as a generator, thereby causing it to deliver current to the external circuit or power service. The fly-wheel cuts down the peaks of the load curve. Since 1915, a number of these plants have been erected; they are costly and suitable only where the hoisting is nearly continuous and high peak loads are heavily penalised in the power service.

Underground Haulage.—For locomotive haulage, the electric trolley system was in 1925 still first in importance, though the use of this system is not permitted in gassy and dusty coal-mines in Great Britain; next to this were the compressed-air locomotives, very rarely used in Great Britain, if at all. Storage-battery locomotives, though invented many years ago, were rarely used until about 1911 and in 1925 were employed to a limited extent only in the mines of the United States and the continent of Europe; their use in British coal mines is at the present time under consideration and a prize was recently offered for a safe and practical locomotive.

Their construction is simple, and, as they carry their power with them, they have the advantage of being able to operate

wherever a rail track is laid, without the necessity of erecting a trolley wire. They are best suited to short distance haulage and light service, as for gathering individual tubs or cars from the working places and making them up into trains or sets on the main haulage roads, or what is termed "secondary haulage." The maximum speed is about five miles per hour and easy track gradients are necessary. Their chief disadvantage is high first

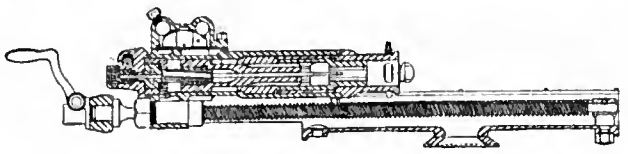

FIG. 3.

cost. A few combined trolley and storage-battery mine locomotives have been built, but they are unlikely to have a wide application. Gasoline locomotives were introduced in the U.S.A. mines before 1905, but were not much used until about 1912. Like storage-battery and compressed-air locomotives, they have the advantage of carrying their own power. Ordinary speeds range from four to ten m. per hour. Although reasonable in first cost and running expenses, gasoline locomotives can be employed underground only where there is freedom from inflammable gas and dust and where there is abundant and active ventilation, because their exhaust usually contains enough carbon monoxide gas to require a large amount of dilution. Their consumption of gasoline at full load is, say, 0·7 to 1·2 lb. per H.P.; considerably more at half speed and load. (U.S. Bureau of Mines, *Bull. No. 74.*)

Shovelling Machines.—These were introduced in the U.S.A. about 1907 for loading broken coal or ore underground. The conditions obtaining in British coal-mines do not permit of the mechanical shovelling of coal at the face. The first was the Thew machine, a dipper shovel of small size, operated by electricity or compressed air and suitable for use in stopes in a flat-lying deposit or in a tunnel. A later design, the Myers-Whaley, consists of a large scoop, which is thrust into the pile of broken ore or rock, then lifted and dumped backward on to a short travelling belt conveyer, for loading into a mine car in the rear. This machine occupies but little space. In 1915 two of them were installed in a long haulage drift, 14 ft. wide by 10 ft. high, in the Crown mines, Transvaal. Interest in the subject has been stimulated by the high wages now prevailing in most mining regions. Where wages are low, however, they cannot compete with hand loading. The use of mechanical loaders has increased enormously in the United States since 1915 and new designs frequently appear. A monograph of 638 pp. on *Mechanical Underground Loading in Metal Mines*, by C. E. Van Barneveld, of the Bureau of Mines, was published in 1925.

Machine Drills.—Important changes were made during 1910–25, especially in the further development of the "hammer" drills

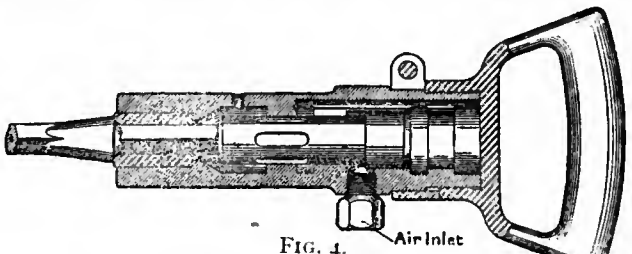

FIG. 4.

which for many kinds of service have largely replaced standard types of piston machines. In the hammer drill, the bit is held stationary in the front end of the machine, and is struck a rapid succession of blows by the reciprocating piston-like hammer. As the bit does not reciprocate, its cutting edge being always in contact with the rock, except during the slight rebound caused by each blow of the hammer, automatic means must be provided for removing the sludge and thus keeping the hole clean while drilling. Hammer drills therefore use hollow bits, through which a jet of compressed air or water is discharged at the bottom of the hole, thus driving out the cuttings. When compressed air is used, and the rock is dry, the dust discharged from the hole is annoying and hurtful to the drill-runner. Hence, a water jet is

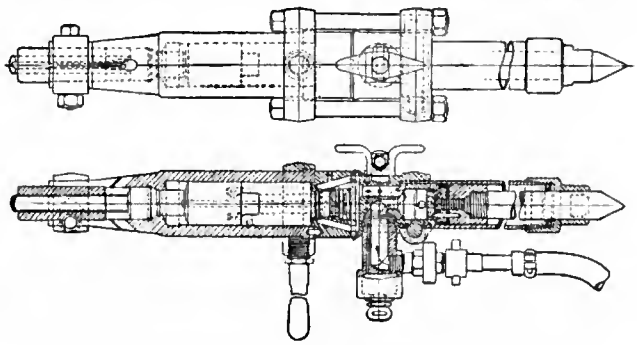

FIG. 5.

in common use. The water is delivered under pressure from a 15-gal. to 18-gal. tank, through a short length of hose. Pressure in the tank is produced by connecting it by another hose with the compressed-air pipe.

Hammer drills are of three types: (*a*) Large machines (fig. 3), corresponding in size and weight with ordinary piston drills, mounted on tripod or column and used for the same kinds of work; (*b*) the small D-handle and cross-handle drills for making holes pointing downward, as in shaft-sinking (fig. 4); (*c*) machines having an automatic air-feed standard, used chiefly for holes directed steeply upward, as in most stoping operations (fig. 5). Machines of classes (*b*) and (*c*) have the advantages of lower first cost, of being operated by one man instead of two, and of eliminating the time lost in cleaning out the hole and in "setting up," as for the standard piston drills and class (*a*) hammer drills. In most rocks and ores, these hammer drills, therefore, do faster work than piston drills. The hammer drill is also applied to the breaking down of coal, and is used with advantage at many European coal mines.

Deep Boring.—In recent years, for prospecting by boring, there has been a great increase in the use of the "churn drill"; that is, a drop drill, suspended by a rope from the operating machinery on the surface, and similar in many respects to the standard oil-well drilling plant. For deep boring, the oil-well "rig," the churn drill and the diamond drill divide the field among them. During the decade 1915–25, many oil and natural gas wells were bored to depths of 4,000 to 5,000 ft., and a few exploratory holes (in Pennsylvania and West Virginia) reached depths of 7,000 to 7,350 feet. For holes of a few hundred ft. in depth, and when cores are desired, the rotary "shot-boring" method, based upon the old Davis Calyx drill, has continued in use to some extent.

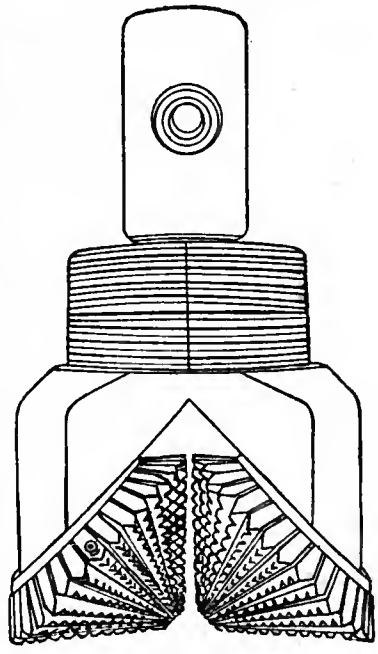

FIG. 6.

For rotary boring in the softer strata, the "fish-tail" bit, with two cutting edges somewhat resembling those of a large carpenter's auger, has come into much wider use for oil and gas wells. In 1908 the Sharp and Hughes cone-bit (fig. 6) was introduced for boring in hard rock, and has been widely used in some of the petroleum and natural gas-fields. It consists of a pair of hardened

steel cones, with serrated or toothed surfaces, revolving on bronze bearings. As the drill rod rotates, the cones roll under pressure upon the rock, crushing and chipping it away. When dull, the cones are readily replaced. These bits in some cases bore as much as 100 ft. of hole in 24 hours. In boring oil wells through soft strata or shattered rock, the sides of the hole often cave before the lining or casing pipe is put in. To overcome this difficulty, "mud-laden" water has been used in the boring operations instead of the ordinary wash-water. Finely divided, clayey material that will remain in suspension for a considerable period of time is employed. The mixture of mud and water should have a specific gravity high enough to afford a counter-pressure that will aid in supporting the walls of the hole; a specific gravity of about 1·33 is usually sufficient. The pressure in the bore-hole is thus kept in approximate equilibrium until the hole can be lined with piping (casing) or screens are set in the oil-bearing strata and cemented in place. This method was introduced in Europe, about 1895, for sinking cylindrical mine shafts in unstable, water-bearing soil by boring. About 1901 it was adopted for boring oil wells in Texas and Louisiana, and since 1906 has been successfully used in a large number of cases. (*See* COAL; COPPER; EXPLOSIVES.)

MINNEAPOLIS, Minn., U.S.A. (*see* 18.546), increased in population from 301,408 in 1910 to 380,582 in 1920, and 425,435 (Census Bureau estimate) in 1925. Among the 88,248 of foreign birth (1920), Swedes (26,515) and Norwegians (16,389) predominated. The total value of manufactured products was $165,405,000 in 1909; $491,383,000 in 1919; $338,329,208 in 1923. Flour-mills (output, 1924, 11,679,130 bbl.) and grain elevators (capacity, 1925, over 56,000,000 bu. kept their dominating place in the city's industries, but the reduction of freight rates *via* the Great Lakes to approximately the pre-War basis, while all-rail rates to the East remained 65% higher, was resulting in the transfer of some of the milling business to Buffalo and other points in the East.

Ranking next to flour in 1923 were motor vehicles and bodies and parts; linseed oil, cake and meal; bread and other bakery products; and knit goods. The vast lumber industry dwindled, with the gradual exhaustion of the pine lands, from a maximum of 600,000,000 ft. sawed in 1899 until in 1920 the last mill went out of existence. Minneapolis is the seat of the ninth Federal Reserve Bank. Bank deposits on Jan. 1 1925, were $319,388,000. The combined manufacturing and wholesaling market in 1924 was estimated at $1,300,250,000.

Navigation of the Mississippi river up to the heart of the city was opened on July 3 1917, when the first steamer passed through the recently completed lock. In Nov. 1925, seven motor-bus companies, operating over 2,000 m. of state highways to the north and west, were merged in an auxiliary of the Great Northern Railway. The Great Northern passenger station, which is used by a majority of the railway lines, superseded, in 1914, the older union station.

Registration in the University of Minnesota reached 18,722 in 1924–5; its Memorial Stadium, seating 50,200, was opened in 1924. Enrolment in the public schools increased 70% between 1910 and 1925, while the increase in population was 41%. The park system by 1925 included 4,722 ac.; a playground for each sq. m. of residential area; five golf courses; and 56 m. of boulevards encircling the city, the so-called "Grand Rounds," one section of which is the Victory Memorial driveway (dedicated 1921). In the summer of 1925 the stream supplying Minnehaha Falls, which had been failing for several years, gave out entirely. To restore the supply deep wells were dug, from which water can be pumped into the creek when necessary.

Minneapolis has a low general death-rate, a low infant mortality, a high percentage of home ownership and a low percentage of illiterates and of children engaged in wage-earning occupations. Cost of living is below the average for American cities. The non-partisan system of nomination for city offices was put into effect in 1912. A city-planning commission was established in 1919, and a zoning ordinance adopted in 1924. In 1925 a new charter, providing for a city manager appointed by the legislative body (the city council) and for a school and library board, was prepared for submission to the voters.

MINNESOTA (*see* 18.548).—The population of the state in 1920 was 2,387,125 as against 2,075,708 in 1910, an increase of 311,417, or 15% for the decade. The total white population was 2,368,936, of whom 1,882,772 were natives and 486,164 foreign born. Negroes numbered 8,809 and Indians 8,761. The density was 20·5 per sq. m.; 25·7 in 1910. The estimated population in 1926 was 2,651,306. The urban population (in places having over 2,500 inhabitants) was 1,051,593, or 44·1% in 1920; 41·0% in 1910. The rural population was 1,335,532, or 55·9% in 1910. The following table gives the population and the percentage of increase of cities having more than 15,000 inhabitants in 1920:—

Cities	1920	1910	Increase %	Estimate 1925
Minneapolis	380,582	301,408	26·3	425,435
St. Paul	234,698	214,744	9·3	246,001
Duluth	98,917	78,466	26·1	110,502
Winona	19,143	18,583	3·0	19,459
St. Cloud	15,873	10,600	49·7	18,860
Hibbing	15,089	8,832	70·8	17,955

Agriculture.—There were 188,215 farms in Minnesota in 1924. These farms covered 30,040,933 ac., two-thirds of which was improved. The total value of farm land and buildings in 1925 was $2,396,005,328. The final stage in the state's progress from pioneer to diversified farming was marked by the decline of wheat from second to third crop. In the years following 1920 the total corn and oat crop was consistently more than four times as great as the total wheat crop, both in quantity and value. The northern part of the state showed a rapid development in stock-raising and dairying.

Minerals.—About 60% of the output of iron ore in the United States is mined in the three great iron ranges of northern Minnesota. The Mesaba range, 110 m. in length, embraces 130 active mines. The Vermillion and Cuyana ranges combined form an additional iron belt of about 50 miles. A total of 44,556,053 tons of ore, valued at $158,402,788, was shipped from Minnesota mines in 1923.

Manufactures.—In 1923 Minnesota ranked twelfth among the states in the value of its manufactures. In the 3,902 establishments (not including hand industries) then existing, the average number of persons employed was 193,344 and products valued at $968,476,565 were manufactured. There was a falling off in manufacturing from 1919, the peak year. The state's five most important industries, in the order of the value of products in 1923, were the flour- and grist-mill, slaughtering and meat-packing, dairy and creamery, the manufacture of cars and general shop construction and repairs by steam railways and lumber and timber industries. In flour and butter Minnesota's products exceed those of any other state. Following 1910 the slaughtering

and meat-packing industries, centred at South St. Paul, showed rapid growth. Because of the depletion of her forests Minnesota dropped from third place among the states in lumber manufacture in 1900 to sixteenth place in 1920; but, though lumbering declined, timber manufacturing increased. Iron ore is now worked in huge iron and steel plants on the St. Louis river near Duluth, and farm machinery is manufactured increasingly.

Transportation.—The railway mileage in Minnesota in 1924 was 9,096 an increase of 7·8% since 1908. In 1924 there were 180·2 m. of electric lines, exclusive of city street railways. With the growth of motor traffic, the demand for good roads greatly increased, and the state engaged in road building on an extensive scale. An amendment to the constitution (1912) authorised the levy of a one-mill tax, the proceeds to be distributed among the counties and used for road building and maintenance; another amendment (1920) authorised the issue of bonds and provided for the taxation of motor vehicles in order to finance a system of state trunk highways covering 7,000 m.; a third amendment (1924) authorised a tax on gasolene used in motor vehicles and to add the proceeds of the tax to the highway fund. There were in 1922 about 107,103 m. of public roads in the state. The U.S. Govt. completed in 1920 the construction of a dam in the Mississippi between St. Paul and Minneapolis, which by means of locks makes the latter city the head of navigation on the river. An attempt is being made to revive freighting on the river, between Minneapolis and St. Louis; and the Ford Motor Company's northwest plant, established in St. Paul and using hydroelectric power from the government dam, is both shipping and receiving goods by water.

Education.—In 1923–4, there were 431 high schools, 746 grade schools, 354 consolidated schools and 6,607 rural schools with 2,900 teachers and 78,000 pupils, and these schools received, in addition to local support, state aid. During 1923–4, $59,316,000 was expended on public education. There are six state teachers' colleges and 12 private institutions of collegiate grade. The University of Minnesota at Minneapolis comprises 13 colleges and schools. A noteworthy development in the medical school was its affiliation with the Mayo Clinic at Rochester. In 1915 William J. and Charles H. Mayo, the famous surgeons, established the Mayo Foundation for Medical Education and Research, endowed it to the amount of $1,500,000 and gave it to the university. The university was thus placed in control of practically all medical instruction in Minnesota. In 1924–5 the university had 12,736 students, 673 faculty members and 253 buildings. An extensive building programme covering a period of 10 years was initiated in 1919, when the Legislature appropriated $5,600,000 for this purpose.

Government.—In 1925 the state government was reorganised by combining the existing state boards and commissions into twelve departments and creating two new departments, the executive council (consisting of the governor, attorney-general, auditor, treasurer and secretary of state), and the Department of Administration and Finance, under the control of a commission of three appointed by the governor and removable at pleasure. The three commissioners—the comptroller, commissioner of the budget and commissioner of purchases—have general supervision and control of the expenditures and personnel of state departments and agencies. The placing of the state's charitable and penal institutions under the Board of Control was completed in 1917, and the board in 1925 had charge of 18 institutions including the recently established asylum for the insane with a special ward for inebriates at Willmar, the state reformatory for women at Shakopee and the colony for epileptics at Cambridge. The new state prison buildings at Stillwater, completed in 1912, cover 22 ac. in a tract of 1,000 acres. Among the duties of the new Department of Conservation are forest conservation, reforestation, and the management of the 20 state parks, eleven of which have areas greater than 100 acres. In addition this department manages the Pillsbury state forest, Cass county and the Burntside state forest, St. Louis County. Two Federal forest reserves are also located in the state: Superior National Forest in St. Louis, Lake and Cook counties; and Minnesota National Forest in Itasca, Cass and Belltrami counties.

Finance.—On June 30 1925 there were 1,375 banking institutions in Minnesota, of which 1,027 were state banks, 21 trust companies, 7 savings banks and 320 national banks. There are also in the state 85 building and loan associations and one credit union. The Federal Reserve Bank for the ninth district is located in Minneapolis. All banking institutions other than national banks are under the supervision of the commissioner of banks of the State Department of Commerce.

History.—The most important political movement of recent years was the growth of agrarian unrest manifesting itself first in the Non-Partisan League and later in the Farmer-Labour party. From 1919–23 this movement was particularly active and two members of this party were elected to the U.S. Senate—one to fill an unexpired term. In 1924, however, the tide was ebbing; at the presidential election the state was carried by the Republican party, and a Republican replaced one of the Farmer-Labour senators. The membership and power of organised labour fluctuated in a way roughly proportional to the fortunes of the Farmer-Labour party. Two important pieces of legislation in 1910–25 were the primary law (1912), which provides for nomination and election on a non-partisan ballot of all state and local officers except the state executive officers, the railway and warehouse commissioners and the clerk of the Supreme Court and the so-called tonnage tax (1921), a 6% tax on the net value of mined ore. Minnesota ratified the Eighteenth (Prohibition) Federal Amendment Jan. 20 1919. The following governors held office after 1909: Albert Olson Eberhart (Rep.), 1909–15; Winfield Scott Hammond (Dem.) (died in office), Jan.–Dec. 1915; Joseph A. A. Burnquist (Rep.), 1915–21; Jacob A. O. Preus (Rep.), 1921–5; Theodore Christianson (Rep.), 1925– (S. J. B.)

MINORITIES.—Groups of population differing by race or religion from the nation of which they form part. One of the most remarkable characteristics in the evolution of modern nations is their tendency to develop political communities increasingly extensive and increasingly homogeneous. In certain countries, such as France, this assimilation is practically accomplished and there is no longer any question of national minorities. But in some cases fusion does not proceed without resistance, and it may be said that the problem of national minorities arises at the moment of the emergence of important groups of persons differing from the majority by race, language or religion, who aspire to an independent life with regard to that majority. These aspirations may vary from the desire for a simple freedom to develop their own intellectual aims and their own traditions to a demand for administrative autonomy, or even a more highly developed political status, on the model of the Swiss cantons.

Historical Survey.—The modern problem of national minorities is identical with the idea of the "National State" which emerged after the break-up of feudalism. Indeed, from the moment when political unity arose on the basis of national unity, every nation which became conscious of a distinct nationality necessarily aspired to the advantages of a more or less complete political independence. Then at the same period, the exhaustion resulting from the religious wars of the 16th and 17th centuries and the advance of toleration were very favourable to the aspirations of homogeneous people for a certain measure of independence. These aspirations found expression from the 16th century onward in international law in the clauses of certain treaties in virtue of which the contracting parties obtained in favour of subjects whom they had been compelled to detach from their rule, or even for certain peoples of the same religion as their own, guarantees for the free exercise of their religion. (For examples see the Capitulations granted by the Sultan Solyman II. to Francis I. in favour of the Eastern Christians, 1535; the Peace of Augsburg, 1555; Treaty of Westphalia, 1648; Treaty of Oliva, 1660; Treaty of Paris, 1763, etc.). The liberation of the English colonies in America, the Declaration of Independence (1776) and the French Revolution with the Declaration of the Rights of Man (1789), crystallised, to some degree, the modern philosophy of nationality which is translated by the formula, "the right of peoples to self-determination."

In the 19th century this was strengthened by a series of brilliant successes: the achievement of independence successively by the Spanish and Portuguese Colonies in America; the liberation of Greece 1821–30; and of Belgium, 1831–2; the gradual elimination of the Turks from Europe in favour of the Christian peoples of the

Balkans; a series of conferences and of treaties (London, 1830; Paris, 1856; Berlin, 1878, etc.) which contained clauses in favour of certain religious minorities.

The World War and Its Consequences

The War of 1914 caused a formidable awakening of national aspirations. Italy and Rumania entered the War against the Central Powers in order to realise their national demands; Irish agitation was intensified under war conditions. In 1916 an important congress of nationalities met at Lausanne. As early as Jan. 22 1917 President Wilson laid down as the principle of the future peace:—

That no nation should seek to extend its polity over any other nation or people, but that every people should be left free to determine its own polity, its own way of development, unhindered, unthreatened, unafraid, the little along with the great and powerful.

Nevertheless, the distribution of the nationalities in Europe is so complex, notably in certain regions where the ethnical elements vary from village to village, that it was evidently impossible in the peace settlement to apply in its integrity the principle of self-determination; it was inevitable that some minorities should remain under the domination of majorities. On the other hand, some majority populations before the War became minorities.

A summary table of European minorities appears in next column.[1]

In Russia there are some 40 different nationalities the statistics of which are ill authenticated. The Union of Soviet Socialist Republics has granted to many nationalities a large measure of autonomy, and comprises at present a great number of republics and autonomous territories.

The Right of Minorities

In Europe alone the multiplicity of minorities, aggravated by the triumph of certain minorities immediately after the World War, has created an extremely dangerous political situation which is a constant source of disturbance. The Peace Treaties of 1919 sought to alleviate this danger by creating wide and fundamental rights for minorities.

The documents sanctioning these rights are of four kinds:—

1. Special articles in the Peace Treaties concluded by the principal Allied and Associated Powers with Austria (St. Germain, Sept. 10 1919); Bulgaria (Neuilly-on-Seine, Nov. 27 1919); Hungary (Trianon, June 4 1920) and Turkey (Lausanne, July 24 1923).
2. Special Minorities treaties concluded by the principal Allied and Associated Powers with Poland (Feb. 13 1920); Czechoslovakia (Sept. 10 1919); The Serb-Croat-Slovene State (Sept. 10 1919); Rumania (Dec. 9 1919); Greece (Aug. 10 1920). All these treaties have been placed under the Guarantee of the League of Nations.
3. Engagements entered into by certain states with the League of Nations to observe toward their minorities, or certain of those minorities, obligations more or less identical with those laid down in the minority treaties: by Finland and Albania, 1921; Lithuania, 1922; Latvia and Estonia, 1923.
4. Bilateral conventions between certain states: Treaty of Brünn between Austria and Czechoslovakia (June 7 1920); convention between Poland and Danzig (Nov. 9 1920); convention between Germany and Poland (May 15 1922).

The great innovation common to these international engagements is the intervention, for the assurance of the protection of minorities, of a supernational power, hitherto unknown, the League of Nations. Obligations with regard to minorities are henceforth conceived no longer as simple assurances of goodwill of a state towards its subjects of another race, but as international obligations which should be recognised by the state concerned as "fundamental laws," which cannot be contradicted by any other laws, and which are placed under the guarantee of the League of Nations. The Council of the League of Nations has been invested with juridical powers to intervene with the Govt. in case of infringement, or menace of infringement of their obligations with regard to minorities; finally, disputes on questions of law or fact which may arise in the carrying out of the

[1] Figures furnished by a minority rarely agree with those given by the majority. The figures marked with an asterisk in this table are derived from the official statistics of the states concerned. Others are taken from recent authoritative works of reference.

Country	Majority	Minorities
Belgium	7,482,100	Germans, 40,000
Germany	61,000,000	Danes, Poles and Wends
Poland	17,667,000	Germans, 1,550,000 Jews, 2,520,000 Ruthenes, 4,220,000 Russians, 1,135,000 Lithuanians, 72,750 Various, 50,000
Lithuania (incl. Memel)	7,702,000	Jews, 153,700 Germans, 29,200 Poles, 65,600 Russians, 50,500
Latvia	1,159,300	Great Russians, 91,500 Jews, 79,300 Germans, 58,000 Little Russians, 66,000 Poles, 52,200 Lithuanians, 25,500 Estonians, 8,700
Estonia	969,900	Russians, 91,200 Swedes, 7,800 Germans, 18,000 Jews, 4,500 Various, 15,000
Finland	3,500,000	Swedes, 380,000 Russians, 6,000
Austria	5,360,000	Czechs, 245,000 Hungarians, 88,500 Jews, 270,000 Serbs-Croats-Slovenes, 117,500
Czechoslovakia	8,760,000	Germans, 3,123,000 Magyars, 745,000 Ruthenes, 461,800 Poles, 75,800 Jews, 180,800 Various, 260,000
Hungary	7,147,000	Germans, 551,200 Slovaks, 141,800 Rumanians, 23,700 Serbs-Croats-Slovenes, 53,900 Jews, 60,000
Italy	41,000,000	Germans, 280,000 French Vaudois, 85,000 Slovenes, 250,000 Croats, 150,000 Albanians, 80,000 Greeks, 25,000
Yugoslavia (Serb-Croat-Slovene State)	9,971,600	Magyars, 472,400 Germans, 518,400 Albanians, 441,500 Rumanians, 229,000 Bulgars and other Slavs, 174,000 Italians, 12,800 Various, 212,000
Albania	817,800	Some thousands of Greeks
Rumania	11,576,000	Magyars, 1,650,500 Germans, 804,000 Ukrainians, 1,100,000 Ruthenes, 793,800 Jews, 770,000 Bulgars, 251,000 Serbs, 62,300 Turcs and Tartars, 230,000 Various, 579,000
Bulgaria	3,441,000	Greeks, 48,300 Gipsies, 115,700 Jews, 43,500 Rumanians, 78,000 Turcs and Tartars, 454,700 Various, 676,000
Greece	5,157,000	Albanians, 162,000 Jews, 110,000 Rumanians, 486,700 Turcs and Tartars, 59,000 Various (Slavs, etc.), 500,000
Turkey	8,518,000	Armenians, 40,000 Greeks, 220,000 Gipsies, 23,500 Jews, 68,600 Various, 2,413,000

said obligations may be referred to the Permanent Court of International Justice, whose decision is final.

Generally speaking, the treaties, conventions or declarations concerning minorities give these guarantees to the minority populations:—

1. Rights equal to those of any nationals of the country to protection of life and liberty and the free exercise of their religion;
2. A special right to the acquisition of the nationality of the country in question and to the exercise of civil and political rights;
3. Free use of their mother tongue in private life, in trade, in religion, in the Press, in publications, in public meetings and in the courts of law; and
4. The right of maintaining at their own expense charitable, religious or educational institutions.
5. In districts in which the minority constitutes a considerable proportion of the population, instruction in the primary schools of the state shall be given in the language of that minority and the minority shall be assured an equitable share in the sums provided by the state and municipal budgets for educational, religious or charitable purposes.

The conditions under which minorities may raise a complaint, and the procedure to be followed by the Secretariat and the Council of the League of Nations are laid down by precise regulations which have been several times revised (Tittoni Report: Resolutions of the Council of Oct. 25 1920; of June 27 1921; of Sept. 5 1923, and June 10 1925; resolutions of the 3rd and 4th Assemblies). An essential condition is that every application which is admitted as being in order is communicated in the first instance to the Govt. of the state against which the complaint is directed for its observations; the second is that every application definitely admitted as in order is examined by the President of the Council assisted by two members of the Council. But the Council is not assumed to be legally and officially informed until one of its members takes it upon himself to draw the attention of the Council to the case in question. When this takes place, the Council " may proceed in any manner and give any instruction that appears to it appropriate and effective in the circumstances."

As a result of this cautious procedure, many complaints transmitted to the Council have not been considered. This failure has caused serious disappointment and has given occasion for numerous grievances. But on the whole the essential rights of minorities are certainly respected, and even the possibility of the bringing of a complaint of the minorities before the Council or the Assembly of the League of Nations inevitably disposes governments to be prudent and moderate in their attitude towards their minorities. Moreover, certain miporities have obtained important advantages through the procedure adopted by the Council. In conclusion, the modern law of minorities as it emerges from the treaties, conventions and declarations enumerated above, has incontestably exercised on the fate of minorities a moderating influence, the great significance of which can hardly be exaggerated.

MINSKY (1856–), the pen name of Nicolas Maximovich Wilenkine, Russian man of letters, was born Jan. 21 1856 at Glubokoe, Vilno (Wilna) province, and was educated at Minsk. He graduated in law at St. Petersburg University, but soon devoted himself wholly to a literary career. His first volume of poems was published in 1877, but was confiscated by the Government and was not re-issued until 1887. It was during the 'eighties that he became well known as a poet of social revolt. In the 'nineties, however, he became one of the leaders of the Russian symbolists. In 1905 he edited with Gorky the socialist paper, *New Life*. Minsky's philosophic ideas are expressed in *In the Light of Inner Revelation* (1890) and *The Religion of the Future* (1905). He also wrote many sonnets, lyrics and a number of plays. His poetical works were published in four volumes in 1907 and appeared in German in 1923. A volume of his works entitled *Echoes* has been translated into English by D. MacAlister (1923).

MINTO, GILBERT JOHN ELLIOTT-MURRAY-KYNYNMOND, 4th Earl of (1845–1914), British politician (*see* 18.564), died at Minto House, Hawick, Scotland, March 1 1914.

MIRBEAU, OCTAVE HENRI MARIE (1850–1917), French dramatist and journalist (*see* 18.574), died in Paris Feb. 16 1917.

MIŠIĆ, ŽIVOJIN (1855–1921), Serbian statesman, was born July 7 1855 at Struganik near Valievo, the son of well-to-do peasant parents. He passed through the old Artillery school in Belgrade and served in the Serbo-Turkish War of 1877 and the Serbo-Bulgarian War of 1885. During the Bosnian annexation crisis he became assistant chief-of-staff to Gen. Putnik, and in this capacity made his name in the first Balkan War, being promoted general. He further distinguished himself in the Bregalnitsa operations during the second Balkan War of 1912–3. When the World War broke out and the Austrians invaded Serbia in Nov. 1914, Mišić was appointed to the command of the I. Army. Mišić's simple and unaffected heroism inspired his soldiers with confidence: his spirit spread to the whole Serbian Army and found expression in the decisive victory of Rudnik early in Dec. by which the Austrians were driven out of Serbia.

Mišić, who had been created voivode after Rudnik, again served with distinction during the retreat of the Serbian Army in the winter of 1915. After a long interval spent in recovering from the strain of the campaign, he resumed command of the I. Army on the Salonika front in Aug. 1917, and in June 1918 was made chief-of-staff. In this position he played a pre-eminent part in elaborating the plan to which the piercing of the Bulgarian front was due. As a convinced believer in the idea of Yugoslav unity, he did all in his power to promote the efforts of the exiled Yugoslav committee to organise Yugoslav legions on every front. He died on Jan. 20 1921.

MISSIONS (*see* 18.583).—The developments of outstanding interest in missionary work since 1910 have been the new spirit of independence in the churches in the mission field, the growth of the spirit of co-operation, and the new educational demands on missionary schools. The first of these tendencies led to considerable transfers of authority from the missions to the churches established by them. The indigenous church rather than the foreign organisation became increasingly responsible for the direction of Christian activities. In the face of the rising spirit of nationalism, evident in so many quarters, it became essential that Christianity should as little as possible bear the character of a foreign religion.

National Christian Councils.—The impulse of the World Missionary Conference held in 1910 quickly extended itself to the mission field. A visit to Asia by the chairman of its continuation committee, Dr. John R. Mott, in 1913–4 led to the formation in India, China and Japan of bodies representative (with one or two exceptions in the case of Japan and China) of all the Christian forces other than Roman Catholicism. These, by a process of evolution, became national Christian councils, and in China and India, in particular, became an active and influential force. While in their beginning missionary initiative played a considerable part, leadership passed increasingly into the hands of Chinese and Indians, who formed in 1925 half or more than half of the members of the councils in their respective countries. A national Christian convention held in Shanghai in 1922 and attended by Chinese Christians and missionaries of all denominations from every part of China, afforded striking evidence of the reality, strength and indigenous character of the Christian movement in China. It was presided over with remarkable ability by a Chinese Christian, Dr. Cheng Ching-yi, and other Chinese Christians took part in guiding the proceedings.

A corresponding growth of co-operation took place among the missionary societies within their own various political boundaries. The Conference of Missionary Societies in Great Britain and Ireland, meeting for the first time in 1911, united all the principal missionary societies in the United Kingdom and Ireland and led to a marked growth in mutual understanding and fellowship and in practical co-operation in many directions. The Foreign Missions Conference of North America (including the United States and Canada), while of older date, made notable progress on similar lines. National missionary organisations were also formed in the Scandinavian countries, in Holland and in Switzerland, the German Missions-Ausschuss being of older date. Internationally, the continuation committee appointed by the World Missionary Conference gave place to the International Missionary Council, the members of which are appointed by the different national missionary organisations.

Education.—Everywhere in the mission field the position of Christian schools was affected by the rapid extension of Government systems of education. The missionary societies recognised that they had to do with an entirely new situation, and endeavoured to meet it by a thorough examination of the new conditions and the demands made by them. In 1919–20 an education commission was sent to India to investigate the problems of rural education and issued a report entitled *Village Education in India*, which exercised a considerable influence on missionary opinion and policy. Two years later a strong commission under the chairmanship of the late Dr. E. D. Burton, president of Chicago University, visited China and produced a valuable Report entitled *Christian Education in China*. In 1921 and 1924 an Education Commission, under the joint auspices of the missionary societies and the Phelps-Stokes Fund, visited, first, West and South Africa and then East Africa, and its two reports, *Education in Africa* and *Education in East Africa*, were recognised not only in missionary but in Government circles as furnishing much needed guidance in regard to the kind of education best suited to Africa. Effective co-operation in education between missions and Government in the British colonies in Africa was furthered by the appointment by the British Secretary of State for the Colonies in 1923 of a permanent Advisory Committee on Native Education in Tropical Africa, and the setting up in most of the colonies of similar advisory bodies on which the missions are represented.

The World War led to the cessation of the work of German missions in most of the territories under the control of the Allied Powers, but in the British Empire in 1925 the restrictions were being relaxed and German missionaries had begun to return to their former fields. In the *World Missionary Atlas* published in March 1925, the numbers of missionaries were given as follows: ordained missionaries from the United States and Canada 3,713; from Great Britain 2,058; from other countries 1,515; laymen, United States and Canada, 1,063; Great Britain 947; other countries 407; unmarried women, United States and Canada, 4,793; Great Britain 2,593; other countries 1,116. It may be interesting to compare the 1925 figures with those for 1907, though these were from another source: the total number of communicant members was 3,614,154 in 1925 as contrasted with 1,817,450 in 1907, while the total Christian community was returned as 8,342,378 as compared with 4,361,138. The total number under instruction in all types of mission schools was 2,440,148 as compared with 1,302,905. The total income of the Protestant missionary societies was given as £14,058,102 (of which the United States contributed £9,736,084 and Great Britain £2,869,353) as compared with £4,473,933 in 1907. The foregoing figures reveal a remarkable increase in the proportionate share of North America in missionary effort.

Roman Catholic Missions.—The figures for Roman Catholic missions for the year 1908 may be compared with those for 1923 published at the Vatican Exhibition, Rome, the earlier ones being shown within parentheses: European priests 8,617 (7,933); native priests 4,095 (5,837); lay helpers 4,018 (5,270); sisters 24,102 (21,320); catechists and teachers 65,641 (catechists 24,524); number of Catholics 12,964,147 (native membership only, 7,441,215); catechumens 1,534,446 (1,517,909); students and children in schools 1,800,000 (906,000); schools 22,358 (24,000); churches and centres 110,932 (71,000). The World War was the cause of a considerable decrease in the number of missionaries, since the various services claimed many of them and a large proportion of these were killed. The possessions of the Allied Powers being closed to German missionaries in the years immediately following the War, the former fields of German societies thus affected were in nearly all cases transferred to other congregations while fresh fields were found for the expelled societies. A regrouping of Roman Catholic missions thus took place on a considerable scale.

An important encyclical (*Maximum illud*) dealing with missionary work was issued by Pope Benedict XV. in 1919, in which extended directions were given for the conduct of missionary work, exaggerated expressions of nationalism were severely condemned, and great emphasis was laid on the importance of developing a native clergy. The first native bishop was to be consecrated in Japan in 1925.

Considerable changes took place in organisation in Europe. The headquarters of the Society for the Propagation of the Faith, the great collecting society of the Roman Catholic Church, were transferred from Lyons to Rome and put expressly under Papal auspices, while its governing body was made fully international. Two other organisations which were established on an international basis under Papal direction are the Society of St. Peter for the training of a native clergy in mission lands and the Missionary Clergy Union, which in 1925 had a membership of 105,000 priests. A notable development after the War was a wider distribution of missionary support among different countries; the pre-eminence of France being no longer so marked as it was. Increased support for missions was forthcoming in Ireland, Holland, Belgium, Switzerland, Spain and Italy, and there was also a revival of missionary interest in Portugal, Bohemia, Hungary and Poland. The financial contributions of the United States grew remarkably and in 1925 exceeded those of any other country, though the number of American missionaries was considerably below that of a good many other countries. Advantage was taken of the presence of many pilgrims in Rome during the Holy Year of 1925 to organise a great missionary exhibition in the grounds of the Vatican. (J. H. O.)

MISSISSIPPI (*see* 18.599).—In 1920 the total population was 1,790,618, being a decrease of 6,496 from the figures for 1910. The negro population was 935,184, or 52% of the total, as compared with 1,009,487, or 56·2% of the total in 1910. The foreign born whites in 1920 numbered 8,019. The density was 38·6 per square mile. The urban population (in places of over 2,500) was 13·4%. The six cities having a population of over 12,000 in 1920, in comparison with the figures of 1910, and their estimated population as on July 1 1925 were:—

	1920	1910	Increase	July 1 1925
			%	Estimate
Meridian . .	23,399	23,285	0·5	24,312
Jackson . .	22,817	21,262	7·3	23,698
Vicksburg . .	18,072	20,814	−13·2	..
Hattiesburg .	13,270	11,733	13·1	14,034
Laurel . .	13,037	8,465	54·0	15,513
Natchez . .	12,608	11,791	6·9	13,070

Agriculture.—In 1925 the number of farms in the state was 257,228, of which 107,095 were operated by whites and 150,043 by negroes. There was a decrease both in the number of farms and the farm acreage as compared with 1920, when there were 272,101 farms embracing an acreage of 18,196,972. Farm values also declined during the same period, the total value of farm land and buildings being $459,936,535 in 1925 as compared with $789,896,778 in 1920, giving an average value per farm of $1,788 in 1925, and $2,903 in 1920. The average size of the farms also decreased from 66·9 in 1920 to 62·4 in 1925. Cotton continues the most important crop but the acreage of cotton decreased from 2,948,387 in 1919 to 2,036,766 in 1924. The livestock on the farms on Jan. 1 1925 comprised 141,952

horses, 330,080 mules, 938,024 cattle and 729,165 swine, having a total value of $62,858,000.

Manufactures.—The value of the output from factories increased from $79,550,095 in 1914 and $114,083,861 in 1921 to $178,581,729 in 1923, Mississippi then ranking 34th among the states in the value of manufactured products and 32nd in number of wage earners, the latter numbering 64,452. The capital invested in manufactures increased from $81,005,484 in 1914 to $154,117,337 in 1920, and $197,746,987 in 1923. The chief manufactured articles are lumber and timber products, cottonseed oil and cake, cotton goods, turpentine and rosin and fertilisers. The chief manufacturing centres are Meridian, Jackson, Greenville, Columbus, Laurel, Hattiesburg, Natchez and Vicksburg. The mineral production of the state is small, its total value in 1922 being $1,600,393, composed chiefly of clay products, sand and gravel.

Education and Charities.—Higher education is taken care of by the University of Mississippi at Oxford, the Mississippi State College for Women at Columbus and two Agricultural and Mechanical Colleges. State normal schools are situated at Hattiesburg and Cleveland, in addition to which there are 175 public high schools and 6,800 elementary schools. Separate schools are maintained for the white and coloured children. Education is state supported, being free to all and compulsory between the ages of 7 and 16. The most important development in education was the establishment in 1908 of county agricultural high schools. Every county may establish one for white children and one for negroes, or two counties may combine and create one set of schools for the two counties. These schools receive state aid on the basis of the number of boarding pupils. The total amount expended for education during the year 1923–4 was estimated at $17,837,000, including a state appropriation of $8,837,404. An industrial training school for delinquent and abandoned children was established at Columbus in 1916, and there are also schools for the deaf and dumb and for the blind at Jackson.

Administration and Legislation.—The constitution of 1890, enacted to ensure white supremacy, has been amended with the object of putting the government more within the direct control of the people. In 1916 the initiative and referendum were adopted by an amendment under which an initiative petition must be supported by 7,500 qualified electors, and a referendum petition by 6,000. Any law bill resolution, constitutional amendment or any other legislative measure is a proper subject for such petition. The judiciary consists of the Supreme Court of six judges elected for eight years and circuit and chancery judges elected for four years. A majority of nine jurors may return a verdict in all civil cases in the circuit and chancery courts. The Legislature is elected for four years and meets in regular session biennially. All financial appropriations are made for two years.

The Torrens System of registration of land titles has been in force since 1915. In 1914 a state department of banking was created with a board of bank examiners consisting of three members elected for four years. Bank deposits are guaranteed by the state. A very comprehensive child labour law was passed in 1912. Under its provisions no child under 12 may be employed in any mill or factory and no child under 16 may be employed for more than eight hours per day. No employee is permitted to work in any mill or factory more than 10 hours per day. The enforcement of this law is placed in the hands of the county health officer. In 1916 a pardon board of five members appointed by the governor was created for the purpose of advising on all petitions for pardons. All such petitions must be published for 30 days in the county where the crime was committed. The board can act only in an advisory capacity, the governor being free to follow their advice or not as he may deem best. A state highway commission was also appointed in 1916.

Mississippi was the first state to ratify the Eighteenth (prohibition) Amendment, doing so Jan. 8 1918. The Legislature, however, refused to ratify the Nineteenth (woman suffrage) Amendment in 1919, and it took no action on the proposed Twentieth Amendment regarding child labour.

In 1926 the state was represented in the U.S. Senate by Hubert D. Stephens and Pat Harrison. The following have been governors since 1910: Edmund F. Noel (Dem.), 1908–12; Earl Leroy Brewer (Dem.), 1912–6; Theodore G. Bilbo (Dem.), 1916–20; Lee M. Russell (Dem.), 1920–4; Harry L. Whitfield (Dem.), 1924– .

MISSISSIPPI RIVER (*see* 18.604).—The U.S. Govt. continued work on the various engineering projects connected with the Mississippi and its tributaries, the Missouri and Ohio, during the years 1910–26. On the upper Mississippi the reservoirs at the headwaters numbered six, namely Winnibigoshish, Leech, Pokegama, Sandy and Gull lakes and Pine river, which have a combined storage capacity of nearly 95,000,000,000 cubic feet. Between St. Paul and Minneapolis the original plan for two low dams has been changed to one high dam (36 ft.) with provision for water-power development. The project was in 1925 practically completed, and the power development was leased to Henry Ford for a large assembling plant now in operation.

On the main upper Mississippi river the plan is to obtain a six-foot depth by contracting the width by brush and stone wing dams, by closing chutes and by revetting banks where necessary, supplemented by dredging. Special treatment by locks and dams is given to two localities—Rock Island Rapids and Des Moines Rapids. At the former point a lock and lateral canal at Leclaire, Ia., overcomes the fall of the Upper Rapids, and a lock and lateral canal at Moline, Ill., overcomes the fall of the Lower Rapids. The project at this point is practically completed. The open channel through both rapids is still maintained. At Des Moines Rapids (Keokuk) private interests have built a water-power dam, concentrating the entire fall of the former canal and locks into a single lock. The project is completed. There is little navigation on the upper Mississippi, but prospects for revival appear encouraging. On the middle Mississippi between the Missouri and the Ohio, the plan is for six-ft. depth above St. Louis and eight ft. below, obtained by contraction and by closing chutes with permeable pile dikes, and by revetting banks where necessary, supplemented by dredging. In that part of the river below St. Louis there is considerable revival of navigation. On the lower Mississippi river, from the Ohio river to the Passes, the plan is for nine-ft. depth, to be obtained by revetting banks, supplemented by dredging.

In 1917 Congress passed the Flood Control Act providing a certain amount of money to be expended by the Mississippi River Commission for improving the river between Cairo and Head of the Passes, and for flood control between Rock Island and the Passes. In 1923 a second Flood Control Act extended the commission's jurisdiction to all tributaries between Rock Island and the Passes, in so far as they are affected by floods in the Mississippi river. As regards the Passes, or mouths of the river, the plans adopted in 1902 having proved inadequate, additional works were authorised in 1916, which have secured a channel through southwest Pass with a controlling depth of not less than 35 feet. The controlling depth in South Pass is approximately 34 feet.

The Missouri.—On the part of the river above Kansas City there is no definite depth to be attained, the project being simply to remove snags and boulders, leaving the natural depth and width of channel, and to revet the banks at certain localities where encroachment threatens great damage. On this part of the river there was in 1926 little commerce. On the section of the river below Kansas City, there is a definite six-ft. project, adopted by Congress in 1910 and being regularly carried out. Here too there was little navigation, but prospects for revival were encouraging.

The Ohio.—A comprehensive project for canalising the Ohio so as to provide a channel nine ft. deep was adopted by Congress in 1910. Slight modifications have since been authorised. As it stood in 1926, the project provides for 50 locks and dams, all of the movable type, except the one immediately below Pittsburg, Pa., which is a fixed dam, completed in 1921, for the purpose of improving conditions in Pittsburg harbour. Of these dams 42 were completed and in operation, and the other eight were under

construction, with the probability that the project will be entirely completed by 1929. The type of dam, together with the relatively low head, does not lend itself to the development of power on a commercial scale. There is one exception to this general statement, at Louisville where the existing navigation dam is being replaced by a power navigation dam eight ft. higher, thereby creating a head of 37 feet.

The total tonnage shipped *via* the Ohio river in 1924 was 10,867,000 tons of which 54% was coal. Commerce on the river has been increasing steadily, particularly on the completed part and many terminals for handling coal have been constructed. A destructive flood occurred in March 1913, and, on that part of the river between Wheeling and Cincinnati and on the tributaries entering from the north in this reach of the river, higher flood stages were reached than had been recorded prior to that date. The flood was particularly destructive in the Miami valley, and, to guard against a recurrence, extensive flood-control works have since been constructed. (H. T.*)

MISSOURI (*see* 18.607).—Since 1910 Missouri continued her transition from the period of frontier influences, of rapid growth of population and development of natural resources, to the stage of industrial development and growth of urban population. In 1925, however, the interests of the state were still primarily agricultural. The total population in 1920 was 3,404,055 as compared with 3,293,335 in 1910, an increase of 110,720, or 3·4%. The percentage of urban population (in centres of 2,500 or more) increased from 42·5% in 1910 to 46·6% in 1920. The total population in 1926 was estimated by the U.S. Bureau of the Census at 3,498,143. Of the total urban population 79·7% in 1920 was in the three cities of St. Louis, Kansas City and St. Joseph. The rural population showed an absolute decrease in both 1910 and 1920. The population of the six chief cities was as follows:—

Cities	1920	1910	Increase %	Estimate 1925
St. Louis	772,897	687,029	12·5	821,548
Kansas City	324,410	248,381	30·6	367,481
St. Joseph	77,939	77,403	0·7	78,342
Springfield	39,631	35,201	12·6	42,140
Joplin	29,902	32,073	−6·8	
Sedalia	21,144	17,822	18·6	22,745

Agriculture.—In 1924, 32,637,043 ac., or 79·1% of the total area of the state, was in farm lands. The average size of a farm was 125·3 acres. The number of farms operated by owners decreased during 1920–5, from 185,030 to 174,390. In 1919 cereal and hay and forage crops continued to lead. Cotton gained from 96,527 ac. in 1909 to 110,027 ac. in 1919 and 475,729 in 1925. Fruit, primarily apples, continued an important crop. After 1909 the acreage in Indian corn decreased to 5,567,079 ac. in 1919, and 5,479,379 in 1924, while the acreage in wheat decreased from 4,564,990 ac. in 1919 to 1,441,071 ac. in 1924. The total value of all farm crops in 1924 was $351,017,000. Indian corn was valued at $163,768,000, wheat at $32,756,000 and oats at $21,290,000. Increasing progress is ensured by the extensive drainage operation in the southeast, and by the increased interests in improved farming methods and in co-operative organisations. The Agricultural College of the state university in co-operation with the Federal Govt. has been very active in agricultural extension work; on Jan. 1 1926 farm-agent work was established in 64 counties. On Jan 1 1925 there were on the farms 714,154 horses, 390,046 mules, 1,657,682 beef cattle, 788,311 dairy cattle, 1,181,000 sheep and 3,584,399 swine.

Mines and Quarries.—The slight increase from 1909 to 1919 in the value of these products of only 5·4% to a total of $33,365,694 was due largely to the post-War depression of the latter year, when it was little more than one-third of the production of 1917, the peak of the War-time stimulation. Lead and zinc continued to be the leading products, of a value of $15,879,177 in 1919, giving Missouri second rank among the states in its production. She ranked third in clay products, with a value of $1,420,585, and second in barytes ($527,817). The other important products were coal ($12,077,845) and limestone ($2,355,736). Since 1923 there has been a marked recovery both in amount produced and in value of mine and quarry products, especially in lead and zinc.

Manufactures.—In 1921 the total value of manufactured products was $1,162,006,299, whereas in 1923 the figures were $1,547,167,429, representing an increase of 33·1%. Sixteen industries in 1923 had a product valued at more than $30,000,000 each. Slaughtering and meat-packing continued to furnish the largest single item—$152,916,678 of the total; motor vehicles were second with $137,447,034; boots and shoes third with $121,830,354. Other important industries were foundries and machine shops $44,086,595, railway cars $38,191,307 and bread and bakery products $40,888,216. The two cities of St. Louis and Kansas City gave employment to over half the wage-earners and produced two-thirds of the total values of the state, St. Louis contributing over half the latter item.

Government.—The movements to adjust the conservative constitution of 1875 to the problems of a modern state were the chief developments. Of 42 constitutional amendments submitted 1910–8, only one, permitting pensions for the blind, was adopted. The opposition to state prohibition (defeated in 1910, 1916 and 1918), and to the single tax (defeated in 1912 and 1918), contributed to the distrust of all amendments. But in 1920 nine amendments out of 13 proposed were adopted, including a provision for a constitutional convention; in 1921 all the three proposed, including the soldier bonus of $15,000,000, in 1922 two out of three, and in 1924 one of four, were adopted.

The executive department was expanded by legislation by the creation of a Food and Drug Commissioner, 1909, a Public Service Commission, 1913, a State Highway Dept., 1917 and a Tax Commission, 1917. The Public Service Commission with real powers of regulation marked a departure from the earlier Missouri practice of leaving the regulation of public utilities to local city boards. Consolidation of executive departments, urged by Gov. Hadley and begun in 1917, was enacted on a comprehensive scale, including a Budget Dept. in 1921, but all the laws were defeated by referendum in 1922.

Constitutional Convention.—The Convention, approved by popular vote in 1921, and elected on a bi-partisan basis in 1922, was in session 266 days between May 15 1922 and Oct. 5 1923. It formulated and submitted to a special election on Feb. 26 1924, 21 constitutional amendments, embodying a comprehensive revision of the constitution. All the more important proposals were rejected by the people. Of the seven amendments adopted, all but one dealt with very minor or special problems. This one was a revision of the Article on the Legislative Dept.; the main changes were the division of the state into senatorial districts by the governor, secretary of state, attorney-general, auditor and treasurer, instead of by the General Assembly; increase of pay of state legislators; authorisation of the pensioning of mothers, and (by cities) of disabled firemen and policemen, and of a workingmen's compensation law. Missouri ratified the Sixteenth Amendment to the Federal Constitution (income tax) in 1909, the Seventeenth (direct election of U.S. Senators) in 1911, the Eighteenth (Prohibition) and the Nineteenth (woman suffrage) in 1919. Missouri remained conservative in social legislation; and a workmen's compensation law in 1920 and 1921 was defeated by the referendum. It was again defeated when proposed by the initiative in 1924. A fairly comprehensive but very moderate Act was passed in 1913 for the health and safety of employees, including limitation of hours for women. The compulsory school-attendance law of 1919 incidentally limited child labour.

Revenue.—The revenue, inelastic through constitutional limitations, proved increasingly inadequate after 1910, until the unpaid current obligations in 1917 totalled over $2,000,000. Attempts to secure relief for special purposes such as schools and good roads by constitutional amendments had all failed. The Assembly of 1917 passed new indirect taxes, a state income tax, a corporation franchise tax, a direct inheritance tax, "soft" drinks stamps and wholesale liquor dealers' licences, which yielded together nearly $2,400,000 in 1917–9. To secure

greater uniformity in taxation and increased revenue the basis of assessed valuation was raised in 1921 to a (nominal) 100% of actual value.

Education.—Missouri appropriates one-third of the general revenue to the support of public schools, amounting to $1,618,341 in 1910 and $3,219,163.35 in 1925. To this must be added $187,040, the interest on the state's common school fund of $3,159,000. The estimated total expenditure for public schools from state and local sources rose (1910–25) from $13,905,188 to $48,760,059. The permanent county, municipal and township school funds increased from $9,825,991 in 1910 to $12,720,879 in 1925. The average daily attendance at the public schools rose from 490,374 in 1910 to 595,305 in 1925. Although the public schools continued to lack sufficient revenue, there was much constructive legislation, especially as to the rural schools. Additional aid was given to rural schools (1909, 1911, 1915) and to high schools (1913) in the poorer districts. The requirements for teachers' certificates was raised in 1911 and 1921, and provision made for the training of teachers in the high school (1913). An effective compulsory attendance law was passed in 1919. The enrolment in the state university at Columbia and Rolla increased from 3,083 (165 at the School of Mines at Rolla) in 1911 to 5,604 (506 at Rolla) in 1925. An Extension Division was organised in 1913; and a School of Commerce in 1914, which was expanded in 1916 to include Public Administration.

Roads.—The state highway system dates from the Hawes Act (1917), passed to take advantage of Federal aid, and the Centennial Road Act (1921). The latter outlined the system and provided for the expenditure of a $60,000,000 bond issue approved by popular vote in 1920. Automobile fees (1922) and a gasolene tax (1924) provided additional funds. Of the total mileage of 7,640 projected, on Jan. 1 1926, 33% had been hard-surfaced and 57½% graded preparatory to surfacing. The work completed represents an expenditure of $73,540,686.

History.—Gov. Hadley was a leading supporter of Roosevelt for the Republican nomination in 1912, though supporting Taft in the election. Wilson that year received 330,746 votes, Taft 207,821, Roosevelt 124,371. In 1916 Wilson defeated Hughes by 28,693, but the Democratic candidate for governor defeated the Republican by only 2,263. In 1918, however, Folk, the Democratic candidate for U.S. Senator, ran 35,283 behind Spencer (Rep.). The disorganisation in the local Democratic party was increased by the opposition of Senator Reed to the League of Nations and, with the general national reaction, resulted in 1920 in the election of a Republican state administration and a Republican majority in both Houses of the Assembly for the first time since 1870, and in a presidential majority for Harding over Cox of 152,363. Senator Reed (Dem.) was re-elected in 1922, but in the presidential election of 1924 Coolidge defeated Davis by 75,733, and Baker defeated his Democratic rival for the governorship by 5,872.

Recent governors have been Herbert S. Hadley (Rep.), 1909–13; Elliot W. Major (Dem.), 1913–7; Frederic D. Gardner (Dem.), 1917–21; Arthur M. Hyde (Rep.), 1921–5; Sam A. Baker (Rep.), 1925– (J. Vi.)

MISSOURI RIVER: *see* MISSISSIPPI RIVER.

MISTRAL, FRÉDÉRIC (1830–1914), Provençal poet (*see* 18.616), in 1906 published a Provençal translation of *Genesis* and *Olivades* in 1912, a collection of Provençal poems. His memoirs appeared, under the title *Mes Origines*, in 1906. He died at Maillane, near Marseilles, March 25 1914.

See P. Brousse, *Frédéric Mistral* (1903); E. Lefèvre, *Bibliographie mistralienne* (1903); H. J. Boeken, *Frédéric Mistral* (1910); J. Brochet, *Frédéric Mistral* (1910); J. Charles-Roux, *Le jubilé de Fr. Mistral* (1912); E. Ripert, *La versification de Frédéric Mistral* (1917); P. Lasserre, *Frédéric Mistral* (1918); J. Vincent, *Frédéric Mistral: sa vie et son influence* (1918).

MITCHELL, PETER CHALMERS (1864–), British zoologist, was born at Dunfermline Nov. 23 1864, and was educated at Aberdeen University, Christ Church, Oxford and at Berlin and Leipzig. From 1888–91 he was university demonstrator in comparative anatomy at Oxford, and for the next two years was organising secretary for technical instruction to the Oxfordshire County Council. He subsequently occupied posts as lecturer in biology at Charing Cross Hospital and at the London Hospital, and was in 1903 appointed secretary to the Zoological Society of London. He also did much useful work as a member of the committees on fishery investigations and on sleeping sickness. During the World War he was attached to the Imperial General Staff and in 1918 acted as liaison officer to the War Office and to the British War Mission. He was elected F.R.S. in 1906. His publications include *Outlines of Biology* (1894), *The Biological Problem of To-day* (1896), *Thomas Henry Huxley* (1900), *The Nature of Man* (1904), *The Childhood of Animals* (1912), *Evolution and the War* (1915) and various scientific memoirs in *The Anatomical Journal*, *The Quarterly Journal of Microscopical Science*, etc.

MITCHELL, SILAS WEIR (1830–1914), American physician and author (*see* 18.618), died in Philadelphia, Pa., Jan. 4 1914. After 1910 he published *John Sherwood, Iron Master* (1911), *Westways* (1913) and *Complete Poems* (1914).

MODERNISM: *see* FUNDAMENTALISM.

MODJESKI, RALPH (1861–), American engineer, was born at Cracow, Poland, Jan 27 1861, his mother being the actress, Helena Modjeska. He graduated at the École des Ponts et Chaussées, Paris, with high honours, and settled in the United States. From 1892 he practised as consulting bridge engineer at Chicago and as a designer and builder of bridges he did distinguished work. Among his best known bridges are the Govt. bridge over the Mississippi at Rock Island; the McKinley bridge at St. Louis; the bridges over the Mississippi at Thebes, Ill., and at Memphis, Tenn.; the Northern Pacific bridge over the Missouri at Bismarck, N.D.; also bridges over the Columbia and Willamette rivers in Oregon. He was a member of the Quebec Bridge Commission, and consulting engineer for the Ohio river bridge at Metropolis, Ill., for the Chicago, Burlington and Quincy Railroad, and the Thames river bridge at New Haven, Conn., for the New York, New Haven and Hartford Railroad. He was chosen chief engineer and chairman of the board of engineers on the Philadelphia-Camden bridge over the Delaware river, which, on its completion, in 1926, was the longest suspension bridge in the world.

MOHAMMEDANISM: *see* CALIPHATE; MAHOMMEDANISM; PAN-ISLAMISM.

MOHN, HENRIK (1835–1916), Norwegian meteorologist, was born at Bergen May 15 1835, and was educated at the Cathedral School in that town and at the University of Christiania (Oslo). In 1861 he became observer at Christiania University, where in 1866 he was elected professor of meteorology and from 1866–1913 was director of the Norwegian meteorological institute which he had been largely instrumental in founding. He carried out much valuable meteorological work, collaborating in 1876–8 with the mathematician Guldberg in a study of the dynamics of the atmosphere and subsequently extending his investigations to the subject of storms, the meteorology and oceanography of the northern Atlantic, the climate of Norway, and use of the hypsometer. Mohn also worked out and published the meteorological observations of various polar expeditions, including those of Nansen and Amundsen. He died at Christiania Sept. 12 1916.

MOLESWORTH, MARY LOUISA (1839–1921), British writer (*see* 18.660), died in London July 20 1921.

MOLNÁR, FERENCZ (1878–), Hungarian dramatist, was born Jan. 12 1878 in Budapest. After studying in that city and at Geneva, he entered journalism and attracted notice by writing short stories, novels and some brilliant farces. His best novel is *The Pál-street Boys* in which child life is portrayed with much humour and power of characterisation. His chief *métier*, however, was the drama. His first successful play, *The Devil* (1907), was exported and, produced in Turin by Zacconi, led to a great demand abroad for modern Hungarian plays. The principal features of Molnár's dramatic works are a keen romantic sense of composition, brilliant technique and a witty and satirical representation of humble life. During the World

War Molnár was a prominent war correspondent of the Central Powers. His plays include *Liliom* (1910); *The Lifeguardsman* (1911); *Carneval* (1917).

MOLTKE, HELMUTH VON (1848–1916), German soldier, was born in Gersdorf, Mecklenburg, May 23 1848, being the nephew of the famous Count von Moltke (*see* 18.677). From 1902 to 1904 he commanded the 1st Div. of the Guards Corps and in 1906 became chief of the general staff of the army. At the beginning of the World War he was the principal director of the German operations, and it is now known that his plans were based principally on the teachings of his predecessor, General von Schlieffen. His modifications of the latter's plans seem to have been, on the whole, unwise, and on him has been placed the responsibility for the German defeat at the battle of the Marne. On Nov. 3 1914 his health being seriously impaired, he was relieved of his post to make way for General von Falkenhayn and was appointed chief of the home general staff in Berlin. He died suddenly, during a function in the Reichstag building, Berlin, June 18 1916. The following works by him were published after his death: *Erinnerungen, Briefe, Dokumente, 1877–1916* (1922), *Aufzeichnungen, Briefe, Schriften, Reden* (1923).

MOMBASA (*see* 18.682), the chief port of Kenya Colony, East Africa, had a population (1921) of 36,846, of whom 656 were Europeans and 7,574 British Indians. In 1924 the population had increased to 42,000 (821 Europeans). Mombasa harbour takes vessels up to 30 ft. draft, but is used mainly by coasting steamers and dhows; the principal harbour is Kilindini, at the southwest end of Mombasa island.

Spacious and land-locked Kilindini accommodates vessels of any size and takes all the traffic of the Uganda railway. A deep-water wharf with two berths provided with all facilities for loading and unloading, built by the Government at a cost of over £1,000,000, was completed in 1926. Much of the cargo had still, however, to be handled by lighters and the administration acquired large areas for development purposes. Steamers entering Kilindini in 1924 numbered 372 (226 British); over 1,400 sailing vessels, mostly Arab dhows, entered Mombasa harbour. See *The East African Red Book* (Nairobi, 1925).

MONACO (*see* 18.684), had a population in 1913 of 22,956. In 1911 Prince Albert of Monaco granted the principality a constitution, providing for a national council of 21 members, elected for four years by universal suffrage and *scrutin de liste*. Government is in the hands of a Ministry assisted by a council of state, acting under the authority of the prince; and legislative power rests with the prince and the national council. The territory of Monaco, which has an area of 8 sq. m., is divided into three communes: Monaco, La Condamine and Monte Carlo, each of which is administered by a municipal authority. On June 26 1922 Prince Louis II. (b. 1870) succeeded his father, Albert, as Prince of Monaco.

The principality exports olive oil, citrons, oranges and perfumes, importing in exchange coal and wine. The principal part of its revenue still comes, however, from the gaming tables. In 1917 £80,000 was paid to the Govt. by the concessionaires; and a scale was arranged providing for the payment of £90,000 in 1927 and £100,000 in 1937.

MONASH, SIR JOHN (1865–), Australian soldier, was born in Melbourne June 27 1865, and educated at Scotch College and Melbourne University. He graduated in arts, engineering and law, and became a successful engineer. He was also interested, as a volunteer, in military work, and at the outbreak of the World War held the rank of colonel. He went to the front in command of the 4th Bde. of the A.I.F.; took part in the landing at Gallipoli on April 25 1915, being thrice mentioned in dispatches; and after the evacuation on Dec. 19 1915, served in the Suez Canal zone till April 1916. He was then given a brigade in France and commanded the 3rd Div. which fought at Messines and Passchendaele. In May 1918 he succeeded Sir William Birdwood as commander of the Australian Army Corps. Although not a professional soldier, he showed a thorough grasp of the principles of the new warfare, and by his brilliant leadership materially contributed to the failure and final collapse of the German offensive of 1918. This campaign he lucidly described in *The Australian Victories in France, 1918*. He was made K.C.B. in 1918 and after the War became manager of Victoria's Morwell electricity scheme.

MOND, SIR ALFRED MORITZ (1868–), British politician, was born at Farnworth, near Widnes, Lancs., Oct. 23 1868, the son of the famous chemist Ludwig Mond (*see* 18.693). He was educated at Cheltenham and St. John's College, Cambridge, and afterwards at Edinburgh University. In 1894 he was called to the Bar, and afterwards joined the North Wales and Chester circuit. He entered the firm of Brunner, Mond and Co., becoming a director in 1895, and also became chairman of the Mond Nickel Co. and a director of the South Staffordshire Mond Gas Co. and various other companies. He was elected to Parliament in 1906 as Liberal member for Chester, losing his seat in 1910, but the same year was elected for Swansea and created a baronet. In 1913 he was sworn of the privy council. On the formation of Mr. Lloyd George's Ministry in 1916 Sir Alfred Mond became First Commissioner of Works, and in 1921 Minister of Health. He lost his seat at the general election of 1923, but was returned for Carmarthen in Oct. 1924. In Jan. 1926, owing to his profound disagreement with the principles embodied in Mr. Lloyd George's land policy, Sir Alfred Mond seceded from the Liberal party and declared his intention of transferring his allegiance to the Conservative party. He published many articles on the alkali trade in scientific and economic journals, besides a volume of essays, *Questions of To-day and To-morrow* (1912).

MONEY MARKET (*see* 17.732).—In no direction were the effects of the World War more striking or far reaching than in the London money market: the great increase in banking deposits, partly as the result of inflation, was but one of the many effects produced by the War upon its dimensions, machinery and general status. Even at the end of 1925 the market was still in a transition state, though in such matters as the size of the floating debt and the value of sterling as related to New York currency there were not wanting signs of a return to more normal conditions.

It has always been regarded as an essential point in the London money market that the Bank of England, while constituting the centre and pivot of the system, should remain a private and independent central institution without State control. In principle, that position was still maintained in 1925, but there were many influences operating during the War which at times made the distinction between a state bank and a private central bank somewhat difficult to determine. The introduction of currency notes, the great size of the floating debt, the growth in the National Debt, and, not least, the fact that shortly after the outbreak of war the State, through the Bank of England, discounted practically all foreign commercial bills in Lombard Street "without recourse," were all developments tending in that direction, as leading to a domination of the money market by the State owing to the magnitude of its financial operations. Some idea of the closeness of relations between the State and the Bank during the War and post-War periods may be gathered from the fact that on more than one occasion the Chancellor of the Exchequer was asked questions in Parliament relating to Bank Rate policy, as though that policy had been inspired by the Government rather than by the Bank Court. On each occasion the Chancellor very definitely disclaimed such responsibility, but it was none the less recognised that of necessity the connection between the Treasury and the Bank of England was more intimate than it had been before 1914.

Following the virtual disappearance of the commercial bill during the war period came the huge flotations of Government Treasury Bills. The effect of this was to make Government operations still further dominate the course of the money market at the expense of the normal power of the Bank of England. The potential power to create credit through borrowings on "Ways and Means" was among the factors which, during the War, gave the Government almost complete control over the money market, and which in the post-War period greatly retarded its return to normal conditions. The *de facto* abandonment

of the gold standard at the beginning of the War and the unrestricted issue of currency notes were further circumstances materially affecting the London money market, particularly the power of the Bank to exert its normal control over the situation through movements in Bank Rate. With the inflation of the currency the Bank Rate lost its power to attract gold, and the exchanges fluctuated widely.

Market Conditions.—While no actual change took place during the period 1910 to 1925 in the general construction of the money market, and while the Bank of England continued to be the pivot of the monetary system, there were many important respects in which the money market was still abnormal at the end of 1925. In at least three important respects money market conditions were wholly abnormal when compared with the pre-War period. In the first place, the volume of commercial bills in Lombard Street was small as compared with the pre-War period. This was only partly due to trade depression, for the disarrangement of international credit machinery by the War, the fact that for many years international commercial transactions were conducted more or less on a cash basis, and, in smaller measure, the growth of the New York money market, were also responsible.

In the second place, there existed an outstanding volume of Treasury Bills to the amount of about £635,000,000 as compared with a standing total in the pre-War days of under £20,000,000. This huge volume of Government floating debt, together with the annual service of the National Debt, which approached £400,000,000 (including the sinking fund) as compared with the pre-War figures of about £23,000,000 and the greatly increased national expenditure, which was about £800,000,000 as compared with £200,000,000 previous to the War, exercised a dominating influence upon the course of the money market. This, in its turn, brought the State and the Bank of England into still closer relation, and heavy borrowing by the Government at certain periods of the year to pay interest on debt increased the difficulty of making the Bank Rate effective. In the third place, although Great Britain had returned to the gold standard, there was, in addition to the Bank of England note circulation regulated by the Act of 1844, a Government currency note issue to the extent of about £300,000,000, of which only a small part was covered by Bank of England notes, which exercised a disturbing influence upon the normal relations between the Bank of England and the outside money market.

The Position of London

Previous to the War London held unchallenged the position both of the leading monetary centre and of the world's banker. Three-fourths of international bills of exchange were drawn upon London, but, by reason of Britain's wealth and the supremacy of her banking system, London was the centre in which foreign countries raised their permanent loans. As a result of the War these conditions were greatly modified, and for the time being America may be said to have challenged London's position of chief lender to foreign countries. During the War dealings in bills of exchange were almost suspended, international transactions being effected on a cash basis through the foreign exchanges, and, with New York as the one free gold centre during the War, there was a tendency for international transactions to take dollar rather than sterling form. Also, by reason of the favourable trade balance obtained during the War years, her gold accumulations and her improved banking system, the United States not only became independent of banking aid from London, but, with the return to more normal conditions after the War, became the country with the largest margin of surplus resources available for foreign investment.

Nevertheless, it was the London money market which took the lead, under the auspices of the League of Nations, in financing the reconstruction of certain of the Central European States. With a view to maintaining the level of sterling exchange, however, a semi-official restriction was placed for a period upon British loans to foreign countries, and it was not until the end of 1925 that the embargo on foreign loans was completely removed. It was, however, more in the direction of long-dated loans than in general money market facilities that relations between London and other centres were temporarily modified, and, while there was a great reduction in bills of exchange dealt in in Lombard street, foreign exchange dealings, which assumed colossal dimensions in the post-War period, tended to centre in London.

Relations with other Money Markets.—A further circumstance, however, which materially affected the relations of the London money market with other centres, and more especially with European centres, was the chaotic condition in many of the European countries after the War. This naturally disturbed the whole international credit system throughout Europe, of which London may be said to have been the centre. Not only, however, were there indications at the end of 1925 of an increase in the general volume of European international trade, but it was also clear that the London money market was holding its old premier position in financing such operations. It should also be noted that, in unison with New York, London was responsible for reconstructing and setting in motion once again the banking and financial machinery at other European centres, notably in Germany and Austria.

Results of the World War

In considering the conditions under which the money market was working after the end of the World War, the changed economic position of Great Britain in relation to other nations, and especially in relation to the United States, must be borne in mind. With a large visible adverse trade balance, with huge gold accumulations in the United States, with an improved banking system in America as compared with the pre-War period, and with America as a large lender to other countries, it had yet to be demonstrated how far and how quickly the London money market would be able to resume its position, not only as the leading monetary centre but as the centre most able to control the foreign exchanges by movements in the Bank Rate. Viewed from the standpoint of actual figures as measured by the wealth of America and of Great Britain, and measured also by the general movements of trade, the task seemed to be an impossible one. Measured, however, by the actual progress made by Great Britain during the post-War period, in spite of the enormous strain suffered, the problem wore a more hopeful aspect. Great Britain is still in the position of one of the largest, if not the largest, holders of foreign securities, while her shipping and financial activities contribute powerfully to her invisible exports. By general consent a great step forward towards a return to normal conditions in the money market was achieved by the return to the gold standard in 1925; but much depended upon whether, in addition to the activities of the London money market and Lombard street, the industrial activities of the country were so organised and arranged as to enable Great Britain to hold the position in international trade which she had occupied before the War and upon which the prosperity of the money market was largely based.

The Discount Houses.—The discount houses and the bill brokers remained a very important part of the money market, though their business, especially as regards the discount houses themselves, was somewhat less strictly confined to bills even before the outbreak of the World War. The deposit business of the discount houses grew materially in the post-War years, and in the matter of fixed deposits they competed somewhat keenly with the banks, upon whom, however, they were still largely dependent for regular weekly loans. During the period of the War, and as a consequence of the virtual disappearance of the ordinary commercial and bank bills, the business of the discount houses and bill brokers may be said to have been confined to Treasury Bills, and, owing to that fact and the abandonment for some years of the gold standard the expert knowledge both of bills and of international financial conditions was probably less required than at any time in the history of the London money market. With the gradual diminution of the volume of Treasury Bills, the growth in the supply of commercial bills and

the return to the gold standard, the need for this expert knowledge reasserted itself, and there was little doubt that in the future the discount market would continue to exercise its old and important functions in the London money market. This, indeed, was the more probable by reason of the fact that, in spite of the improvement in the banking system in the United States, the discount market at New York had not assumed any great importance.

Meanwhile, however, owing to the fact that the growth in the volume of commercial bills had not been commensurate with the decline in the supply of Treasury Bills, the London discount market earned no small amount of its profits by jobbing in short-term Government securities on the Stock Exchange. Moreover, the fact that the joint stock banks during 1924 and 1925 charged the bill market for weekly loans at a level of 1% below Bank Rate, whereas for many years the custom was to make the charge 1½% below Bank Rate, somewhat adversely affected the discount houses and bill brokers. In one respect, conditions in the discount market had not altered greatly from the pre-War period, namely in the dependence of the market, and especially of the bill brokers, upon the Bank of England for assistance at the end of each half-year. On these occasions the joint stock banks call in heavily their short loans from the discount market, and, in connection with what has been described as half-yearly window dressing in the shape of the half-yearly and annual balance sheets, it has become customary for the discount market to have to borrow from the Bank of England during the closing days of each half-year something like £30,000,000. The loans are usually for a period of a week to 10 days, and are almost invariably repaid within the prescribed period (*see* also BANKING; CURRENCY; STOCK EXCHANGE).

MONGOLIA (*see* 18.711).—In inner Mongolia the most important political development is the Japanese claim to the eastern section as part of her sphere of influence. The history of Outer Mongolia, however, has been extremely chequered. In the main, there have been, as for a number of years past, three factors at work: Mongol restlessness under foreign control, and China and Russia. Both of the latter, no matter what their Government, have persisted in an ambition to control the country.

At the time of the revolution in China, in 1911, there was a growing unrest among the Mongol princes against San-to, the Manchu Amban at Urga, for the latter had adopted a vigorous policy of resisting Russian influence and of increasing the power of China through the promotion of Chinese immigration and trade and the strengthening of Chinese garrisons. The Mongol princes therefore took advantage of the disorder occasioned in China by the overthrow of the monarchy to oust the Amban and his subordinate (Dec. 1911), to declare their independence, and to set up the Urga Hutukhtu (Living Buddha) as their ruler. This gave Russia her opportunity, and on Nov. 3 1912 an agreement was signed between the Tsar's Govt. and that in Urga, whereby the former pledged its assistance in maintaining the independence of the latter, and the privileges of Russians in Mongolia were confirmed and extended. China naturally was dissatisfied with this arrangement, and negotiations followed between China and Russia. These resulted, Nov. 5 1913, in an exchange of notes whereby China recognised Mongolian autonomy and Russia recognised Chinese suzerainty over Mongolia. On June 7 1915, after nine months of negotiations, there was signed at Kiakhta a tripartite agreement between Russia, China and the Urga Government. By the terms of this agreement Chinese suzerainty was to be represented at Urga by a resident-general with deputies at three other places, but Outer Mongolia was to remain autonomous under the virtual protectorate of Russia.

Upon the collapse of the old régime in Russia the Chinese took steps to increase their power in Mongolia, and in 1919 Hsu Shu-tseng ("Little Hsu," assassinated Dec. 1925) was appointed "Defence Commissioner." He arrived in Urga in Oct. 1919, and within a few weeks coerced the Mongols into a cancellation of their autonomy. The tyranny of his rule, however, created unrest. Hsu lost his position after the overthrow at Peking of the clique to which he belonged, the Anfu Club, in the summer of 1920, but the feeling against the Chinese continued, and after one unsuccessful attempt in Oct. 1920 Baron Ungern von Sternberg, leading a force made up of several nationalities and professing bitter antagonism to the "Reds" of Russia, early in Feb. 1921 drove the Chinese out of Urga. The Living Buddha now returned to Urga, and an independent Mongol Govt. was proclaimed with the Hutukhtu as ruler and Ungern as chief military adviser. Ungern, who was probably mentally unbalanced, was extremely cruel to his enemies, and it is not surprising that he was defeated by Red forces, suffered from a revolt of his troops, was captured by Mongols (Aug. 1921) and executed by the Soviet authorities. Red troops now organised a government at Urga, and although the Living Buddha (died May 20 1924) was acknowledged as spiritual chief, and Russia technically recognised the new government as independent, Soviet troops remained in Urga. A treaty of Nov. 5 1921 provided for Russian influence. The Chinese naturally objected to this renewal of Mongolian independence under Russian "protection," and the situation became an obstacle in the negotiations between China and the Soviet Government. In the agreement between China and Russia, signed May 31 1924, Russia recognised Outer Mongolia as an integral part of China and agreed to withdraw her troops. In 1925 the Soviet Govt. announced that the withdrawal had been completed, but the influence of Russia was still far greater than that of China. (*See* CHINA.)

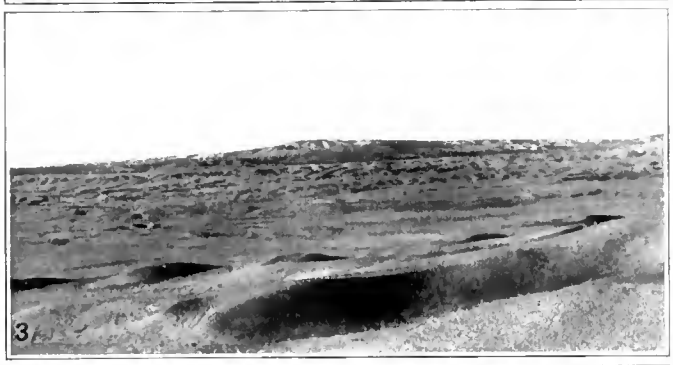
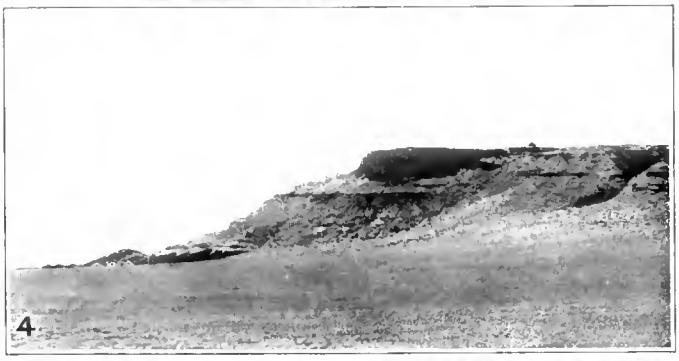
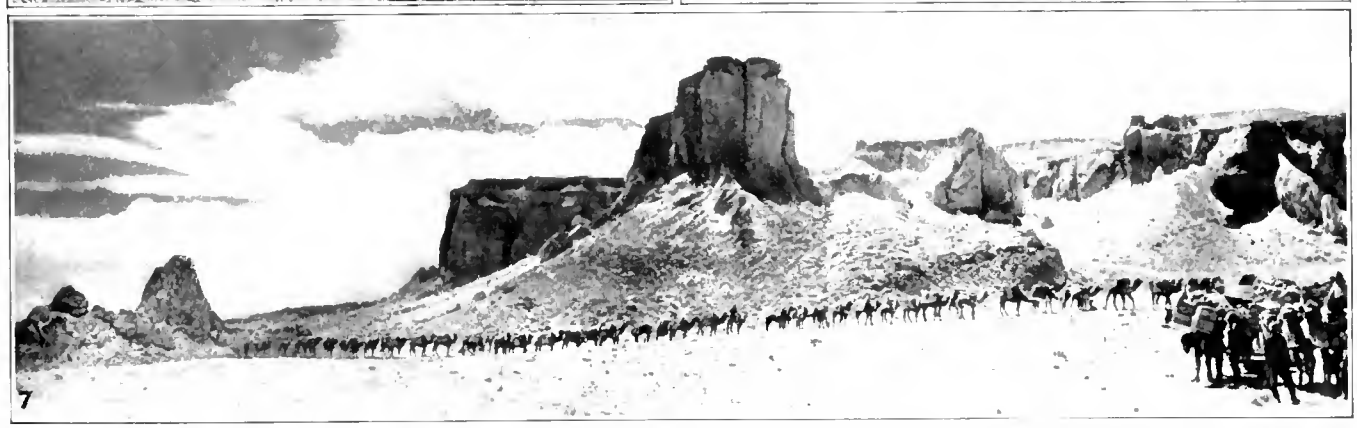
MONGOLIA, PALAEONTOLOGIC DISCOVERIES IN (*see* 20.579).—An important new chapter in palaeontology and geology, in the life history of the earth, has been opened by the discoveries of the Mongolian expeditions of the American Museum of Natural History under the leadership of Roy Chapman Andrews. The most recent discoveries of 1925 reveal Man in three or four culture levels of the Stone Age. During the year 1924 Andrews projected a new five-year expedition, to be known as the Central Asiatic Expeditions of the American Museum of Natural History, adding to the staff a botanist, an archaeologist and three expert topographers. With the full consent of the Mongol officials of the Urga Govt., the Expedition of 1925 completed a survey of outer Mongolia, extending their reconnaissance northwest in the direction of Uliassutai.

Palaeontologic Discoveries, 1922–5.—Central Asia, especially the region east and south of Chinese Turkestan, had long remained the *terra incognita* of geography, geology and palaeontology. In 1900 the present writer predicted that this unknown region, rather than the well-known Asiatic provinces of the south, such as the Siwalik Hills of India explored by Falconer (1831–42), would prove to be the chief centre of mammalian origin and distribution, from which radiated waves of mammalian life to the continents of Europe and of North America. The explorations of the American Museum of Natural History have not only completely verified this prediction but have revealed the central Asiatic plateau as the chief home of the terrestrial dinosaurian reptiles of Cretaceous time. The epicontinental geologic column of Mongolia, heretofore an entire blank, has been largely filled by the geologists Berkey, Morris and Granger during three seasons of explorations, 1922–3 and 1925, and in the remaining three years of the Central Asiatic expeditions the remaining blanks may be successfully filled. The palaeontologic column, as it is known in 1925, is shown in Table I.

Through these discoveries the Quaternary, the Tertiary and the Cretaceous epicontinental formations, corresponding altogether with the unique "Han-Hai" beds of Richthofen (1877)





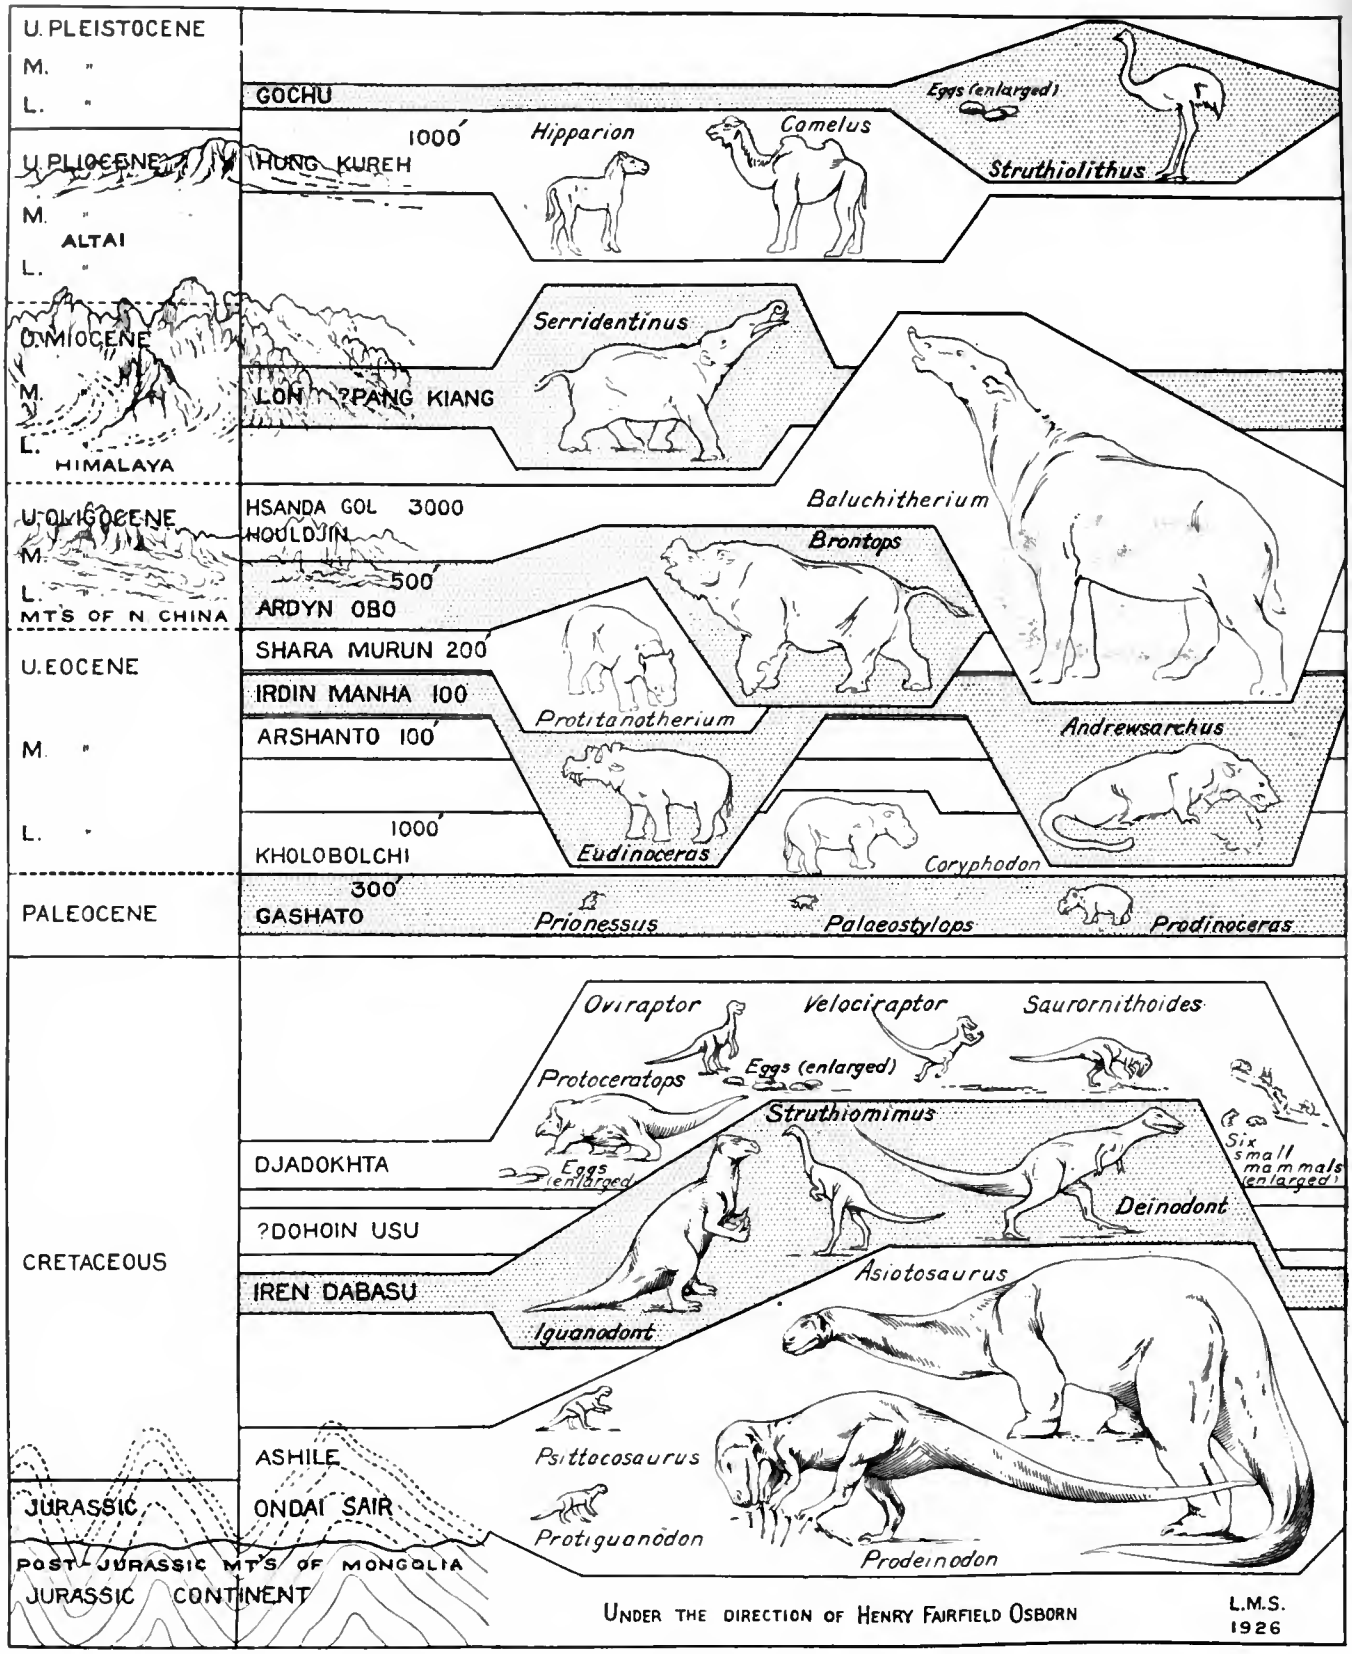


CRETACEOUS AND TERTIARY FORMATIONS, GOBI DESERT, AS DISCOVERED BY THE CENTRAL ASIATIC EXPEDITIONS UP TO 1926

Camel transport of the Central Asiatic Expeditions, 1925, in the foreground.

PLATE II.

MONGOLIA: Palaeontological Discoveries in



REPTILIAN and MAMMALIAN LIFE SUCCESSION in the GOBI DESERT as discovered by the Central Asiatic Expeditions to the end of the year 1925. Left to right, first column: Four periods of mountain uplift. (1) Post-Jurassic mountains of Mongolia, forming by erosion the chief floor of the present Gobi desert; (2) probable Tertiary uplift of the mountains of northern China bordering the Gobi on the south; (3) Uplift, probably culminating in Miocene time, of the Himalaya Mountains bordering the central Asiatic plateaux on the southwest; (4) Upper Pliocene uplift of the Altai Mountains in the middle of the central Asiatic plateau. Second column: Ten Tertiary formations extending from Lower Pleistocene to Paleocene time, also five Cretaceous formations extending from Middle Cretaceous to Upper Jurassic time. Third column: Animals, reproduced to uniform scale, chiefly characteristic of each formation and life-zone, some of which are represented by complete skeletons, others by skulls, still others by highly characteristic teeth (*e.g.*, the giant sauropod *Asiatosaurus* and the theropod *Prodeinodon*).

TABLE I. *Stone Age, Tertiary and Cretaceous Formations of Mongolia*
In Descending Order

Regions	Formations and Thickness Estimated in Feet	Probable or Estimated Geologic Age	Human Culture, Mammal and Reptile Life-zones
Altai piedmont	Shabarakh Usu 50′+	Upper Palaeolithic	?Azilian-Campignian
Altai piedmont	Orok Nor 5′–40′	Middle Palaeolithic Lower Palaeolithic	?Aurignacian-Mousterian ?Acheulean or ?Eolithic
Orok Nor Basin	Khunuk 27′–120′	Lower Pleistocene	*?Equus. ?Mastodon*
Tsagan Nor Basin	Tsagan Nuru 50′± Gochu 1000′±	Lower Pleistocene	*?Equus.* ?Struthiolithus
Eastern Altai Mts.	Hung Kureh 1000′±	Upper Pliocene to Lower Pleistocene	*Hipparion. Camelus* zone
Iren Dabasu Basin	Pang Kiang 500′	?Miocene; age doubtful	Rodents. *?Ochotona*
Eastern Altai Mts.	Loh 100′–1000′	Middle Miocene	Mastodon (*Serridentinus*) zone
Eastern Altai Mts.	Hsanda Gol 3000′	Middle to Upper Oligocene	*Baluchitherium grangeri* zone
Iren Dabasu Basin	Houldjin 30′–50′	Middle to Upper Oligocene	*Baluchitherium grangeri* zone
Orok Nor Basin	Elegen 0′–200′	?Middle to Upper Oligocene	?Mammals undetermined
Uliassutai trail	Baron Sog 5′–30′	?Middle Oligocene	?Large titanotheres
Uliassutai trail	Ulan Gochu 2′–60′	?Lower Oligocene	?Large titanotheres
Uliassutai trail	Ardyn Obo 500′	?Lower Oligocene	*Brontops gobiensis* zone
Uliassutai trail	Shara Murun 200′±	Summit of Eocene	*Protitanotherium mongoliense* zone *Amynodon mongoliensis*
Shara Murun Basin	Tukhum 50′+	Upper Eocene	?Titanotheres
Iren Dabasu Basin	Irdin Manha ?100′	Upper Eocene	Eudinoceras, *Andrewsarchus* zone
Iren Dabasu Basin	Arshanto 40′–100′	?Middle Eocene	Lophiodonts, *Schlosseria* zone
Kholobolchi Nor Basin	Kholobolchi 1000′±	?Lower Eocene	*Coryphodon* zone
Eastern Altai Mts.	Gashato 300′	Basal Eocene (Paleocene)	*Prodinoceras* zone, *Palaeostylops*
Eastern Altai Mts.	Djadokhta 500′	Middle Cretaceous	*Protoceratops Andrewsi* zone
N. E. of Shabarakh Usu	Dohoin Usu 200′±		*Dinosauria, Crocodilia, Chelonia* ?zone
Iren Dabasu Basin	Iren Dabasu 180′	Lower Cretaceous ?Wealden	*Iguanodont. Ornithomimidae*
Oshih Basin	Ashile 2000′	Upper Jurassic	*Psittacosaurus* zone *Asiatosaurus* *Prodeinodon*
Tsagan Nor Basin	Ondai Sair 500′	Upper Jurassic	*Protiguanodon* zone

and the "Gobi Series" of Obruchev (1892–1909), have been subdivided by the American Museum party into from 15 to 23 distinct geologic formations more or less rich in animal life, connected with either Western Europe or North America, the Tertiary with a total estimated thickness of from 6,500 to 9,000 ft. and the Cretaceous with an estimated thickness of 3,380 ft., as shown in Table I. This table includes results up to the end of the season of 1925, in which the most welcome discovery was abundant evidence of the Stone Age in Mongolia, below the Iron, Bronze and the Neolithic, namely, culture levels of Upper Palaeolithic (?Azilian-Campignian), of Middle Palaeolithic (?Mousterian) and of Lower Palaeolithic (?Acheulean) time. No

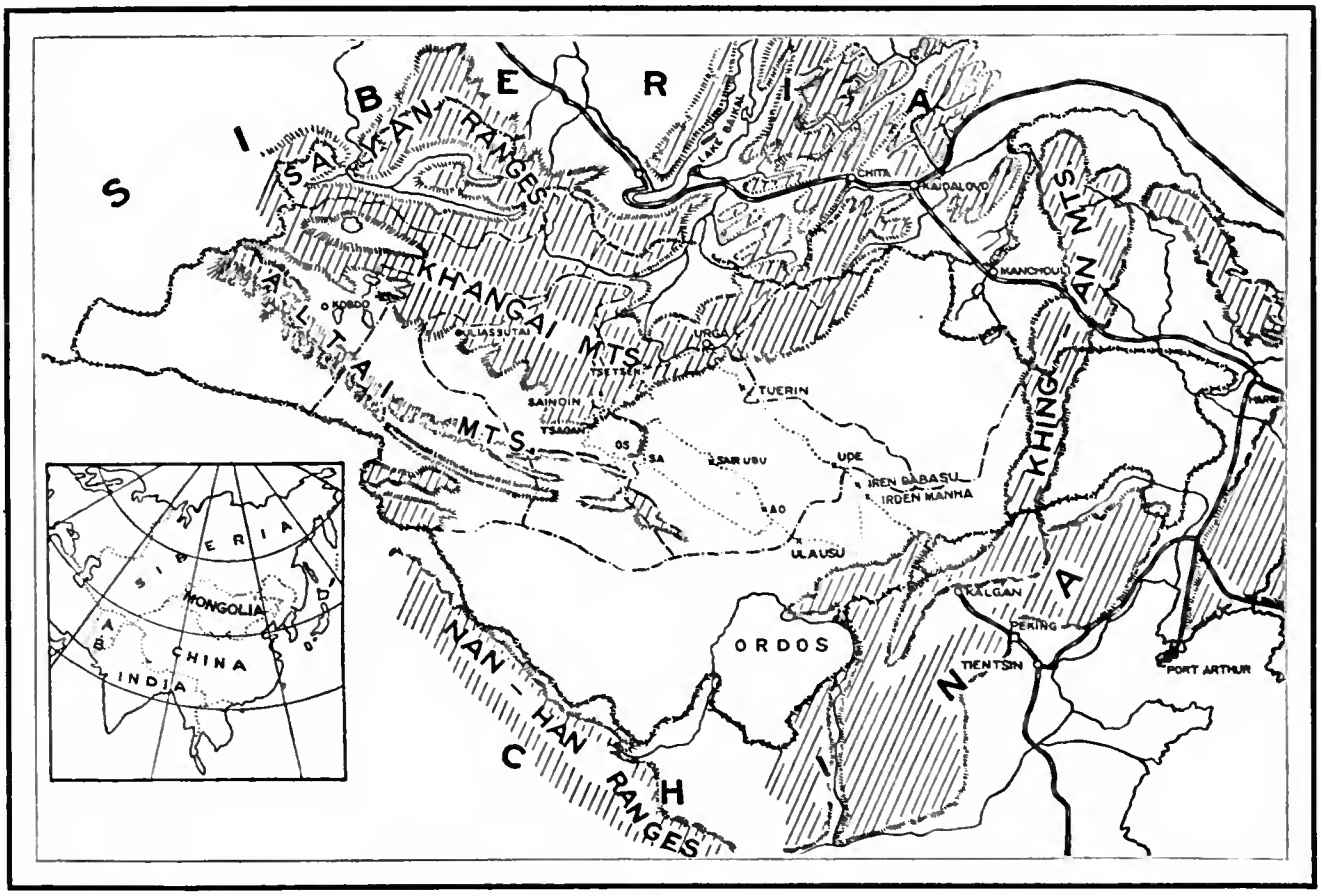


FIG. 1.—Map of Mongolia showing the routes of the Central Asiatic Expeditions of 1922–3. Slanting lines indicate mountain areas; the unshaded area is the Gobi desert.

human fossils were found; the industrial levels are not as yet precisely determinable, but the chief anthropological fact is established that Stone Age tribes spread over the southern Gobi Desert region during Pleistocene time. This accords with the prior discovery (1923) by Licent and Teilhard of the Mousterian industry in the Ordos region of China.

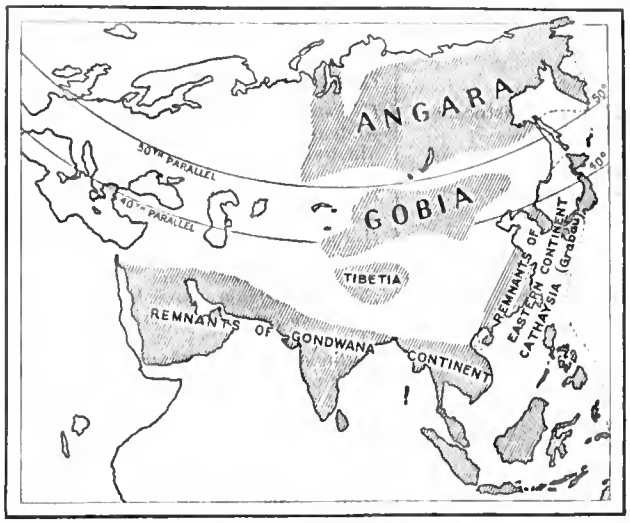

FIG. 2.—GOBIA (Grabau), a theoretic Upper Jurassic Continent in the heart of Central Asia. To the extreme south, the GONDWANA Continent (Suess). To the north, the theoretic Continent of ANGARA (Suess).

Equipment, Personnel and Itinerary.—It was in 1920 that R. C. Andrews first crossed the broad level Mongolian plains and conceived the plan of a camel caravan for heavy transportation of gasolene and supplies, with light and heavy automobiles for detour and reconnaissance work. The camel caravans, composed of from 150 to 250 animals under Mongol drivers, averaged from 12 to 15 m. a day; the automobile trains proved capable of 10 times this speed, carrying an American party of from eight to 12 members, 12 Chinese helpers and an equal number of Mongols. The expedition had the advantage of speed over the work of previous explorers, who had entered or crossed the desert with camels only, namely, Raphael Pumpelly (1864), Ferdinand von Richthofen (1871–2) and V. A. Obruchev (1892–1909). The American palaeontologists and geologists, Granger, Berkey and Morris, also had the advantage of prolonged experience in the fields and geologic formations of the western United States, which between the 50th and 40th parallels of latitude present conditions remarkably similar to those in the desert of Gobi (*see* map on p. 943).

In the easterly region of the Gobi desert, previously declared unfossiliferous, in which Obruchev found only a single fragmentary "rhinoceros" tooth, the expedition, leaving Kalgan April 15 1922, discovered on May 3, 260 m. northwest of Kalgan, rich strata near Iren Dabasu of probably Lower Cretaceous age, full of large iguanodonts, megalosaurs and also ostrich-mimicking dinosaurs. Overlying this deposit (Iren Dabasu formation) were discovered much more recent Tertiary formations of Upper Eocene (Arshanto and Irdin Manha formations) and Upper Oligocene (Houldjin) age, which correlate very closely with the classic Upper Eocene formations of Cuvier in France and similar fossil beds in Utah, Wyoming and Nebraska of the Rocky Mountain region. These Mongolian formations immediately established the Gobi region as a great central life zone, half-way between Europe and the Rocky Mountain region, according to the theory of 1900.

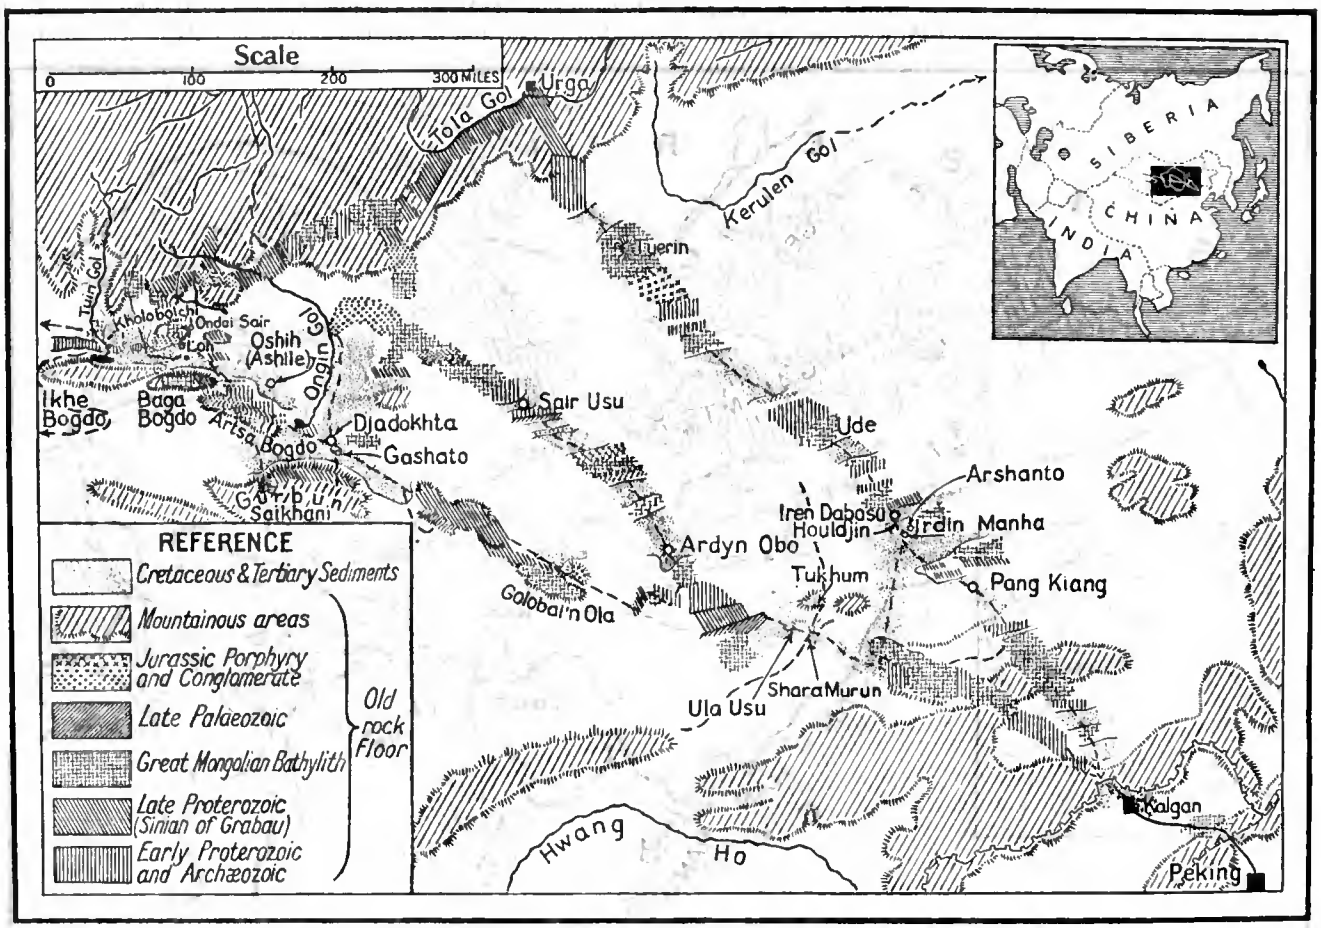

FIG. 3.—Sketch map of central Mongolia, showing the general geology along the routes of the Central Asiatic Expeditions of 1922, 1923, 1925, the main and side routes indicated by long dashes. The arrows west of Baga Bogdo indicate northern routes along the Uliassutai Trail. Finely stippled areas indicate location of chief Cretaceous and Tertiary formations listed in Table I. Hung Kureh and Gochu lie S.E. of Loh.

Encouraged by this brilliant initial success of 1922, the American Museum party made a 3,000-m. reconnaissance to the north as far as Urga, the capital of Mongolia, and southwest to the Altai mountains where five additional fossil horizons (Ondai Sair, Ashile, Hsanda Gol, Loh and Hung Kureh formations) of Upper Jurassic, Upper Oligocene, Miocene and Pliocene age were discovered; then southeast along the Altai mountains, where in the Djadokhta formation of Middle Cretaceous time the now famous dinosaur eggs were found, together with marvellously preserved series of dinosaur skeletons, chiefly of herbivorous types such as *Protoceratops* and of small carnivorous types. Thus the 1922–3 expeditions virtually circled the entire desert of Gobi east of the Altai mountains (fig. 1). On the return, toward Kalgan in north China, three additional Tertiary fossil horizons (Gashato, Ardyn Obo and Shara Murun) were discovered and a few representative fossils from each were brought back.

The types of dinosaurs, and of mammals which chiefly characterise these formations or horizons, are diagrammatically

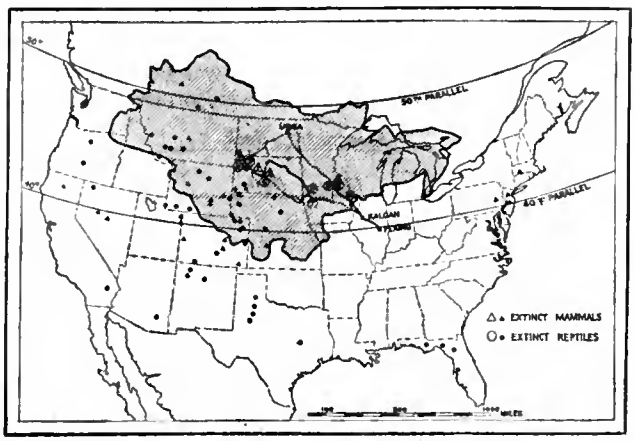

FIG. 4.—Areal map of Mongolia, projected upon map of United States of America. Similar 50° and 40° parallels of latitude. △, ○, = chief fossil localities of central Mongolia discovered to the end of the year 1925. ▲, ●, = chief fossil localities of terrestrial dinosaurs and mammals of the United States. This map demonstrates that the Mongolian and North American faunas occupied similar isothermal regions in central Asia and central North America from Upper Jurassic to Tertiary time.

shown in Plate II., which displays the ancient "life zones" of Mongolia as we descend from Lower Pleistocene into Upper Jurassic time. The animals represented in this life zone chart are known either by complete skeletons (*e.g., Protoceratops, Protiguanodon, Psittacosaurus*) or by complete skulls (*e.g., Baluchitherium, Protitanotherium*) or, finally, by highly characteristic teeth (*e.g., Asiatosaurus, Prodeinodon*). In all of the Cretaceous horizons the correlation with Europe and with North America is provisional; in all the Tertiary horizons, excepting the ?Miocene Pang Kuang, the correlation is either absolute or fairly close.[1]

In the season of 1923 the expedition explored intensively the fossil beds visited in 1922, and returned with the camel caravan heavily loaded from the 15 or more horizons extending from the Upper Jurassic (Ondai Sair, Ashile) to the very summit of the Upper Pliocene (Hung Kureh).

These discoveries have established Mongolia as a treasure house of the life history of the earth from the close of Jurassic time onward to the close of Pleistocene time, *revealing especially the hitherto unknown high continental life of Cretaceous and Tertiary times*. Consequently, the outstanding geologic discovery of the expedition is, first, that *GOBIA* (fig. 2) since Jurassic time has been a central Asiatic continent extremely favourable to the evolution of reptiles, mammals, insects and plants hitherto known only along the Cretaceous shore lines of Europe and the Cretaceous sea borders of the centre of America, and second, that this now terribly desert region, traversed by the gazelle and the wild ass, was certainly luxuriant with life throughout Cretaceous and Tertiary time, sparsely forested, with limited rain supply like the high plateau region of Africa to-day.

These upland conditions of Mesozoic and Caenozoic time, also favourable to the origin of the human race itself, led to the further generalisation by H. F. Osborn, on returning from Iren

FIG. 5.—Irdin Manha Upper Eocene formation of the Iren Dabasu Basin, eastern Mongolia. Rich in titanotheres and other large mammals of American Upper Eocene affinities. (Compare fig. 3.)

Dabasu in 1923, that the ancestors of man occupied this region during Caenozoic time and are likely to demonstrate the central Asiatic theory of human origin. This generalisation was partly verified during the year 1925.

TABLE II. *Human Culture, Mammalian and Reptilian Life Zones in Descending Order*

1. *Mongol graves* of early historic time.
2. *Iron and Bronze ages* represented by monuments and graves in the Gobi desert.
3. *Neolithic* represented in the upper levels of Shabarakh Usu deposits; pottery, etc., ostrich eggs (*Struthiolithus*).
4. *Uppermost Palaeolithic of Shabarakh Usu.* Indurated sands containing flints, resembling those of the ?Azilian and Campignian industries of Europe; eggshell ornaments made of *Struthiolithus* and of fossilised dinosaur eggs. The "dune-dwellers" of prolonged occupation. True Upper Palaeolithic not found.
5. *Lower Palaeolithic.* Near Orok Nor, 20 m. from Kholobolchi Nor. Flint industry of possible Aurignacian age; flints certainly of Mousterian age, of IV. Glacial and pre-Glacial time resembling those of the Ordos.
6. ?Acheulean or ?Eolithic flints of uncertain age.
7. *Tsagan Nuru, Gochu.* Regarded as base of the Pleistocene. The Gochu, 1,000 ft. in thickness, overlies the Hung Kureh at the foot of the Altai range Baga Bogdo. The sands of Tsagan Nurud contain *Equus* and *Struthiolithus*.
8. *Hung Kureh.* Lower Pleistocene and Upper *Pliocene.* Containing in lower levels, a true Upper Pliocene horizon, *Hipparion, ?Elephas, Cervus, Castor, Camelus, Gazella*, rhinoceros, ?Coelodonta. Compare Plaisancian-Astian of France and Italy.
9. *Loh.* These gravels and clays, directly overlying the Hsanda Gol, are apparently of Middle Miocene age. Containing a mastodont, *Serridentinus mongoliensis*, and a diminutive baluchithere, *Baluchitherium mongoliense*. Compare Lower and Middle Miocene Burdigalian-Helvetian of France.
10. *Hsanda Gol.* Great formation 3,000 ft. in thickness, of Middle to Upper Oligocene, or Stampian to Aquitanian. Containing abundant remains of *Baluchitherium grangeri*, a skull having been found in 1922 and a leg and feet in 1925; small rhinoceros; very large small-mammal fauna, several thousand jaws belonging to 30 genera of rodents, creodont carnivores, true carnivores, insectivores related to *Tupaia* (the tree shrews) and *Macroscelides* (the jumping shrews). The prevailing affinities of this fauna are with the Quercy Phosphorite of France; there are also distant affinities to modern African rodents and insectivores; relationship to North American and the Middle Oligocene White River fauna is less close, except in the wide-ranging carnivores like *Hyaenodon*. The larger rhinoceros *Baluchitherium* resembles that of Baluchistan (Forster Cooper) and the *Indricotherium* (Borissiak) of Turkestan.

A formation of similar age in the Iren Dabasu basin is the *Houldjin*, where Obruchev discovered his "rhinoceros" tooth, probably a baluchithere.

Apparently intermediate between the well-determined Hsanda Gol and the Ardyn Obo formations, there were found in 1925 three other horizons in which the faunas are still to be determined, namely, *Elegen*, Middle to Upper Oligocene, *Baron Sog*, Middle Oligocene and *Ulan Gochu*, Lower Oligocene.

11. *Ardyn Obo.* 500 ft. thick. On the Uliassutai trail. Contains rich Lower Oligocene (Sannoisian) fauna, chiefly of ungulates, including giant titanotheres (*Brontops gobiensis, Menodus mangoliensis*) broad-skulled and long-skulled titanotheres similar to those of South Dakota and Colorado; also an amphibious rhinoceros, *Cadurcotherium* mongoliense, intermediate in character between *Cadurcotherium* of the Lower Oligocene of France and the American *Metamynodon*. The creodont carnivores include *Hyaenodon* and aberrant oxyaenids ancestral to Hsanda Gol forms. Compare Infra-Tongrian, Ronzon, Quercy.
12. *Shara Murun.* Richly fossiliferous formation on the Uliassutai trail, representing the very summit of Eocene time. Contains

[1] To clearly understand the above description the reader should carefully examine Plate I., correlation chart, and Table II., faunal succession.

imposing titanothere fauna (*Prototitanotherium andrewsi, P. mongoliense, Dolichorhinus*), quadrupeds extraordinarily similar to those of Utah in the Rocky Mountain region. Here occur the amphibious amynodonts, also a long-limbed rhinoceros ancestral to *Baluchitherium*, and numerous smaller odd-toed ungulates suggestive of *Tapirus* and the cursorial *Colodon* (*Deperetella*), all of strong American resemblance. Most important is the pro-ruminant *Archaeomeryx*, in all respects ancestral to the higher ruminants (*Cervidae*, etc.). The carnivores of this horizon (*Hyaenodon, Pterodon*) are again of Franco-American affinities. Compare Ludian stage of France, Gypse de Montmartre.

Tukhum is another formation discovered in 1925, which has not yet been fully studied. It directly underlies the Shara Murun.

13. *Irdin Manha.* In this great flood-plain horizon, only 100 ft. in thickness but of vast horizontal extent, we again observe very close relationships to the Upper Eocene of the Rocky Mountain region. Outstanding types are the titanotheres (*Dolichorhinus, Protitanotherium, Mesatirhinus*); the giant *Eudinoceras*, four-horned and tusked, comparable to *Dinoceras* Marsh of the Rocky mountains; finally, the giant *Andrewsarchus*, a primitive creodont carnivore named after Andrews, the leader of the Central Asiatic Expeditions.

14. *Arshanto.* A little-known formation directly underlying *Irdin Manha*, probably of Middle Eocene age, containing small lophiodonts.

15. *Kholobolchi.* In this newly discovered horizon occur animals similar to the *Coryphodon* of the Suessonian of France and the Lower Eocene Wasatch of the Rocky mountains.

16. *Gashato.* Rich fauna of Paleocene age, including *Palaeostylops*, an herbivore related to a South American genus as determined by Matthew; also the long-tusked amplypod *Prodinoceras*, ancestor to *Eudinoceras* and related to a smaller form in the Rocky Mountain region.

No horizons have been discovered representing the close of Cretaceous time but the beginning of Upper Cretaceous time is probably represented by the famous *Djadokhta* horizon containing *Protoceratops* and the nests of fossilised dinosaur eggs.

17. *Djadokhta.* These flaming red cliffs of aeolian sand apparently preserve the entire reptilian fauna of this locality, which appears to have been a nesting ground of the primitive horned dinosaur known as *Protoceratops*. The delicate red sand contains in nearly perfect condition nests of eggs varying from 12 to 20 in number, belonging chiefly to *Protoceratops*, representing at least three species or genera of dinosaurs. This primitive horned dinosaur is represented by nearly seventy growth-stages, from the tiny skeleton within the eggshell to skulls about two feet in length. Small carnivorous dinosaurs, *Velociraptor* and *Saurornithoides*, are found, also the ornithomimoid *Oviraptor*, so named because its skeleton rested directly upon a nest of dinosaur eggs. Most remarkable were small mammals of the size of mice and shrews, represented by six skulls, related to small creodont carnivores and to insectivores.

18. *Dohoin Usu.* A fossiliferous basin, the fauna of which has not yet been examined.

19. *Iren Dabasu.* A very rich horizon in eastern Mongolia containing dinosaurs of Lower Cretaceous, possibly Wealden, age; *Iguanodont* equal in size to the *Ibernissartiensis* of Belgium; also a carnivorous dinosaur, possibly resembling *Deinodon* of the American Middle Cretaceous; finally, a toothless ostrich resembling *Struthiomimus* in size.

20. *Ashile.* In the Oshih basin, containing small parrot-beaked iguanodont dinosaur known as *Psittocosaurus mongoliensis;* the giant sauropod *Asiatosaurus*, resembling *Camarasaurus* of the American Upper Jurassic Morrison horizon; and *Prodeinodon*, resembling *Allosaurus* of the Morrison of Wyoming. This fauna appears to be of sub-Wealden age and to represent the close of Upper Jurassic time.

21. *Ondai Sair.* A small parrot-beaked leaf-eating iguanodont *Protiguanodon mongoliense*, more primitive in tooth structure than *Psittocosaurus*, remotely related to Huxley's *Hypsilophodon foxi* of the Wealden of England. This horizon contains a rich insect fauna.

BIBLIOGRAPHY.—The scientific and semipopular literature is already extensive. In *Asia Magazine*, which helped to finance the expeditions and which owns the copyright of many of the photographs, has appeared a series of narrative articles (1922–5) by the leader of the expeditions, Roy Chapman Andrews, which are being republished in his volume, *On the Trail of Ancient Man* (1926): Preliminary scientific papers by the geologists and palaeontologists of the expeditions, Messrs. Berkey, Morris, Granger, Matthew and Osborn, have appeared chiefly in the American Museum *Bulletins* and *Novitates* and are collected in a volume entitled *Preliminary Reports of the Central Asiatic Expeditions*, vol. i., which has been distributed to 100 of the chief scientific institutions of the world. More mature scientific publication is projected in a series of 12 volumes, of which vol. ii., *Geological Reconnaissance in Mongolia*, by Charles P. Berkey and Frederick K. Morris, will appear first.

(H. F. O., R. C. A.)

MONITOR.—Almost immediately on the outbreak of the World War it became apparent that the German occupation of Belgium could be to a certain extent out-flanked along the coast by bombardment of the ports which were being used as bases for torpedo boat destroyers and submarines. As the water is very shallow for a considerable way out, it became necessary to have vessels drawing very little water, and soon after the outbreak of war the British Navy took over three river monitors, built by Messrs. Vickers for the Brazilian Govt., with a view to using them on the Belgian coast. These were only small vessels, renamed the "Humber," "Mersey" and "Severn," mounting 6-in. and 4·7-in. guns, and it soon became evident that vessels of the monitor type, with heavier guns and better protection, would be very useful. An interesting account of how the suggestion arose to add big gun monitors to the fleet in 1914 is given by the then First Lord of the Admiralty, the Rt. Hon. Winston Churchill, in his book "The World Crisis 1911–4."

At a conference with Lord Fisher and Mr. Schwab concerning submarine contracts, Mr. Schwab offered to supply to the Admiralty four turrets, each mounting two 14-in. guns, which had been almost completed for the Greek battleship "Salamis," then building in Germany for Greece. This offer was accepted, and Mr. Churchill, remembering the good work done by the three small ex-Brazilian monitors "Humber," "Mersey" and "Severn" off the Belgian coast, suggested monitors should be built to carry these 14-in. guns close inshore to attack the enemy.

Thus the idea of the 14-in. monitors was born, and in Nov. the four vessels to carry these guns were ordered, the "Abercrombie," "Havelock" and "Raglan" from Messrs. Harland and Wolff, and the "Roberts" from Messrs. Swan and Hunter.

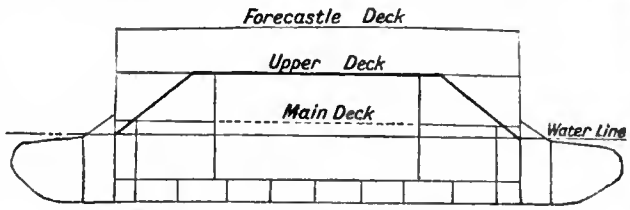

FIG. 1.—Section of a typical monitor.

Main Features.—The characteristics of these monitors were shallow draught and very good under-water protection by means of a complete bulge, and a typical section of a big gun monitor is shown in fig. 1.

The fact that both these qualities diminished very greatly the risk of successful torpedo attack brought to the fore their great possibilities. So highly thought of, in fact, were these possibilities that additional guns were sought to provide the armament for further vessels of this type, and this was done by using two 15-in. gun turrets, which were ready for battleships under construction, stripping the old "Majestic" class of battleship of their 12-in. turrets and the "Powerful" and other vessels of their 9·2-in. guns. With these guns around which to design the monitors swift progress was made.

Toward the end of 1914, eight vessels were ordered to carry the 12-in. guns, followed by further orders early in 1915 for two vessels to carry the 15-in. guns, 14 to carry the 9·2-in. and five to carry the 6-in. guns.

The names of these various types were as follows, and the tables below give the detailed particulars:—

14-in. Monitors: "Abercrombie," "Havelock," "Raglan" and "Roberts."

12-in. Monitors: "Lord Clive," "General Crauford," "Earl of Peterborough," "Sir Thomas Picton," "Prince Eugene," "Prince Rupert," "Sir John Moore" and "General Wolfe."

15-in. Monitors: "Marshal Ney," "Marshal Soult" and two of a later type, "Erebus" and "Terror."

9·2-in. Monitors: M.15 to M.28.

6-in. Monitors: M.29 to M.33.

A typical profile of a big gun monitor with a 9·2-in. gun is shown in fig. 2 and the detailed particulars of the various vessels are given in table on p. 945.

The 9·2-in. and 6-in. vessels were designed for river work and for manoeuvring in closed waters, and were not bulged.

Machinery.—In the construction of all these monitors time was essential, and in several cases the big gun monitors were launched within four months of the keel being laid, and completed ready for service within just over six months. It was

Type	Length between perpendiculars	Length over-all	Breadth ext.	Load draught mean	Displacement	S.H.P. of Engines	Speed at load drght.	Fuel capacity	Armament
	ft.	ft. in.	ft.	ft.	tons		knots	tons	
14-in.	320	334–6	90	10	6,150	2,000	6–7	400 coal	2–14-in. 1–6-in.
12-in.	320	335–6	87	10	5,900	2,300–2,500	6–7	350 coal	2–12-in. 1 to 4–6-in.
15-in.	340	355–8	90½	10½	6,670	1,500	6–7	235 oil	2–15-in. 8–4-in.
9·2-in.	170	177–0	31	6	540	480–800	12–13	30 oil	1–9·2-in. 1–3-in.
6-in.	170	177–0	31	4	355	400	10	45 oil	2–6-in. 1–6-pdr.
"Erebus" "Terror"	380	405–0	88	11	8,000	6,000	12	750 oil	2–15-in. 8–4-in.

neccessary, therefore, to take, in many cases, whatever machinery happened to be available, and in consequence the machinery installations varied somewhat. The 14-in. and 12-in. monitors all had either quadruple or triple expansion reciprocating engines, but the 15-in. vessels, "Marshal Ney" and "Marshal Soult," had twin sets of internal combustion engines, originally designed for oil carriers. All the 6-in. monitors were twin screw with steam engines and oil-fired boilers. The oil engines in the two 15-in. monitors were never quite satisfactory, and this, combined with the somewhat bluff form of the boats, gave rather a poor speed on service, and after a time it was decided to build two larger and faster vessels to carry these 15-in. guns to better advantage. This decision was modified owing to various other conditions which arose, and it was ultimately decided to take out the guns from the "Marshal Ney" and to provide in addition a new twin 15-in. mounting to complete the two sets of guns necessary for the two new vessels.

The "Erebus" and "Terror."—These vessels had special bulge protection of an improved type, and with their more powerful machinery of 6,000 H.P. and improved form had a speed of 14 knots. Ordered in Sept. 1915, and completed in 12 months, they proved very efficient on service, and although both were heavily struck by German torpedoes, neither was seriously damaged and the repairs were quickly effected.

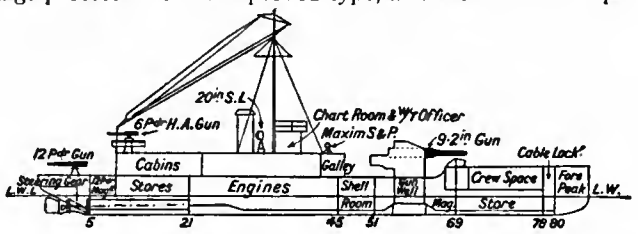

FIG. 2.—Profile section of monitor mounting a 9·2-in. gun.
From Brassey's *Naval and Shipping Annual.*

Two other vessels, although not of the true monitor type, were converted for similar service to that on which monitors were employed.

"Glatton" and "Gorgon."—The "Glatton" and "Gorgon" were armed with two 9·2-in. guns and six 6-in., together with several smaller. Originally the coast defence vessels "Bjorgrin" and "Nidoros," building for the Norwegian Govt. by Messrs. Armstrong and Whitworth, they were finally put into commission toward the end of 1918 after the fitting of bulge protection.

The "Glatton" was unfortunately lost in Dover Harbour soon after her completion owing to an explosion on board causing an outbreak of fire. To prevent possible further explosions it was decided to sink the vessel at anchor, and owing to the bulge protection, it took three torpedoes at close range to do this, and these caused the vessel to sink slowly.

With the exception first mentioned of similar monitors originally designed and built for the Brazilian Govt. which were taken over by the British Govt., none of the foreign powers appear to have developed this type of vessel to any extent during the War, although the Italian Govt. mounted some heavy guns on a kind of barge, but these were much more of the nature of an improvisation than the British vessels, and there appears no question that this type of vessel is only needed for very special work in shallow waters, and no more have been built. During the Gallipoli campaign several of the monitors were sent out there and did good work in bombarding the Turkish lines at long range.

Quite at the end of the War it was decided to mount two very big guns on three of the 12-in. monitors, and an 18-in. gun was mounted on the "Lord Clive," the "General Wolfe" and the "Prince Eugene." Only two of these vessels were completed with their 18-in. mountings before the end of the War, but they fired a good many rounds of this huge projectile into the German lines in the neighbourhood of Bruges.

Of all these vessels produced during the War with such great expenditure of money and concentrated energy, only three of the big-gun type now remain on service. These are the "Erebus" and "Terror" and "Marshal Soult," all of which are the 15-in. gun type, and these are at present being used as drill ships. Of all types of warships carrying heavy calibre guns the monitors were in action far more often and for longer periods than any other type, whether battleship or battle-cruiser, and the losses, as shown below, were correspondingly heavy.

"Raglan," 14-in. type. Sunk by gunfire of the German battle-cruiser "Goeben" in action off Imbros on Jan. 20 1918.

M.15, 9·2-in. type. Torpedoed by a German submarine off Gaza on Nov. 11 1917.

M.21, 9·2-in. type. Mined off Ostend on Oct. 20 1918.

M.25, M.27, 9·2-in. type. Lost during operations on the Dvina river, north Russia, on Sept. 17 1919.

M.28, 9·2-in. type. Sunk by gunfire of the German battle-cruiser "Goeben" in action off Imbros on Jan. 20 1918.

M.30, 6-in. gun type. Sunk by Turkish batteries in the Gulf of Smyrna, on May 13 1916.

MONOD, GABRIEL (1844–1912), French historian (*see* 18.730), died at Versailles April 10 1912.

MONOPLANE: *see* AEROPLANE.

MONRO, SIR CHARLES CARMICHAEL (1860–), British soldier, was born June 15 1860, and joined the army in 1879. In 1897–8 he saw service at Malakand, in the Mohmand country, in Bajour and in Tirah and he was on the staff in South Africa (1899–1902). He was afterwards commandant of the School of Musketry at Hythe, Kent. Having commanded the 2nd Div. in the first fighting in 1914, Monro was, at the end of 1914, placed in command of the I. Army Corps, and on a III. Army being organised in July 1915, he was given charge of this. He was chosen in October to take over the command of the Mediterranean Expeditionary Force and to decide whether the campaign in the Gallipoli Peninsula was to be continued. Monro acted with rare decision. Although the Govt. was disposed to cling to the peninsula, he insisted upon its abandonment, and he was, after some delay, allowed to have his way, with the result that the forces were withdrawn from a most dangerous position without appreciable loss. He returned to the Western Front to succeed Sir Douglas Haig in command of the I. Army, but in Oct. 1916 he was selected to be commander-in-chief in India.

In his new sphere Sir Charles Monro proved himself to be a military administrator of the first rank. By untiring energy and skilful organisation he succeeded in adding substantially to the strength of the native army, in creating a number of fresh regiments and in greatly developing the non-combatant and hospital services on progressive lines. The consequence was that he was enabled to dispatch considerable and badly needed reinforcements to Mesopotamia and to Egypt and Palestine. In Sept. 1923 he was appointed to the position of governor and commander-in-chief of Gibraltar.

MONS, BATTLE OF: *see* FRONTIERS, BATTLES OF THE.

MONTAGU, EDWIN SAMUEL (1879–1924), British politician, second son of the 1st Lord Swaythling (head of the financial firm of Samuel Montagu and Co.), was born Feb. 6 1879 and educated at the City of London School and at Trinity College, Cambridge. At Cambridge he was president of the Union and acquired a considerable reputation for ability. When he entered Parliament in 1906, as Liberal member for the Chesterton division of Cambridgeshire, he was chosen by Mr. Asquith, then Chancellor of the Exchequer, as his parliamentary secretary, and continued in that position when his chief succeeded to the premiership. Early in 1910 he was appointed Under-Secretary for India, under Lord Morley, and remained in the post, under Lord Crewe till 1914; and so made his first official acquaintance with India under the influence of Lord Morley's reforms and Lord Crewe's Durbar changes of 1911. As both his chiefs were in the Lords, he was the spokesman of the office in the Commons, and he acquitted himself well. That he might equip himself the more completely for his duties, he took the unusual course of visiting India in person.

After holding during the World War the posts of Financial Secretary to the Treasury—where he had much to do with the introduction of War Savings Certificates—Chancellor of the Duchy of Lancaster (1915) and Minister of Munitions (1916), he returned in 1917 to the India Office as Secretary of State and began a tenure of that post which will always be memorable in Indian annals.

He visited India in the following winter for the second time, and held prolonged conferences with the Viceroy, Lord Chelmsford, the leading members of the Indian Civil Service, ruling princes and native politicians, and along with the Viceroy received deputations and memoranda from all classes. Ultimately in July 1918 there was published an elaborate report, signed by the Viceroy as well as by the Secretary of State, recommending a series of constitutional reforms which should give the Indian peoples a large and real share in their own government. The report was received so cordially in the House of Commons that Mr. Montagu was able to claim at the end of the debate as "a remarkable fact" that all speakers admitted the principle of self-government for India. In Dec. 1919 he had the satisfaction of passing through Parliament the Government of India bill, which established in India, in accordance with the report, what was called a "diarchy," a partition of the powers of Government between the civil service and the native population.

Unfortunately, by the time the Act was passed the situation in India had become grave. The Rowlatt Sedition bill had provoked alarm and excitement throughout the country; Mr. Gandhi had organised passive resistance; serious disorders had broken out in Delhi and other places and in the Punjab had become something like open rebellion, in the course of which there had been a tragedy on April 13 1919 at Amritsar, where General Dyer's troops in dispersing a mob had killed nearly 400 persons. Inquiry was instituted and Dyer had to retire; but much ill-feeling remained, and Mr. Gandhi started a non-co-operation movement as the new councils began to work. Mr. Montagu's policy lost its attractiveness for a large section of the House of Commons, and in the debate on the address in 1922 he was attacked on account of the unrest and crimes in India. In March he had to resign his office for having published, without the authority of the Cabinet, a telegram from the Government of India urging the advisability of pursuing, in India's interest, a more friendly policy towards Turkey. He defended his action by maintaining that Cabinet responsibility had been destroyed by Mr. Lloyd George's dictatorial methods. At the general election of 1922 he lost his seat in Parliament, and went into the City, becoming vice-chairman of the De Beers Co. He had married in 1915 Beatrice Venetia, youngest daughter of the 4th Baron Sheffield, and he died in London Nov. 15 1924.

MONTANA (*see* 18,752).—In 1920 Montana had a population of 548,889, an increase of 172,836, or 46%, during the decade. The urban population was 172,011, or 31·3%; the rural 376,878, or 68·7%. In 1910 the ratio was 35·5% urban and 64·5% rural. The relative increase of rural inhabitanrs over urban was due largely to the immigration of an agricultural population, particularly to the eastern part of the state. The total number of foreign-born whites in 1920 was 93,620. In 1920 there were 12 cities with a population of 5,000 or more, of which six had over 10,000. These six, with their increase in the preceding decade, were as follows:—

	1920	1910	Increase
			%
Butte	41,611	39,165	6·2
Great Falls	24,121	13,948	72·9
Billings	15,100	10,031	50·5
Missoula	12,668	12,869	−1·6
Helena	12,037	12,515	−3·8
Anaconda	11,668	10,134	15·1

Agriculture and Irrigation.—In 1910 there were 26,214 farms with a total acreage of 13,545,603, of which 3,640,309 ac. were improved. In 1920 there were 57,677 farms with an acreage of 35,070,656, of which 11,007,278 ac. were improved. Of the land improved, about 4,000,000 ac. were under tillage. In 1925 the number of farms had decreased to 46,896. In 1920 about 1,700,000 ac. were irrigated; many new projects were under way, and in 1925 nearly 2,000,000 ac. were irrigated. In 1924 about 3,000,000 ac. were planted to wheat, the most important crop, and the crop was estimated at 51,668,000 bushels. Flax, hay, sugar beets, oats, beans, potatoes, corn and peas rank next in order of value, but wheat in 1924 was worth more than all other crops combined. The total value of crops in 1924 was $144,463,000. During the period from 1910 to 1925 the open range was superseded by the fenced ranch. The number of sheep declined from 5,381,000 in 1910 to 2,083,000 in 1920, but increased to 2,536,000 in 1925. In 1910 there were 943,000 cattle; in 1920, 1,269,000; and in 1925, 1,505,000 (estimated). In 1925 there were 220,000 milch cows, and dairying has become an important industry. In 1910 there were 316,000 horses; in 1920, 669,000; and in 1925, 593,000. All livestock in 1925 was valued at $94,000,000.

Forests.—In 1923 the national forests in Montana included 15,881,715 acres. The state owned 566,000 ac. of forest land and there were 5,000,000 ac. in private hands. A part of this forest area is valuable also for agricultural land and will be so used when the timber is removed. The remainder will be reforested as the old trees are cut.

Mines.—The World War gave a great impetus to the production of copper and other metals, but after the Armistice the output declined acutely. In 1910 the production of copper was 283,000,000 lb.; in 1916, 352,000,000 lb.; and in 1921, 49,000,000 pounds. Since then it has increased to 224,000,000 lb. in 1923 and to 249,000,000 lb. in 1925. In 1918 the production of zinc was 104,624 tons; and in 1922, 59,535. The production of lead dropped from 18,568 tons in 1918 to 11,565 tons in 1921, increasing to 21,226 tons in 1924. Silver production has remained steady at about 12,000,000 oz. per year, but gold dropped from 158,704 oz. in 1918 to 80,145 oz. in 1922. The output of coal in 1924 was estimated at 2,700,000 net tons. In 1915 oil was discovered in the state, and the output has steadily increased until in 1924 it was estimated at 2,781,000 barrels.

Manufactures.—The vast supplies of water-power in Montana give hopes of great industrial development. The hydroelectric plants in 1923 had a capacity of 400,000 H.P., an increase of 120,000 in three years. Much of this was used for the operation of electric trains. The potential hydroelectric development is estimated at 4,000,000 horsepower. In 1920 Congress passed a bill authorising the Secretary of the Interior to lease the undeveloped power-sites, and the completion of such enterprises will add greatly to the electric power available. In 1909 the total value of manufactures was $73,000,000; in 1923 it had increased to $174,874,000. In 1920 there were 195 lumber-mills, 75 flour-mills, 31 creameries, 7 cheese factories, 2 canning factories. The most promising field for manufacture appeared to be products of copper and wood. One plant for turning out copper rods and wire had a capacity of 6,000,000 lb. of copper per month.

Education.—In 1920 the Russell Sage Foundation of New York ranked the Montana schools first among all the public-school systems of America. The public-school fund belonging to the state amounted in 1924 to about $20,000,000, the income to nearly $1,000,000 per year. The total expenditures for schools in 1924 was $14,878,000. In 1924 there were 118,000 pupils in elementary and high schools out of a school population of 157,745. In 1912 President E. B. Craighead, of the State University, started a campaign for the consolidation of all the state institutions of higher education into one university. His plan was defeated, but all the institutions were placed under one administrative head called the chancellor.

Legislation.—The state has made steady progress in labour legislation. In 1911 the Legislature provided an eight-hour day for miners. In 1914 the state limited the working day for women in factories, laundries and stores to nine hours, and in 1917 reduced this to eight hours. In 1915 a Workmen's Compensation bill was enacted. In 1915 provision was made for state inspection and grading of grain, and a Farm Loan Act was passed. In 1917 the state provided insurance against hail for farmers. In 1911 the Legislature authorised cities to adopt the commission form of government, and in 1917 sanctioned the commission-manager plan. In 1912 the people established through the initiative a system for direct primaries to nominate all state and local officials and to express their preference for presidential candidates. They also passed a rigid Corrupt Practices Act limiting campaign expenses, providing for their publicity and forbidding electioneering on election day. In 1914 the people ratified a constitutional amendment for woman suffrage. The important social legislation in recent years included a Mothers' Pension law; a Teachers' Retirement Pension law; and an Act to provide for the establishment and maintenance of county libraries. In 1921 Gov. Dixon proposed an income tax, an inheritance tax and a tax on the production of oil wells and of coal and metal mines. The Legislature opposed these recommendations as radical, but finally agreed to a small tax on oil and coal production. In 1924, however, the people passed an initiative measure providing for a graduated tax of from 0·25% to 1% on the gross product of metal mines. In 1923 the Legislature passed an effective inheritance tax law.

History.—Montana entered upon the second decade of the 20th century under very prosperous conditions. A new railway had just been built across the state. Mines were operating successfully, and there was a growing demand for Montana lumber. Great irrigation projects were under way, and in many sections of the state dry-farming was proving a success. The World War stimulated the mining and lumber industries, but it put a stop to the great reclamation works. During the later years of the decade drought seriously hampered the dry-land farmers and there was a decline in farm production. State politics have largely hinged upon matters of taxation, particularly the taxation of mines. The constitution provides that mines "shall be taxed at the price paid the United States therefor," although the "net proceeds . . . shall be taxed as provided by law." The mining interests maintain that, since mining is a speculative business and the mines are being gradually exhausted, the net proceeds should be taxed at no higher rate than real estate or personal property. Their opponents maintain that since practically no tax is imposed on mines as such, the tax on "net proceeds" should be much higher than the property tax. The constitution limits taxes for state purposes to two mills on the dollar unless increased by special vote of the people. This was adequate during the early years of the state's history. Since 1910, however, due to greater demands upon the state government, this constitutional restriction has produced a serious deficit. In 1920 the deficit amounted to about $2,500,000; June 30 1924 it was $3,595,558; and June 30 1925 it was $3,817,402. In the fall of 1925 the metal mines tax provided an income of approximately $500,000, and through the death of W. A. Clark the inheritance tax produced about $900,000.

In 1914 Jeanette Rankin was elected representative to Congress as a Republican, the first woman to be a member of that body. During the World War the Non-Partisan League spread over the state. It started first among the farmers, but soon extended among the labour groups. In 1918 it elected a number of members of the state Legislature. In 1920 the farmers and labour men went into the Democratic primaries and nominated a former U.S. district attorney, Burton K. Wheeler, for governor. The merchants and other business interests organised the Montana Development Assn. to oppose the Non-Partisan League. This organisation supported Joseph M. Dixon, former Senator and manager of Roosevelt's campaign in 1912, for governor on the Republican ticket. The Republican platform declared for a conservative programme, and the entire Republican ticket was elected. Gov. Dixon's demands for the taxation of mines, and for other special taxes, however, lost him the support of the larger business interests. In 1924 he was defeated by John E. Erickson who announced a programme of economy and no increase in taxes.

The governors of Montana after 1910 were as follows: Edwin L. Norris (Dem.), 1909–13; Sam V. Stewart (Dem.), 1913–21; Joseph M. Dixon (Rep.), 1921–5; John E. Erickson (Dem.), 1925– .

MONTELIUS, OSKAR (1843–1921), Swedish archaeologist, was born in Stockholm Sept. 9 1843. He studied at the University of Stockholm, and took the degree of Ph.D. in 1869. In 1888 he was appointed a professor in the Museum of National Antiquities, Stockholm, and in 1913 became state archaeologist. As an archaeologist his aim was to utilise and develop the typological method explained by him in his book *Die Typologische Methode* (1903). His numerous other works are devoted principally to Swedish and Italian archaeology and include *The Civilisation of Sweden in Heathen Times* (1888); *Les temps préhistoriques en Suède et dans les autres pays Scandinaves* (1895); *Kulturgeschichte Schwedens* (1906); and *La civilisation primitive en Italie depuis l'introduction des métaux*, 3 vol. (1895–1910). Montelius died in Stockholm Nov. 5 1921. See *Oscar Montelius in Memoriam* (Stockholm, 1922).

MONTENEGRO (*see* 18.766), a territory included in Yugoslavia, formerly an independent kingdom. The area of the district which corresponds to the old Kingdom is 3,733 sq. m. and the population (1921) 199,857.

Montenegro as a Kingdom 1910–8.—In 1910 Prince Nicholas took advantage of an apparent lull in the Balkan situation to proclaim himself King, a step welcomed in Vienna as a reversion to the old position of two competing Serb dynasties. But the unrest in Turkey soon forced Montenegro once more into close alliance with Serbia, and Nicholas, so far from resisting the current, was the first to embark on war in Oct. 1912. His lack of heavy guns and the imperfect discipline of his gallant troops compelled him to resort to Serbian military aid on a considerable scale before Scutari could be reduced in April 1913. Austria-Hungary insisted upon the surrender of Scutari to the new Albania, and threatened war. Nicholas only yielded to an international naval blockade of the Montenegrin coast, and Serbian troops were withdrawn from the Adriatic. The first Balkan war gave Montenegro and Serbia a joint frontier, the former Sanjak of Novi Pazar being partitioned between them; and Montenegrin troops joined Serbia against Bulgaria in the second Balkan war. Early in 1914 the Montenegrin statesman, Miušković, began serious discussions with Pašić for a financial and customs union between Serbia and Montenegro, a fusion of the two armies, a joint foreign policy and diplomatic representation, but retention of the two dynasties.

These negotiations became known to Vienna, who warned Petrograd that "Austria-Hungary would not remain a silent observer," and regarded union as a challenge to her Adriatic interests. On this, Sazonov advised Pašić to postpone the negotiations. But the movement for union was rapidly becoming

irresistible when the World War broke out and the two States found themselves side by side in resistance to Austria-Hungary. Prince Nicholas and his sons were, however, jealous and reserved, blocking the action of the Serbian General Janković, who had been sent at Russia's instance to reorganise the Montenegrin Army. In May 1915 Prince Peter had a secret meeting in Dalmatia with the former Austro-Hungarian military attaché, Hubka, and in Nov., during the invasion of Serbia, Crown Prince Danilo, through his friend Baron de Kruyff in Sofia, made overtures to the Central Powers, offering to cut off the Serbian retreat to the coast in return for territorial concessions to Montenegro in western Serbia and northern Albania.[1]

During the retreat the attitude of the Montenegrin dynasty remained highly equivocal and the key position of Mount Lovćen was surrendered to the Austrians almost without a struggle. Parliament voted unanimously in favour of holding out to the end with Serbia, but the King negotiated on his own initiative without authorisation from his government, and on Jan. 1916 addressed a telegram of submission to Francis Joseph. Failing to obtain the terms which he had hoped, he and his family, with the Premier Miuškovič, fled to Italy. During the next two years his second son, Prince Mirko, intrigued in Vienna and was connected with various Austrophil projects for a vassal Yugoslav state under the Petrović dynasty; he died in 1918 in an Austrian sanatorium. Meanwhile, King Nicholas resided in France and tried to silence criticism from the Left by making Radović his Premier. But when the latter advocated the formal proclamation of union and a simultaneous abdication of Nicholas and Peter in favour of the Prince Regent Alexander, Nicholas threw himself definitely into the arms of the anti-unionists, and by the end of the War found his court reduced to a tiny clique of personal dependents and adventurers.

Union with Serbia.—When Austria-Hungary collapsed in Oct. 1918 and national councils were erected in all the Yugoslav provinces, the current in Montenegro set more strongly than ever in favour of union. A National Assembly was convoked on Nov. 12 at Podgorica and proclaimed the deposition of the Petrović dynasty and the union of Montenegro with Serbia. On the death of Nicholas the royal title fell into abeyance, as Crown Prince Danilo did not wish to assume it and his nephew Michael was a minor.

Even before the Balkan wars Montenegro was desperately poor, and in normal years had to import grain for its scanty population; only the dynasty had grown rich by its arbitrary methods. The long strain of war increased the misery tenfold, and acute discontent was aroused by the bad administration, favouritism and centralist tendencies of Belgrade. There were numerous cases of brigandage and party vengeance which were conveniently misrepresented abroad as a movement for independence. In 1924, however, a marked improvement began. In the summer of 1925 King Alexander paid his first official visit to Montenegro, and the remains of his great-great-grand-uncle the Vladika Peter (the greatest of Serbian poets) were transferred to a mausoleum built at the King's expense on the summit of Lovčen by the Dalmatian sculptor Meštrović. (*See* BALKAN WARS; SERBIA.) (R. W. S-W.)

MONTERO RIOS, EUGENIO (1832–1914), Spanish politician, was born at Santiago de Compostela, Corunna, Nov. 13 1832. He was originally intended for the priesthood, but became a barrister and a teacher of ecclesiastical history. In 1864 he was appointed professor of canon law at the University of Madrid, and in 1869 entered the Cortes. He followed Ruiz Zorilla and as Minister of Justice in General Prim's Cabinet he introduced a number of important judicial reforms and drew up the act of abdication of King Amadeo. In 1881 he helped to found the Radical party and became Minister of Justice in 1889. From 1894–5 he was president of the Senate. He was chief of the Spanish delegation which negotiated the Treaty of Paris with the United States at the close of the Spanish-American War of 1898. In 1899 he was again president of the Senate. In 1903 he was elected leader of the Liberal party and in 1905 became Prime Minister. He resigned the leadership of the Liberal party in 1906 and was president of the Senate for the third time from 1909–14. He died at Madrid May 12 1914.

[1] Telegram of Tarnowski, to Burián, No. 1449. Nov. 11 1915, transmitting Danilo's wire to Kruyff.

MONTESSORI, MARIA (1869–), Italian educationist, was born at Chiaravalle near Ancona. She studied at the University of Rome and graduated in medicine in 1894, being the first woman in Italy to do so. She then took up the subject of educating defective children. From the experience thus acquired, she came to the conclusion that similar methods might be applied to normal children of a lower age, and after a series of experiments on a small scale she extended them to a large number of children in certain private and public infant schools in Rome. Dr. Montessori encountered a good deal of opposition from advocates of orthodox methods in education who regarded her system as destructive of discipline. At the same time she was warmly supported by a certain number of enthusiastic reformers, experienced and otherwise. Her system was applied on a larger scale in countries where elementary education was not under rigid state or municipal control and not carried out according to fixed programmes. From 1900 to 1907 Dr. Montessori lectured on pedagogical anthropology at the University of Rome and in 1922 was appointed Government inspector of schools in Italy. Her ideas on education are set forth in *The Montessori System* (1912), which has been translated into English and other languages. (*See* EDUCATION; MONTESSORI SYSTEM.)

MONTESSORI SYSTEM.—The Montessori system of education aims at self-education by the pupils themselves. There are no time-tables, no set lessons, no classes. There are no rewards or punishments of the ordinary kind. The pleasure of succeeding and gettings things right is the only incentive. "Each child is doing what, for the time being, pleases him best. When he is admitted to the school he sees small groups of children playing at various 'games,' and he joins the group which happens to take his fancy. Then and there his education begins. All kinds of interesting 'occupations' are going on, and wherever he goes he will get help and guidance from the teachers. If he gets tired of playing at this thing he goes off and plays at that. But he is never idle, for whatever he does interests him." Apparatus, elaborately devised by Dr. Montessori, is provided for the educational games by which the children acquire knowledge; and this "didactic material" constitutes a distinctive part of the originality of the system.

The first stage is to develop the senses of touch, sight and hearing; both by games of various sorts and by guiding the attention systematically to the association of things, names and ideas. When a child washes his hands, for instance, he is given first cold and then hot water, and led to observe and understand the difference; the distinction of rough and smooth is emphasised by the different cards for fingering and sorting. The child to know the words, "hot," "cold," "rough," "smooth," and thus the knowledge of language is extended in all directions ("high," "low," "thick," "thin," "round," "oval," etc.) before any question of writing or reading arises. Ideas of form and colour are given precision by games with blocks, cylinders, etc., of varying sizes, to be fitted into frames, or with shades of silk to be arranged to match; touch is practised by playing the games blindfold; hearing is developed by the "silence" lesson, and by the use of small cylindrical boxes containing stones, sands and different substances to be rattled by the children, who arrange them in order of intensity of sound and so forth. Skill and neatness in the use of the fingers and movement of limbs are stimulated partly by the mobility of the light furniture, which the children rearrange for their own comfort, and partly by games at tying and untying, hooks and eyes, dressing and undressing, waiting on one another at table, washing up and so on. Many of these occupations are preliminary to writing and reading, and lead naturally up to both.

Writing comes essentially before reading, on the Montessori system. Emery-paper letters gummed on cards are provided, with which the child is familiarised by games of hide and seek,

etc., so that, without any active teaching of the alphabet, he knows them by sight, by name and by feeling. He learns how to imitate them, partly by a touch game of passing the fingers over the paper letter, thus making the actual motion of writing, and partly by playing at pencilling and colouring with specially devised cards on which an outline is given. The child learns to write before he knows that "writing" is what he is learning; the sounds and shapes of the letters being known it is a natural transition to build up the letters and their sounds into words.

The next thing is for the child to "read"—not merely to re-translate into sound a word he has translated into symbol, which goes with the acquisition of "writing," but to extract a previously unknown idea from written or printed symbols of the same sort not put together by himself. At any rate in so phonetically spelt a language as Italian, this is very quickly learnt. Numbers of words, well known to the children, are written on cards, and various games are played in identifying them with their objects; and from single words the children pass to phrases and sentences, the teacher writing on the blackboard, for instance, questions or orders which form part of a game. Arithmetic is introduced to the children's minds by the employment of counting games, in which an apparatus of striped poles, counters, etc., is used. The whole curriculum is devised for the content and happy employment of the natural energies of the child, who is left free to respond to his own impulses, under the influence of "didactic material," rather than under the discipline of a teacher.

BIBLIOGRAPHY.—Report to English Board of Education, by E. G. A. Holmes, *The Montessori System of Education* (Education Pamph., No. 24, 1912) contains a critical examination of the system. See also M. Montessori, *The Didactic Material for the Education of Children from 7 to 11 Years; The Advanced Montessori Method* (1917–8); *The Montessori Method* (Eng. trans. by A. E. George, 1919). (H. CH.)

MONTEVIDEO (*see* 18.778), the capital city of Uruguay, had a population on Dec. 31 1923 of 407,249. The municipal revenues increased from $2,850,000 in 1916 to $4,590,000 in 1921, and for 1924–5 were estimated at about $5,342,000. Extensive port improvements by the Government deepened the entrance and part of the harbour in order to admit the largest ocean-going vessels, which formerly had been obliged to anchor outside. Docks, warehouses and loading equipment also were much improved. Three large meat packing plants (*frigoríficos*), two of them American and one British, were added to the industrial establishments of the city. Manufactures, though still relatively unimportant, included flour, paper, cigars and cigarettes, soap, candles, shoes, textiles and knitted goods; there were also tanneries, breweries and a sugar refinery. The general appearance of the city was improved by new buildings and the extension of paving and lighting. The University of Montevideo had in 1922 344 teachers and an enrolment of 1,615 students.

MONTREAL, Canada (*see* 18.790), the commercial metropolis and the largest city of the Dominion of Canada, had an area of about 50 sq. m. and a population of 836,304 in 1924. The population at the Dominion census in 1921 was 607,063, and was more than half French and about three-quarters Roman Catholic; Jews, who have increased largely in number in recent years, number about 6%.

The port is the second largest in America, with eight miles of deep water and wharfage with berths for a distance of 17 m.; 18 vessels of 1,000 ft. in length can berth at the same time. A large scheme of harbour improvements has been undertaken in recent years, including the reclamation of 30 ac. of land for a new dry dock, the electrification of the water front, the building of a huge elevator, wharves, warehouses, etc. The improvements to navigation in the gulf and river of St. Lawrence have resulted in a large increase of tonnage; 1,194 ocean-going vessels of 3,932,637 tons passed through the harbour in 1922, as compared with 820 of 2,690,535 tons in 1913. Over a quarter of the total export trade of Canada passes through Montreal, which is the greatest grain port of the world. There were 2,820 factories in the city in 1924, including very large flour-mills. The form of municipal government underwent several alterations in the decade following 1911, and eventually the control of municipal affairs was placed in the hands of an administrative commission of four, appointed by the provincial government.

The construction of a tunnel under Mt. Royal and the centre of the city by the Canadian Northern Railway Co., was an important engineering feat completed in 1918. The company (since merged in the Canadian National railway system) built an imposing new terminal station in the centre of the city at the tunnel head, supplanting its old Moreau street station. Electric trains running through the tunnel to the northwestern side of Mt. Royal caused the growth of a new suburb on that side of the mountain.

Education.—Important educational buildings erected since 1911 include the McGill Medical building, a magnificent structure that replaced the building destroyed by fire in 1907, the Macdonald Engineering building of McGill University; a large and finely equipped technical school in connection with Laval University; a new high school; a public library; an art gallery, and a fine pile of buildings to house Loyola College, a Jesuit school of high standing.

McGill University, benefiting by gifts from Sir William Macdonald, was able to develop further its faculty of music, to establish new degrees in law, commerce and household science, and to extend some of its departments. A school of physical training was opened in connection with the university, and a department of social service was inaugurated. The McGill stadium, one of the finest athletic amphitheatres in North America, was opened in 1918. After the death of Sir William Macdonald in 1910, provision was made for the further endowment of Macdonald College at Ste. Anne de Bellevue, the university's agricultural centre, and in 1924 Lady Strathcona gave £24,000 for a zoological department. The administrative buildings of the Montreal branch of Laval University were destroyed by fire in the autumn of 1919. A movement, that had been gaining strength for some years, to separate the Montreal branch from Laval University at Quebec, culminated in the foundation of the University of Montreal, the buildings of the old branch of Laval being taken over by the new institution. A number of new courses were added, including social and political science, and the faculty of applied science was further developed. Considerably over $3,000,000 was raised by public subscription as a building fund.

MONYPENNY, WILLIAM FLAVELLE (1866–1912), British journalist, was born in Ulster Aug. 7 1866. Educated at Trinity College, Dublin and Balliol College, Oxford, in 1893 he joined the editorial staff of *The Times* (London), and early in 1899 became editor of the Johannesburg *Star* in the Transvaal. He played a useful part, as a publicist, on the side of the Reform party there, and when war came he joined the Imperial Light Horse and was one of the defenders of Ladysmith. Returning afterwards to his position on the *Star*, he did much to promote Lord Milner's work of reconstruction, but resigned in 1903 owing to his hostility to the introduction of Chinese labour into the mines. He was then entrusted by *The Times* with the task of writing the official biography of Disraeli, and also did other work for that paper, becoming in 1908 a director of the company. Owing to ill health the first volume of the *Life of Benjamin Disraeli, Earl of Beaconsfield* (ultimately extending to six volumes) did not appear until 1910, and the second shortly before his death. It was completed in 1920 by Mr. G. E. Buckle, formerly editor of *The Times*. Monypenny died in the New Forest, Hampshire, Nov. 23 1912.

MOODY, WILLIAM VAUGHN (1869–1910), American poet and playwright, was born at Spencer, Ind., July 8 1869. He was educated at Harvard University and was assistant in English there 1894–5. From 1895 to 1907 he was at the University of Chicago as instructor and, after 1901, as assistant professor. He died at Colorado Springs Oct. 17 1910. Moody was the author of the *Masque of Judgment* (1900); *Poems* (1901); *The Fire-Bringer* (1904); *The Great Divide* (1907) and *The Faith Healer* (1909). He compiled (with Robert M. Lovett) *A First View of English and American Literature* (1902), and edited *The Complete Poetical Works of John Milton* (1899. Cambridge ed.) and (with George Cabot Lodge and John Ellerton Lodge) *The Poems*

of Trumbull Stickney (1905). His complete works were edited with an admirable introduction by Prof. John M. Manly (1912).

MOOKERJEE, SIR ASUTOSH (1864–1924), Indian jurist and educationist, son of a medical practitioner, was born at Bhawanipur, Calcutta, on June 29 1864. Graduating at the Presidency College, Calcutta, in 1885, he gained the doctorate in laws in 1894. He wrote much for learned societies on mathematical subjects, and his "Geometry of Conics" (1892) and other papers were incorporated in text-books for Cambridge University. He became a fellow and syndic of Calcutta University in 1889, and was appointed to the Tagore law professorship in 1898. From 1904 until his resignation in 1923 he was a judge of the Bengal high court, and won a great reputation as a jurist. He was knighted in 1911. His spare time from the Bench was devoted with unflagging zeal to the affairs of Calcutta University. He was a member of the Calcutta University Commission 1917–9, and signed the report without dissent, but afterwards offered strong opposition to the projected legislation. Though advanced in some matters of social reform, he lived very simply as an orthodox Brahman. He died at Patna on May 25 1924. His *Addresses, Academic and Literary*, were published in 1915.

MOORE, GEORGE (1853–), Irish writer (*see* 18.808), broke fresh ground in 1016 with *The Brook Kerith*, a work of fiction based on the Gospel story. He had professedly taken leave of literature in three remarkable volumes of quasi-reminiscences, entitled *Ave* (1911), *Salve* (1912) and *Vale* (1914). Later he produced two privately printed volumes de luxe, *Avowals* (1918) and *A Story Teller's Holiday* (1920), and retold the story of *Abélard and Héloïse* (1921). In 1922 he published *In Single Strictness* and 1926 *Ulick and Lorachal*.

MOORE, JOHN BASSETT (1860–), American jurist, was born at Smyrna, Del., Dec. 3 1860. He graduated at the University of Virginia in 1880, studied law in an office in Wilmington, Del., and was admitted to the Delaware bar in 1883. Two years later he entered the Dept. of State as a law clerk, and in 1887 was appointed third assistant secretary of state. He was secretary to the conference on Samoan affairs in that year and U.S. secretary at the conference on the North Atlantic fisheries, 1887–8. He was appointed professor of international law and diplomacy at Columbia University, 1891, frequently being granted leave of absence to accept appointments in the national interest. On the outbreak of the war with Spain in 1898 he was appointed Assistant Secretary of State, and he acted as secretary and counsel to the U.S. Peace Commissioners at Paris at the close of the War. Among the later official positions which he filled were those of U.S. agent before the United States and Dominican Arbitration Tribunal, 1904; U.S. delegate to the Fourth International American Conference at Buenos Aires, 1910; special U.S. plenipotentiary to the Chilean Centenary, 1910; U.S. delegate to the International Commission of Jurists, Rio de Janeiro, 1912; counsellor to the Dept. of State, 1913; a member of the Permanent Court of Arbitration at The Hague, 1913; U.S. delegate to the Pan-American Financial Congress, 1915. He was appointed in 1921 a judge of the Permanent Court of International Justice. He was also the U.S. delegate and chairman of the International Conference on rules for aircraft and radio in time of war held at The Hague 1922–3.

Moore's publications include *Extradition and Interstate Rendition* (1891); *History and Digest of International Arbitrations*, 6 vol. (1898); *American Diplomacy: Its Spirit and Achievements* (1905); *Digest of International Law*, 8 vol. (1906); *Four Phases of American Development* (1912); *Principles of American Diplomacy* (1918); *International Law and Some Current Illusions* (1924); and *The Permanent Court of International Justice*, a pamphlet (1924).

MORALE: IN WAR.—Modern conditions of war are gradually extending the domain of *morale* and increasing its influence. For, among belligerent nations, war affects a greater number of people and does so with methods of increasing violence.

1. THE SOLDIER IN THE RANKS

In battle, an enemy's long-range guns make their effects felt as far back as 5, 10 or 15 m., and, as they are capable of rapid firing, their effects become formidable to troops even at those distances. Difficulty in seeing their objective does not limit their powers, for they are aided by aeroplanes which inform them concerning the situation of their objective and the results of their fire. At lesser distances they are supported by light artillery in large numbers, mobile, and capable of making the most advantageous use of chance features of the ground over the whole of the area at their command; and further support comes from machine-guns, which, of light weight and slender dimensions, can penetrate everywhere to equip in a short time the whole of the terrain.

Range of Fire.—It follows, then, that the soldier who approaches the battlefield and advances to carry the enemy position, finds that, at great range and over an extremely wide extent, that is to say during a long space of time, he is exposed to a heavy fire, the effects of which are multiplied in severity the further he advances to the position. Frequently, before being able to advance, he is forced to wait until, thanks to supplies of material, cannon, trench mortars and machine-guns, his army has gained a mastery of the fire, and the destructive capacity of the adversary has been thus reduced.

In this time of waiting hours succeed hours, nights follow days and weeks go by, always under the rain of steel from the enemy. It is under incessant bombardment that the march to victory has to be resumed and continued. Rarely is the battle decided in one day. And the nervous tension, the crisis imposed on the combatant, lasts the same time. During all this wearing period he must fulfil, automatically and often left to his own resources, his function as soldier, marksman, machine-gunner, pioneer, link in the chain of intelligence, carrier of supplies and so on. That is to say this function must be part of his own nature, and to fulfil it he must have received a serious training.

Interception of Supplies.—Furthermore, bombardment spreads its havoc no less widely on the rear of the battle-front, cuts communications, prevents the arrival of supplies. Not only has the combatant to show a bold face to the danger which threatens him, but he often finds himself reduced to a most precarious existence; along with the rigours of nights in the open, he has to put up with shortage of supplies. And thus physical exhaustion comes to be added to nervous shock, and the severity of the ordeal is heightened.

Tenacity and Endurance.—In the wars of the past, movement and enthusiasm, the qualities of dash and courage and personal pride, could suffice the soldier in a moment of intoxication to meet, with brilliance, the crisis of collision with the enemy. But to-day, if he is to traverse the long road of the hell which is the modern battle and reach a decision, he must possess an unbreakable tenacity and an energy ready for any sacrifice, and both must be unwavering for long days on end. To what greatness of soul must we not appeal, then, to see the emergence of virtues so solid, so tenacious, so generous? We must leave the answer to the soldiers of the Marne and Yser, Ypres and Verdun.

Further, who can forget the moving spectacle of the British leave-trains returning to the front during the War? The men were accompanied to the station by a silent throng composed for the most part of women and children. A few handkerchiefs furtively sought the eyes of those who were left behind, especially when the train began to move off. On board the vessel at Dover, the returning men donned their life-saving waistcoats, and stood closely crowded together on deck, imprisoned in their own thoughts. If, from a group here and there, came a song or a noisy demonstration, it was from young soldiers going out to the front for the first time. The others remained impassive, silent, gloomy, and their eyes gave token of the cold energy and the spirit of savage resolve on which they had fallen back. It was to the cry of "*Lusitania!*" that they would soon be marching to attack. Experience had taught them that mere knowledge of their duties and a fine, fleeting ardour would not suffice to bear the long and bitter ordeal of the modern battle. They required a spirit which must be imbued with the highest feelings, and, quickened with them, a spirit proved in the crucible of discipline.

The soldier of our national armies has drawn the spirit of sacrifice, the sentiment of discipline and duty, from love of his

country, from attachment to the family as to the race, and from the indispensable military training, which left its strongest impression. Of this he gives proof in action by strict obedience to orders. But let there be no mistake; he conserves and maintains these virtues in lasting fashion only in proportion as the commanders have won his confidence by the care with which they surround his daily life; only in proportion as they know how to conserve that life by their vigilant economy of his blood.

As a whole, the war of the present day demands of the soldier a moral greatness, and a professional training, both developed in very high degree. The conservation of those forces, a conservation which alone can assure victory, is incumbent on the commanding officers. And in this way the rôle and responsibility of the officer expand in an exceptional degree, and grow sharply defined, especially in battle.

II. THE OFFICER

In the course of any action of necessarily long duration, the officer can conserve the value of his unit, section, company or battalion, only by protecting it from the disasters which are continually menacing it, and by leading it step by step to the goal, to the final objective which has been assigned to it by the higher command, and the gaining of which constitutes for it the victory. He cannot confine himself to being a daring soldier, superior to his subordinates by his courage and personal example. He must show himself to be constantly dominated and impelled by a double preoccupation: to avoid the destruction of his unit and to bring it nearer its objective.

Avoidance of Loss.—To avoid its destruction, because he is in the presence of an armament capable, by suddenly inflicted losses, of destroying the unit, or at least of shattering its *morale* for a long time, if adequate precautions have not been taken in time. Hence springs the necessity that he should be familiar with the dispositions appropriate to this continual menace, and that he should be able to order and put readily into practice these dispositions, which by his selection of rendezvous, his tactical formations, by hastily constructed earthworks or by any other procedure, keep the troops halted under cover from the observation, projectiles or poison-gas of the enemy.

How many long hours will not troops have to pass in waiting, in preparation, before seeing the moment for action arrive? How often has not the officer to provide for these secure dispositions? Yet in this situation the slightest negligence is unpardonable. At that moment will appear all the vigilance and all the power of decision which the officer must bring to the field of action, in addition to the acquired knowledge and the experience, necessarily incomplete though this be, of manoeuvres. What is required of him, even at these moments, is the all-embracing eye, the sense of fitting opportunity and the gift of decision.

Precision in Attack.—Then, the moment of action having arrived, the operations of the unit must be carried out without hesitation or disturbance, in the presence of an adversary who, flinging all his resources again into action, may be able to regain some of his preponderance, to restore to his armament its formidable strength. That is to say, the operations must have been directed in all their details by a commanding officer who has previously assured himself of the participation of neighbouring troops, and has gauged as exactly as possible the position of the enemy which he is approaching.

To sum up, together with the feeling of readiness for action called up by the receipt of orders, but before the moment for action has come, it is by foresight and precision that an officer should be inspired and guided in his procedure. Without these he steps into imprudence, and he draws his troops along with him. They run the risk of not returning. He, and he alone, is to blame.

Value of Experience.—Without going into the increased need for technical knowledge resulting from the employment of material, at once more various and more potent and also more delicate, the art of bringing troops on to the battlefield has assumed in our day a capital importance. Every officer ought to concern himself with this, and shape himself for it in time of peace as fully as he devotes himself to the instruction of his men, so that he may be able, when the great day comes, to present himself armed with a certain peace-time experience, and armed above all with faculties well maintained, developed, and turned ever on the alert in the direction of the march toward the objective. He must be ready on that day to resolve the difficulties of this march, difficulties which only the actual conditions will reveal to him, for peace gives no complete idea of the effects of modern weapons on a body of troops. War will bring him face to face with new problems, and will demand that he possess, over and above his professional knowledge, the habit of reflection and prompt decision on fresh circumstances. It is a habit which he will need to have acquired during peace-time.

It is needless to remark that these faculties of foresight, of adaptation to new problems, ought to be developed the more fully in an officer the higher his rank and the greater the instruments of control which are in his hands. For in this case his orders cover vast spaces, are laden with more far-reaching consequences, and are more difficult to modify in their execution. The moral forces and the capacities which the commander must bring to war, if he is to act in such a way that negligence or imprudence, both always disastrous, may be avoided, have increased in notable proportions, even for the lower ranks.

III. THE NATION

But war, to pursue the theme further, does not confine its material and moral effects to the battlefields and the invaded regions. It extends them toward the rear, to populations which were formerly kept aloof from it by the barrier of distance. It spreads them overseas in every direction, even to non-belligerents, and produces the most complete upheaval.

The Non-Combatants.—In the rear, not to speak of refugee populations fleeing before the ravages of invasion, and terror systematically loosed in defiance of the laws of humanity, it is the women, the children and the aged who live in the emotions of the struggle, as a result of the facility and speed of communications; who undergo on occasion the stress of hostile bombardment from the air; who in any case suffer privations of every kind. This means that the field is open, in the heart of the country itself, to the most opposed sentiments and passions, as also to nervous shock and physical exhaustion. But, despite these difficulties, the interior of the country must hold firm to the end, and, what is more, must maintain in foodstuffs, arms, and munitions and support in energy of spirit, those who fight at the front. In its united aspects, the country becomes and must remain by its sentiments and its productive activity the source of the warring capacity of the armies.

Thus, in the old Europe, each country is perforce the near neighbour of powerful states, sees its warlike resistance measured by the degree of union between the interests and sentiments which it comprises, by its jealous watch over its independence, by its progress toward that moral unity which is the essence of a nation, and consequently by the depth of its national sentiment. Only in these moral factors is to be found the energy which will resist concussions of every kind, and will pursue, through ever-increasing sacrifices and through all the vicissitudes of the struggle, the success of the enterprise which will liberate it, once and for all, from all its anguish.

And if, among the states of the New World, where menace is less direct, the immediate danger does not demand the organisation of territorial defence, a blow struck against the principles whereby they live will awaken the apprehensions of the peoples and, in community of sentiments, will arm them for the safeguarding of their free civilisation. In short, a sturdy sentiment which binds the entire people as one, imposing itself upon them by the justice of their cause and the necessity for defending it, is indispensable to the success of a modern war, for that alone is capable of obliging them to the privations and sacrifices which war entails.

IV. THE GOVERNMENT

To maintain and guide this sentiment during the days of the struggle, to exploit it and to extract victory from out of it—

such is the task of the Government. In these days the Govt. must not be simply the representative of the interests of the country, but rather the expression of the passions which are animating it, and to that end, the organiser of defence, the creator of the material resources, the arms, munitions, foodstuffs essential to the struggle, and the motive and inspiring power and of the forces assembled on the field of operations. It must show itself a " war government," with an active and effective policy, taking a wide view of the ends which it is possible to attain, bearing in mind the means at its disposal. And it must be animated by the will always to augment those means to hasten those ends, while still maintaining, in the interior of the country, the spirit which does not disarm.

It is obvious, then, that war calls for peculiar qualities in the statesmen who preside over it. Without these, it must inevitably end in impotence, or even defeat.

V. CONCLUSION

To sum up, whether we are dealing with the soldier, the high command, the nation or the Govt., in each of these divisions war demands an ever-increasing share of the moral forces whose close union and wise combination are alone capable of producing victory. It is to the insufficiency of certain of these forces, or to the lack of cohesion between them, that we must look to grasp and explain the collapse, in the course of the last war, of certain Great Powers, and likewise of armies of formidable repute, which in themselves certainly did not fall short of that repute.

BIBLIOGRAPHY.—The most important works to be consulted are those of Marshal Foch himself: *Des Principes de la guerre* (1903) with English translation by Hilaire Belloc (1918); *De la conduite de la guerre*, 3rd ed. (1915); *Préceptes et Jugements du Maréchal Foch; extraits de ses oeuvres, précédés d'une étude sur la vie militaire du maréchal par A. Gasset* (Nancy, 1919), with English translation by Hilaire Belloc (1919). See also J. R. (ancien élève de l'école supérieure de guerre), *Foch. Essai de psychologie militaire* (1921), and Émile Mayer, *La psychologie du commandement: Avec plusieurs lettres inédites du Maréchal Foch* (1924). (F. Fo.)

MORANT, SIR ROBERT LAURIE (1863–1920), British civil servant, was born at Hampstead April 7 1863. He was educated at Winchester and New College, Oxford, and on leaving the university was for a few years a schoolmaster. Later he went to Siam as educational adviser, and was entrusted by King Chulalongkorn with preparing a scheme of education for the whole country. In a few years he returned to England, and after some experience of social work in the East End of London, was appointed in 1895 to assist in the direction of the office of special inquiries and reports in the Board of Education. He became private secretary to successive ministers, and on him devolved a great deal of the preparation of Mr. Balfour's Education Act of 1902. In 1903 he was appointed permanent secretary of the Board of Education. In this capacity he proved himself a most efficient administrator, and in 1907 he was created K.C.B. In 1912, on the introduction of the National Insurance bill, Morant was appointed chairman of the Insurance Commission, a position which led naturally to his appointment as secretary to the Ministry of Health on its formation in 1919. He died in London, after a few days' illness, March 13 1920.

MORE, PAUL ELMER (1864–), American author, was born at St. Louis, Mo., Dec. 12 1864. He was educated at Washington University and Harvard, and he was assistant in Sanskrit at Harvard, 1894–5, and associate lecturer in Sanskrit and classical literature in Bryn Mawr College 1895–7. He was literary editor of *The Independent* 1901–3, and of the New York *Evening Post* 1903–9, and editor of *The Nation* 1909–14. In 1915 he was elected to the American Academy of Arts and Letters.

He is the author of *Shelburne Essays* (11 vol., 1904–); *Life of Benjamin Franklin* (1900); *Platonism* (1917); *The Religion of Plato* (1921); *Hellenistic Philosophies* (1923); and *The Christ of the New Testament* (1924), in addition to a number of translations from the Greek.

MORESNET: *see* EUPEN AND MALMÉDY.

MORET Y PRENDERGAST, SEGISMUNDO (1838–1913), Spanish politician, was born at Cadiz June 2 1838. He was educated at the Central University, Madrid, and became professor of political economy there. In 1863 he entered the Cortes as a Liberal, took part in the revolution of 1868 and in the constituent assembly of 1869. Colonial Secretary in 1870 under General Prim, and later finance minister, he was for a few months in 1872 Spanish ambassador to Great Britain, and after resigning this post accepted the directorship of a large London bank. A year later he returned to Spain. He re-entered Parliament in 1879, and helped to found the Democratic dynastic party. He was Minister for Foreign Affairs under Sagasta in 1885 and again in 1893–4, Minister of the Interior 1885–8, and Minister of Colonies 1897. In this capacity he advocated the grant of autonomy to Cuba and Porto Rico, and was opposed to the war with America of 1898. He was Prime Minister in 1905–6 and again in 1909, and at the time of his death in Madrid on Jan. 28 1913 was president of the Chamber. He had a cultivated mind and a noble spirit but was not sufficiently resolute for the difficult political times in which he lived.

MORGAN, ARTHUR ERNEST (1878–), American engineer and college president, was born at Cincinnati, O., June 20 1878. He received his early education in the high schools at St. Cloud, Minn., and then spent three years in Colorado in various occupations, including a short term at the University of Colorado. Returning to Minnesota, he worked for his father, a land surveyor, and studied engineering at night. In 1902 he commenced practice for himself at St. Cloud, making a special study of floods and flood control. In 1907 he became supervising engineer of U.S. Govt. drainage investigations, but in 1909 founded the Morgan Engineering Co., of which he became president. His firm undertook many reclamation projects in the southern states. In 1913, after the Dayton flood, he was consulted on behalf of the sufferers with a view to prevent a recurrence of the disaster, the result being the formation, under special statutory powers, of the Miami Conservancy District, consisting of all cities, towns and land within the flood area, and the necessary work was done under his supervision as chief engineer. In 1921 he acted as chief engineer to the Pueblo Conservancy District, formed to protect Pueblo, Colo., from floods. He planned and superintended a large number of projects for water control, and drafted or assisted to draft drainage codes for a number of states. In 1921 he was appointed president of Antioch College, Yellow Springs, O., which was reorganised, under his inspiration, in order to carry out a comprehensive experiment in the correlation of cultural and industrial education (*see* ANTIOCH COLLEGE).

He was the author, among other works, of *The Drainage of the St. Francis Valley in Arkansas* (U.S. Govt. 1911); and *The Miami Valley and the 1913 Flood* (1917).

MORGAN, JOHN PIERPONT (1837–1913), American financier and banker (*see* 18.834), died in Rome March 31 1913. In Jan. 1913 he sailed from New York for Egypt, where he became seriously ill. He was carried to Italy but never recovered. His will provided that after the distribution of enumerated bequests amounting to about $17,000,000, chiefly to his family, the residue of his estate should pass to his son, John Pierpont Morgan. In 1916 the estate was finally appraised at $69,499,732. He left only some $700,000 to charities; but while living he had been a generous giver, and in his will suggested that his son continue certain accustomed annual contributions. His works of art and books were left to his son without restrictions, although in his will he said: " It has been my desire and intention to make some suitable disposition of them or of such portion of them as I might determine, which would render them permanently available for the instruction and pleasure of the American people." In the summer of 1913 most of the art collection was placed as a loan exhibit in the Metropolitan Museum of Art, New York City. Later, some items, mostly replaceable, were sold. The remainder, consisting of over 3,000 pieces, was presented to the museum by the son in Dec. 1917, and a new wing was added to the building to house them permanently. This was opened in June 1918. This collection covered all periods and included matchless bronzes, enamels,

porcelains and tapestries. The library (dedicated by the son by public charter in 1923 as an institution of research for scholars and provided with liberal endowment, in memory of his father) was appraised at $7,500,000, and consisted of about 25,000 volumes of illuminated manuscripts, early printed books, examples from famous presses and association copies.

MORGAN, JOHN PIERPONT, JR. (1867–), son of John Pierpont Morgan (1837–1913), succeeded his father and continued as active head of J. P. Morgan and Co., and of its associated banking houses in Philadelphia, London and Paris. He was born at Irvington, N.Y., Sept. 7 1867, prepared for college at St. Paul's School, and graduated from Harvard in 1889. He received the honorary degree of LL.D. from Cambridge University in 1919 and from Harvard in 1923. In 1891 he became a member of the firm of which his father was the head, and later spent 12 years with the London house of J. S. Morgan and Co., now Morgan, Grenfell & Co. Within 16 months after Mr. Morgan succeeded his father in 1913, as head of the house, the World War began. Almost immediately the finance department of the City of New York became confronted with a grave situation. Owing to the dislocation of the foreign exchanges, the City of New York found itself unable to meet its obligations maturing in London and Paris, aggregating upwards of $80,000,000. Thereupon Mr. Morgan undertook the organisation of a successful bankers' syndicate for $100,000,000 gold, through the operation of which the city's credit was maintained intact.

Within a year the British Govt., followed by the French Govt., enlisted the services of Mr. Morgan and his partners to undertake the vast work of co-ordinating and finally purchasing in the United States their all-important supplies of foodstuffs and munitions. The purchases which the firm made for the British and French governments aggregated several billion dollars, and the work which the Morgan firm accomplished in organising sources of industrial supply in America proved of great service to the United States Govt. when, two years later, in 1917, it undertook to secure its supplies upon a huge scale for the prosecution of its part in the War. Before America's entry into the War, Mr. Morgan undertook the work of financing a great part of the Allies' requirements for credits in the United States of America, and prior to April 1917 had arranged total loan issues to the British and French governments of $1,550 million. During the period of world reconstruction following the War, Mr. Morgan continued active; the publicly issued loans which his firm arranged to Great Britain, France, Belgium, Italy, Austria, Germany, Switzerland, Japan, Argentina, Australia, Cuba and Canada aggregating between April 1917 and April 1926 approximately $1,700 million. During America's participation in the War, Mr. Morgan served as a member of the Liberty Loan and other important committees. For five years he was a member of the advisory council of the Federal Reserve Board. In 1922, at the request of the reparations committee, he served at Paris upon a committee of bankers whose report, laying down the essentials of the German reparations problem, was an important preliminary to the work of the Dawes committee two years later.

In 1920 Mr. Morgan presented his residence at Prince's Gate, in London, to the U.S. Govt. for an embassy. In 1923, by public charter, he dedicated his father's library (to which he had made important additions) as an institution of research for scholars, at the same time providing liberal endowment for it. Under the terms of the gift it will be preserved intact as a complete unit for the period of 100 years from March 31 1913, the date of his father's death.

MORLEY OF BLACKBURN, JOHN MORLEY, VISCOUNT (1838–1923), British statesman and author (*see* 18.840), continued to hold the seals of the India Office till Nov. 1910. One of his last official acts had been to resist the appointment of Lord Kitchener to the vice-royalty, pressed strongly upon ministers by King Edward just before his death. Lord Morley remained in the Cabinet in the less onerous position of Lord President of the Council, and was one of the four counsellors of state to administer the kingdom during King George's visit to India for the Delhi Durbar in the winter of 1911–2.

In the critical period of domestic politics which began with the budget of 1909 he played a somewhat prominent part. He defended that budget in the great debate of Nov. 1909 and, while admitting that the Lords had the legal right of rejection, said that to assert it was a "gambler's throw." Owing to the temporary failure of Lord Crewe's health, Lord Morley led the House of Lords during most of the session in which the Parliament bill, which he warmly supported, was passed; and it was he who read out to the House on the last night of debate that definite assurance from King George of his assent to a creation of peers which finally secured the exiguous but adequate majority of 17. He not only took charge of the India Office during Lord Crewe's illness, and of the Foreign Office in Sir Edward Grey's short holidays, but he was an outstanding figure in the Home Rule debates of 1913 and 1914.

The entrance of Great Britain into the World War brought Lord Morley's official career to an abrupt termination. He felt that his pacifist outlook was sufficiently well-known to make it unnecessary for him to give reasons for resigning; and he withdrew to the retirement of his Wimbledon villa, where he occupied himself with writing two most interesting volumes of *Recollections*, which were warmly welcomed on their publication in 1917. In 1921 his publishers brought out a complete edition of his works in a handsome *format;* and he was generally regarded, during his last years, as sharing with Mr. Hardy the position of *doyen* of English men of letters. He died at Wimbledon, London, after a somewhat long period of ill health, on Sept. 23 1923. See Viscount Morley, *Recollections*, 2 vol. (London, 1917).

MOROCCO (*see* 18.850), a state of Northern Africa. The district of Tangier (*q.v.*) is internationalised; the northern zone is a Spanish protectorate; the remainder a French protectorate. The approximate area is 231,500 sq. m. (Spanish zone, 18,360 sq. m.; Tangier, 200 sq. m.). The estimated population (1925)is: French zone, 4,410,000; Spanish zone, 500,000; Tangier, 70,000. The reigning Sultan in 1925 was Mulai Yusef.

I. POLITICAL HISTORY

In Oct. 1910 there was a general rising of the tribes round Fez against Mulai Hafid, who had become unpopular owing to his dependence on the French and the exactions of his grand vizier. Fez was besieged in March 1911. In April and May French troops were sent to occupy Fez and pacify the district. This action, although its necessity had been notified to the Powers, was resented by Spain and Germany. In June Spain occupied El Qsar and Larache (El 'Araish). On July 1 the German Govt. suddenly dispatched the gunboat "Panther" to Agadir, nominally to protect the interests of German subjects (*see* EUROPE). The situation was so critical that war seemed imminent; but Great Britain declared her intention of standing by the entente, and her formal objection to Germany's obtaining territorial influence in Morocco. France and Germany signed a treaty on Nov. 4 1911; in return for territorial cessions in the Congo, Germany recognised France's political protectorate (the word was used in the letters accompanying the treaty, although not in the treaty itself) over Morocco, economic equality between the two countries being reaffirmed.

The Franco-Spanish Treaty.—On Nov. 27 a Franco-Spanish treaty was concluded. This arranged such debated points as customs, the management of the projected Tangier-Fez railway and the appointment of the Sultan's *khalifa* (deputy) at Tetuan. It slightly revised the Franco-Spanish boundaries determined by the convention of Oct. 3 1904. The boundary of the northern Spanish zone follows the Muluya from its mouth to near Meshra 'Klila; thence, turning west, it runs immediately north of the Wad Wergha R. to Jebel Mulai bu Shota; thence it strikes northwest to the Wad de Kkus, follows its course, and, afterwards, Lat. 35° N., to the Atlantic coast. Both banks of the Lekkus and El Qsar and Larache fall within the Spanish zone. The treaty also recognised the rights of Spain in the south over the enclave of Ifni, bounded to north by the Wad bu Sedra,

to south by the Wad Nun, to east by a line about 15 m. from the coast. The negotiations of 1911–2 between the Powers resulted in the internationalisation of the Tangier zone, consisting of Tangier, its environs and the territory of the El Fahs tribe to south and west of it—about 100 sq. m. in all. By this understanding Tangier was "to be given a special régime to be agreed upon later."

In 1913 a commission sat to determine the nature of this régime; but its findings were not accepted by Spain, and the outbreak of the World War shelved the question. A convention determining the new régime was drawn up on Dec. 18 1923 (*see* TANGIER). On March 30 1912 Mulai Hafid signed a treaty with France accepting the protectorate, which was subsequently recognised by the Powers, who withdrew their diplomatic representatives. General Lyautey was appointed resident-general.

On Aug. 12 1912 the Sultan Mulai Hafid abdicated, appointing as his successor his brother, Mulai Yusef. (E. G. S.)

II. ADMINISTRATIVE HISTORY

General Lyautey's Administration.—The history of French Tangier from 1911 to 1925 was largely military (*see* MOROCCO, CAMPAIGNS IN). France was fortunate in possessing a remarkable administrator in the resident-general, General Lyautey, who was assisted by remarkable subordinates: Generals Poeymiran, Henrys, de Sumothe, Colonel Huot, etc. Instead of evacuating the interior of Morocco during the War, Lyautey was able to extend his control in it, and even to continue public works and hold fairs and exhibitions to maintain confidence. By the end of the War he was well on the way to becoming master of "le Maroc utile," that is, such parts of the country as possessed a real military, political or economic interest. The pacification was complete in 1923; but in April 1925 the Riff outbreak in the Spanish zone extended to the French zone. Lyautey resigned on Sept. 29 1925. Regret was unanimous, and was freely expressed by Sultan Mulai Yusef and the natives, who remembered the "generosity and broadmindedness" which had been the ideal and practice of his policy. Few, if any, Christians had enjoyed such a privilege as he: all Morocco prayed for him in the mosques during his illness in 1923. His successor, M. Theodore Steey, who had successfully filled the post of Governor-General of Algeria, was appointed on Oct. 3 1925.

The Sultan's Govt.—In his difficult task Lyautey enjoyed the loyal co-operation and help of the Sultan, who generally resided at Rabat, the seat of government. Close attention was paid to the maintenance of the Sultan's prestige, and his authority and initiative were carefully respected in internal affairs, the measures decided by him being, however, always taken in accord with the French authorities,[1] by application of the treaty of Fez (March 30 1912). Mulai Yusef, on succeeding to his brothers Abdel Aziz and Hafid, immediately continued and completed the reforms, already begun, of the *Maghzen* (Central Govt.), especially in the matter of native justice and religious land property (habus). He worked regularly with his viziers (the Grand Vizier and the ministers of Justice, Domains, Habus, Public Instruction, and the presidents of the High Sherifian Tribunal and the Tribunal of Appeal of the Chraa (Mussulman law), seven in all, taking a special interest in educational matters. The competency of the local judge, the Kadi—*i.e.*, in reality, a religious magistrate, civil matters relating to marriage, the family and inheritance, etc., being regulated by the Koran—has been maintained towards Europeans in the matter of the acquisition[2] of land property (Articles 11 of the Madrid Convention, July 3 1880) and 60 of the Algeciras Act (April 7 1906). Hence the importance of the Ministry of Justice and of the tribunals.

The Sultan remains the head and tutor of all the members of the Sherifian house. He appoints a special Sherif (the "mezuar" or "naquib") in all the principal towns, who settles disputes between the Shorfa Alauites (*i.e.*, the above members) and watches over their conduct. He has four "Khalifas" in Fez, Marrakesh, Tiznit and the Spanish zone, whose rôle is of a representative character. The civil list amounts to 5,250,000 fr., *plus* 2,200,000 fr. for the Sultan's special negro bodyguard.

Pashas in the towns and Kaids among the tribesmen in the country represent the temporal authority of the Sultan, as opposed to the Kadis (*see* above), and are in charge of criminal justice and judge also in cases where movables and commercial matters are concerned. In the principal towns they are controlled by the French officials of the Protectorate acting as commissaries of the Government. Care has been taken to preserve as far as possible among the Berber tribes the customs (izref) to which they are deeply attached. Their Kaids are judges in penal and commercial matters; disputes as to personal status, property, etc., being settled by the djemaas (popular assemblies) according to custom and not by the Kadis.

Native Representation.—Arrangements were made for taking the advice of the natives on certain questions. The programme of the monthly meeting of the Council of Government is communicated not only to the Maghzan but, through the French "contrôleurs," a week beforehand, to the native sections (created by a *dahir* of Jan. 20 1919) of the chambers of commerce and agriculture, who, as occasion offers, deliberate either separately or concurrently with the French sections. They are also represented in the municipal councils presided over by the pashas in the principal towns. In both cases they are appointed by the Government.

French Administration.—The administration is under the authority of the "Commissaire" Resident-General (decree of June 11 1912), assisted by a delegate and a secretary general of the Protectorate. The central government comprises the secretariat general, to which are attached the following services: civil control, personnel, legislative studies, general security, general administration, penal justice and the special direction of native affairs and the intelligence service. The other central services are divided up between the following Directions générales: 1. Finances and public domains; 2. Public works (with the mines, ports, mercantile marine and the post, telegraph and telephone office; 3. Agriculture, commerce (and industry) and colonisation (with the forests and the land registrations and survey); 4. Public instruction, fine arts and antiquities; 5. Public health. The "exterior services" are classed by regions, Shawiya, Rabat, Gharb, Ujda, etc.), and distributed between 22 controls (and their annexes) or municipalities in the civil territory; and eight regional bureaux, with their 14 circles, in the military zone. The French judicial organisation, which comes into play whenever Frenchmen or Europeans are concerned, comprises 12 civil courts; three tribunals (Casablanca, Rabat, Ujda and a court of appeal (Rabat).

In order to ensure "a constant and regular collaboration between the Government and French colonists," the presidents of the chambers of commerce and agriculture of Rabat, Qnitra and Casablanca, and of the mixed chambers of Marrakesh, Mazagan, Ujda, Safi, Meknes and Fez (whose members are elected), assemble once a month in a Council of Government, the agenda of whose sittings is always communicated a week in advance. There is a municipal commission in each important town (the same as above), theoretically presided over by the Pasha, representing the Sultan, and practically by the French chief of the municipal services. They have a consultative voice, except in Casablanca, where it is deliberative.

Public Instruction.—In 1916 there were 140 schools under French supervision, with 470 masters and 14,834 pupils. In 1924 the schools numbered 199 (90 French; 67 Franco-Arab; 42 Franco-Jewish and Jewish), the masters 938 and the pupils 29,030—417 for higher instruction; 2,822 for secondary education; 23,327 for primary education; 1,029 for the technical schools and 1,435 for the evening courses in two or three big towns. A distinction is drawn between the primary schools for the sons of "notables" and the other primary schools. The teaching of housekeeping (Écoles menagères) has been started for native girls. There are two Mussulman colleges, in Rabat and Fez, where selected pupils from the special schools for the sons of notables receive, in a course of studies of six years, higher education in Arabic (language and literature) and Mussulman religion and law, with the elements of French, mathematics, general geography and practical science. Those studies are completed in the institute for higher Moroccan studies at Rabat (also open to French pupils), where Arabic literature and language are taught thoroughly, as well as the special history and geography of Morocco, the Berber customs and dialects, ethnography, French and Mussulman law, and lectures on the administrative organisation of the country. It is the seminary for officials and interpreters. There is also an important Sherifian scientific institute (10 laboratories) in Rabat. An industrial and commercial school exists at Casablanca (232 pupils) with evening courses (360 pupils). There are official workshops (ateliers) for apprentices in the principal towns, and also a few for girls (carpet-making, etc.), and technical schools for Europeans in Casablanca and Ujda. A special service is in charge of the historical monuments, both Roman (Volubilis, etc.) and Moorish. Local laws, inspired by the French director of the service, protect the artistic remains in the towns, and some restorations have been undertaken. Special lodgings and studios have been provided in the most interesting towns for European painters and architects, who can come and study in the country.

[1] The link is secured by the French councillor to the Sherifian Govt. (decree of May 19 1917).

[2] After they have been *immatriculated*, land properties fall under the new land laws and French tribunals.

III. ECONOMIC HISTORY

Population.—The 1921 census, completed (1924) by the latest official statistics, gives an urban population of 612,987 for French Morocco. The rural population is not really known, certain parts of the country being still outside French administration, and others very lightly administered. The estimated total is 4,410,000 inhabitants. There are three principal towns: Marrakesh (145,000), Fez (124,500), Casablanca (110,900). The next in order of importance are Meknes (38,000), Rabat (33,000) and Safi (25,800). Then come Sali (24,300), Ujda (22,200), Mazagan (22,000) and Mogador (19,500).[1]

Frenchmen numbered (1924) 51,889 (24,799 in Casablanca, 7,218 in Rabat, 4,400 in Ujda, 2,800 in Fez, 1,700 in Marrakesh, etc.); Europeans 32,320 (17,487 in Casablanca; 5,000 in Ujda, etc.). The Jews total 73,400 (in the towns, descendants of immigrants from Andalusia). There are also a few Jewish converts among the Berbers in the country. Spaniards rank first among the Europeans, Italians come next.

In 1923 (official figures) 23,473 passengers arrived at Casablanca, of whom 5,133 came to stay (3,682 Frenchmen, 532 Spaniards, 382 Italians, 63 British, etc.) Of these, 660 came for commerce, 424 as engineers, contractors or as workmen for the building trade, etc.; and 1,200 tourists visited Morocco. On the other hand, about 30,000 natives (including a certain number of Riffans) crossed over to Algeria as harvest labourers; 4,596 Moroccans went to France as labourers; 1,250 returned the same year, bringing back over 2,000,000 fr. savings.

French Colonisation and the Land Question.—At the end of 1913 French properties numbered 1,127, representing 1,073,000 ac., lying principally in the El Gharb region (north of Rabat—about 250,000 ac.); the Shawiya (south of Casablanca), the environs of Rabat and Ujda coming next. Other European properties numbered 117 (Spanish 28, Italian 39, English 20, etc.), covering 52,700 acres. Farms of less than 100 hectares (250 ac. represent 44·8% of the total surface in European hands; large farms (over 1,250 ac.), 14·3%. The rest (40·9%) varies between 250 and 1,250 ac. (*colonisation moyenne*). Of the total surface, 179,000 ac. had been given away by the official colonisation system (sales), and the rest bought directly from the natives. About half the French colonists come from Algeria and Tunisia and are already familiar with local conditions.

The establishment of French power brought about a great change in economic and social conditions in agriculture as elsewhere. Both the soil and the climate are, in many parts of Morocco, far more favourable to settlement than to nomadism. The feebleness of the central native power (Maghzen) and continual intertribal strife used to render private property (*melk* lands) almost illusory. But, especially since 1919, in the pacified parts, the natives have settled on the land which was, before, "common" land (*arch*), inalienable according to Mussulman law and custom. It is both wise and just to reserve a part of them (it is estimated that about 5,000,000 ac. can be cultivated instead of being left for sheep grazing) for French and other colonists, who can put them into far better value.[2] There are also maghzen and habu (religious property) lands that can be better utilised. Land registration has been introduced in Morocco since 1913, and 5,826 titles had been registered at the end of 1923, on which, at that date, 186,000,000 fr. had been borrowed on mortgage. Natives are also beginning to register their lands.

The colonists cultivate the same crops as the natives: wheat (durum principally), barley, oats, beans, etc.; the olive tree, flax (for seed). There have been a few experiments in growing castor-oil seed and in cotton and hemp since the War. Orange culture in the regions of Meknes and Marrakesh is promising. Vineyards only occupy a few hundreds of acres; and for the moment the raising of early vegetables (so successful in Algeria) is confined to the suburbs of a few big towns for their European inhabitants. Stock raising (sheep especially) is also carried on, sometimes in association with natives; the number of sheep was estimated in 1924 at about 10,000,000, of which 7,200,000 paid the tax tertib, and about 100,000 were in European hands. The amelioration of the local breed, both from the point of view of the flesh and the wool,[3] is being steadily pursued; as also the study of several other important agricultural problems in the official farms and experimental fields.

Budget.—The 1924 budget foresaw 312,629,000 fr. ordinary receipts; of which, customs produced 83,000,000 fr.; tertib, 66,000,000; taxes on consumption (sugar, tobacco, etc.), 60,000,000. The 312,442,000 fr. of expenses were principally distributed as follows: public debt, 62,000,000; justice and general administration, 72,000,000; services of economic interest (public works, agriculture and commerce, etc.), 91,000,000; services of social interest (education, health, etc.), 29,000,000, etc. The total actual debt of the Protectorate amounts to 705,624,000 francs. Morocco contributed (1924) 46,000,000 fr. to the French military expenses in the country. At the end of the same year France had spent 4,271 million fr. since 1907 in Morocco. But if the ordinary garrison expenses (not special to Morocco) are deducted—2,501 million fr., or 63·6% of the total—the total cost proper of Morocco to France represented at that date 1,431,000,000 francs.

Railways and Public Works.—The 1,300 km. of narrow gauge military railways existing in 1923 registered that year 61,620,000 kilometric-passengers and 67,750,000 kilometric-tons of merchandise. They are gradually being replaced by the standard gauge, 400 km. of which were already in operation in 1926, and which will be partly electrified when the Casablanca central power station is finished. Including the Tangier-Fez line (310 km.), the new system will have a total length of about 1,000 kilometres. The admirable phosphate region of El Boruj-Wed Zem is already linked up with the port of Casablanca, which now possesses a length of 425 metres of quays for big ships (depth 48-50 ft.) under the protection of a jetty over a mile long (2,000 metres). The other ports are Qnitra, Rabat, Fdala, Mazagan, Safi and Mogador.

The network of roads consisted (end of 1923) in 2,665 km. of principal and 577 km. of secondary roads, and 933 km. more were being constructed or projected. There existed at the same date 12,300 km. of telegraph lines. Besides the sea postal service, Casablanca is in daily postal connection by aeroplane with Toulouse, by Algeciras, Barcelona and Perpignan.

The year 1925 marked important progress in the value of Moroccan commerce: 1,754,000,000 fr. (imports, 1,189; exports, 565), as against 139,0,000,000 fr. in 1924, and 850,000,000 in 1923. Figures in tons are still more decisive.

	1923	1924	1925
Exports . . .	339,236	815,160	982,921
Imports . . .	448,293	426,572	569,640
Total (tons)	787,529	1,242,732	1,552,560

The great growth in exports is due to the progress in the exploitation of the magnificent phosphate beds of Wed Zem (finer than those of Tunisia): 720,000 tons exported in 1925. By far the greater part of Moroccan commerce is centred in Casablanca (1,135,600 tons, 1,082,000,000 francs). The two ports ranking next are Qnitra (138,700 tons) and Safi (90,600 tons). Fdala is last on the list. Commerce by land with Algeria (Taza-Ujda) amounted to 77,860 tons. On Jan. 1 1924 there were 615 industrial establishments in European hands in Morocco, employing 7,223 hands and 22,868 horsepower. The capital invested amounted to 273,600,000 francs. Electricity heads the list; flour-mills, slaughter houses, lime and cement factories come next. Casablanca comes first (140,000,000 fr. invested). Rabat, Marrakesh, Fez, Qnitra and Ujda rank afterwards, in the order named.

BIBLIOGRAPHY.—Official and general publications and periodicals: *Annuaire Economique et Financier* (Casablanca); *Archives Marocaines* and *Hesperis* (Rabat); *Bullétin de l'Afrique Française*, with its remarkable supplements (Paris); *La Renaissance du Maroc, Dix ans de Protectorat* (Rabat, 1922); Prosper Richard, *Le Maroc* (Paris, 1925), with an English adaptation by C. Heywood, *Morocco, Mysterious Islam*; P. Louis Rivière, *Traités Codes et Lois du Maroc* (Paris, 1925, 3 vol.); Victor Pictet, *Le peuple Marocain, le bloc berbère* (1925); Ali bialelse, *Le Collier de Perles, un des discours de politique indigène du Maréchal Lyautey* (Rabat, 1925). Special: J. Ladreit de la Charrière, *Le rêve d'Abd el Kerim* (Paris, 1925); L. Milliet, *Les terres Collectives* (blad djemaa) (Paris, 1922); Paul Marty, *Le Maroc de demain* (Paris, Comité de l'Asie française, 1925), important on the vital question of the education of the natives. (H. BR.*)

III. SPANISH MOROCCO

The Spanish zone in Morocco extends over an area of 18,360 square miles. Accurate returns of the population are impossible. The civil population in the towns in 1923 was estimated at 118,305, of whom the majority were Mahommedans. Tetuan, the capital of the Protectorate, had an estimated population of 23,447 in 1923. Other towns were Melilla, 60,000; Larache, 15,430; Alcazarquivir, 12,368.

Education in Spanish Morocco is conducted under the auspices of the different creeds. Catholics, Mahommedans and Jews have their own schools. The budget of the Protectorate provides the salaries of professors at the university in Tetuan. There were 175 primary schools, of which 74 were specially for Moorish children. The total number of pupils attending the primary schools in 1923 was 24,670.

Administration.—By a royal decree of Jan. 18 1924 the direction of affairs in Spanish Morocco was entrusted to the Premier

[1] "Urbanism" was a great feature under Lyautey. If Casablanca is certainly an overgrown town, the plans for the extension of the principal towns (drawn up by M. Henri Prost) are remarkable, and carefully preserve the native quarters.

[2] In Tunisia, for instance, in 1921, the 190,000 ac. cultivated in wheat by Europeans produced 68,000 tons, whereas the 1,250,000 ac. in native hands only gave 120,000 tons. In Morocco, where a French colonist loses 7% of his sheep stock, a neighbouring *Kaid* will lose 48%—a case of direct observation.

[3] Wool of the *Abudia* commercial type, of the Beni Hassen, is already of a superior quality; it is perhaps the original *merino*.

of Spain, with the exception of military matters, which were confided to the Ministry of War. The Spanish Govt. is represented in the Protectorate by the High Commissioner, who presides over the Civil Services. A royal decree of March 1925 fixed the limit of the Spanish forces in the Zone at 80,000—65,000 Europeans and 15,000 natives. The intermediary between the higher command and the Moorish troops is the officer known as the *Caid Interventor*.

The reverse suffered by the Spanish arms in 1921 through the defection of a friendly tribe, when Gen. Silvestre was killed, precipitated a political crisis in Spain, which culminated in the proclamation of the Military Directory in Sept. 1923. The policy of the President of the Directory, Gen. Primo de Rivera, was to establish a single front, to effect which the army was withdrawn from portions of the occupied territory and a number of positions were evacuated.

Spanish subjects in the Protectorate enjoy all the civil rights recognised by the law in Spain; foreign residents enjoy the same rights subject to certain provisions. All residents, whether Spanish subjects or not, must conform with regulations relating to the police and public security. The budget for the Zone for 1924–5 was 15,607,500 pesetas. The total trade values, in pesetas, for 1922 were: imports, 4,367,401; exports, 7,080,413—a favourable trade balance of 2,713,012 pesetas. Agriculture in the Spanish Zone has made progress since 1923, and of the 330,000 hectares of land available for cultivation in the eastern zone 120,000 have been taken up for production. Lemons, oranges, olives and many cereals are grown. The *Agrupación agraria* at Alcazarquivir has inaugurated a new era of agricultural progress.

The Spanish Zone is served by three railways: Ceuta-Tetuan, Nador-Titztutin, Larache-Alcázar, with a total mileage of 90 miles. Public highways have been constructed in the central, eastern and western regions.

MOROCCO, CAMPAIGNS IN.—The colonisation of Morocco has always been attended by violent encounters with the numerous tribes inhabiting that country. Since 1910 France and Spain, the two protecting powers, have both had to contend afresh with native hostility, encouraged and assisted to some extent by agents of Germany. The following account of this aspect of Moroccan history is given under three headings, namely, I. Spanish Campaigns; II. French Campaigns; and III. Franco-Spanish Campaigns. The last deals with the combined action of France and Spain against the tribes of the Rif.

I. SPANISH CAMPAIGNS

The history of Spain in the Rif has been one of intermittent warfare ever since, at various dates in the Middle Ages, she obtained possession of and occupied her "Presidios" on this coast of North Africa—Melilla, the Zaffarin Islands (Islas Chafarinas), Alhucemas, Peñon de la Gomera and Ceuta. Confined to the narrow limits of these possessions, it was ever Spain's desire to obtain more breathing-room so as to be able to put them to a greater utility than mere penal settlements. At various periods, for instance after the Spanish Moroccan War of 1859–60, the Spanish Government had demanded and obtained some territorial expansion at Ceuta and Melilla, but the other points, rocky islands off the coast, remained at the mercy of the tribesmen of the mainland and could only with difficulty be provisioned. As was only natural the relations between the Spanish and the Rifis were difficult.

Spanish Expansion.—The loss of her colonies at the end of the 19th century caused Spain to seek compensation in Africa; and the Franco-Spanish Treaty of 1912, to which Great Britain was a consenting party, gave her the opportunity she sought. By this treaty the Spanish zone in Morocco was delimitated and Spain's hands were freed to undertake its occupation. Already in 1909 she had fought a costly campaign in the Melilla district which had left a comprehensible desire in the Spanish Army for revenge. In 1912 the occupation of various parts of the Spanish zone was begun and in that and the succeeding years Tetuan, Larache, El Qsar (Alcazar), and Arzila were reached and the neighbouring districts occupied. At the same time Spanish forces marching south and westward from Melilla succeeded in penetrating some distance into the Rif without meeting with serious resistance.

Effect of the World War.—The Spanish task was at first much facilitated by the World War, during which the Spanish zone was used by the Germans as a base of active propaganda and action against the French Protectorate. Money was lavishly distributed amongst the tribesmen for the purpose of raising Rif forces for inroads into French territory, and Rifi attention was largely withdrawn from the more imminent danger of Spanish invasion. The end of the war put a stop to this anti-French action and the Rifis, who had received from the Germans large sums of money and no small quantity of arms, turned against the Spaniards. In 1919 General Berenguer, the Spanish High Commissioner, was forced to open a campaign in the Jibala highlands which led, in the following year, to the occupation of Sishawen (Sheshuan). Raisuli, sherif and ex-brigand, whose influence amongst the tribes was great, facilitated on this occasion Spanish action.

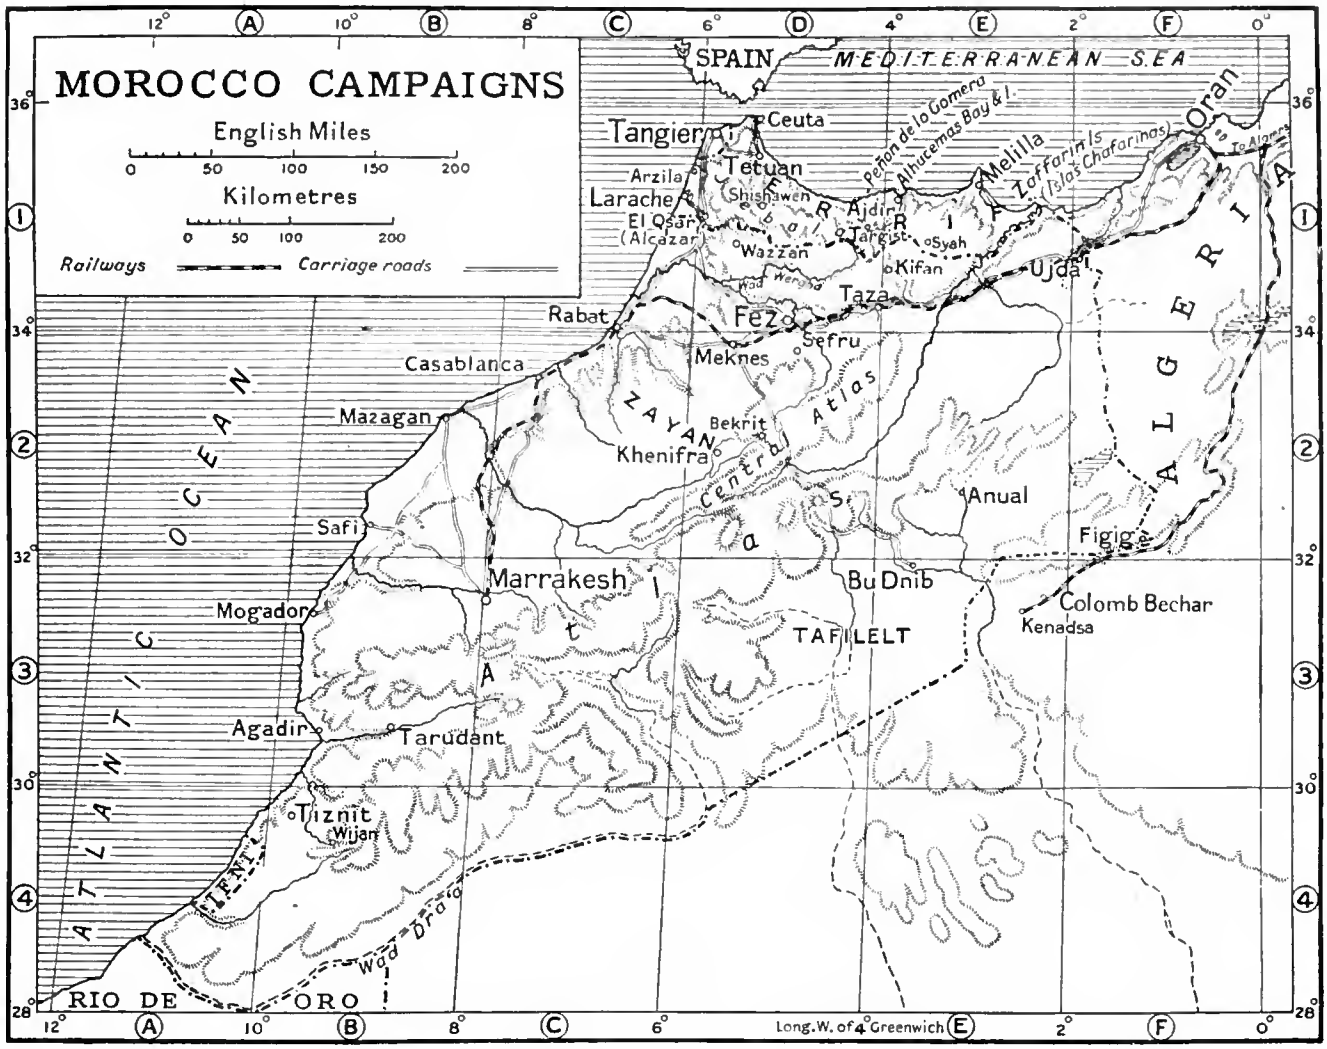
'Abdel Krim.—Further east 'Abdel Krim, the son of a Beni Uryaghel (Ouriaghel) chief, had deserted the Spanish service and was stirring up resistance to the Spaniards in the Rif. In 1921 a Spanish Army of nearly 20,000 men holding the country between Melilla and Alhucemas was annihilated by the Rifis. This disaster, which began with the fall of the advanced post of Anual and the death of General Silvestre, leading to a subsequent panic, ended in the loss to Spain of all that had been acquired in several years of campaign and diplomacy. At least 16,000 soldiers were killed, after the perpetration upon many of them of every kind of atrocity. Melilla itself was for a time at the mercy of the tribesmen, but for some unexplained reason they did not enter the town.

These Moroccan events led to a crisis in Spain and in Sept. 1923 the Constitutional Government was replaced by a Military Directory under Gen. Primo de Rivera. The situation in Africa was serious. The outlying Spanish positions, often cut off altogether, were threatened in every direction and the president of the directory recognised that immediate action was necessary if the Spanish garrisons and Spanish prestige were to be saved. He decided upon the wise and courageous course of a general withdrawal from the front, including the evacuation of Shishawen. It was not until the autumn of 1924 that this difficult manoeuvre was accomplished, after considerable loss in men, in artillery and in arms and ammunition. New lines were occupied, passing from the immediate south of Tetuan to the frontier of the Tangier zone and thence southward to near El Qsar and the frontier of the French Protectorate. The road from Tangier to Tetuan was preserved as a couloir, strongly guarded on both sides, through enemy country. The evacuation by the Spaniards of those extensive regions added not a little to 'Abdel Krim's influence and prestige. Raisuli, ill and bedridden, was taken prisoner by the Rifis and died a few months later, a captive at Adir, 'Abdel Krim's headquarters. (W. B. H.)

II. THE FRENCH CAMPAIGNS

The Fez rising which took place in Oct. 1910 (*see* MOROCCO, was followed by continued trouble in the Fez-Sefru district during the autumn of 1911. A new pretender, Hamed el Hiba, occupied Marrakesh in Aug. 1912, but he was expelled in Sept. and therepon fled south. In Oct. Gen. Lyautey occupied Agadir. Fighting in Western Morocco continued for some months; but this district and that of Fez were occupied by the spring of 1913, and the French concentrated their attention on Eastern Morocco. The important strategic point of Taza, which commands communications with Algeria, was occupied in May 1914, Khenifra captured in June.

The World War Period.—On the outbreak of the World War, the French commander received telegraphic orders from the Ministers of Foreign Affairs and of War (July 27–28 1914) "to reduce the occupation to the principal points on the coast," as "the fate of Morocco would be settled in Lorraine," and asking



Lyautey to send all available men and material to the French front. Lyautey immediately dispatched 37 battalions and other troops; but refused to evacuate the interior. The tribes round Taza, and the Zayan in the west, promptly rose, but the *kaids* of the Atlas and the *bashas* of Tarudant and Tiznit in the south near Agadir remained friendly, the latter keeping El Hiba's forces in check. The Spanish zone was used by the Germans as a basis of active propaganda and action against the French Protectorate. The tribesmen received lavish donations of arms and money from the Germans. Throughout 1915 and 1916 chiefs in German pay conducted a campaign along the Wad Wergha. Nevertheless, the small French force more than held its own. In May and June 1917 Abd el Malek was driven from Taza. On March 24 1917 El Hiba was severely defeated at Wijan; his force was finally dispersed in the following spring. The Tafilelt was definitely occupied at the end of 1917. In Aug. 1918 a revolt began among the Aid Atta, which was suppressed by April 1919 with the help of El Glawi.

French Activity, 1918-23—After the War the French continued their operations, taking the offensive, now on one, now on the other, of their four fronts: the Northern (Spanish zone; Djebala and Rif tribes), the Berber (Central Atlas), the front of the big *kaids* (El Glawi, M'tongi, Goundafi) and the Southern front (Kut Aissa, Tafilelt). In 1919 the 80,000 French troops were successful in the Bu Dnib territory in the southeast (Jan.–March), on the Wenah (northwest) in April, in the Taza Corridor (June–Oct.). In 1920 the chief activity was in the Central Atlas until Sept., when Wazzan, in the north, was taken, and operations began in Nov. north of Agadir. For 1921 the main operations were again planned for the Berber front, but in Feb. the Djebalis, headed by Kacem ben Salah and Abd el Malek, again rose unexpectedly. Though reinforced by the Beni Mestara and the Beni Mesguilda, they were put down by General Poeymirau in April. General Aubert settled the Beni Waghrain question in June, and Poeymirau once more filled up the Bekrit "pocket" in the Zayan country in the autumn. By the end of 1923 the French zone was pacified, 1923 being especially devoted to wiping out the Taza "stain" (*la tache de Taza*). The last French operations were largely dictated by the need of gaining control, for irrigation and other purposes, of the "Water Castle" of the Central Atlas. Meanwhile the anti-French subventions ceased and the Rifi, now well-armed and financed, turned against the Spaniards. (H. Br.*)

III. THE FRANCO-SPANISH CAMPAIGN

Until April 1925 the Rifi had been at war with Spain alone; but the gradual occupation by the French of the northern limits of their Protectorate, which reaches as far as the southern borders of the Rif, brought a new factor into the field.

'Abdel Krim's Offensive.—'Abdel Krim considered that his country was threatened by this advance and in April he launched a furious attack upon the French front to the north of the Fez-Taza-ujda road, the great highway between the Moorish capital and Algeria. Under this unexpected blow the French front collapsed. The Rifi penetrated far behind the lines, forced or persuaded the surrounding tribes to rebel and pillaged and massacred when obedience was refused. The situation became critical. For some reason the French Govt. hesitated to send the reinforcements necessary until the campaign had taken an importance which might have been avoided had more troops been at once available. Wazzan and Taza were threatened and European women and children were withdrawn to places of safety.

By the end of June, Fez, the capital, was in danger. The Sultan, in order to give confidence by his presence, arrived there in the latter days of that month. The efforts to save Fez were successful but many of the rich agricultural districts of this northern part of the French Protectorate were overrun and pillaged. Wherever it was possible the more distant military posts were evacuated, but many, with their garrisons killed, fell into the hands of the enemy with such artillery and arms and ammunition as was in them, immensely increasing the Rifis' war material. In July the French Govt. decided to send Marshal Pétain to take supreme command of the French Army, which now numbered over 160,000 men. Marshal Lyautey remained in charge of the political and administrative Government. A month was lost in the reorganisation which this new decision necessitated. Meanwhile immense quantities of material, artillery, mechanical transport, aeroplanes and all the implements of modern warfare arrived on the front.

Franco-Spanish Alliance.—Realising the common danger the French and Spanish Govts. held a conference at Madrid and drew up a programme for combined political and military action in Morocco. Monsieur Painlevé and Gen. Primo de Rivera offered peace to 'Abdel Krim on generous terms. The Rifi leader refused, demanding in return the absolute independence of the Rif. It was agreed at the conference that while the French Army should advance northward from its base the Spaniards should undertake a landing in Alhucemas Bay and thus occupy the region of Ajdir, which formed 'Abdel Krim's headquarters. On Sept. 8 and subsequent days a Spanish Army of 15,000 men was successfully disembarked while, at the same moment, French forces marched northward from their base at Taza, via Kifan. A junction was carried out at Syah between these French columns and Spanish contingents advancing westward from the Melilla district.

There is no doubt that the objective of this combined force was to reach Ajdir by land and join up with the Spanish troops which had been disembarked at Alhucemas, but the autumn rains broke and the united columns found themselves in difficulties. The tracks through this inhospitable country became quickly impassable and there was an imminent risk of isolation. The French troops retired 18 m., and all along the front winter-quarters were prepared. Pétain returned to France and Lyautey resigned. M. Steeg, who had been Minister of Justice and Governor-General of Algeria, was nominated high commissioner.

The active phase of the Franco-Spanish combined action against the Rif came to a close with the advent of winter weather and such French troops as could be spared from the front were sent to more hospitable quarters—Fez, Meknes and Rabat. The campaign had been marked by no incidents of military importance. The French had succeeded at great cost and at considerable loss of life in retaking the districts they had evacuated, but neither security nor tranquillity were assured. The mobility of the Rifis made them largely immune from the results of artillery attack, and long experience in the Spanish zone had taught them how to take cover from aerial bombardment. Their losses were thus comparatively small. The absence of all war impedimenta rendered their mobility most disconcerting to troops educated on the European battlefield. In short the methods employed by the French were in many respects quite unsuitable to this kind of colonial warfare, and the hoped-for results had not been achieved when rain put an end to the autumn campaign. The constant penetration of the French lines by groups of natives who, uniting in the rear, became formidable bands, caused constant anxiety. Convoys and posts were attacked; peaceful country was invaded and farms and villages burnt.

Rifi Activity: Winter 1925.—It had been 'Abdel Krim's desire and intention, by intense propaganda to raise rebellion amongst the Protectorate tribes further south; but although at one moment there were signs of hesitation, and even of disloyalty, amongst some of the nearer Berber tribes, the spirit of rebellion was suppressed almost before it had become apparent. It was a proof of France's admirable administration in Morocco that with the exception of the tribes which inhabited the borderlands of the Rif, and thus fell directly under Rifi influence, the rest of Morocco remained loyal.

As soon as the French and Spanish troops, on the breaking of the weather, withdrew to winter quarters, 'Abdel Krim began the reorganisation of his forces. The Spanish disembarkation at Alhucemas was a heavy, but apparently only temporary, blow to his prestige, though it necessitated the abandonment of his village capital of Ajdir. But he was able to withdraw to a place of safety within the mountains his artillery and stores of war material. Only a very few of his guns fell into the hands of the Spaniards on their landing. Moving his headquarters to Targist, south of Ajdir, he set to work to prepare for a renewal of the campaign. His first action was to obtain a moral revenge for the Spanish landing at Alhucemas, and for this purpose he despatched four cannon to the mountains that overlook Tetuan, the capital of the Spanish zone and the residence of the high commissioner.

By almost superhuman efforts the Rifis dragged these guns over the rugged mountains to a spot within nine km. of Tetuan and set them up in caves situated at least 2,000 ft. above the town and valley. From this vantage ground they opened on Sept. 28 a desultory bombardment of the capital, which was still being continued in December. The skill with which these guns had been mounted and could be withdrawn into the caves after every shot protected them from the fire of the Tetuan batteries. To send an expedition to destroy them was considered unduly costly. The moral effect, however, was important and a large number of the civil population left the town.

Close of 1925.—In Dec. 1925 the French and Spanish armies were in comfortless and insecure winter quarters, difficult to provision, and very trying to the health of the troops. 'Abdel Krim was organising his army in preparation for a continuance of attacks upon his enemies during the winter and for a new campaign in the spring of 1926, which appeared inevitable unless meanwhile a settlement by negotiation could be brought about.

Peace Negotiations: April 1926.—Early in 1926, however, the prestige which 'Abdel Krim had established over the tribes of the Rif began to wane and his position was much weakened by the readiness with which various tribes contemplated the cessation of hostilities. In these circumstances 'Abdel Krim, in the first days of April, offered to negotiate with the Franco-Spanish Governments. An unofficial armistice came into being, and a meeting of French, Spanish and Rifi delegates was arranged for the third week in April. The French and Spanish Govts. reached an agreement as to the terms on which they were prepared to negotiate for peace. (W. B. H.)

On May 30, 'Abdel Krim surrendered unconditionally at Taza to General Boichut, the French commander in Morocco. In a manifesto addressed to the Rifi tribes, M. Steeg said that his fate would be decided by Mulai Yusef, the Sultan of Morocco. The French losses during the campaign were 2,162, exclusive of the casualties among native troops.

The close of the Rif campaign left some questions for solution between France and Spain, and conversations began at once between M. Steeg and the Spanish high commissioner, General Sanjurjo. Apart from the future of the Rif itself, the two tribal federations in the west, in the Djabala and the Chomara, remained to be dealt with; even the French zone had not been fully occupied. (*See* 'Abdel Krim.) (Ed. *E. B.*)

MORRIS, EDWARD PATRICK MORRIS, 1st Baron (1859–). Newfoundland statesman, was born at St. John's, Newfoundland, May 8 1859. Educated at St. Bonaventure's College and the University of Ottawa, in 1884 he was admitted a solicitor, and in 1885 was called to the bar. The same year he was elected to the legislature of Newfoundland as the representative of St. John's in the Liberal interest. From 1890 to 1895 he was acting attorney-general for Newfoundland, and from 1893 to 1906 was a director of the Newfoundland Savings Bank. In 1898 Morris left the Liberal party and was leader, first of the Independent Liberals and later of the People's party (1908–19). In 1902 he became attorney-general and subsequently Minister for Justice. He was knighted in 1904. In 1909 he became Prime Minister, retaining this office until 1918, and representing Newfoundland

at various Imperial and other conferences. In 1913 he was made K.C.M.G., and in 1917 was a member of the Imperial War Conference. He was raised to the peerage in 1918, having been since 1911 a member of the Privy Council. Lord Morris edited an edition of the Newfoundland law reports from 1820 to 1905, usually called *Morris's Reports*.

MORRISON, GEORGE ERNEST (1862–1920), British journalist and traveller, was born at Geelong, Australia, and educated at Melbourne University. From 1882 he travelled extensively in the South Sea Islands, where he studied the Kanaka labour question; in Australia, which he crossed on foot from the Gulf of Carpentaria to Melbourne; and in New Guinea. He took his M.D. degree in 1887 and after journeys to the United States and the West Indies he worked in his medical capacity in Spain, Morocco and Australia. In 1893 he abandoned medical work and set off on extensive travels in the Far East. In 1895 he was special correspondent of *The Times* (London) in Siam and two years later became Peking correspondent of the same journal. In this capacity he visited every province and dependency in the Empire, with the exception of Tibet, and gained an intimate knowledge of men and affairs. In 1911 at the outset of the revolutionary movement in China he proclaimed his sympathy for the programme of Dr. Sun Yat-sen and the Cantonese Radicals. In 1912 after the abdication of the Emperor he resigned his *Times* appointment and became political adviser to Yuan Shih-K'ai, president of the newly formed Chinese Republic. Dr. Morrison's published works include *An Australian in China* (1895). He died at Sidmouth, Devonshire, May 30 1920.

MORTON, LEVI PARSONS (1824–1920), American banker and politician (*see* 18.882), died at Rhinebeck, N.Y., May 16 1920.

MOSBY, JOHN SINGLETON (1833–1916), American soldier (*see* 18.890), died in Washington, D.C., May 30 1916.

MOSCOW (*see* 18.891), the capital of the Union of Socialist Soviet Republics, called by the Russians Moskva, had in 1925 a population of 1,845,000. The great increase in population was due to the transfer of the seat of government from Petrograd to Moscow after the Revolution. It fell during the famine period, but increased by 716,000 from 1920 to 1924 owing to the return of many who had left the city and to the increase in the number of officials and of traders. The natural increase (the excess of births over deaths) is about 25,000 per annum. The records showed in 1925 270,000 persons engaged in government offices, schools, trade unions and co-operative organisations, etc., 35,000 employees in private trading concerns, 150,000 factory and mill workers, and about 37,000 home craft workers.

The great influx of population created a serious and dangerous housing situation, intensified by the circumstances of the famine period when many wooden houses were destroyed for use as fuel, and by the cessation of building and of ordinary repairs. In 1920–1 25% of the already inadequate houses were derelict. Quarters were requisitioned, and the great apartment houses of central Moscow were run by house committees which allotted floor space to occupants, charging only the costs of repairs, lighting, cleaning, etc. The New Economic Policy was followed by a return to a more normal rent system. Houses were put in order, pavements restored, and a considerable amount of new buildings was put in hand in 1923 and 1924. In 1912, with a population of 1,618,000 Moscow had 281,500 apartments; in 1925, with a population nearing 2,000,000 she had 200,000 apartments. The pressure of population led the Soviet Govt. to transfer certain commissariats to Leningrad in 1925. The streets of Moscow, radiating from a common centre, have an excellent tramway system which makes the suburbs easily accessible; in 1925 a certain number of English motor-buses were running. The tramways carried 394,000,000 passengers in 1925 as against 257,000,000 in 1913. Part of the suburban train service is in process of electrification. Power is supplied to Moscow from a power station burning the soft coal of the Moscow district. A new electric power station, the largest in the U.S.S.R., which burns peat fuel, has been erected at a cost of 28,000,000 rubles, and began to supply power to the Moscow industries in 1926. The principal industries of Moscow, textiles, engineering, food, had not recovered their pre-War output in 1925.

Moscow has always been an important trade centre, and its position in the home market became steadily more important after the establishment of the headquarters of the various state trusts in the city. The Moscow Goods Exchange, established by the Trade Commissariat registered a turnover of 2,991,000 rubles in 1924–5. It is stated that only 5 or 6% of this is private capital.

Even with the opening of private shops and the repair of streets and buildings Moscow had not recovered its former busy aspect; the general poverty of the people prevented that. Some of the former palaces of the Moscow aristocracy and merchants have been turned over for public purposes, or for the use of foreign legations and missions. Many of the principal streets have been renamed after revolutionary personages. The city still remains an important literary and artistic centre, and the Moscow theatres are still among the first in Europe in the variety and beauty of their productions.

MOSELEY, HENRY GWYN-JEFFREYS (1887–1915), British physicist, was educated at Eton and Trinity College, Oxford. As lecturer in physics in Rutherford's laboratory at Manchester University, and subsequently as John Hartling fellow, he carried out a brilliant series of researches, proving the existence of a simple relationship between the X-ray spectrum of an element and its atomic number, and establishing a new and valuable method of chemical analysis. He was killed in Gallipoli Aug. 10 1915.

MOSLER, HENRY (1841–1920), American artist (*see* 18.898), died at New York City April 21 1920.

MOSUL (Vilayet) (*see* 18.904).—This former vilayet of the Turkish Empire now forms part of 'Iraq. It includes the livas of Mosul, Arbil, Kirkuk and Sulaimaniya making an area of 35,130 square miles. Its boundaries are Syria on the west, 'Iraq on the south and southwest, Persia on the east and on the north the disputed Brussels Line dividing it from the Bitlis vilayet. As regards the ethnographical details of the population, the estimates provided by a pre-War Turkish census and those compiled by British officials in 1921 differ widely. The total population appears to be roughly 750,000, nine-tenths of the inhabitants being Moslems. In the town of Mosul and the surrounding plain the Arabs are the predominant race; in the mountains, the Kurds. The League of Nations Commission (1925) stated that the district was inhabited by Kurds, Arabs, Christians, Turks, Yezedis and Jews in that order of importance. Upon the corn grown in the plains round Mosul a wide area extending to Lakes Vrumia and Van depends for its sustenance, while the almost impregnable mountain ranges give Mosul a strong strategic position in regard to 'Iraq. The great rivers of 'Iraq have their headwaters in Mosul, and he who is master in Mosul is also master of 'Iraq's most vital necessity, being capable of threatening the safety of the vast oil resources of 'Iraq.

By the Armistice of Mudros, hostilities were suspended between Great Britain and Turkey from midday Oct. 31 1918. Nevertheless on Nov. 3 General Cassels informed the Turkish authorities that he had been ordered to advance beyond the Armistice line and occupy the town of Mosul. This apparent violation of the Armistice terms was subsequently declared to be justified by Article 7 of the Armistice—" dans le cas où il surgirait une situation qui menacerait la sécurité des Alliés, ceux-ci auront le droit d'occuper tout point stratégique." The Turks on the other hand maintained that no such menace existed, and protested strongly against this action on the part of Great Britain. Later on further advances were made by the British forces; on Sept. 30 1924 a provisional frontier, known as the Brussels Line, was proposed by the League of Nations and accepted by both Great Britain and Turkey, pending a final settlement of the dispute. This Brussels Line was at its nearest points no less than 150 km. north of the Armistice frontier. It ran from the Hazil to the Khabur river, then across the mountains north of the valley of the Great Zab and then due east to the Persian frontier. Roughly speaking it runs on the crest of the mountains cut through by the three rivers named.

The question of the vilayet figured prominently in the discussions at the Lausanne Conference. Clause 3 of the Treaty of Lausanne provided that the dispute between Britain and Turkey should be brought before the League of Nations unless settled by agreement within nine months; the Turks had agreed to this on Lord Curzon assuring them that "the decision of the Council, upon which the Turkish Govt. will be represented, will have to be unanimous, so that no decision can be reached without your consent."

Sir Percy Cox carried on fruitless negotiations in Constantinople (May 19–June 15 1924); but the Turks refused to abate their claim to the whole of the former Mosul vilayet. In Aug. the matter came before the League, which appointed a commission to study the question. In Sept. the Turks crossed the provisional frontier and drove some 8,000 Assyrians to take refuge in 'Amadiya where they were supported by the 'Iraq Government. Thereupon at a special meeting in Brussels in Oct. the League defined a provisional frontier, the Brussels Line, which Turkey agreed to accept as a *status quo*. The Commission reached Baghdad in Jan. 1925 and reported in Aug. that the historic right was with Turkey; but suggested that Mosul should be left to Turkey if Britain intended to withdraw from 'Iraq in 1928, but assigned to 'Iraq if Britain was willing to undertake a mandate for 25 years.

Turkey contended that the League could not give a binding decision; the question was referred to the Hague Court, and was still pending when further military movements by the Turks in the neighbourhood of the Brussels Line in Sept. 1925 resulted in the violent deportation into the interior of Turkey of Christians living immediately to the north, and in some cases even to the south of the provisional frontier, while some 3,000 Chaldeans took refuge in a destitute condition in 'Iraq. The League appointed a second Commission to examine the complaints on both sides and report any violations of the frontier.

This report was presented to the League in Dec. and left no doubt as to the harshness with which the refugees had been handled by the Turks. The ruling of the Hague Court—that an arbitral decision was binding—had already been received; but the Turkish delegate refused to accept the decision of the League and withdrew. Turkey, however, renewed her proposal of a plebiscite of the Mosul population, and further offered (1) a four-nation Pact (Britain, Turkey, 'Iraq and Persia) which should guarantee the integrity and independence of 'Iraq, (2) the cession of the valuable Syale basin containing some of the oil-fields of the vilayet and the main sources of 'Iraq's irrigation. In the absence of the Turkish delegate, the League awarded Mosul to 'Iraq under certain conditions which were accepted by the British House of Commons five days later.

The inclusion of Mosul in 'Iraq was finally agreed by the treaty signed on behalf of Great Britain, 'Iraq and Turkey at Angora on June 5 1926. By this treaty Turkey accepted the Brussels line with small modifications as the frontier between Turkey and 'Iraq, the exact line to be determined by a mixed commission an the spot. A pact of security for ten years was agreed between Great Britain, Turkey and 'Iraq. Turkey enjoys a share in the royalties on Mosul oil for a period of 25 years. Subsequently an agreement was reached on the compensation to be paid for Turkish public works in the former vilayet. An exchange of notes following the treaty gave Turkey the option of capitalizing her share of the oil royalties at a present value of £500,000. This was an important event both for politics and oil. (*See* LEAGUE OF NATIONS.)

Gidel, *La Frontière entre la Turquie et l'Irak* (Paris); E. G. Mears, *Moslem Turkey;* H. C. Luke, *Mosul and its Minorities* (1925). The text of the treaty of June 5 1926 is printed on a white paper (Cmd. 2672 of 1926).

MOSUL (City) (pop. 40,000), capital of the former vilayet of Mosul (*see* 18.904), has acquired importance since the World War. On Nov. 18 1918 (that is, 19 days after the signature of the Mudros Armistice), the city was occupied by British troops. The advent of the railway, which now reaches a point only some 70 m. distant, Sharqat, will doubtless help to revive the industrial prosperity of Mosul, which at present possesses practically no industries, not even its once famous manufacture of muslin, deriving its name from the town. The population exhibits an amazing intermixture of races and creeds; but in the city of Mosul the Arabs have a clear preponderance.

Several churches of great architectural interest are found amongst those belonging to the various sects, Nestorians, Jacobites, Uniate Chaldeans, Syrians, Catholics (also Uniate) and that strange remnant of the Gnostics, the so-called "Christians of St. John." A promising field for antiquarian research lies in the great mound of Nebi Junus, on the opposite bank of the Tigris, which covers the ruins of Esar-Haddon's palace. This site, hitherto closed to the excavator, may probably be rendered more accessible under the new Government. The exploration of the neighbouring mound of Tell Quoyunjuk produced under Layard and others the well-known relics of Sennacherib's palace now in the British Museum. See H. C. Luke, *Mosul and its Minorities* (1925).

MOTION PICTURES (*see* 6.374c).—This article will deal, first, with the rise and development of motion pictures, second, with the technology of film production and the exhibition of the picture and, third, with the motion pictures as a distinctive form of art.

I. HISTORY

While the commercial history of the motion picture covers only 30 years, beginning in 1894–5, the screen springs from roots which reach into the unrecorded past, with the earliest efforts at the re-creation of events. This effort, guided and controlled chiefly by the facilities and tools available, led variously to the evolution of pantomime, sign languages, rituals, drama and literatures. The motion picture, as the complete visual re-creation of the desired event, came as soon as adequate materials and technology were evolved.

Early Investigation of Scientific Principles.—Scientific investigation leading up to the motion picture was definitely begun by Peter Mark Rôget, secretary of the Royal Society of Great Britain, who in 1824 investigated the laws of vision with reference to objects in motion. That year he read before the Royal Society a paper entitled *Persistence of Vision with Regard to Moving Objects*. Several scientifically minded persons were interested, including Sir John Herschel, and among them was evolved a device consisting of a bit of cardboard bearing a picture of a bird on one side and a cage on the other, so mounted on a string that when the card was twirled the bird appeared in the cage.

Michael Faraday followed Rôget's observations with a long series of experiments. On the Continent Dr. Joseph Antoine Ferdinand Plateau, at the University of Ghent, and Dr. Simon Ritter von Stampfer, in Vienna, engaged in experiments on the persistence of vision. Simultaneously they arrived at an identical device for viewing hand-drawn pictures representing successive phases of motion. The pictures were mounted in sequence on the rim of a disc and were observed through corresponding slits in a parallel disc revolving on the same axis. This was the first motion-picture machine. Baron Franz von Uchatius, an Austrian artillery officer, in 1853 combined the disc device with the magic lantern and projected the pictures on a screen. William George Horner, of Bristol, England, built a toy on the principle of Plateau's machine, mounting pictures on the inside of a cylinder in such a manner that they could be inspected through slits in the opposite side of the revolving cylinder. In 1860 one Desvignes improved upon it and patented a similar device.

The Kinematoscope.—In 1860 Coleman Sellers, of Philadelphia, a mechanical engineer, attempted to apply photography to the creation of motion-picture effects. He photographed poses of motion and presented the resulting pictures on the blades of a paddle-wheel device, viewed directly by the eye. This machine was patented in the United States as the Kinematoscope Feb. 5 1861. Louis Arthur Ducos du Hauron, in France, April 25 1864, filed a patent application which was in effect an almost

complete anticipation of the motion picture. Ducos' ideas were all on paper; he did not achieve material results.

The Phasmatrope.—Henry Renno Heyl, of Philadelphia, on Feb. 5 1870 presented projected photographic pictures, made by the Sellers method of posing the figures for the camera, which still required time exposures. Heyl's machine was called the Phasmatrope. It carried small prints of the successive pictures, transparencies made on glass plates, mounted on the rim of a wheel which presented them, with an intermittent motion, to a beam of light cast by a magic lantern. Heyl used 6 poses, repeated 3 times, giving 18 images, or the equivalent of slightly more than one foot of modern film pictures. Photographic projection had come, but the camera could not yet record rapid motion.

Rapid Motion Photographs.—In 1872 Leland Stanford, a railway magnate of California, determined to investigate the gaits of the horse. He engaged Eadweard Muybridge to endeavour to make photographs recording the postures of the horse in motion. Muybridge's first efforts, made at Sacramento, were unsuccessful, due to the inadequacy of the camera and the photographic materials then available. His labours were interrupted for the time by a domestic tragedy. Meanwhile Stanford, impatient with the unsatisfactory results, had assigned the photographic problem to John D. Isaacs, a young engineer employed on the technical staff of the Central Pacific Railway. Isaacs contrived a system using a battery of cameras with shutter controls actuated by a series of electrical circuits. The shutter mechanisms were improved and the speed of the photographic emulsions increased. His device permitted the making of the first real photographic records of objects in rapid motion. Exposures as brief as one two-thousandths of a second were made. When Muybridge resumed activity he used the Isaacs' equipment installed at Palo Alto. Subsequent writings and tradition have erroneously credited the method and machinery to Muybridge.

Stanford while visiting Paris met Jean Louis Meissonier, the painter, then engaged in a controversy with French academicians over the postures of horses in his pictures. Meissonier found vindication in Stanford's photographs from Palo Alto and prevailed upon the latter to send Muybridge to France. Meissonier confronted his critics with these pictures. He also synthesised the appearance of motion by projecting transparencies made from these pictures on a machine similar to the Heyl Phasmatrope. Muybridge renamed the machine the Zoopraxinographoscope and hastened to Great Britain to deliver lectures. The name suggests a relation to the similar contemporary machine invented by Émile Reynaud, a French physicist, under the name of the Praxinoscope. Reynaud used hand-made pictures.

An era of motion-picture photography on glass plates followed, with slight refinement of methods but no important increase in scope. All motion-picture records, made with series of cameras, when projected, gave the illusion of the moving object standing still with the adjacent scenery sweeping past. Wallace Goold Levison, of Brooklyn, N.Y., devised a camera which obviated this difficulty by presenting successive plates in one camera, making all the pictures from a single point of view.

Edison Kinetoscope.—In 1887 Thomas A. Edison, of New Jersey, having perfected the phonograph, wished to supplement it with an accessory device which should present an optical record together with the sound. The first efforts recorded pictures of microscopic size in spirals upon a cylinder, after the manner of the phonograph record. Later strips of film were constructed of collodion, and experiments were made with strips of heavy celluloid. In Aug. 1889 samples of the first Eastman Kodak film made on a nitro-cellulose base were obtained by Edison. This material resulted in the completion of the motion-picture machine. On Oct. 6 1889 demonstrations of the Edison Kinetoscope were made in the laboratory at West Orange. It was the peep-show device for viewing the motion pictures recorded by the Edison camera, named the kinetograph. The film strips were about 50 ft. in length and an inch in width. Each photographic image occupied one-sixteenth of a foot of this film. Forty-eight exposures were made to record each second of action. In the kinetoscope the pictures were viewed by transmitted light through a magnifying lens in the peep-hole of the machine Only one person at a time could view the picture.

The Edison machine was commercially presented to the public for the first time in New York, April 14 1894. Hundreds of these machines were sold in the open market, and they carried the motion picture to the principal capitals of the world. The first motion pictures made at the Edison plant were records of portions of prize-fights, fencing matches, dances and vaudeville skits. The camera was immobile and limited in its range. The pictures could record only about 15 sec. of action.

A demand then arose for a machine which would project the film pictures on a screen, making them available to a large audience. Edison demurred for commercial reasons, believing that screen showings would exhaust the novelty market too rapidly. Meanwhile experimenters in other parts of the world were engaged in the problem of combining the kinetoscope with the magic lantern to produce screen pictures. Edison held dormant the projection efforts of his own laboratories. He failed to patent his motion-picture devices in foreign countries.

The Cinématographe.—Feb. 22 1895, Woodville Latham, father of Otway and Gray Latham, kinetoscope exhibitors, demonstrated a projector using a kinetoscopic film in New York City. The device was highly imperfect and was given prematurely to the public, May 20 1895. A better projector known as the *Cinématographe* was produced by Louis and Auguste Lumière, photographic manufacturers, of Lyons, France, who were inspired by an Edison kinetoscope exhibition in Paris. They took out a French patent Feb. 13 1895, and demonstrated their machine March 22 1895 in Lyons.

The Modern Projector.—In June 1895 Thomas Armat of Washington, with whom C. Francis Jenkins was for a time associated as an experimenter, arrived at the principle of the modern projector, a device in which the film, moving intermittently, has periods of rest and illumination in large excess of the period of movement from image to image. This machine was shown to the public first in Sept. 1895 at the Cotton States Exposition at Atlanta, Georgia. In London, Robert W. Paul, maker of scientific instruments, was called upon to make duplicates of imported Edison kinetoscopes, and in sequel made a camera early in 1895 to supply the machines with film. In Feb. 1896 he demonstrated a projection machine. Several other projectors of slightly later date and less influence on the development of the art were evolved, resulting in an endless conflict of claims of priority. The new projection machines introduced the screen motion picture largely through the vaudeville theatres beginning in London and New York, and by lecture and demonstration tours in which the Lumières were especially active. The motion picture was still only a novelty.

In the autumn of 1897 the young industry in America was thrown into a complex and violent war of litigations over patents, which continued for a decade. In Europe the art long suffered disfavour as a result of the Charity Bazaar fire in Paris, May 4 1897, in which 180 French notables died. The fire was traced to the motion-picture machine.

Improvement of Films.—Films gradually attained greater length than the 50 ft. of the peep-show subjects. March 17 1897, Enoch J. Rector exposed 11,000 ft. of film photographing the Corbett-Fitzsimmons fight at Carson City, Nevada. In the autumn of that year Rich G. Hollaman, of Eden Musee in New York, staged a version of the "Passion Play" on a roof and pictured it in about 3,000 feet. Important elements of camera technique were evolved in the pictures of feats of magic made by George Melies of the Theatre Robert Houdin in Paris, involving expedients of double exposure, fade-outs, dissolves and other now familiar optical effects used in photoplay construction.

In 1903 Edwin S. Porter of the Edison studios in New York produced "The Great Train Robbery," about 800 ft. in length, which, with some latitude of interpretation, may be considered the parent photodrama. In this picture the screen achieved narration. It produced a sensation in the yet small world of the motion picture. Many similar screen narratives followed, known

to the trade as "story pictures" to differentiate them from the mere record and novelty pictures of the earlier period.

The Nickelodeons.—"Story pictures" resulted quickly in the rise of the motion-picture theatre. Sporadic efforts at the operation of theatres devoted solely to the screen had appeared for several years. In Nov. 1905 Harry Davis of Pittsburgh, real-estate operator and proprietor of a stage theatre, opened a five-cent show in that city with "The Great Train Robbery" as the first programme. It was tremendously profitable and a wave of five-cent theatres, commonly called "nickelodeons," swept over the United States, with the foci of development in the polyglottic foreign labour centres of the manufacturing zones, where the universal language and art of the screen found its most eager and abundant market.

Increased demand from the screen theatres forced the picture-makers to the erection of large studios and the organisation of stock companies of actors to enable an increased output and steady flow of film. Commercial expediency resulted in a truce in the patent wars and the ultimate formation of the Motion Picture Patents Co. in New York, Dec. 18 1908. It was in effect a cross-licensing system, and included all American producers.

The standard motion picture of the period was a sensational action story of one reel in length. Pictures were rented to theatres on a quantity and age basis, a normal programme being about 28 reels a week supplying a daily change of programme of four reels.

Censorship.—The motion picture early began to encounter censorship restrictions. In 1895 the police of Atlantic City, New Jersey, forbade the exhibition of a film showing a dance, brought to the United States from Cairo. Occasional local agitations occurred in later years. In 1907 national attention was attracted to the matter, and in Nov. of that year Chicago put motion pictures under police censorship control. In New York in the same period the Children's Society prosecuted exhibitors for showing pictures of "The Great Thaw Trial" to audiences of young children. In Dec. 1908 New York's motion-picture theatres were ordered to be closed pending an inquiry by the mayor, with subsequent injunction litigation. The result of this controversy was a licensing system and the establishment of the National Board of Censorship by Charles Sprague Smith and others of the People's Institute, a disinterested civic organisation. This censorship body continues, in unofficial status, as the National Board of Review of Motion Pictures, to which the picture-makers voluntarily submit their films. Beginning in 1911 with Pennsylvania, a number of American states, including Kansas, Ohio, Maryland and New York, passed motion-picture censorship laws. As a sequel to the defeat of James Jeffries for the heavyweight championship of the world by John Arthur Johnson, a negro, at Reno, Nev., July 4 1910, the Sims Bill forbidding interstate traffic in prize-fight films was enacted by Congress in 1912.

Sweden established a national censorship in 1911, Spain in 1912, Italy in 1913–4 and France in 1916. Russia and Japan exercise film censorships. Canada has various provincial censorships. In Great Britain the Cinematograph Exhibitors' Assn. established a censorship, with the approval of the Home Secretary, following the Cinematograph Act of 1909 which put screen theatres under licence, and in 1920 made submission of pictures to the Board of Censors compulsory for members.

The direct influence of censorships upon motion pictures has been on the whole slight as compared with the extent of the agitation. As internal standards of the art have improved, censorship movements have tended to lose vigour.

Development of Stage-craft.—In 1908 D. W. Griffith, an actor from the stage, entered the service of the American Biograph Co. in New York, as a writer of scenarios, and in the ensuing four years had an important influence in the development of the art of screen narration. He wove the facilities of the camera and its effects of manipulation, such as close-ups, dissolves, fadeouts and the like, into the syntax of screen story-telling. In 1909 Gladys Smith, a child actress from the melodrama stage, now known as Mary Pickford, was employed by Griffith.

By 1911 a tendency to increase the scope of the picture beyond its orthodox one-reel length of 1,000 ft. began to appear, notably through the importation of some pretentious European efforts, among them Homer's "Odyssey" and "The Fall of Troy." A kindred American effort was made with a like saga in "The Life of Buffalo Bill," pictured in three reels. In 1912 Adolph Zukor, a New York motion-picture exhibitor, in alliance with Edwin S. Porter, Daniel Frohman and others, imported "Queen Elizabeth," a four-reel picture with Sarah Bernhardt in the title rôle. This picture, made by Louis Mercanton of Paris, was the forerunner of a new era of longer and more pretentious multiple reel dramas, known in the trade as "features," to differentiate them from the one-reel programme pictures of the nickelodeons. George Kleine, a member of the Patents Co. group, in this period imported and exploited with sensational success an Italian production of "Quo Vadis." In the next few years the "feature" movement remade the screen industry and increased the screen audience. The motion picture now became a real competitor of the drama of the stage.

Picture Theatres.—The first large and pretentious screen theatres arose in California and Australia because there the film art, shipped in a can, could overcome the obstacles of geographical remoteness. In 1914 with the opening of the Strand Theatre, on Broadway in New York, a new order of film presentation and showmanship appeared. Late in 1913 Charles Spencer Chaplin, a British actor and pantomimist, was employed in California for Keystone comedies under the direction of Michael Sinnott, better known as Mack Sennett, founder of the slapstick school of screen comedy. Chaplin's extraordinary ability made him world-famous within a few months. In 1916 he was employed by John R. Freuler of the Mutual Film Corp. at $670,000 a year. Chaplin with other major stars, including Miss Pickford and Douglas Fairbanks, outgrew pay-rolls and presently became independent producers. D. W. Griffith in 1915 presented "The Birth of a Nation," a tale of the American South of Reconstruction days, based on *The Clansman*, a novel by the Rev. Thomas Dixon, and again a new standard of screen narration and spectacle presentation was set.

American Dominance.—The cessation of production activities in Great Britain and on the continent of Europe resulting from the outbreak of the World War left the screen art and industry almost entirely to America, where it developed intensively with an increasingly War-prosperous public. The post-Armistice period found the American film industry with a 90% domination of the world market, with the corporation interests of the industry extending themselves in terms of theatre control in the more important foreign fields, including France, Germany, England and the Far East.

The prestige value acquired by pictures shown in the metropolitan theatres of the Strand type early led the picture-makers to the acquisition of theatres for "Broadway first runs," extending presently into key cities in all parts of the United States. Competitive results led in turn to the acquisition of chains of theatres, pooling booking power and taking box-office profits direct. This development found its most marked expression in the formation of Public Theatres, Inc., in New York, a federation of the theatre interests of Balaban & Katz of Chicago and those of the Famous Players-Lasky Corporation, headed by Adolph Zukor, which is credited with control of approximately 800 theatres in the United States. The motion-picture industry, like other industries, as a whole tends toward vertical trust formations, beginning with the plays and novels and ending with the screen and theatre box office. A group of three major corporations dominates the world industry.

Organisation of Trade Interests.—The early era of violent competition found those engaged in the industry slow to recognise a common interest. The first efforts in this direction were expressed in the formation of the Motion Picture Board of Trade in New York in 1915, followed two years later by the National Assn. of the Motion Picture Industry; this soon lost power within the industry and status with the public. Growing abuses of the trade, involving credits and contracts, salacious productions, destructive competitive selling and the like, together with

a series of disastrous scandals involving allegations of grave misconduct on the part of important screen figures and executives, led at last to the formation (March 5 1922) of the Motion Picture Producers and Distributors of America, Inc., headed by Will H. Hays, who resigned as Postmaster-General of the United States to take the post. The Hays organisation is in effect a trade association with broad powers which affect merchandising practice, selection of photoplay subjects, international trade policies and public relations in general, with special attention to problems of taxation and censorship. Its activities have exerted a marked effect in improving the status of the motion picture in the public mind and the clarification of internal problems. A minority organisation, opposed to the Hays organisation, was formed under the name of the Independent Motion Picture Assn. of America with I. E. Chadwick as president.

Economic Effects.—A new international phase of the motion picture began to be apparent in 1925 with the discovery that American control of the screen with its presentation of the fashions and equipments of American life was exerting an important influence on world trade in fields as varied as the adoption of American shoes in France and American motor-cars in Java. Various national agitations followed, marked by parliamentary debates and proposals for embargoes, tariffs and ratio laws governing importation of the American screen product, all calculated to encourage indigenous screen industries. Great Britain, Germany, France and Italy, were the countries most concerned.

To meet this condition American producing interests showed a tendency to internationalise their productions both by the importation of foreign stars and directors and by the making of pictures for the world with American stars working on foreign locations. It was planned in this way to evade the quota and ratio restrictions in other countries, while still retaining the American market. With this development a readjustment of picture values began. From the beginning of the World War, for a period of nearly 10 years it was the accepted basis of film calculations that the United States market represented 80% of the value of a picture. With the economic readjustments of Europe a new world-market for the screen developed with the prospect that the foreign rights of a picture might ultimately equal the domestic American value.

Trade Figures.—In 1925 it was estimated that there were in the whole world 50,000 screen theatres, of which 20,000 were in the United States. Statistics prepared under the auspices of the Hays organisation gave, 1924:—

Total number of persons permanently employed	300,000
Average number of feature pictures produced yearly	700
Admissions paid annually at theatres	$500,000,000
Salaries and wages at studios, annually	75,000,000
Annual advertising expenditure in newspapers and magazines	5,000,000
Expenditure for posters, photos and like accessories of advertising	7,000,000

Few foreign productions have proved successful in the American market. In 1922 a total of 425 foreign features were offered the American trade, but only six were accepted. The American success of a European film has always been followed immediately by American acquisition of the star and director concerned, as in the adoption of Pola Negri as an American star following her success in the German-made film "Du Barry," retitled "Passion" in the United States.

A steady increase in the working life of motion pictures has characterised the evolution of the art, from the days of the nickelodeon theatres, with their programmes of single-reel pictures changed daily, to the feature period where in typical theatres in large centres week runs and more were given to a single picture. In the nickelodeon period films were sold according to their age, depreciating in value day by day for 30 days, after which they were classed as "commercial" and rented at as low as 50 cents a reel a day. Under present conditions theatre runs are often for months, and the working life of a picture may continue several years. "The Birth of a Nation" continues with an earning power more than 10 years after initial presentation.

Present Policy.—Production policy, long dominated by nickelodeon influences, tends away from programme or volume production toward the treatment of each picture as an individual enterprise, separately produced and individually exploited, first as a "road show" following metropolitan presentations in New York, London and Paris, after the pattern of stage-play practice, with subsequent "release" for general distribution to screen theatres, as in the instances of "The Covered Wagon" and "The Ten Commandments."

The motion picture which began in 1894 as peep-shows in films 50 ft. long costing $25 each has reached the length of a full evening's entertainment of perhaps 12,000 ft. of film, with costs ranging into the millions.

Technological Improvements.—Technological developments in the art of the motion picture have added little save refinement to the product since the years of invention. Edison produced so-called talking pictures as early as 1895 with a synchronised peep-show and phonograph. Various devices have appeared periodically since, but with no evidence of public interest. Stereoscopic motion pictures were produced in the first decade of the screen and several systems of producing the steroscopic result have been achieved, all entailing the use of a viewing device which limits the effect and appeal. Coloured motion-picture processes were begun in the Edison plant in 1896 with hand-coloured prints. Various artificial tinting processes have been evolved, the most successful being the Pathé stencil colour method used in France. Natural colour photographic researches for the motion picture were begun in England by Edward Turner, under the patronage of Charles Urban. Turner died in the midst of his labours and the work was carried on by Urban and G. Albert Smith, of Brighton, resulting in kinemacolor, presented in 1910. Kinemacolor pictures used a two-colour process of recording through filters and reproduced by projection through corresponding filters, the process resulting in a screen synthesis of the colours. More recent processes, notably Prizma, evolved by William Van Doren Kelley, and the Technicolor process which now dominates colour work for the screen, translate the camera's colour record into pigments and tones embodied directly in the film, making it available in any standard projection machine.

The use of panchromatised negative film, which is sensitive to a greater range of colour and tonal gradation than ordinary film stock, has markedly increased, thereby improving photographic quality on the screen. Also especially sensitised film reacting only to the infra-red rays of the spectrum became available in 1925, enabling various special manipulations, important among them the production of "night effects" by daylight.

The cost of making motion-picture positives for projection has decreased with lowered cost of raw film and the development of machine-finishing processes replacing costly hand labour until prints in 1926 cost approximately one-half the production price of the early years. An increased use of motion-picture films outside the amusement field for general commercial purposes and in the home tends to follow this development.

II. TECHNOLOGY

Motion-picture work is technically a branch of photography. The general principles which cover the production of photographic images therefore apply to it, and the article on PHOTOGRAPHY should be consulted. The manufacture of the film is dealt with under PHOTOGRAPHY.

The Film.—The film is supplied in rolls 35 mm. (1·38 in.) wide and 200–400 ft. long in the case of the negative films, which is used in cameras. The positive film, on which the prints are made, is frequently supplied in rolls 1,000 ft. in length in order to diminish the necessity for making joins. Negative film is generally sup-

plied in two speeds, known as *Par-speed* and *Super-speed*, while a variety, sensitised by means of dyes, is known as *panchromatic* film. On the edge of the film are perforations by means of which it is moved through the apparatus, and the exact dimensions of the film and of the perforations are very carefully standardised. Fig. 1 shows the standards adopted by the American Society of Motion Picture Engineers.

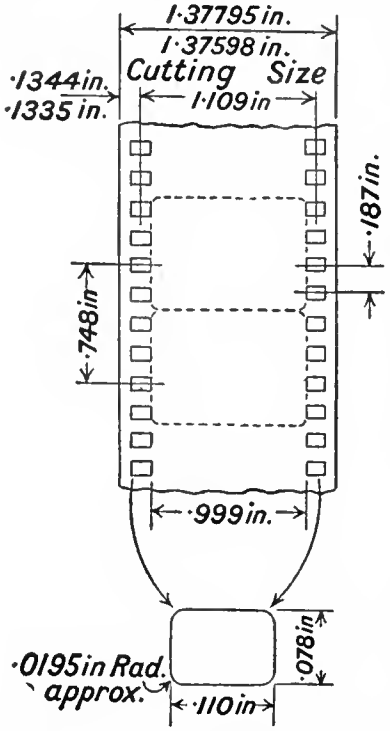

FIG. 1.—Standard dimensions of 35 mm. film. Specifications, with tolerances, allowed for cutting and perforating standard motion picture positive film.

The Camera.—The motion-picture camera (fig. 2) is arranged to move the film step by step through the *gate*, in which it is exposed to the light coming through the lens, the intermittent movement being accomplished usually by means of a claw, which is operated by a cam. The commonest form uses a triangular cam known as the *Lumière* cam because of its introduction by A. and L. Lumière of Lyons, France. By means of a sprocket, the film is fed continuously from the magazine in which it is held to the claw, and after passage through the gate is wound on to another magazine by the same or a second sprocket. Between the lens and the gate there is fitted a rotating shutter which protects the film from the light while it is being pulled down by the claw and then exposes it while it is stationary.

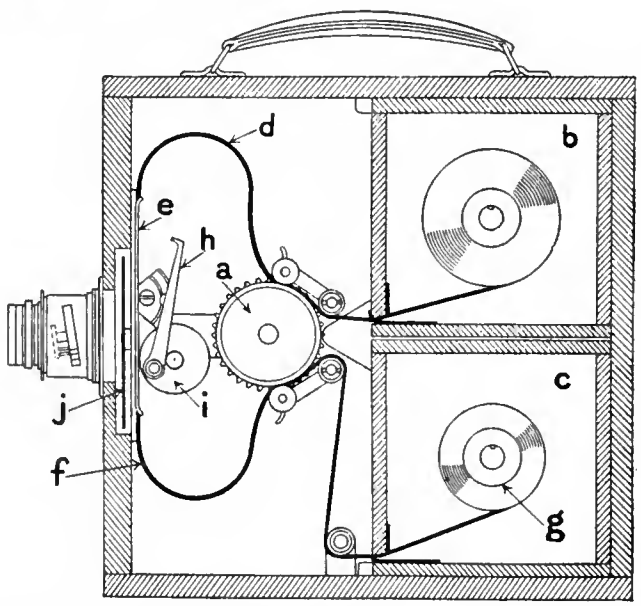

FIG. 2.—Diagram of motion picture camera, and Lumière cam. *a.* sprocket; *b.* upper film magazine. *c.* take-up magazine; *d.* unwind loop; *e.* film gate; *f.* lower loop; *g.* take-up (driven by belt); *h.* pull down claw; *i.* crank (operating pull down claw); *j.* shutter.

Lenses.—The lenses used on motion-picture cameras are of short focus and large aperture, the general focal length being 50 mm. (1·97 in.), with a relative aperture of f/3·5. Not infrequently apertures approximating f/2 are used. The operator can thus control his exposure by adjusting both the opening of the shutter and the aperture of the lens. By using these lenses the pictures are taken at a uniform speed of 16 pictures a second, so that if the shutter opening is 180°, the exposure of each frame is $\frac{1}{32}$ of a second.

Development.—After exposure the negative film is developed, each scene being usually treated separately so that the best possible results can be obtained. It is customary to cut a short length from the end of the scene, which is purposely made too long, and to develop this by trial. The film is then wound on a rack and developed for the time which has been found best.

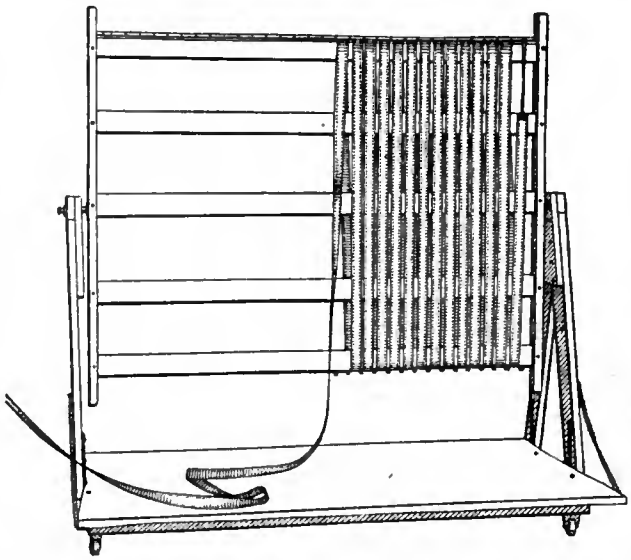

FIG. 3.—Developing racks. Wooden rack with the film being wound on it between the separator pins.

In this way exposures corresponding to different contrasts in the subject may be developed to give uniform negatives. The racks on which the film is developed are of the type shown in fig. 3. The development is carried out in deep tanks, the film being moved carefully in order to reduce possible marks to a minimum and prevent air bubbles remaining on the film. The fixing, washing and drying of the negatives are carried on with the greatest care, since they are extremely valuable owing to the cost of the production and must be preserved for many years. It is usual to use two cameras for each scene.

Printing.—Afterdevelopment a first print is made from the negative. These first prints, known as *rushes*, are viewed as soon as possible so that any scenes that have to be remedied can be retaken at once. The negatives are then assembled and a first print is made which is passed over to the producing company to be *cut* and assembled in a form corresponding to the finished picture.

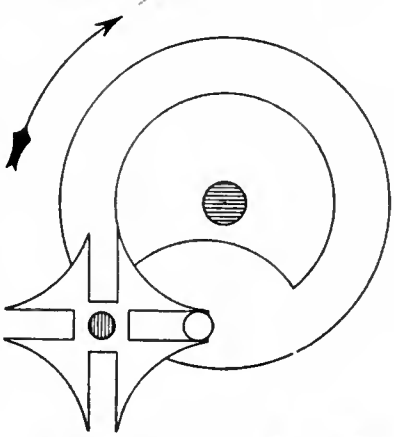

FIG. 4.—Enlargement showing the Maltese cross movement. The continuously moving wheel pulls the cross through 90°, when the pin on the wheel enters the slot on the cross. The cross is attached to a sprocket, over which the film passes, and as this sprocket moves intermittently it pulls the film down in the gate.

The printing of the negative is performed on a printer which may take one of two forms: in one, the two films are moved intermittently through a gate just as in the camera, the positive film being printed through the negative by means of a

light which is cut off by a shutter while the films are being moved. In the other form of printer, the negative and print are moved continuously past a narrow opening and are printed in contact while moving. In both forms it is necessary that the intensity of the printing light should be modified from scene to scene according to the density of the negative. To effect this, a chart is made showing the exposures which it is necessary to give to each scene, and the negative is notched so that as the notches come into place in the gate they will operate a contact mechanism which, acting through a solenoid system, will change the intensity of the printing lamp. Sometimes these changes are produced by the operator.

Automatic Development.—The positive film can be developed in the same way as the negative, being wound on racks for this purpose, but in modern practice it is more usual to develop it on an automatic machine, of which there are several types. In one the film passes through a number of tubes in which it travels from the top to the bottom and then up again, tubes being assigned in succession to the operations of developing, fixing, rinsing and washing, after which the film passes through a drying cabinet, from which it emerges ready for projection. In another form of continuous machine, tanks are used in place of the tubes, the film travelling in a spiral through the tanks. These continuous machines have a great capacity, it being quite usual for a machine to process as much as 20,000 ft. a day. Machines are generally erected in batteries.

After processing, the film is usually treated with wax or other lubricant to facilitate its passage through the projector. Much of the film used is made upon tinted base, the colour being applied to the base during its manufacture. This use of tinted base has supplanted the older method of dyeing the finished print, partly because it was difficult to apply the dye evenly and partly because many of the dyes used made the gelatine brittle. Not infrequently also the image is toned by different processes, so that by a combination of tinting and toning very pleasing results can be obtained upon the screen. A small proportion of film is coloured either by hand or by the use of stencilling machines, while a growing amount is produced by the processes of natural colour photography (*see* PHOTOGRAPHY).

Projection Machines.—The projection machines are essentially of the same type as the camera; that is, they evolve an intermittent movement of the film during which the light is cut off by a shutter, but this intermittent movement is usually accomplished by means of what is known as the Maltese cross or Geneva movement (fig. 4). This moves intermittently when the operating wheel carrying the pin which enters the cross is moved continuously, and the movement has the advantage over the claw and cam system that it is very robust and can be made to work immersed in oil. The shutter has three blades, only one of which is used to cut off the light during movement of the film, the other two interrupting the light while the film is still and thus diminishing the flicker seen on the screen.

Sources of Light.—The light sources used for projection are chiefly arc lamps. In modern theatres either high intensity arcs having carbons loaded with chemicals are used or mirror arcs in which the crater of the arc is turned away from the gate and the light from it is thrown forward by a large concave reflector. For projection at a short distance or with small screens good results are obtained by the use of high intensity incandescent lamps. The projectors are installed in a special projection-room fitted with ports through which the light beams are thrown and with arrangements for protection against fire. A great deal of work has been done on continuous projectors in which the film moves through the gate continuously and the image is kept stationary upon the screen by means of some optical system of rectification, such as a rotating ring of lenses which compensate for the movement of the film or a prism or mirror which holds the image still. These machines have not come into general use though some of them appear to be satisfactory mechanically.

After projection the film must be rewound and should be examined carefully and all damaged portions or weak places repaired. (C. E. K. M.)

III. THE MOTION PICTURE AS ART

From a toy, the motion picture developed into an industry in accordance with two major principles: the scientific, leading to perfection of the instrument; and the commercial, tending to the maximum of financial return in the shortest possible time. There was little energy to spare for the consideration of the third, the aesthetic, principle. The two preceding divisions of this survey have discussed those phases of the motion picture which created it and made it popular. It is the function of this third section to deal more with possibilities than with actualities; what the motion picture can become, artistically, being of far greater significance than what it is.

Natural Potentiality.—A logical critic, observing the machinery in complete ignorance of its history, would say that the name itself, especially in the common form of "moving pictures," told nearly the whole story; a camera taking pictures and a projector giving to those pictures the sense of action—movement governed by light. Assuming that the result was to be an art, this critic would hold essential the independence of the motion picture; just as music cannot always be "incidental music" or painting only illustration, the motion picture would have to develop a separate existence, drawing inspiration, perhaps, from the other arts, but fundamentally independent. It would share with painting its communication through the eye; with sculpture its power to create forms; with the dance the interest of movement. These three relations, it is understood, derive from the nature of the instrument rather than from any use to which the instrument may be put; they do not imply that the motion picture must be sculptural, pictorial or choreographic; only that it may be all of these without violence to its inner nature. They do imply as the essence of the picture that it must be all visual: the use of light and movement in the creation of visual images is the essence of the motion picture as an art form.

The Value of the "Absolute" Film.—Thirty years after the birth of the motion picture this essence is the goal of a few experimenters, chiefly in France and Germany. Theorists and experts are trying to create the absolute film, as far removed from the commercial film as a fugue of Bach is from "Il Trovatore" or a cubist painting from "The Doctor." The variation in rapidity as groups of inanimate objects or forms are shown in movement is calculated, in these experimental films, to produce a psychological effect; the relations between geometric figures, changing their proportions, fading into and displacing each other—abstract visual effects—intend the same. In the reel made by Fernand Léger and Dudley Murphy (1924) the most effective portion, emotionally, was that showing a woman carrying a burden up hill; at the final moment, as she reached the crest, the scene shifted back again to the bottom of the hill, and this was repeated again and again. There was no suggestion of narrative; the effect was purely kinematographic: but it was notable that the presence of a human figure more readily evoked emotion than any pure relation of forms. Yet there can be no doubt that the absolute film, abstract to the last degree, like music without melodic interest or like abstract painting, is a legitimate end for the motion picture. It is, in fact, the only goal so far suggested which proposes to utilise the instrument in all of its capacities and does violence to none; it is also the only one which makes proper use of the science, and is unaffected by the industry, of the motion picture.[1]

If between the absolute and the commercial, there should occur a third type, the art film, the absolute film will have the function of annulling the errors made necessary by commercial exploitation, the first error being a misconception of the nature of the instrument itself. The machinery of the motion picture was quite properly accepted as a supremely credible record of the

[1] The abstract film created by Comte Etienne de Beaumont and his collaborators lacked "human interest" entirely, but managed perfectly to convey emotions. Changing shapes, changing speeds, and objects seen out of their normal relations, gave both thrill and beauty to *A quoi rêvent les jeunes fille*. It is notable that these, the advance guard of films in one direction, are psychologically very close to the early melodrama; so more obviously is "Caligari." Speed is substituted for pursuit, and so on, the abstract for the specific, but the appeal to the eye is essentially the same.

actual; scenes, events, phenomena, were made visible and the screen became an aid to education, an invaluable record of history, and even an instrument of discovery in the natural sciences. It was put into the service of phenomenal truth, and functioned perfectly.

It was only when this service, in all its perfection, was employed in place of the imagination, in the domain of art, that it became a disservice. The motion picture always transposes its material, either mechanically, as a phonograph does, or imaginatively, as an artist does. The impressive fact that the camera could reproduce the actual, led to its use, almost from the start, as an instrument of photographic realism, against creativeness. This was natural in a civilisation devoted largely to mechanical progress and in a country negligent of the imaginative arts; but it neglected a prime value in the instrument itself, to wit, its capacity to transpose, to distort, to displace the object upon which its eye was trained. The motion picture was, in its very beginnings, used by magicians as a new trick, a new way to create "illusion." Almost at once, however, this use was abandoned; the real magic of the picture was suggested—and forgotten.

Persuasiveness, a Prime Quality.—The power of the picture lay in its exceptional persuasiveness. It gave its spectators the primary pleasure wrongly called recognition—the ordinary sense of identifying known things presented without disguise. The actual pleasure of recognition which implies that the artist has rendered, and the spectator penetrated to, an object is one of the qualities we associate with the arts; and these, lacking mechanical perfection, fail, if they ever try, exactly to reproduce the object. The motion-picture machinery comes close to this perfection in reproducing, and the response of the spectator was a natural consequence. "This is so" was followed by "this must be so" when the motion picture took its decisive step and, by false analogy, entered into rivalry and collaboration with the theatre.

The Place of "Story."—In the absolute film, "story" is anathema; in the commercial film it is everything; the art film can only ask that the story be appropriate to the instrument and be rendered entirely by the instrument. When, as early as 1908, the French Academy and the *Comédie française* collaborated for the screen, it was in the sense of filming an actual stage production; later the idea of famous players (stage actors) in famous plays became the basis of the organisation now pre-eminent in the manufacture of commercial films. Materials consecrated by public approval were taken over with almost complete disregard of their suitability to the new medium and the motion picture became an illustrated supplement to novels and plays. Acting, a form of expression adapted to the stage, using gesture in direct relation to the spoken word, was reproduced with slight modification, in the soundless medium of the film. An acted plot became the accepted definition of the moving picture—the fusion of two borrowed elements in a crucible which was itself, if one were aware of it, a magic cauldron.

These acted plots remain in 1926 the chief interest of most producers, although the close relation between stage and screen has been interrupted. The motion picture had so much vitality that in spite of the ignorance of its masters it asserted itself. The famous players (none of whom was a player specifically for the screen) failed and an obscure actress, without developing a real screen technique, yet more naturally adaptable to the screen by reason of her meagre experience of the stage, became a world's favourite: Mary Pickford. At the same time the melodrama, the thriller, the spectacle and the slapstick comedy all succeeded; in a small way the motion picture began to develop its own resources. It is this process which at present holds the greatest promise; and makes one regret that the lapse into association with the stage should so irremediably have left its mark on the motion picture in the form of scenario and acting.

Importance of Movement.—The melodrama and the thriller were important because, whatever their story, they expressed it all in movement, rather than in gesture, facial expression or subtitles. The scenarios were such as needed movement, utilising the screen's capacity to present simultaneous parallel activities, bringing them together in climax. The formula was lacking in adaptability, the material was intellectually contemptible; but the expression was completely kinematographic, not literary, not theatrical. This was true also in the spectacle films. The difference between the poetic beauties of "Cabiria" (on a scenario by Gabriele d'Annunzio) and the non-literary, kinematographic excellence of "The Birth of a Nation" (which was adapted with exceptional propriety from a bad novel) is marked. In the latter (1915) D. W. Griffith exploited the characteristic quality of the American spectacle film; its use of the melodramatic element of suspense in direct connection with the spectacle itself. The "last minute rescue" has always been well managed by American directors, generally by subdividing it into parts—the victims, the attacker, the rescuers—and alternating these in scenes of accelerating rhythm. This is "good movie" and distinguishes the American spectacle from the German, which often handles masses better, creates the sense of multitudes or expanse with none of the gross lavishness of second-rate American directors, but lacks excitement proportionate to its duration and scope. The spectacle had little to learn from the stage; from fiction (specifically from Dickens, if one accept the Griffith version) came alternating sequences, cutbacks and other devices for keeping several incidents simultaneously in development.

From the still camera came the close-up, an unhappy device not only because of its inherent ugliness, but because it definitely breaks the precious continuity of a picture, whereas the other devices, even the subtitle, only suspend continuity and allow interest to remain cumulative.

Economy and Effect.—It was in the thriller and the melodrama that the American moving picture learned also to unroll its plot succinctly. Padding is common enough; but no one comparing the average American and the average European film can fail to note that, when they want to, American directors are able to present their effects with superior conciseness and economy. There is also, in American films, an appreciable working up to climax and, their chief virtue, a neatness of execution, in which phrase may be included a multitude of technical devices, cleverness in general methods, discovery of settings which lend themselves to dramatic action, expertness in camera work, absolute clarity of the projected film, ingenuity, inventiveness. Even in their sum these qualities fall short of the meanest artistic stature; they are good qualities none the less. They were, or most of them, inherent in the silly Westerns and serials of the picture's earliest day.

The Right Road.—It is the writer's belief that the first halting steps of the motion picture were along the proper, the kinematographic, road from which it has since been diverted, to which it must return, enriched by experience, if it is to have a future. Another early type fortifies this belief: the slapstick. It is no accident that the one figure in the pictures to which some degree of immortality is universally accorded should have come from slapstick: Charlie Chaplin. These comedies, especially in their beginnings, were close to the type of the *commedia dell'arte;* they were almost all improvised before the camera. In them developed a type of playing which was purely kinematographic, and could be related to the stage only by way of American burlesque. Slapstick was remarkable also because it instantly saw the motion picture as a medium for fantasy, grotesque no doubt, but in essence fantastic. The properties of the physical world, all reality, were annihilated by the tricks of the camera for specific comic effect; retarded and accelerated motion, the repertory of the stopped camera, all suspended the mind of the spectator, as a pun might or a paradox, between the intellectual certainty that a thing is impossible and the visual certainty—it is here that the credibility of the camera becomes significant—that it has just happened. The thriller employed what was hazardous or difficult; slapstick brought to the film the impossible and the unreal. Fantasy appeared elsewhere as dream and as fairy-tale, with no impropriety but, except in rare instances (Crainquebille among them), without imagination. In slapstick, fantasy was built out of the elements of common life and flourished with extraordinary imaginative vigour. Whether the material was

worthy of this treatment has been debated; to some observers slapstick shows an honest vulgarity far more endearing than the pretentiousness, the intellectual fatuity, the errors of taste, the bad manners of its more serious counterparts in the films.

Dangers of Realism.—The use of indifferent materials in the usual American feature film was made doubly dangerous by the pedestrian realism of the direction. The motion picture seemed in 1920 to be destined forever to photography, to lack all bearing on created art. (It is worth noting that except for scientific purposes the motion picture cannot be exact; absolute fidelity in photographing "He walked six miles before breakfast" would result in unbearable tedium.) Fore-shortening, indirect suggestion, the creation of images capable of evoking the desired emotion—all the processes of the arts must find their counterparts in the films and will be governed, after the ruling direction of the mechanism, by the physiology of the eye, and by the psychology of attention; that is, if the picture is an art in the old sense. There are critics, wholly favourable to the motion picture, who consider that its real future is in developing outside of the sphere of the fine arts and in conscious hostility to their precepts. The break in 1920 came with the exportation of a German film, the famous "Cabinet of Doctor Caligari."

Without immediate effect on public or producers, this film is memorable because of its effect on the critics; it may be said that "Caligari" created motion-picture criticism in England and America. French critics hold it in low esteem because of its elaborate scenario; yet even they allow its chief virtues: that it worked chiefly through the camera (although the subtitles in the American presentation were lengthy and frequent) and broke entirely with realism on the screen. The change was marked by the use of cubist and expressionist settings in place of actual built or discovered "locations." The settings were psychologically correct for the story; the picture was perfect in the moments when its chief players, Conrad Veidt and Werner Kraus, so played before the distorted backgrounds as to give the whole picture a logical, complete, acceptable rhythm of its own, a life of its own, recognisable not as reality, but as a possible reality, an escape from or transposition of reality. "Caligari" was notable because it was artistically right in showing that the picture was most effective when it was not photographic; it was psychologically right because it brought the imagination of the spectator into play. It has been shown in Europe for six years (and finally made into play); it is in no sense a failure. That it failed in America may be ascribed, by critics hostile to the naturalistic film, to the stultification of popular taste in the preceding 10 years of the film's wanderings on the wrong road. "Caligari" means that the motion picture must be created, not photographed; painted backgrounds are incidental.

Five years later another German film, superficially less striking, claimed universal attention: "The Last Laugh" ("The Last Man" is another name for it). Films without subtitles had appeared before; the distinction of this one was that everything the picture had to say, and it said some subtle things, was said by means of the camera. What is more, the correlation of scenes was perfect, the separate sequences held together, and needed no connection or explanation. The American director, aware of American distaste for long series of pictures without subtitles, is prone to let his story hang loosely, trusting to its titles to draw it together. The slower-moving Scandinavian and German films are closely knitted in the sequences of the picture and can give psychological explanations which the faster American films skip or explain in words.

Importance of Imagination.—The artistic film will be characterised by imagination and will express itself visually, *i.e.*, through the camera. Ingenuity has already used the camera, notably in the excellent trick films presented for the trick alone; the news pictures have also learned kinematographic methods well. Creation has lagged behind, partly because there have been so many temporarily acceptable substitutes. The imaginative communication of emotions in "The Last Laugh" may prove a failure; but a few thousand dollars invested in a railway wreck is likely to make a picture a success. The director, at present the most interesting figure in the motion picture, has always known this. The future of the picture depends upon his capacity to free himself from tricks, from detailed scenarios, bad acting, "screen personalities" and other misfortunes. More, it depends upon his intelligence to see that the completed film must be a unit, not a series of separate scenes which a scenario-writer has invented and an editor-cutter will piece together for a title-writer to render reasonable as a plot. The motion picture conceived as a unit will have internal growth, development, rhythm; the relation between its parts and between the durations of its parts will have purpose; the bearing of the parts on the whole will be effective; the picture will have both style and form. At present few directors have manners so definite that their work can be identified without recourse to their tricks. Actual style, a personal way of expressing something experienced or observed, is almost entirely lacking, and that a picture as a whole should have form is a heresy still unheard in Hollywood.

Style and Form.—The future of the picture as an art depends, nevertheless, on the growth of elements of style and form, such as, with natural differences, distinguish the other arts: economy of means, sobriety, seriousness of purpose—all the other tests for an artistic creation are certain to vary with the individual artist, but the moving picture will not begin to be an art until it is conceived as the communication of a precise emotion or experience (communication by a group of artists or by a director through a group of interpreters of his vision). The expression of such a personal vision in a highly personal style distinguishes Chaplin as actor; a bluntness of perception, an imperfect sense of form, make him less than supreme as a director. But one looks vainly elsewhere for more than the beginnings of his qualities. Perhaps a half-dozen directors in America, twice as many in all Europe, seem at moments to approach the question of the motion picture as an art, but none offers a solution to it.

Except for striving for the film which shall have the illusion of depth, science seems satisfied with the motion picture. (The twin mistakes—the film synchronised with a talking-machine and the colour-film—may be perfected; but as each relieves the director of an obligation, instead of compelling him to fulfil one, they are not necessary developments of the film as art.) At the same time, the film as commerce may become stabilised; the pioneer days when companies were hastily organised to make the most of a nine days' wonder are over. With these two effective agencies reduced to secondary places, the moving picture as an art may flourish. So long as it remains a popular art, it will require novelty. Its greatest novelty, at the moment, must be an artistic one. (G. Se.)

MOTORING.—From 1910 onwards the development of all types of motor vehicles was wonderfully rapid. In 1911–2 the charabanc, the motor omnibus and the smaller passenger and goods van, used in town and country alike, began to make an impression on the travelling public of Great Britain, and though before the outbreak of the World War such traffic was of small dimensions compared with its present volume, the tramways and railways had already begun to feel the competition. The public at once showed its preference for the new method of locomotion, and students of transport admitted that free-wheeled vehicles, flexible in traffic, able to put passengers down on the pavement and not in the middle of the road, less noisy and more comfortable, more convenient and cheaper, would become formidable rivals to transport on rails. The railway companies were at first contemptuous of the new competition, but year by year not only were more and more passengers travelling by road, but much of the short distance goods traffic began to leave the railway. Between large centres of population not more than a few miles apart, such as the numerous large towns existing in the north of England, and between London and its immense suburbs, the public found it cheaper as well as quicker to go by road rather than by rail to their daily work.

In 1910–1 the dust nuisance became really acute throughout the United Kingdom. The main roads, which had been repaired for years with friable stone or dusty gravel, broke up under the increasing strain of traffic, resulting in muddy surfaces in winter

and much dust in summer. Roadside dwellers, who complained with reason, had a real grievance in that they had to keep their windows shut most of the day, while their food was liable to become gritty and their children were smothered in dust while playing by the roadside or in the cottage gardens. The Road Board, first established in 1910 in accordance with the Budget of 1909, devoted its first efforts to making roads dustless, and a year or two later much of the mileage of the main roads near or in towns and villages had been tarred or bituminised. Various local authorities all over Great Britain began to send in applications for grants for making roads dustless and for special purposes. By the Act of Parliament establishing the Road Board the money raised from motor-car taxation was to be allocated solely to improvements, and it was specially stipulated that no ordinary maintenance was to be considered. The Road Board's revenue for the first year was estimated at £750,000. Sixteen years later (1926–7) the revenue from motor vehicles was estimated at £21,600,000, and it is likely that even this huge sum will be exceeded every year for many years to come, though there are already nearly 2,000,000 motor vehicles on the roads, and 2,250,000 driving licences issued.

Improvements in Design.—In the motor-car trade, the years 1911 and 1912 were memorable for the beginning of the "American invasion." As the American cars were cheap in virtue of mass production and the elimination of every needless part, and were fitted with new and attractive devices in the shape of dashboard fittings, screens, self-starters, etc., they rightly scored a success in Great Britain and all over Europe. They taught British makers a much needed lesson, and stimulated the brains of British inventors, designers and constructors. In the earliest days of motoring covered cars did not exist, but a tendency towards closed instead of open bodies soon developed, and became more pronounced year by year. Nowadays (1926) the open car is the exception rather than the rule, and though in the smaller classes there are still many open cars, all are provided with efficient hoods, which have been much improved. Bodywork also has become much more comfortable, and in the more expensive types the luxurious interior of closed cars is a credit to the motor coachbuilder.

The development of cylinders from 1910 onwards is also interesting. Originally (1898–1900) De Dion built his engine with only one cylinder. Then two, and in a few cases three, cylinders came into use. Eventually the four-cylinder engine became the usual type, and by 1910 was practically the only kind to be built. With the Otto cycle (*i.e.*, one power stroke for every four movements of the piston) the four-cylinder engine gives an even torque. But Napier and Rolls-Royce preferred six cylinders, and for the more powerful types this system soon prevailed. Even eight cylinders have sometimes been used, but the six-cylinder engine has been found by experience to be the best type for everyday use. The four-cylinder car is still commonest, however, on account of its cheapness and its light weight.

The gradual development of British automobilism from 1910 up to the beginning of 1914 was much helped by successive shows at Olympia and in many of the provincial towns, which became every year more popular. Racing, too, has played its part in developing speed and reliability. Year after year new speed "records" were set up, and with each year came the destroying of the previous year's recorded speeds. The chief long distance race was for the Gordon Bennett Cup, held on the European continent (except in 1903 when it was run in Ireland), but a road race has never been run in Great Britain owing to the tortuousness of the roads, the congested state of the traffic and the strong public sentiment against speed contests on highways. Brooklands, the first great motor racecourse in the world, was constructed in 1907, entirely through the public spirit and enterprise of Mr. Locke-King. Here regular meetings on the lines of horse-race meetings were organised, provision was made for scientifically accurate timing, and Brooklands began to be one of the most useful institutions in the development of the motor-car.

The motor-car with its internal combustion engine has been the pioneer of many inventions. The aeroplane, of course, is by far the most notable of these, but among land-travelling vehicles the first place belongs to the "caterpillar" type of machine, which includes many varieties adapted to widely different purposes, from the little Citroens which have crossed the sands of the Sahara desert to the gigantic tanks that came into being during the World War. The "caterpillar" system, where the vehicle runs on an articulated endless steel band attached to the vehicle itself, is likely to be of great use in undeveloped countries where there are no roads, and where soft ground, dense grass or reeds or sand make ordinary wheeled traffic impossible.

The motor-car engine continues to improve. The super-charger has been evolved, which increases the pressure of any given engine by supplementing the vacuum created by the descending piston by actual pressure, thereby enabling a greater amount of the explosive mixture to enter the cylinder before the explosion and power stroke takes place. In regard to the number of revolutions, at the Paris show of 1902 an engine was exhibited which attained the then unprecedented rate of nearly 2,000 per min. —an impossibility, according to a high scientific authority, who asserted that no engine could ever run at more than about 1,500 revolutions, as the big ends and crank pins would fly apart owing to the great centrifugal force developed, with the result that the engine would be wrecked! Nevertheless, since then in the Grand Prix races engines have been used and have functioned well which attained 6,000 to 7,000 revolutions per minute! Engines of small cubic capacity have been designed which produce great and unexpected power in proportion to their size. Progress in the science of metallurgy has also contributed to the efficiency of modern engines and gears. Steels of wonderful hardness and strength have been produced to comply with the needs of the modern explosive engine, and further developments are taking place. Before long also we shall no doubt have an infinitely variable gear, superior springing and other improvements. There is food for thought in the fact that, while railways have just celebrated their centenary, the motor-car has had at the most 27 years of active life—about a quarter of that time. When our descendants celebrate the centenary of the motor-car it is probable that the vehicles of to-day which we think so wonderful will have been improved beyond our knowledge or imagination.

Goods Transport.—The development of the motor-lorry has also been considerable, and it may be said without fear of contradiction that the British lorry is recognised as the most efficient and convenient, in addition to having a better appearance than the heavy vehicles produced in any other country. An increased road transport trade has grown up between big centres of industry, especially where manufactures are carried on within a short distance of a seaport, such as in Lancashire, where raw cotton from the ship's side is taken up to the mills by lorry, and finished manufactured goods are taken back as a return load. There has also been a considerable development in the lighter loads, most trading concerns using small lorries and vans for the collection and distribution of their goods. In the country districts the old carrier's horsed cart has been replaced by the carrier's motor-car, running the same journeys in far less time, with greater comfort to the passengers than formerly. There is also in many countries a network of village-to-village and town-to-town services. For agricultural purposes also, not only are motor ploughs being used to a greater extent, but mechanical vehicles are taking the place of the farmer's gig and even his wagon.

Another significant increase has been in the number of motor cycles, of which over 500,000 are running on the roads of Great Britain in 1926. The increase, however, has been somewhat checked by the coming of the small cheap car, which is used by all classes of the community.

United States.—As regards the position in other countries, there are now (1926) in the United States about 20,000,000 motor vehicles, or about one to every six of the population. In many of the large American towns the street cars have become almost deserted, and the workman proceeds to work in his own small cheap car. The growth, too, of roads in the United States has been very remarkable, and new highway construction is proceed-

ng apace, tens of thousands of miles being made every year. The Lincoln Highway now extends right across America from New York to San Francisco, via Pittsburgh, Chicago, Cheyenne and Salt Lake City. The Dixie Highway runs South from Sault Ste. Marie on the Canadian border to Miami, Fla., via Chicago. A number of other important main trunk roads were under construction in 1926 and rapidly approaching completion. In the neighbourhood of New York alone £60,000,000 was being spent in 1926 in abolishing level crossings, making bypass roads and in generally improving the exits from the city.

Europe and the East.—In France, though the number of motor-cars has increased since the War, there has not been the same comparative increase as in other countries, the total number being still under 500,000, as against 1,500,000 in Great Britain. In Germany, Austria, Italy, Hungary and the rest of Europe the general increase has been retarded by the comparative poverty of the population over large areas. In India the country roads are being improved for motoring. In China 4,000 m. of main roads have been made to accommodate the increase in motor traffic.

The Future.—The only serious bar to the future increase in motor vehicles in some of the older countries is that all governments are inclined increasingly to consider them as luxury vehicles, and therefore a fit subject for extra taxation. In reality, the day is long past when the ordinary motor vehicle can be considered to be an example of luxury. Ninety-nine per cent of motor vehicles are used for professional, trade, business and other purely utilitarian purposes. There is also the problem which has yet to be solved, namely, how to accommodate in towns the vehicles of those who are employed or occupied for a short or long time during the day. There is no room in the streets, as a rule, to enable this to be done with safety or convenience, and the garage accommodation is wholly inadequate. (*see* MOTOR VEHICLES: ROAD CONSTRUCTION: TANKS: TRAFFIC PROBLEMS.) (M. OF B.)

MOTOR TRANSPORT, MILITARY.—Transport by motor vehicles has profoundly modified the art of war. Their employment enables a commander, despite the unwieldiness of modern armies, to achieve surprise effects which give him victory. In the following account, illustrated by practical examples taken from the use of motor vehicles during the operations of the Allied Armies on the French front, there will be discussed the general principles underlying (1) transport of troops, (2) transport of *matériel* and (3) intensive traffic on roads.

I. TRANSPORT OF TROOPS

The Vehicle.—Troops have sometimes been carried in ordinary touring cars. During the battle of the Marne (Sept. 9 1914), at the moment when the French Army of Gen. Maunoury was massing outside Paris, there were grouped together all available taxicabs to take direct to the front the infantry of a division which, arriving by rail from the Vosges, was detraining in the stations of the northern suburbs of Paris. This method can only be employed in exceptional cases, because the car or taxicab has so small a carrying power, requiring one driver for every three or four combatants carried, while such vehicles for the most part differ in speed. On the other hand, such motor vehicles as are designed to convey a larger number of passengers in peace-time, *e.g.*, motor-omnibuses or *chars-à-bancs*, are eminently serviceable.

The ideal vehicle is the common motor-lorry (or truck, as Americans call it). It is necessary to adapt it, *i.e.*, to place in it movable benches, which can be very rapidly installed when it is necessary to carry men, and can be removed without difficulty when it is necessary to carry *matériel*. In accordance with the capacity of the body, which itself partly depends on its load capacity, the lorry can carry from 16 to 25 men with their arms and equipment.

During the World War not only were units of infantry transported but also artillery formations; likewise, in some exceptional cases, cavalry with their horses. When horses are to be carried the body of the lorry must be as large and the bottom as low as possible, to make the loading more easy, and the ceiling must be high enough to prevent the horses from being injured by striking their heads. The horses may be placed either lengthwise or crosswise. But they should be close to one another, to save them from bumping; and there should be no difficulty of access to where their heads are, in order that they may eat and drink on the road. These precautions taken, it has been found that horses travel as well by motor-lorry as in a railway wagon.

Organisation of Lorries.—Lorries move grouped in formations of varying importance, but two essential conditions must be observed: efficient control and effective maintenance. The basic unit, the smallest formation to be placed under the orders of an officer, should be formed of 15 to 30 vehicles. The officer who commands this unit is the veritable sheep-dog of his troop of lorries; he must himself have a touring car (which should be open and not too fast), so as to allow him to follow his lorries when they are on the move, and above all when they are formed into a large column. The officer ought not to lead himself, but he able to keep his attention free, and to jump quickly from his car and speak to his drivers. Next above the basic unit, the "section," is placed the "company" or the "group," normally comprising three or four sections. The commander of the group or company is no longer the sheep-dog of his lorries; he is the shepherd. It is he who guides them in their itineraries, places them in billets and allots them to their work.

The second point in an organisation is to ensure effective maintenance. Automobiles require constant care on a long journey, *e.g.*, 200 kilometres. Some will have breakdowns, some even fall out, too seriously damaged to go on. Minor casualties must be attended to, however, as soon as possible. That is the rôle of the workshops. If the workshop is to move with the group, it must be on lorries, and have a stock of tools and spare parts.

As soon as large transport movements have to be carried out, higher control above the group must be organised. The transport of the infantry of a division requires 12 groups. Placed in a column on the road, this would make a file 36 km. in length, a reasonable distance for each group being 3 kilometres. This mass would be formless and incapable of manoeuvring unless vivified by organisation. It is a common saying that the action of a commander ought to be limited to directing four immediate subordinates and no more. Experience of large demands on transport during the War shows, however, that six groups could be united under one control, if the commander in charge was supported by a fully qualified staff. Such was the composition of the grouping in the French Army; such or something very near it was the composition of the "Bus Park" of the British Army. The grouping of six groups had a capacity for 6,000 infantry; the automobile service of the French Army comprised 25 groupings in 1918.

Organisation of Troop Transports.—Let it be supposed that a grouping is ordered to carry out the transport of 6,000 infantry, to take them up in their billeting area, and to bring them to the field of battle some 100 km. from billets. To accomplish this mission efficiently the staff must first fix the embarkation-points, *i.e.*, the points at which the infantry will be loaded into lorries. In order that this operation may be quickly carried out there must be many loading-points functioning at the same time; to embark one battalion (1,000 men) into a group (80 lorries) requires from 20 to 30 minutes.

When the commander of an automobile grouping has prepared the organisation of his embarkation-points, he must come to an agreement with the infantry headquarters concerned as to the time and place of embarkation of each battalion. The work which devolves upon the command of the lorry grouping in the disembarkation of the troops is generally similar to the above; but there is an additional difficulty, caused by uncertainty as to the exact points of disembarkation, which often depend at the last moment on the military situation. Nevertheless, the procedure must he arranged as early as possible, in close touch with the higher staff which has to fix the disembarkation zone; and an understanding must be arrived at with headquarters as to the probable alternatives, between which a decision will be made later, when the lorries are quite near to the arrival zone. The itinerary between the two zones must be reconnoitred and

marked out. This is the duty of the officer assisting the commander of the grouping. The "route officer," with his own staff, marks the itinerary by posting up placards (and, for night work, hanging lanterns) bearing the distinguishing mark of the grouping and an arrow indicating the direction of the march and the route to take. Further, the commander of a grouping must organise the movement of his service lorries, supply lorries, work lorries, etc.

Transport of Complete Divisions.—An interesting example occurs when, together with the infantry of a division, it is necessary to transport all or part of their artillery with its horses. With horse-drawn artillery it may be a very serious matter for a general of a division not to be able to bring up to the battlefield, in support of his infantry, the artillery who are accustomed to manoeuvre with him. It is thus very desirable to be able to transport artillery with horses. The loading of guns and limbers on lorries does not present any special difficulty; it is sufficient to have fixed rules for putting the *matériel* in place, and these are the same as the loading-rules for the same *matériel* on railway wagons.

II. TRANSPORT OF MATÉRIEL

Lorries are not specialised for the transport of *matériel*. The same type is employed as for troops, and therefore, the organisation is similar. A lorry-group capable of moving a battalion of infantry can alternatively move 100 tons of *matériel*. Experience in the World War has shown that, during the periods of active operations, a division requires an average of 200 tons per day in foodstuffs and ammunition. This is equally true in the case of defensive areas, as at Verdun; in offensive actions of the type of the Somme battles in 1916; or those of July, Aug. and Sept. 1918, on the Marne. Two groups are therefore required for the supply of a division, subject to the distance from the railway being, at furthest, within a radius of 40 kilometres. Four groups are necessary if the division is 70 km. from a railway. An average of 3 hours must be reckoned for loading at the stations; with allowance for difficulties arising amid intensive operations, 7 or 8 hours are taken up on the journey and 2 hours in unloading. This gives about 13 hours for work, and leaves 11 hours per day for the maintenance of *matériel*, feeding and rest. If the traffic operations are to be continued for a number of days, any more than this cannot be demanded of the personnel or of the *matériel* without risking excessive wastage. On the day after a journey with loads the vehicles return empty, and on the day after that they recommence the journey loaded. As 200 tons a day are required for a division there must be a double set of two groups, with a total capacity of 400 tons.

Non-Specialisation of Matériel.—At a general mobilisation like that at the opening of the World War, the resources available for transport are necessarily limited not only by financial conditions, but by the number of vehicles in existence in the country capable of being requisitioned, and by the maximum production of the manufacturing firms. On the other hand, there is no limit to the requirements in lorries, because no general worthy of the name thinks he has a large enough stock of transport at those critical times when every addition means an increase in his power of manoeuvre. During the 20 days which intervened between May 27 and June 15 1918, the lorries of the French Army had to transport about 800,000 tons of foodstuffs and munitions, in order to ensure the supplies of those armies which were making headway against the German attack. And yet, during this same period, the French Headquarters Staff had transported by automobile the infantry of 63 divisions. It was necessary also to make numerous evacuations of public records, civil populations, hospitals and engineer parks. This wonderful effort was only possible because in the French Army the principle of non-specialisation was adopted. Every lorry was controlled by the motor transport service of the armies, and was utilised by it for any form of transport needed. No vehicle was specially or permanently attached to this or that higher or lower formation. When a higher formation, such as a division, had need of transport, the automobile service arranged the transport, but as soon as it was finished the lorries employed on this service returned and were available for other transport services. In short, the lorry capital never remained unproductive.

The Use and Duties of Depôts.—The reasons for avoiding the wastage of lorries apply likewise to avoid wastage of movements. The carrying-out of "detail" transport is the principal cause of low efficiency. In the battle of Verdun, March 1916, the supply of munitions was taken by rail to Bar-le-Duc and to Baudonvilliers. Trains of munitions arrived daily at these two stations to supply the artillery of the 10 divisions deployed around Verdun, some 60 km. from the stations. If, to supply each of these divisions, there had been allotted a motor formation, which could come to load up at the stations and go as far as the batteries, bringing munitions, the efficiency would have been mediocre and uncertain. An accident at a depôt, an interrupted road, an advance or a check at the front, would set back the whole time-table of the formation, and one would have seen them arriving in the station for loading their lorries in twos and threes in disorder, and at different hours. There can never be efficiency unless there is regularity of movements. It is never possible to have regularity unless the traffic of the back areas, which can be regular, is definitely separated from the traffic of the front areas, which is always uncertain. This separation can be effected by the creation of depôts depending on the lines-of-communication authorities, and supplied by them where the formations from the front areas come to refill exactly as they would refill from the railway if there were stations at these fronts.

III. INTENSIVE TRAFFIC ON THE ROADS

The Route Gardée.—For the organised employment of automobiles on the roads, like that of railway trains, the essential condition is to be master of the road. If all and sundry are permitted to put columns of troops or vehicles on a road, it is useless to attempt to carry out important movements. It is an absolute rule, based on experience, that it is not possible to launch a big transport movement involving several hundreds of lorries without being absolutely certain of the complete freedom of the road, during the whole time that the movement will last. Hence the organisation of the *routes gardées*, with their personnel of guards and their traffic orders.

A *route gardée* is not necessarily reserved exclusively for automobiles. But in every case there must be a responsible authority, having power to give orders and have them carried out. In the French Army, during the War, this authority was a motor regulating staff (C.R.A.). In the British Army, the control of traffic in France was part of the duties of the provost marshal (A.P.M.). The organisation of the route, on a railway model, is based on the block system. The route is divided into a series of districts, each of which is under the direction of a district chief, having assistants for supervision. The district chief is in constant touch by telephone with the neighbouring districts, and with the office of the C.R.A.; he knows all the movements which affect his district, and also keeps a record of all movements which occur there and all the incidents of the traffic. Thus at the office of the C.R.A. it is always known what the state of the traffic may be on every *route gardée*, and the necessary arrangements for launching an important movement can be made in given time. The route orders for the *routes gardées* are more or less drastic according to the breadth of the road, and whether or not there are relief routes.

The length and the importance of the districts on a *route gardée* depend, obviously, on special difficulties to be overcome, *e.g.*, the number of adjacent routes, the localities traversed, narrow passages, etc. Between Bar-le-Duc and Verdun there were six "districts" varying in length from 5 to 10 kilometres. It is quite unnecessary to control in this permanent fashion a route over which there is not continuous traffic. Whenever such a road is needed, for the time being, for an intensive transport, it is sufficient to occupy it immediately and transform it into a *route gardée*. This requirement leads to the C.R.A. (or any corresponding organisation) being given a territorial zone of operation. In each zone it is the immediate business of the C.R.A. concerned to guard any portion of the road over which the transport will

be moving. For this purpose the C.R.A. had at its disposal specially organised personnel, which may be fairly accurately designated "mobile districts," and which, being in the habit of operating in this way and supplied with the means of rapid installation, can, in two or three hours, make themselves masters of the traffic on whatever part of the road is entrusted to them.

Maximum Efficiency over a Road System.—When one is master of "circulation" throughout a given region, one is free to aim at maximum efficiency. Formerly, when the staff proposed to carry masses of troops to a theatre of operations it traced the greatest number of parallel and serviceable roads which led to the zone of action decided on, and there was thrown on each of these roads a column of all arms scientifically echeloned in depth. Thus it was that Napoleon moved from the Rhine to the Main in 1805; thus, also, Moltke moved from the Sarre to the Moselle in 1870. When this system is applied to present-day conditions the efficiency of the road system is low, because the increase of speed due to the automobile is not turned to account. All modern armies have tractor-drawn heavy and automobile light artillery, and possess the means of transporting the bulk of their infantry by motor lorry. There remain the horse columns, on which it is no longer necessary to impose the speed limitations of marching infantry. In consequence, in co-ordination with the movements made by railway, the movements by road ought to be organised in the form of special itineraries, on each of which move columns of elements that are homogeneous from the point of view of speed. Thus combination of movements can be worked out in which much time is saved, as compared with the old methods.

The existence of regulating commissions in charge of zones of movement and masters of the traffic, considerably eased the French problem. But the regulating commissions must have control not only of automobile traffic, but of all traffic; in their zones no movements must occur without their having received notice and taken the necessary measures to facilitate the execution of the movements in question. They must be able to arrest all false movements in good time. And they must be in close touch, so as to form a complete network, covering the whole area over which it may be necessary to move any column. It was by the functioning of an organisation of this nature that the French Army was able to make its concentrations of considerable numbers of troops at very short notice in March, May and July 1918.

Strategic Transport by Road.—As the automobile has brought on the road again the tourist who had deserted it since the middle of the 19th century, so transport by motor lorry has brought into use again strategic movements by road. And, for the production of surprise effect, by adding the roads to the railways, it has been possible to put to full use all available means of communication. The air alone has not been utilised; but in the future it may be utilised for the quick transport of combatants. In order that movements by roads should be serviceable, it is necessary for them to be rapid and powerful; this is attained by applying the same principles as in rail movements—that is to say, the temporary break-up of large units for transport.

Combined Use of Railway and Motors.—In the majority of cases use is made of railways and roads in combination. The end to be attained is always a rapid move of powerful forces; the staff should therefore make use simultaneously, and as efficiently as possible, of every means of transport which it possesses. One must never lose sight of the fact that the efficiency of the railway is much superior to that of the road; a train of 50 wagons is equivalent to 150 lorries. At a speed of 30 kilometres an hour, and with four departures an hour, one has four trains in a length of 30 kilometres, or the equivalent of 600 lorries. We have seen that 600 lorries form on the road a length of 20 to 25 kilometres. Railway and road have therefore very nearly the same output. But the lorries, going 15 kilometres an hour, are only half as quick. Further, at the end of 100 kilometres it is necessary for the lorries to stop in order to rest the drivers, for, save in exceptional cases, relief crews are out of the question. The weak point in transport by rail really lies in the necessity of having stations for embarking and for disembarking. Save in quite exceptional cases it is an absolute technical necessity to load and unload in stations, and, even so, only in those where there are sidings sufficient to take the military trains so as to leave free the main line during the times of embarking and disembarking. Without this precaution all the traffic will be blocked. Further, when it is a question of loading *matériel* it is necessary to place it on the platforms. While special platforms or docks are indispensable on the railway, it is always easy, on the road, to find or organise quickly loading-places for lorries.

Big movements by railway can be made only from a zone A to a zone B, if the two zones A and B are equally rich in loading-places. But—apart from those points which come into the initial concentration scheme, and on which, therefore, work can be done in peace—it is impossible to ensure, in the large movements which military operations may necessitate at any given moment, that the beginning and the end of rail transports shall take place in zones that are rich in loading-places. On the other hand, it is generally possible to find, within a radius of 50 to 100 kilometres in the zones A and B under consideration, one or more regions rich in loading-places. The normal combination consists therefore in utilising motor transport to prolong railway transport, and to carry the troops or *matériel* (1) from their stationary zone to the places of embarkation, and (2) from their places of disembarkation to the zone of operations. The relatively short movements (50 to 100 kilometres) it requires are those in which the efficiency of the lorry is at its greatest. And between the two zones of loading thus actually used, the efficiency of the railway will equally be a maximum.

Naturally, other combinations are also practicable; for example, that by which, on Nov. 20–21 1917, three French divisions were to be carried from Meaux and Château-Thierry to Péronne; the infantry, with their machine-guns and cooking-carts, being conveyed in motor lorries, and the artillery by train. The object of these movements, very quickly ordered on Nov. 19, was to reinforce the successful British attack in front of Cambrai with the first use of tanks in mass, and had overwhelming results. While the embarkation of the artillery was proceeding at railway stations in proximity to the divisional billets on the Marne, the C.R.A. of Meaux and Château-Thierry loaded up on 3,000 lorries the infantry, etc., of the three divisions.

There are many details which complicate considerably the task of the transport officials; such as the question of food supply for the troops during their transportation and at their disembarkation, and the question of moving troops simultaneously with the building-up of the munition dumps which they will require. One last remark should be made: transportation by automobile and by railway, which, we have seen, supplement one another happily in regard to distance, is equally satisfactory in regard to time. Large movements by railway require concentration of *matériel*, often difficult to achieve; and, in the case of moves decided on in a hurry, the possibility of motor transport on a large scale assumes very great importance, since it takes four or five days for the railway to show its full powers.

Conclusion.—The experience of the War shows the rôle which transport by motors is called upon to sustain becoming more and more important. The Allied Armies, together, placed on the French front about 20,000 motor vehicles in Oct. 1914; four years later the number exceeded 200,000. At the time of the Armistice, the inter-Allied transports reserve, the creation of which had just been decided on, was of a size to transport simultaneously 10 divisions of infantry complete, with all their means of fighting, machine-guns and artillery included. This was a fighting mass of more than 100,000 men, which the Higher Command was able to pick up at short notice and carry at the speed of 100 kilometres a day to any point where it was required.

As regards the transport of *matériel* at the end of the War, it had become possible—independently of the resources just mentioned—to keep supplied with food and munitions 40 divisions at a distance of 100 kilometres from the railways.

MOTOR VEHICLES (*see* 18.914).—The greatest industrial development of the first quarter of the 20th century was that of the motor road vehicle. Development of the self-propelled, petrol-engined vehicle began in Germany in the eighties with the work of Daimler and Benz, and was carried forward particularly energetically in France for more than a decade, from 1895 on.

I. HISTORY OF MOTOR VEHICLES

About 1910 the United States assumed the leadership in the production of this type of vehicle. Transport and other conditions naturally favoured the use of motor vehicles there. American manufacturers cut down their production costs materially below those in Europe, in spite of the higher wages paid by them, and thus sold their cars at very reasonable prices. By 1925 more than one half of all the families in the country had their own car and more than 83% of all the cars in the world were owned in the United States. Registration figures showed that on Jan. 1 1926, there was one vehicle to every 5·7 persons in the whole country, while in California, the state with the greatest "motor density," there was one to every 2·8 persons. Motor-vehicle manufacture had become the greatest manufacturing industry in the country, in point of value of output.

Economic Reasons.—While the World War accelerated production of motor-cars in the United States and retarded it in those European countries which were engaged in the conflict from the start, the chief reasons for the pre-eminence of the United States as a motor-using country are of an economic nature. America is a land of magnificent distances; in many sections towns and cities are far apart, and long trips must often be made over the public roads, for which purpose horse vehicles are quite unsatisfactory. Petrol (in the United States called gasolene), the fuel commonly used for motor vehicles, is a native product, comparatively cheap and plentiful. The *per capita* wealth is greater than in most countries and well distributed.

Not all conditions were favourable to the introduction of motor-cars, however. The industrial countries of Europe had magnificent systems of hard-surfaced roads, which were practically non-existent in the United States at the beginning of the motor era. This, though a handicap, did not prove a serious obstacle. In the early years of motor-car development the private passenger car was generally regarded as a means of pleasure, and in Europe this remained its chief function. But in the United States and Canada (where the proportion of motor-cars to population was not much less than in the United States) it became a great factor in business life. In New York City, for instance, a very large proportion of the street traffic in 1925 was by motor, and in the main thoroughfares horse vehicles were almost a rarity. Such agricultural states as Iowa and Nebraska had relatively more cars than the industrial states, and the farmers used their cars chiefly for business purposes. As the substitution of the motor-car for the horse came about gradually, it did not greatly impress the general public; nevertheless, it profoundly influenced modern life.

Bus and Jitney Services.—In the cities of the United States the once familiar horse cabs and hansoms had disappeared before the motor-propelled taxicab by 1925. Numerous bus services competed with the tram services, particularly in outlying districts, and even cut heavily into the local passenger business of the railways. About 1915, many owners of private cars began carrying passengers in competition with tram lines, their vehicles being known as jitney buses (jitney, a Russian coin about equal in value to five cents, then the common tram fare). These jitneys did much business, especially during the "rush" hours when people go to work and return home, as their passengers avoided the crowding of the street-cars and the annoyance of frequent stops. In some sections of the country conditions were made rather hard for the jitney owner by legislation, and the business shrank or ceased entirely; while in others, and particularly in Detroit, it was still thriving in 1926.

Freight Haulage.—Motor-trucking and the haulage of freight by motor vehicle began to assume importance in the United States only about 1910. This branch of the industry up to then had been more successful in Great Britain and Germany. From 1910, however, it consistently increased in the United States, where under war conditions the motor-lorry even entered into competition with the railways. An enormous amount of motor freight traffic grew up over certain routes between important industrial cities, as between Detroit, Mich., and Toledo, O., and between Akron and Cleveland, Ohio. One large tire manufacturing company in Akron, O., with cotton mills in Boston, Mass., over 600 m. away, established a fast freight service, between these two cities, of motor-trucks on pneumatic tires. Some of this development was evidently due to the abnormal conditions which made railway freight service inadequate during and immediately after the World War. Military operations gave a great impetus to motor-truck development. In addition to the urgent demand for trucks for military purposes there was also a strong demand for business purposes, owing to the intense industrial activity and to the breakdown of the railways under the war strain.

Advantages.—The substitution of the motor-car for the horse was beneficial in various ways. In the first place the car is much more speedy and more comfortable for transport. With a motor-car a physician, for instance, can extend his practice over a much wider territory; contractors can oversee more thoroughly a number of projects under way at the same time; stores and factories can deliver goods in the country, at distances of 30 m. or more, in their own vehicles, while horse delivery was limited to the city. Stables, always a nuisance and a breeding place of disease, have been practically eliminated from cities, and street-cleaning has been rendered much easier. Real estate remote from railways has in many instances considerably appreciated in value as a result of the advent of the motor-car, rendering it accessible to the city man.

In the foregoing the utilitarian aspect of the motor-car has been specially emphasised. While cars are still being built that can properly be classed as vehicles of sport and luxury, they form a small proportion of the whole production. In New York City an annual show was established for this class of car; it started as the Importers' Salon, but during the World War, when the importation of European cars was very difficult, it gradually changed its character and became a show of high-grade domestic as well as imported cars. At the salon in Nov. 1920, there were exhibited cars selling at upward of $20,000, whereas a serviceable five-passenger car could be bought for as low a price as $550. The luxury cars exhibited at these shows were characterised by high power and high speed, elegant body finish, fine upholstery and superior equipment.

European Conditions.—In 1910, Great Britain had the leadership among European countries as regards the number of cars in use, whereas France led in respect to volume of production. About one-half of the number of cars produced in France at that time were exported. In continental Europe the introduction of motor-cars was hampered by heavy taxation on the cars themselves and on the fuel. The use of motor-trucks, on the other hand, was encouraged by the so-called subsidy system, by which purchasers of trucks suitable for military purposes were offered by their governments a bonus on the purchase price and also on the upkeep cost, in consideration of their keeping the trucks always in fit condition and agreeing to turn them over to the Govt. in case of war. Great Britain, France and Germany had such subsidy systems before the war; Japan adopted the same policy later. As soon as war was declared the motor-car factories were set to work for the war departments, either making trucks or other vehicles for the transport corps or else manufacturing aero-engines or munitions. Soon all the petrol available was needed in war service, and the use of motor vehicles by private parties practically ceased.

In England some use was made during the War period of town gas for motor fuel; this was carried in a collapsible bag of rubberised fabric, on the roof of single-deck omnibuses, for instance. With this fuel it was possible to obtain about 85% as much power from an engine as with petrol, and a satisfactory mileage on one filling was secured. Under normal conditions the gas would have

been carried in steel bottles under high pressure, but owing to military requirements no steel could be spared for this purpose. The Central Powers suffered much more from fuel shortage than did the Allies, and extensive researches on substitute motor fuels were carried out in Germany. After their petrol supply ran low the Germans used benzol, petroleum mixtures, benzol-alcohol mixtures, alcohol, wood alcohol, tar oil, gas oil and shale oil, as well as fuel produced synthetically from water gas by catalytic hydrogenation under high pressure and at high temperature.

Registration in Great Britain.—According to an announcement by the Minister of Transport, Great Britain, on March 31 1920, had 185,700 private passenger vehicles and 71,400 public-service vehicles. The numbers of lorries and motor-cycles in service on that date are not available, but during the period Jan. 1—March 31 1921, licences were issued for 15,000 motor lorries and 278,500 motor cycles. How rapidly the use of the motor vehicle increased during the next four years may be judged from the following figures issued by the same authority as on May 31 1925: licences issued for private passenger cars, 532,900; for motor cycles, 518,457; for commercial goods vehicles, 216,966; for hackneys, 92,024; trade vehicles, 13,018, and official vehicles, 14,912.

Registration in the United States.—The figures given in Table I. are based on information furnished to *Automotive Industries* by the registration officials of the different states. Allowances

[1] Includes both passenger cars and lorries.

II. TECHNICAL DEVELOPMENTS

A most desirable feature in a motor car is flexibility, that is, the ability to pass from a low to a high speed by merely opening the throttle valve. This is secured by using an engine of great power in proportion to the combined weight of the car and load. American cars have been specially noted for their flexibility, due to the use of very large engines, notwithstanding the fact that the high fuel consumption per mile travelled tends to increase with the displacement of the engine. As motor fuel was much more expensive in Europe, European designers could not ignore the factor of fuel economy as American engineers could.

Engine Design.—In engine design the constant endeavour is to get greater output from an engine of given piston displacement. Horsepower output depends upon two factors, the mean effective pressure upon the piston head and the linear speed of the piston. It was not possible to increase greatly the mean effective pressure; in fact, changes in the character of the fuel used for motor cars, by which some very much less volatile fractions were included than in motor fuel of the earlier period, made it necessary to operate with lower compression, which resulted in a lower mean effective pressure. However, improvements in combustion chamber design and other changes more than balanced this loss. A great gain was made by increasing the speed of operation. In 1905 the average engine speed corresponding to maximum engine output was about 1,000 ft. per min.; in 1926 it was approximately 2,500 ft. per min. for passenger-car engines and over 4,000 ft. per min. for racing engines. The first step to increase engine speed was enlargement of valve ports and passages, enabling the engine to draw in a normal amount of charge at a higher speed. The valve timing was also changed, the exhaust valve being given a greater lead and the inlet valve a greater lag.

Next, the reciprocating parts (piston and connecting-rod) were lightened, so as to reduce the inertia forces on them and the bearing pressures resulting therefrom. This led eventually to the adoption of aluminium alloy pistons. Aluminium has a higher co-efficient of heat expansion than cast iron, so that the aluminium piston must be given a greater clearance in the cylinder, which tends to result in unpleasant piston slap when the

engine is cold, and also in "oil pumping," that is, transfer of lubricating oil from the crank chamber to the combustion chamber, with consequent smokiness of the exhaust. These difficulties were overcome in later designs by the use of the split-skirt or constant clearance type of piston, in which the skirt or lower part is separated from the upper part or ring belt all around and is saw-slotted longitudinally so that when the aluminium expands the saw-slot will become narrower and the clearance between piston and cylinder wall remain substantially the same. In a few instances magnesium alloy pistons and heat-treated duralumin connecting rods were used, magnesium having a specific gravity about two-thirds that of aluminium, and duralumin, an aluminium alloy responsive to heat treatment, having the strength of mild steel with only one-third its specific gravity. Special means were resorted to in attempts to build ultra high-speed engines, as for racing and similar purposes. These included the use of two inlet and two exhaust valves per cylinder, the use of two simultaneous ignition sparks in each cylinder, and the use of crankshafts in which each individual throw was counterbalanced.

Cylinder Development.—By increasing the number of cylinders above the one or two employed in the first machines, engines can be reduced in weight, and the objectionable vibration can be minimised. In 1926 the four-cylinder engine was the foremost type for use on vehicles of a strictly utilitarian character; the six-cylinder was the luxury type in Europe, while in the United States it was the preferred type for passenger cars of intermediate and higher grades. Most of the more expensive passenger cars in the United States then were fitted with eight-cylinder engines. The twelve-cylinder or twin-six engine enjoyed a spell of popularity during and immediately after the War but disappeared from the market as a motor-car power plant in 1923. In a petrol engine the torque impressed upon the crankshaft is always non-uniform, no matter how many cylinders there are, but the fluctuations decrease with an increase in the number of cylinders. In a four-cylinder engine there is, as with one or two cylinders, a reversal of the torque; that is, just before the end of each stroke the flywheel not only supplies all the power delivered by the engine, but also some of the power necessary for keeping the crankshaft and pistons in motion. Six cylinders are the smallest number delivering continuous torque at the crankshaft; but while continuous, the torque is still far from being uniform; with eight cylinders the torque fluctuations are reduced, and with twelve they are still smaller.

Arrangement of Cylinders.—Four and six-cylinder engines were always arranged vertically, with all cylinders in a row; eight-cylinder engines were originally built in V form, but in 1926 the majority of the makes had all eight cylinders in line. In an eight-cylinder V engine with the two cylinder blocks at an angle of 90°, and with a single plane crankshaft there is an unbalanced periodic inertia force in the horizontal plane, the period of which is equal to the time of one-half a crankshaft revolution. By placing the two cylinder blocks at an angle of 60° a uniformly rotating unbalanced inertia force of constant value is obtained, of a magnitude considerably less than the maximum value of the unbalanced force in the 90° V, and this led two makers, Lincoln and Wills, to use this arrangement of the cylinders, which, incidentally, suffers from the disadvantage that the explosions are not evenly spaced but come at 60° and 120° intervals. A method of completely balancing an eight-cylinder 90° V engine was discovered by Prof. Archibald Sharp and described in his book on *The Balancing of Engines*, issued in 1907. It was first practically adopted by the Cadillac Motor Co. in 1923. Instead of having all four throws of the crankshaft in a single plane, the throws are arranged in two planes making an angle of 90° with each other, and the crankshaft is provided with two heavy balance weights, as shown in fig. 1, which represents the Cadillac crankshaft. In deciding upon the form of the crankshaft of a multi-cylinder engine and the angle between cylinders in a V engine two objects are aimed at, namely, to ensure uniform spacing of explosions and inherent balance of reciprocating parts. Both objects can be attained in six and eight-cylinder engines; in a four-cylinder vertical engine there is an unbalanced reciprocating force in a vertical plane, causing vibration of the engine. This can be overcome only by the use of an anti-vibrator, invented by F. W. Lanchester, consisting of an unbalanced mass directly below the crankshaft and driven from the latter at twice its speed.

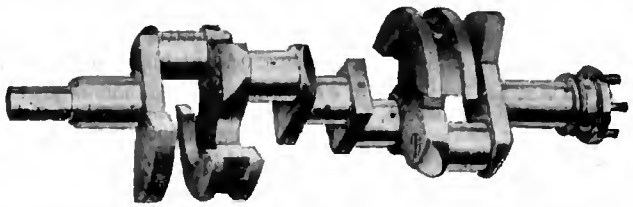

FIG. 1.—Balanced crankshaft for 90° V-type eight-cylinder engine (Cadillac).

When multi-cylinder engines were first used the cylinders were generally either cast separately or in pairs; later it became the practice to cast all cylinders in one row in one block. This greatly simplified the outward form of the engine, as with such a cylinder block only one pipe connection each need be made for the cooling-water inlet, the cooling-water outlet, the combustible charge from the carburetter and the exhaust. Some manufacturers even cast the top part of the crankcase integral with the cylinder block and made the lower part a steel pressing. This construction lent itself well to quantity production. Most makers of the higher-priced cars, produced in smaller numbers, cast all parts of the crankcase of aluminium. Cylinder heads were generally cast separate from the cylinder block and fitted to the block with a gasket of sheet copper and asbestos between. This construction facilitated manufacturing operations, and when the engine was in service permitted decarbonising the combustion chamber by scraping without removing the cylinder. It also made it possible to machine completely the combustion chambers, and thus to get all the chambers in one engine of exactly equal volume.

Combustion Problems.—As the speed of automobile engines increased it became necessary that the combustion of the fuel mixture charge be completed in a shorter period of time, in order that the maximum fraction of the heat energy might be converted into mechanical work. Racing engines in 1925 operated at speeds above 5,000 r.p.m., at which the time of one complete piston stroke is less than $\frac{1}{100}$ sec., and combustion should be completed before the end of the stroke. Prof. Bertram Hopkinson observed in 1912 that the rate of flame propagation through a combustible mixture can be increased by producing turbulence in the mixture (in the experiment, by means of a revolving fan in a closed vessel containing the mixture). In order to obtain a similar effect in the combustion chamber of an engine, Harry Ricardo has suggested the use of a "turbulence cylinder head," as illustrated in fig. 2. The compression space is in the form of a pocket in the cylinder head, mainly over the valves, which are located in a side pocket, but partly over the cylinder itself. At the end of the compression stroke the piston approaches very close to the flat portion of the cylinder head, and this produces a lateral rush of the combustible gases into the compression pocket, causing turbulence. Compression heads of this general form were widely used in 1926.

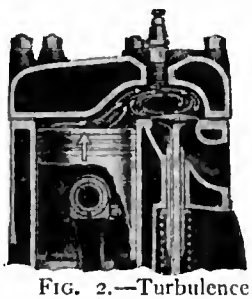

FIG. 2.—Turbulence type cylinder head.

The compression space should be as compact as possible, so that for a given volume its surface area and the distance from the spark points to the remotest portion of the charge are both a minimum, as this tends to promote rapid combustion, to prevent detonation (excessive explosion pressure and resulting phenomena) and to reduce the loss of heat energy to the cylinder jacket. Recognition of these relationships led to the gradual abandonment of the T head type of cylinder (with inlet and exhaust valves in pockets at opposite sides) and to the wider

adoption of the valve-in-head engine, which latter in 1926 was used on racing cars to the exclusion of all other types. Valves in the cylinder head can be operated either from a camshaft in the crankcase through tappet rods extending up the side of the cylinder and tappet levers on top, or from an overhead camshaft. The overhead camshaft design reduces the weight of the valve reciprocating parts, and with given valve spring pressure makes possible the use of higher engine speeds. Racing and air-craft engines (*see* AERO-ENGINES) were generally fitted with overhead camshafts. On the other hand, in passenger car engines valves in the cylinder head were generally operated through long tappet rods, as it was found difficult to obtain the desired degree of silence with overhead camshafts.

Marmon, in the United States, used a cast aluminium cylinder block for a passenger car engine for a number of years prior to 1920, but gave it up because it proved impossible to keep the cylinder bores true. Cast-iron sleeves were inserted in the blocks to form bearing surfaces for the pistons, and the valves were located in cast-iron cylinder heads. The trouble was evidently due to distortion of the aluminium castings under the high temperature of operation. It was later found that distortion of aluminium engine castings in service can be prevented by subjecting them to a heat treatment after machining, at a temperature slightly higher than the maximum they reach in service. Some years after the War, German engineers became interested in aluminium engines, and at the Berlin automobile show of 1923 there were exhibited six makes of car with such engines.

Fuels.—The continual lowering of the volatility of the fuel used caused both manufacturers and users of motor cars a great deal of trouble, particularly between 1915 and 1920. When motor cars were first used, the fuel sold consisted of a comparatively narrow range of highly volatile hydro-carbons. When sprayed into air at atmospheric temperature in the required proportion of about one part by weight of petrol to 15 parts of air it vaporised readily. The fuel supplied in the United States in 1920 had an end point of nearly 475° F., that is, the least volatile constituents, when under atmospheric pressure, boiled only at that temperature. Hence, in order to vaporise this fuel completely it was necessary to supply heat to the mixture or to the components before they were mixed. When trouble from incomplete vaporisation was first experienced the carburetters were provided with a jacket through which hot water from the engine jacket was circulated. When this no longer sufficed, the air for the carburetter was drawn through a muff surrounding a part of the exhaust manifold, and to prevent recondensation after the mixture was formed, the inlet manifold was so arranged that it was completely surrounded by hot water.

This also proved inadequate, and then the hot spot or exhaust-heated manifold was introduced. When the fuel is incompletely vaporised the liquid particles tend to separate out of the mixture at the bends in the manifold, and it is very difficult to insure that all cylinders get mixture of the same composition. Those portions of the manifold wall where the liquid particles tend to accumulate are then made to form parts of the exhaust manifold wall also, so that they are constantly kept at a high temperature, and the liquid particles upon striking them flash into vapour. The change in the character of motor fuel between 1916 and 1919 is strikingly illustrated by the diagram (fig. 3) of distillation curves of the fuels purchased in Detroit, Mich., at various times during that period. Later the fuel improved again slightly and a survey made by the U.S. Bureau of Mines on Jan. 1 1925, showed an average end point for petrols sold in different parts of the country of 425° Fahrenheit.

Carburetters.—Numerous improvements in carburetter design were made between 1910 and 1926. Decreased volatility of the fuel necessitated the provision of special means to facilitate engine starting, particularly in cold weather. American engineers, who were confronted with the problem first, generally made use of a choke valve in the air inlet, which is closed when it is desired to start. This greatly increases the suction on the fuel nozzle and results in a great excess of fuel being drawn in. As only the most volatile part of this fuel will be vaporised, this excess of fuel

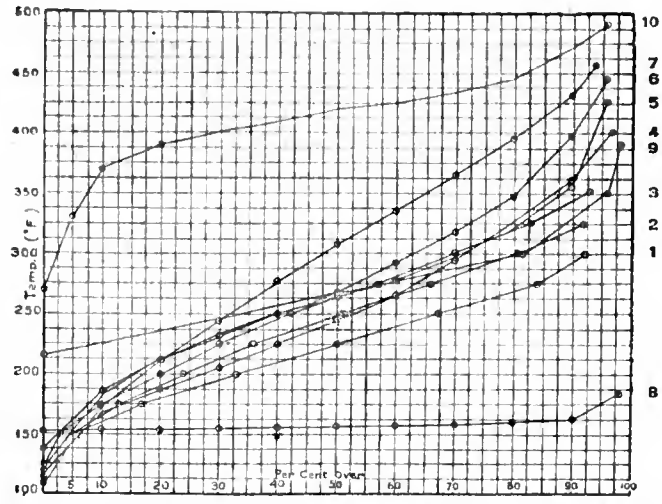

FIG. 3.—Distillation curves of motor fuel sold in Detroit, Mich., from 1916 to 1919. The data for each curve are as follows:—

assures the formation of an ignitable mixture. Another scheme, which originated in Europe, consists in the provision of a special starting nozzle delivering fuel into the carburetter passage above the throttle valve.

For starting, the throttle is closed and the effect on the starting nozzle is then the same as that on the main nozzle when the choke valve is closed. Most of the earlier carburetters had the fault of delivering an impoverished mixture in case the throttle valve was opened suddenly, causing the engine to halt and even to stop. With later carburetters the fuel-metering orifice is placed at the bottom of the carburetter instead of at the top of the spray nozzle. Between it and the top of the nozzle an accelerating well is provided which filled with fuel when the engine was stopped or throttled down to a low speed. Then, if the throttle were opened suddenly, the contents of the well were discharged into the induction system almost instantly, and the richness of the mixture was maintained.

Another improvement that came into wide use on carburetters between 1920 and 1926 was the economiser. Research work on carburetters and engines showed that for best all-round results the strength of the mixture must be varied with the demand on the carburetter. Maximum power is obtained from the engine with a petrol-air mixture of about 1:12·5, whereas the maximum fuel economy is obtained with a mixture of about 1:16. At extremely low speeds the mixture should be comparatively rich, because the fuel then is not sprayed very energetically and not all of it is vaporised, and only the vaporised fuel counts in the mixture. Throughout the greater part of the range in demand the carburetter should furnish the maximum-economy mixture, for obvious reasons. However, if the throttle is opened wide, the driver wants either the maximum torque (as in ascending very steep hills), or else the maximum power (as in a burst of speed), and in that case the carburetter should deliver the maximum-power mixture. This is accomplished by making the stem of the throttle valve, when approaching the position of maximum opening, change the setting of the fuel metering devices in such a way as to enrich the mixture.

Air Cleaners.—About 1920, American manufacturers began to use air cleaners on passenger car engines, to prevent road dust from getting into the cylinders and causing abnormal wear. The cleaners used were of either the centrifugal or the strainer

type. With the former the air is set in rotation in a cylindrical chamber by being drawn in by the engine suction through tangential or helical passages. Centrifugal force caused the heavy dust particles to collect on the cylinder wall and to drop out into a collector, often a glass jar, while the air, deprived of its dust content, is drawn off at the centre of the cylinder. With the strainer type the air is drawn through a large area of filtering felt.

One difficulty encountered in the use of exhaust heat for vaporising the fuel is that the heat supplied does not vary in accordance with the needs when the load on the engine is varied. When the engine is heavily throttled and runs under light load at low speed, the suction on the spray nozzle is small, and consequently the fuel is not finely sprayed. Relatively more heat is needed to ensure the vaporisation of the larger globules of fuel, but under these conditions of operation the exhaust does not supply a great amount of heat. A device designed to overcome this difficulty was developed by the Packard Motor Car Co., and is known as the fueliser. With this (see fig. 4) a variable fraction

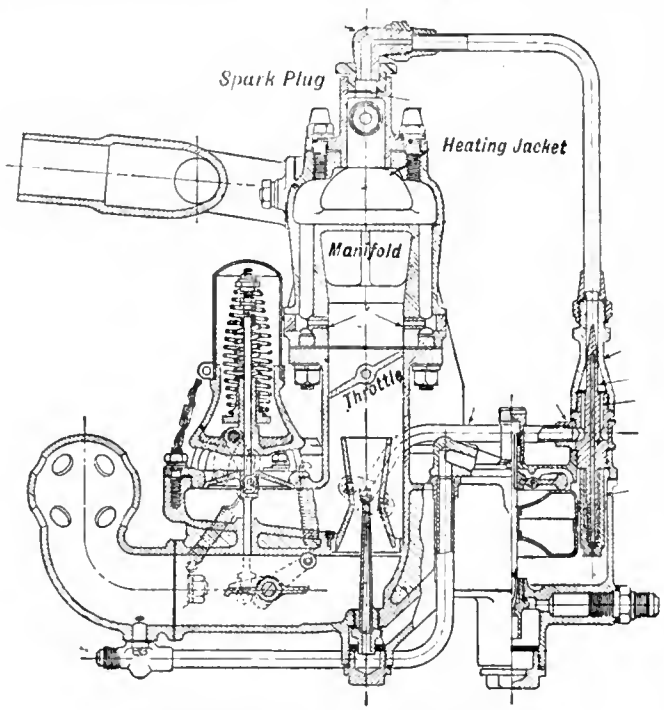

FIG. 4.—Cross section of Packard fueliser.

of the mixture prepared in the carburetter mixing-chamber is shunted around the throttle valve and through a heating jacket of the carburetter, where it is kept burning by a constant stream of sparks delivered by a sparking plug. The products of combustion are combined with the main stream of combustible charge and pass on into the cylinder. When the throttle valve is fully open there is very little resistance to the passage of the combustible mixture past it, and very little then flows through the by-pass or heating jacket; on the other hand when the throttle is nearly closed the passage through it offers much more resistance, and a much greater proportion of the fuel charge passes through the heating jacket, which is in accordance with the requirements.

Feed Systems.—In early cars the fuel tank was almost invariably located in the front seat, and the fuel was fed by gravity to the carburetter. Later the bodies were constantly lowered, partly to secure greater stability and partly for the sake of appearance, and at the same time the carburetter had to be raised in relation to the engine, owing to the lessened volatility of the fuel. The result was that sometimes when the car had to ascend a steep grade and there was little fuel in the tank there was no head on the fuel, and none would flow to the carburetter. Some of the earlier high-class cars were provided with a pressure fuel feed system, by which gas under pressure, taken through an " adapter " from the engine cylinders, was made use of to force petrol from a tank carried on the frame at the rear to the carburetter. There were two major objections to this system of feed: carbon particles from the engine cylinder often got into the fuel tank (in spite of the gas being passed through a fine-mesh wire-gauze strainer) and thence into the carburetter jet, which sometimes became clogged; besides, every time the fuel tank was filled the compressed gas escaped, and to get an initial flow it was necessary to obtain pressure by a hand air-pump. By placing the fuel tank under the cowl instead of in the front seat, sufficient head for gravity feed was generally obtainable, but the cowl tank usually had an awkward shape and was of rather small capacity.

The solution was found in the vacuum feed system, developed by the Stewart-Warner Speedometer Corp., Chicago, by which (fig. 5) the suction or vacuum in the inlet pipe of the engine was used for transferring the fuel from a rear tank to an auxiliary tank mounted on the forward side of the dashboard, as high as possible. The auxiliary tank had two compartments, upper and lower. Into the upper compartment the fuel was drawn by the vacuum, and it was periodically transferred to the lower by a float valve. Thence it flowed to the carburetter by gravity. There was always sufficent fuel in the carburetter float chamber and in the auxiliary tank to start the engine after the main tank had been refilled.

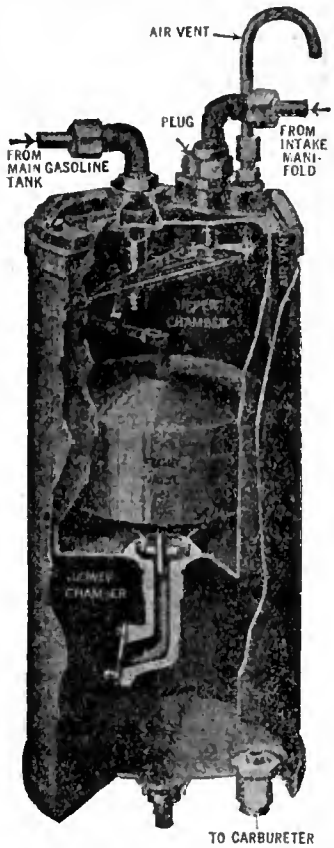

FIG. 5.—Cut-away view of Stewart vacuum tank (fuel feed system).

Ignition.—In 1910 ignition on practically all motor-cars was by high-tension magneto. In 1926 all American passenger cars, with the exception of the Ford (which had a flywheel type of magneto of the maker's own manufacture), had battery ignition. In European countries, on the other hand, although a beginning was made with the replacement of the magneto with the battery and coil system, upon the adoption of electric starting and lighting the movement was soon checked, and in 1925 only 16 out of 133 British models had battery ignition, while in France battery ignition was even less popular and in Germany it was practically non-existent. What led American engineers to change from magneto to battery ignition on passenger cars was the adoption of electric lighting and starting during the period 1912–4. Any car so equipped had an electric generator and a storage battery; consequently there was a constant and plentiful supply of current available, and there was no need for an additional current generator in the form of a magneto. As compared with the early coil and battery systems, the only differences consisted in the use of a plain coil instead of a vibrator coil and of a mechanical interrupter instead of a timer. Sometimes safety devices were provided for automatically opening the circuit or reducing the current flow if the operator should forget to open the switch when the motor stalled.

Use of Thermostats.—No fundamental changes were made in the cooling system, with the exception of the introduction of the thermostat for the control of the circulation. This instrument is connected in the cooling circuit in such a manner that it prevents circulation through the radiator until the jacket water has attained a certain predetermined temperature, generally

about 170° Fahrenheit. The result is that in starting from cold the engine reaches normal working temperature in shorter time, and trouble due to incomplete vaporisation of fuel is reduced. The thermostat used, known as the sylphon, consists of a corrugated copper cylinder filled with a liquid which vaporises at the temperature at which the thermostat is to act (fig. 6). An al-

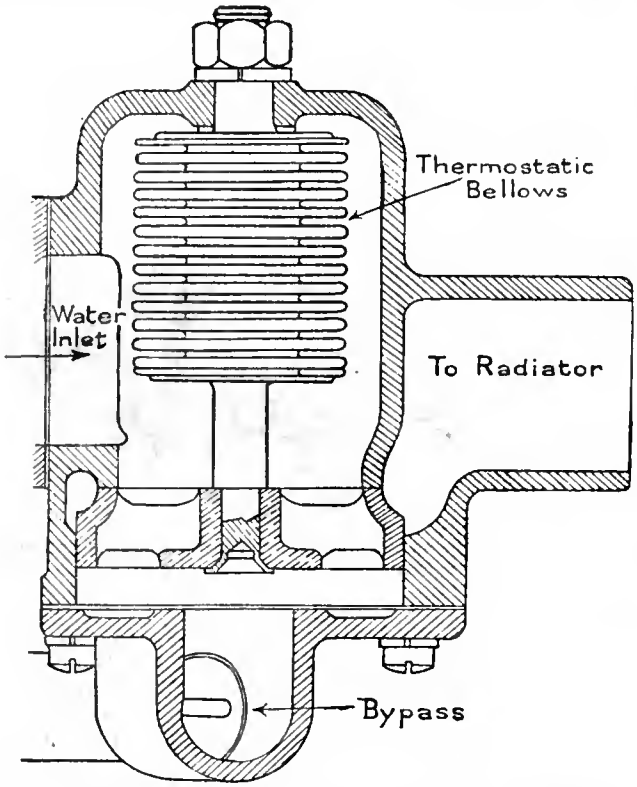

FIG. 6.—Thermostatic valve for control of engine temperature.

ternate system consisted in the provision of a set of radiator shutters, thermostatically controlled. Many passenger car radiators are fitted with a radiator thermometer in the filler cap, which is a help to the operator in trying to keep his engine running at its best temperature and gives an early indication of incipient overheating.

Lubrication.—As regards engine lubrication two basic methods came into use, the circulating-splash and the force-feed or "drilled crankshaft" system, as well as combinations of the two. Both systems were employed on early cars, but the force-feed system came into much more extensive use with the development of the high-speed engine. The problem of engine lubrication was rendered much more difficult by the change in the character of the fuel used. A good deal of the fuel entered the cylinder in the unvaporised state, and some of it leaked past the pistons into the crankcase, where it diluted the lubricating oil. In 1920 it was a common experience to find a fresh supply of lubricating oil lose much of its viscosity, and hence of its lubricating value, during the first 100 m. of running. Heating of the crankcase oil also reduces its viscosity, and to reduce this heating many British engines were cast with cooling flanges on the bottom of the oil sump.

Starting and Lighting Gear.—One of the greatest advances in motor car practice was the development of electric starting and lighting systems. The first such system on a car in regular production was on the Cadillac in 1912, and was the design of C. F. Kettering. Electric lighting alone had been used on petrol cars for some years previously, in fact ever since the advent of the tungsten filament bulb. At first the lamps were supplied with current from a storage battery only, which had to be recharged periodically from electric mains; later they were fed with current from a generator and storage-battery installation. The adaption of an electric generator to storage-battery charging on a motor car presented considerable difficulties, for the reason that the petrol motor runs at widely varying speeds, and that the voltage of the generator, therefore, tends to vary within wide limits, whereas a substantially constant voltage is needed for charging.

Many systems of regulation were used with more or less success, but finally the so-called third-brush system was adopted by a majority of the manufacturers of electrical equipment. In this system the generator field was provided with a winding similar to a shunt field winding, but instead of connecting the positive commutator and negative brushes it was connected between one of these brushes and an auxiliary brush, so that only a fraction of the voltage generated in the armature was applied to the field coils. This system of control did not give a constant generator voltage, but with a storage battery connected to the generator it kept both the voltage and the charging current within permissible limits of variation.

In connection with the electric starter the main problem was that of the drive to the engine crankshaft. After trying various devices nearly all manufacturers in the United States and a good many in Europe settled upon the use of the Bendix drive (fig. 7), developed by Vincent Bendix of Chicago. On an extension

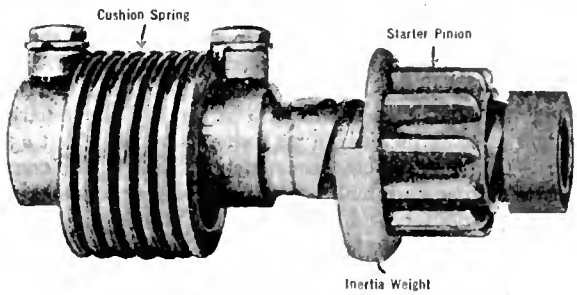

FIG. 7.—Bendix drive for electric starters.

of the starter armature shaft was loosely mounted a sleeve, which was placed in driving connection with the shaft through a coiled spring. The spring had a coarse, square thread cut on its outside, and on this was mounted the driving pinion, the hub of which was cut with a corresponding female thread. When current was applied to the starting motor, which was always of the series wound type, the armature started to revolve at great speed, carrying along the threaded sleeve on its shaft. Owing to its inertia the pinion lagged behind, and was screwed along the shaft and thus shifted into mesh with a gear-ring on the flywheel rim. Upon abutting against a collar it became fast upon the sleeve, and the starter then cranked the engine, the shock being relieved by the coiled spring.

As soon as the engine began to pick up its cycle the flywheel ran ahead of the driving pinion, and the latter was automatically thrown out of mesh by being forced along the screw. Fig. 8,

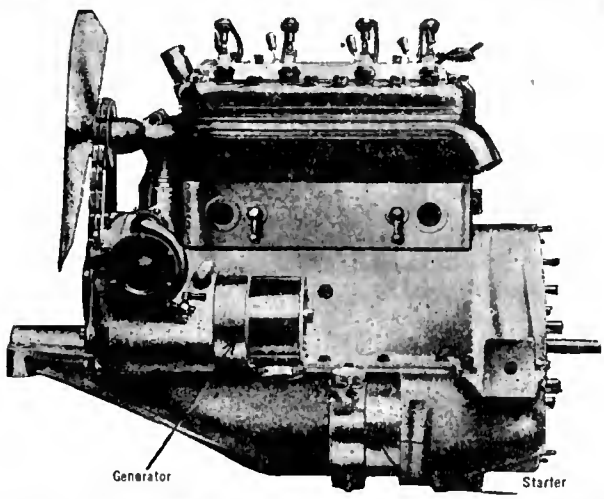

FIG. 8.—Fiat (Italian) engine, showing method of mounting electric generator and starter.

illustrating the Fiat motor car engine, shows one method of mounting the generator and starter. A necessary part of practically all motor car electric equipments was a battery cut-out, which automatically disconnected the battery from the generator when the engine speed dropped so low that the generator voltage was less than the battery voltage, and connected it on increasing engine speed when the generator voltage surpassed the battery voltage. Ground return wiring was very much used, all electric appliances having one insulated and one grounded connection. The standard voltage for motor car electric systems in the United States was 6 v., while in Europe a pressure of 12 v. was much used.

Superchargers or means for forcing into the cylinders a greater mass of charge per cycle than they can draw in by their pumping action received a good deal of attention during the latter part of the War as a means of maintaining the power of aircraft engines at high altitudes. In 1926 the supercharger was commonly used on racing engines and permitted of greatly increased output from an engine of given displacement. On one make of stock car, the Mercedes, the supercharger was fitted as standard equipment. An air-pump of the Roots blower type was mounted at the forward end of the engine and driven from the crankshaft through a friction clutch, which latter was controlled by the accelerator pedal. As long as the throttle was not fully opened the clutch was disengaged and the supercharger therefore idle. A further movement of the pedal after the full-open position of the throttle had been reached, closed the clutch, set the supercharger in action and gave an increase in maximum power of about 65%.

Gears.—Unit-power-plant construction, that is, the combination of the engine, clutch and change-speed gear in a single unit, became very popular, and in the United States was the almost universal practice for passenger cars. About 1910 the dry-disk type of clutch (fig. 9) began to displace the multiple disk-in-oil and the cone type. It was very similar to the lubricated type of disk clutch in construction, but one set of the metal disks was faced with disks of asbestos fabric on both sides. Its advantage over the lubricated disk clutch was that its operation was not affected by changes in atmospheric temperature, as was that of the latter. Most of the earlier dry-disk clutches were of the multiple-disk form, but from 1920 on the single-disk type gained constantly in popularity and in 1926 was used with engines of as much as 70 horsepower. This differs from the multiple-disk form not only in having only a single driven disk, but also in having a set of reducing levers which make the thrust on the throw-out collar about one-quarter the pressure between the disks, whereas in the multiple-dry-disk design illustrated in fig. 9 the two forces are equal. There were no important developments in the design of gearsets or transmissions; nearly all manufacturers of passenger cars used the selective sliding pinion type, and this type was also used on most commercial vehicles.

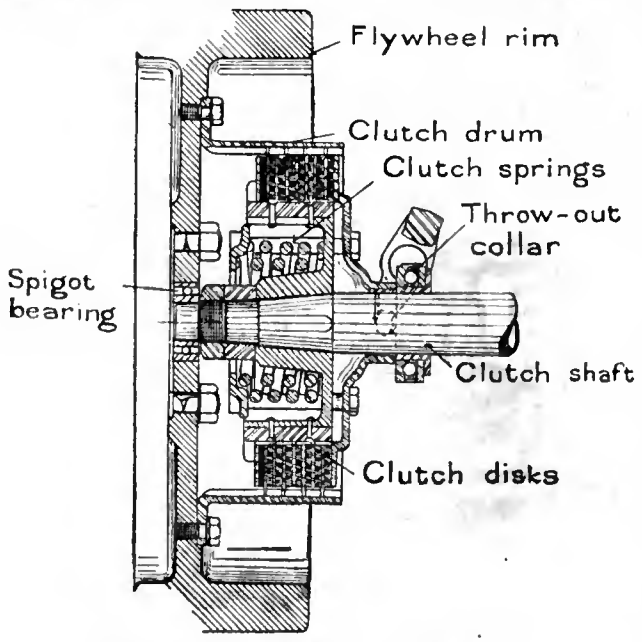

FIG. 9.—Sectional view of dry-disk clutch.

Chain drive was almost entirely discarded, except on trucks in continental Europe, and shaft and bevel-gear drive became the standard for passenger motor cars throughout the world. But two important improvements were made in this drive. One was the substitution of spiral bevel for straight bevel gears, to secure quiet operation, and the other the partial substitution of disk universal joints for the metallic type, the former requiring no lubrication. The spiral bevel gear (fig. 10) was made possible by a gear-cutting machine developed by the Gleason Works of Rochester, N.Y., and the fabric disk universal joint (fig. 11) by a fabric structure originated by Ed. J. Hardy & Co. of Coventry, England. Practice in regard to final drives for motor lorries remained in a chaotic state in 1920. In continental Europe the chain was still predominant, while in Great Britain and the United States the worm drive was in most extensive use. Of the lorry models manufactured in Great Britain in 1926 50% had worm drive, 5% chain drive, 12% bevel gear drive, 1% internal gear drive, and 25% the double-reduction drive, or drive by one pair of bevel and one pair of spur gears enclosed at the middle of the axle. In the United States the most popular drive next to the worm, for trucks of over 1½ tons capacity, was the internal gear drive, in which there was a first reduction by bevel gears at the middle of the axle and a second by internal gears at the driving wheels.

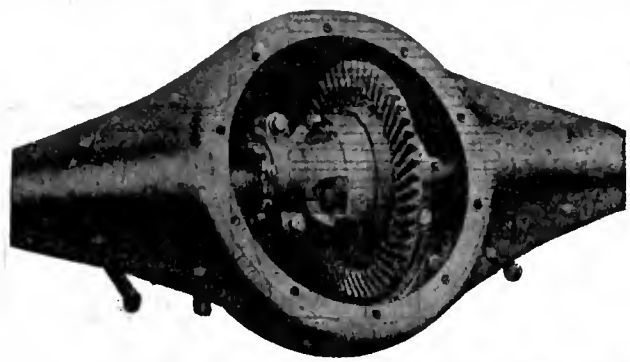

FIG. 10.—Central part of a rear axle with inspection cover removed, showing spiral bevel gear.

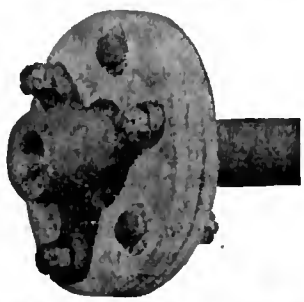

FIG. 11.—Thermoid-Hardy fabric universal joint.

Axles and Springs.—In connection with lorry axles, mention should be made of the development and use, mainly in the United States, of so-called non-stalling differential gears. A vehicle fitted with this type of differential would not lose all traction when one driving wheel gets on slippery ground; on the other hand, in turning corners the drive was entirely through the inner wheel. A type of body suspension spring that gained much in popularity between 1910 and 1920 was the cantilever type first used by F. W. Lanchester in England. The most extensively used type in 1926 was the half-elliptic. Many attempts were made to solve the problem of furnishing the springs with effective means of lubrication, to make them as supple as possible and to prevent squeaking, and in England the practice of enclosing the springs in leather gaiters gained some ground. In the connection between the rear axle and the frame, provision must be made for taking up the driving thrust necessary to overcome the air resistance and the resistance encountered by the front wheels, as well as the reaction to the rear-wheel driving torque, which tends to turn the axle housing in the direction opposite

to that in which the wheels are turning. In the Hotchkiss drive, both the drive and the torque reaction were taken up on the body springs, which were securely clipped to the axle housing and directly pinned to the frame at their forward end. This pattern became very popular in the United States for both passenger cars and lorries, and was successfully used even on heavy military lorries.

European designers, on the other hand, favoured the torque-tube construction for passenger cars. In this the propeller shaft was surrounded by a torque tube, which was rigidly secured to the housing at the centre of the rear axle, and at its forward end had either a forked or a spherical connection to a cross member of the frame or the rear end of the transmission case. In the United States one manufacturer after another adopted the plan of mounting the steering post on the left side, realising that in a country where the "right-hand" rule of the road obtains, the balance of advantages rests with the left-hand drive. Left-hand steering fits in well with brake and gear-shift levers mounted in the centre of the car, as the driver can use his right hand to operate them. In Great Britain, where the rule of the road is to "keep to the left," right-hand steering has the same advantages as left-hand steering in other countries.

Wheels.—The wheel equipment of the earlier cars was almost entirely of wood-spoked type. Woods suitable for rims and felloes became rare, however, especially in Europe, and a strong tendency toward the use of metal wheels then set in. In fact, with one exception, all British manufacturers of passenger cars fitted metal wheels as regular equipment on their 1925 models. There were three types of metal wheels for passenger cars, viz.: wheels similar in shape to wood-spoked wheels, made of two steel pressings welded together (chiefly used in England), wire-spoked wheels and disk wheels (figs. 12, 13 and 14). An improvement in wire-wheel design, which was a great factor in rendering these wheels practical for heavy, powerful vehicles, was the triple lacing due to John V. Pugh of England.

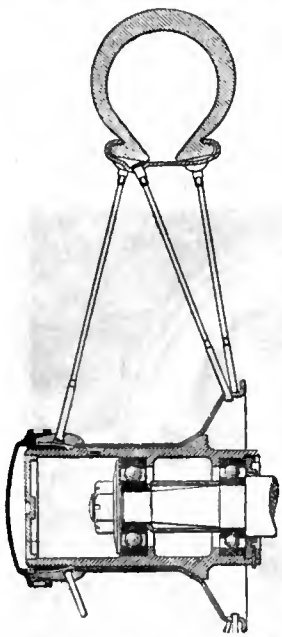

FIG. 12.—Section of Rudge-Whitworth demountable wire wheel with Pugh triple lacing.

Disk wheels came into extensive use during the War; they may be divided into single and double disk types. To secure the necessary lateral stiffness with a single disk it was customary to cone the disk, and, moreover, the disk was usually reduced in thickness from the hub toward the rim, either by turning in the lathe or by rolling.

All motor-vehicle wheels are provided with steel rims designed to take the pneumatic or solid rubber tires (*see* TIRES). The original type of motor-vehicle rim for the double-tube pneumatic tire was the clincher rim, the edges of which are formed into clinchers to hold the beaded edges of the tire cover. This type of rim remained the standard in Europe, but American manufacturers early adopted the detachable rim, which permits of the use of a steel cable core in the edges of the tire cover to make it inextensible. In the earlier detachable rims one flange of the rim was removable, and the tire could be stripped off sideways after the flange had been detached. Some of these detachable flange rims could be used with both clincher and straight-sided tires, and were therefore known as universal rims. Later, when the clincher tire was given up by American manufacturers for all except the smallest sizes, a different type of detachable rim was introduced, in which there is a joint in the circumference of the rim. After opening the locking mechanism of this joint the rim can be contracted sufficiently to pass through the tire. In order that detachable rims may always be free-working the rims must be thoroughly rust-proofed, and care must be taken in handling the rim not to distort it.

Tire Repairs.—In the early years of the motor-car, when a tire was punctured or otherwise defective, the operator was obliged to make a repair on the spot, or at least remove the tire cover, insert a new tube, replace the cover and inflate the tire anew. The difficulty was overcome by the adoption of the demountable wheel in Europe and the demountable rim in America. American motorists thereafter carried one or two spare rims fitted with fully inflated tires, and in case of a puncture merely removed the rim with the defective tire and replaced it with a spare rim and inflated tire, an operation usually requiring from 10 to 15 minutes, leaving the repair of the damaged tire to be done at home or at a tire service station. European motorists carry spare wheels with inflated tires in the same way. The advantage of the demountable rim over the demountable wheel is that the spares weigh less; the advantage of the demountable wheel is that it weighs less than a wheel with a demountable rim, and especially that with it there is less weight near the circumference of the wheel, where it has a strong flywheel action. Moreover, with the detachable wheel the detaching mechanism is at the hub, farther removed from rust-promoting influences.

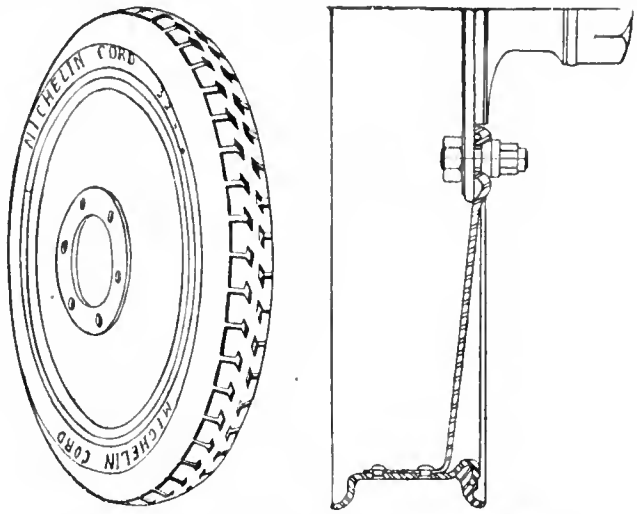

FIG. 13.—Michelin disk wheel, outside view and section.

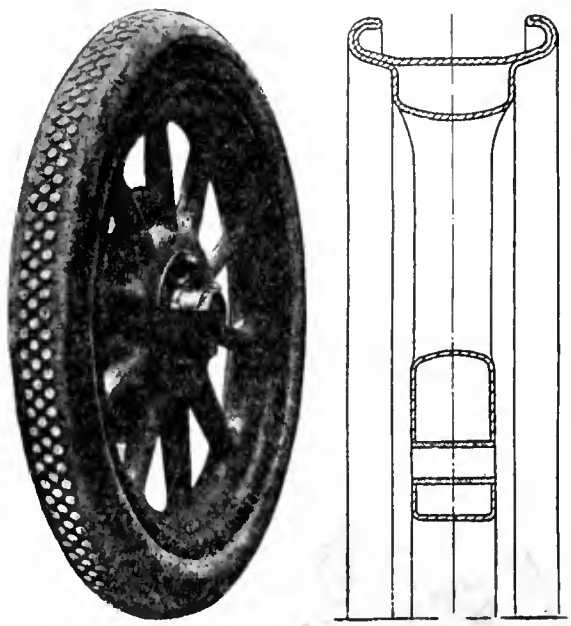

FIG. 14.—Sankey pressed steel wheel, and section.

The structure of demountable rims may be briefly described as follows: forced over the felloe of the wood wheel is a steel felloe band with a wedge surface on its outside, and an inward flange on one edge through which end the wood felloe pass the felloe band bolts. Over this felloe band is passed the rim carrying the tire, which is formed with a wedge surface on its inside, adapted to engage the wedge surface on the felloe band. Rim lugs with wedge-shaped projections are threaded over the ends of the felloe band bolts, and the nuts on the bolts are then screwed up, forcing the wedges into the space between the felloe band and the rim. In this way the rim is subjected to both radial and lateral pressure and is centred and firmly held on the felloe band. Both clincher and detachable rims can be used in connection with demountable rims.

Solid rubber tires are vulcanised on to the steel base bands, and wood wheels to be fitted with such tires have a steel felloe band shrunk over them. The tires are then mounted on the wheels in a demountable way by means of wedge rings, side flanges and bolts. Cast-steel wheels generally have one wedge ring cast integral and do not need a side flange on that side.

Brakes.—Practically all the cars manufactured up to the end of the War had brakes acting on the rear wheels only, but from that time on a rapidly increasing number were equipped with brakes acting on all four wheels. Four-wheel brakes were pioneered by Henri Perrot, engineer of the Argyll Motor Car Co., of Glasgow, in 1910. They permit of making a stop in substantially one-half the distance as with rear-wheel brakes, thus adding to the safety of automobile travel. The minimum stopping distance depends upon the pressure against the ground of the wheels through which the brakes take effect, and when the brakes are applied there is a decrease in the ground pressure of the rear wheels and an equal increase in that of the front wheels, which tends to make the front-wheel brakes particularly effective. In the application of brakes to the front wheels certain conditions must be met. Setting of the brakes must not prevent steering motion and, *vice versa*, the deflection of the wheels in steering must not change the setting of the brakes. Moreover, it must be practically impossible to lock the front wheels by means of the brakes, because the car will not respond to a steering motion if the wheels do not revolve.

Two general types of four-wheel brake were worked out. In one the power necessary for the application of the brakes was transmitted entirely by mechanical means, which in the case of the front wheel brakes involved some difficulty, owing to the relative motion between brake drum and axle. It was necessary to provide a universal joint in the shaft of the brake-expanding cam or the brake-band-contracting lever, whose centre lay in the axis of the steering knuckle pivot, so that steering motion of the wheels would not affect the setting of the brakes. The brakes on all four wheels were linked to the brake pedal. To obviate the danger of locking the front wheels, some designers divided the force of brake application unequally between front and rear, usually about 40% to the front brakes, while in the Perrot design the linkage was so arranged that as the front wheels were swung around in turning there was a tendency for the brake on the outside front wheel to release automatically, thus preventing locking of this wheel and consequent loss of control. As regards equalisation there was absolutely no uniformity of practice in 1925. In some systems the force of application was equalised between front and rear and between right and left, while others used no equaliser at all. A mechanically operated front-wheel brake is shown in fig. 15. A is the lever to which the brake rod or link attaches; B, the cam-shaft; C, the cam; and H, the means of adjustment for wear.

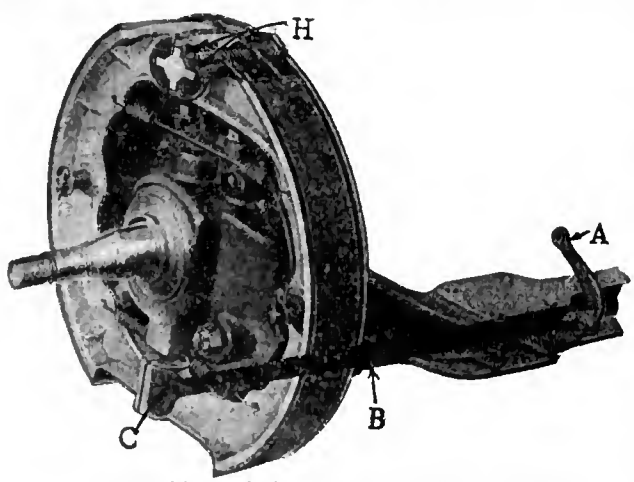

FIG. 15.—Mechanically operated front wheel brake.

In the other type of brake referred to, the force of application was transmitted by means of a confined liquid, this type being known as the hydraulic brake. The brake at each wheel comprised a cylinder in which there were two pistons which acted upon the brake bands, or shoes, through bell cranks. These cylinders communicated through heavy hydraulic hose and copper tubing with a master cylinder within which there was a piston that was connected to the brake pedal. The whole system was filled with a liquid (a castor oil and alcohol mixture) that does not congeal in winter and does not attack the rubber hose. Pressing on the pedal forced some of the liquid from the master cylinder through the tubing into the brake cylinders, thereby forcing the two pistons in each brake cylinder apart and applying the brake. The slight loss of liquid from the system, by leakage, was made up by pumping additional liquid into it from a reserve tank on the dashboard, provided with pump and shut-off valve. One feature of the hydraulic brake was that it was always fully equalised.

With otherwise equal construction four-wheel brakes require substantially twice the effort on the part of the operator to apply them, hence persons of limited physical strength, particularly women drivers, found it hard to apply the brakes to the locking point. This led to the development of so-called servo brakes, in which the momentum of the car was utilised to reinforce the effort of the driver in applying the brake. The simplest form of servo brake is a band brake anchored off centre, and after the adoption of four-wheel brakes most band brakes had the band so anchored that the section which tended to wrap up on the drum when checking forward motion of the car was considerably longer than the other (unwrapping) section. The principle of the mechanical servo brake may be very simply explained as follows: Imagine a drum mounted on a shaft which is positively geared to the rear axle. Let a rope be wound around the drum, one end of the rope being connected to the brake pedal and the other to the lever of the brake-expanding cam. Then, if the operator presses on the pedal and thereby exerts a pull on the forward end of the rope and assuming the rope to be wound around the drum in the right direction, the resulting friction between rope and drum will multiply the tension in the rear end of the rope and the pull on the brake lever will be several times as great as if it were connected directly to the pedal. With internal or expanding brakes a servo effect was obtained by providing a floating shoe, which was pivoted to the free end of the anchored shoe. If only these two shoes were provided the brake would have very little effect in holding the car against reverse motion, and for this reason the Bendix-Perrot brake, illustrated in fig. 16, was made with three shoes, the third shoe being depended on mainly for checking reverse motion. Some cars, notably the Fiat in Italy and the Studebaker in America, were fitted with an hydraulic servo mechanism. This consisted of an oil pump combined with the transmission gear, which was always running as long as the car was in motion. Normally the oil was bypassed from the delivery to the suction port of the pump, and no effect was produced, but by closing a valve between these two ports by means of the brake pedal, a pressure was set up in the system which moved a piston connected by mechanical linkage to the different brakes. If the hydraulic mechanism failed to work for any reason (owing to leakage of oil, for instance), by pressing the brake pedal down farther than required to operate the hydraulic system, the operator could apply the brakes directly by foot pressure. A diagram of the hydraulic servo mechanism used on Fiat cars is shown in fig. 17.

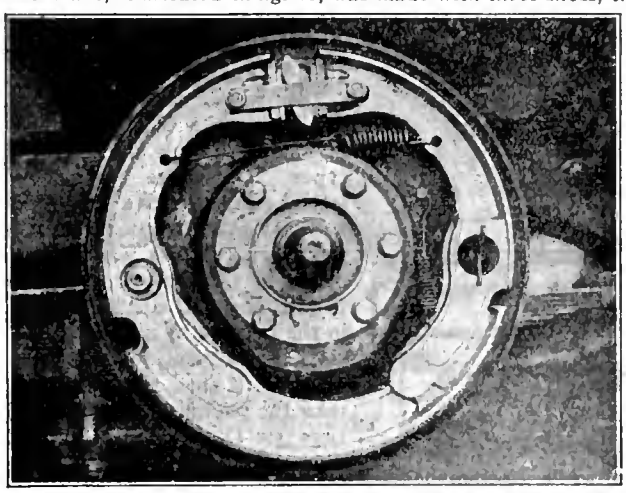

FIG. 16.—Bendix-Perrot three-shoe servo brake.

III. EQUIPMENT

There is one notable difference in the commercial practices of American and European motor-car manufacturers. In the

United States it is customary to sell cars complete with bodies and all necessary equipment, so that upon being filled with fuel and water they can immediately take the road. The equipment usually includes such items as wind-screen, lamps, speedometer, jack, tire pump and tools. European manufacturers, on the other hand, previous to the World War, often made it a practice to sell only the bare chassis and let the customer arrange for the body with a coach-builder and select the equipment himself. After the War they began to follow the American practice, especially with low-priced cars.

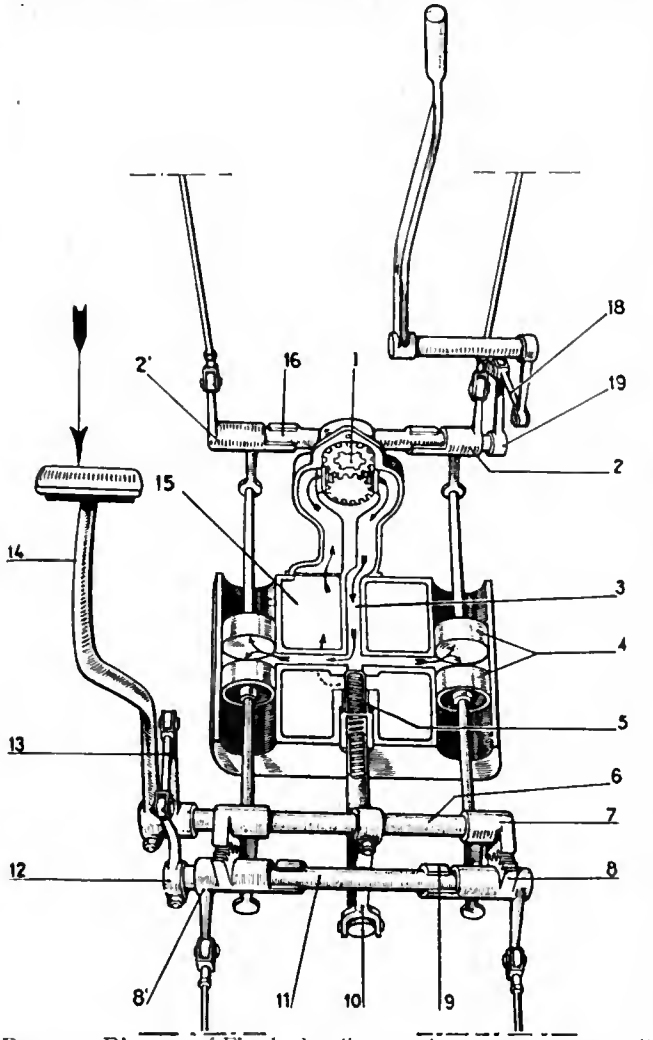

FIG. 17.—Diagram of Fiat hydraulic servo brake: 1, gear type oil pump; 2, 2', floating levers in front wheel brake linkage; 3, delivery passage of pump; 4, servo pistons; 5, servo control valve; 6, brake pedal shaft; 7, gear sector on brake pedal shaft; 8, 8', gear sectors on floating levers in rear wheel brake linkage; 9, nose on shaft 11 which engages with corresponding nose on hub of floating lever; 10, lever on brake pedal shaft to which servo control valve is connected; 11, cross shaft connected to brake pedal through lever 12 and link 13; 14, brake pedal; 15, oil by-pass; 16, cross shaft operated from brake hand lever through link 18 and lever 19.

Mass Production.—Many of the cars produced in the United States were made on what is known as the assembling plan; that is, the various major components, such as engine, clutch, gearset, axles, frame, springs and steering gear, were all manufactured in different factories by concerns specialising in these products, and were assembled into a complete car in the assembling plant. The advantages of this plan are obvious and include the possibility of intensive development of design and the economy of quantity production. The extent to which assembling was practised may be judged from the following figures: Of the American passenger-car models for 1920, 92% were fitted with stock carburetters, 75% with stock steering gears, 66·7% with stock clutches, 65·1% with stock rear axles, 58·7% with stock transmissions and 42% with stock engines, all these stock parts being made by specialists. In the field of commercial vehicles the practice of assembling was even more prevalent.

Bodies.—After the War the use of closed cars increased very rapidly in the United States. Previous to that time a limousine or any other of the closed types then in use cost substantially twice as much as the corresponding open model, and this naturally limited sales. Moreover, most of the earlier closed cars were of the chauffeur-driven type, in which the driver's seat is partitioned off the passengers' compartment. Endeavours to reduce the cost of production of closed bodies resulted in greatly widening the possible market for this type of car. A new low-cost design known as the coach was evolved and popularised by the Hudson Motor Car Company. It promptly met with great favour and was soon offered by a large number of manufacturers. The coach is essentially a five-passenger closed car with only two doors. The seat adjacent to the driver's folds forward, thus giving access to the rear seat through the door on the right-hand side (with left-hand drive). Coaches in some instances sold at prices lower than those of the corresponding open models, this being made possible by the fact that the particular maker had a much larger production on the former than on the latter. The growth in popularity of the closed car in the United States may be judged from the fact that the proportion of closed cars in the total production rose from 1.5% in 1915 to 17% in 1920, and had attained 56% in 1925.

On open or touring cars the collapsible top was to a large extent superseded by the California type or permanent top. It was found that repeated raising and taking down was quite injurious to the folding top, causing it to crease and appear shabby, and this difficulty was eliminated by the permanent construction, which also prevented sagging between bows, a common fault of old folding tops. A number of British and German makers provided a compartment in the body into which the top disappeared when folded, but generally the appearance with the top up was not all that could be desired. Many attempts were made to produce double purpose or convertible open and closed bodies. In the early types the whole superstructure was removable as a unit, but this did not prove successful in the long run. In England the "all-weather" type of body became very popular. One of the first British cars to be equipped with an "all-weather" body was the Standard, and after 1920 many other British makers fitted it.

As made in England, the "all-weather" body comprised a regular open body with folding top and more or less rigid, transparent panels which could be used to close the sides during periods of inclement weather, these panels taking the place of the flexible side curtains with transparent inserts previously used. The transparent medium was either glass or celluloid. Usually there were a number of fairly rigid frames of flat steel, covered with fabric leather and secured to the doors and the sides of the body. The transparent element was of smaller dimensions than the supporting frame and the space in between was filled with fabric leather, hence there was no possibility of the glass being broken by distortion of the body frame communicated to the panel frame. The panels on the doors swung open with the latter, but in some cases they were secured by snap fastenings to valances on the top, and these fastenings had to be loosened first. At the front the panel was joined to the windshield pillar, and endeavours were made to have this joint rain- and draught-proof. Similar joints were made between the upper edge of the panels and the top. Usually there were three panels on each side, but sometimes there was a fourth at the side of the rear seat. Some of these panels were so designed that they could be used as rear wind-screens when the top was down, being entirely independent of the top for support. Provision was made for storing the panels inside the car, either in a tray under the front seat or in a compartment in the rear cowl.

The Weymann Type.—A type of closed body that was distinguished by light weight, low cost of construction and freedom from squeaks was brought out by Weymann in France. It had a framework of 1½-in. square wooden members which, however, were joined together by means of comparatively light metal strips bent to angle shape and secured with wood screws. Thus the wooden members did not come in contact with each other and the cause of squeaks was eliminated. The seats were made separate from the body and supported directly on the chassis frame, which caused the passengers to be seated lower and permitted the body to be lower. The framework was covered with fabric leather, which was painted the same as the metal panelled body. Another advantage claimed for this construction was that it entirely eliminated "drumming," an objectionable feature of practically all closed bodies with metal panels. According to Weymann, a four-passenger saloon body for a 130-in. wheelbase chassis built on this plan need not weigh more than 440 lb., including fenders, valances, running boards, spare-wheel carrier and tool box, which is a great deal less than the weight of the usual open body for a car with this length of wheelbase. A disadvantage of the Weymann pattern limited the designer practically to straight lines, and some of the early Weymann bodies were of rather severe appearance.

Numerous items of equipment added to the comfort and convenience of driver and passengers. In the United States it was customary in 1926 to equip closed cars with exhaust heaters for use in cold weather. Ventilators were provided in the cowl and in the roof, or ventilation was effected by slightly raising the windshield. The windows in the doors and sides of the car could be raised and lowered at will, and with all the windows down the passengers were as much in the open air as with an open car, while under all conditions the

vision was as good as from an open car with the top up. With windows closed it was impossible for the driver to give the usual signals to drivers behind by extending his arm, and this was rendered unnecessary by providing the cars with a stop light at the rear which lit up automatically whenever the brake was applied.

In case of rain or snow a section of the windshield in front of the driver's eyes was kept clear by means of a windshield cleaner, consisting of a swinging metal arm carrying a rubber squeegee, which was operated by hand on some of the lower-priced cars and by a vacuum engine (connected to the inlet manifold of the car engine) or by an electric motor in the majority of the models. A visor over the windshield protected the driver's eyes against direct sunrays. The button for the signalling horn was located at the centre of the steering wheel; depressing this button sounded the horn, and by turning it slightly around its axis the headlights could be dimmed to prevent annoyance from glare to on-coming drivers and could be brightened again when no one was approaching. All control instruments, sometimes including an engine thermometer and a fuel-tank gauge, were conveniently and neatly arranged on the instrument board. Many of the items of equipment enumerated were also furnished on open cars. Many owners had their cars fitted with bumpers at both front and rear, as a protection of the exposed parts, such as headlights, fenders, radiator, etc., in case of a minor collision.

Body Finish.—A new method of finishing motor-car bodies was introduced by one of the large American makers during the summer of 1923, and came into wide use in the industry within a short time. It consisted in giving the bodies a finishing coat of a lacquer of which pyroxylin was the base.

Previous to that time all the bodies built partly or wholly of wood were finished in varnish, which was open to the objections that the process of finishing was very tedious, owing to the fact that a long time had to be allowed for drying after each coat had been applied, and that the surface obtained was not sufficiently proof against scratching. Bodies constructed entirely of metal were generally "flowed" or sprayed with enamel and baked in ovens. This overcame both of the disadvantages experienced with varnish, but most of the bodies had a wooden frame and these could not be enamelled, as the wood would have been injured by the high temperature of the baking process; besides, with enamelling, the finish could be had only in black, as colours would have been affected by the baking heat. Pyroxylin base lacquer had been used previously; but its applications had been limited, owing to certain difficulties which were overcome in 1923.

The first lacquer of this type to come on the market was known as Duco, but it was soon followed by many other brands. When finishing a body with pyroxylin base lacquer, the same priming and surfacing coats are applied as with varnish. Usually the body is given either two or three coats of the lacquer. When the last coat of lacquer has dried it presents a so-called egg-shell finish, and a polish is then obtained by rubbing the surface with pumice and rottenstone and applying a coat of polishing wax. A glossy surface can be obtained by giving the surface a coating with a clear lacquer of a pyroxylin base. To the car manufacturer the advantage of the pyroxylin finish resides chiefly in the cutting down of the time required for the finishing process. Aside from this saving in time and the consequent saving in the manufacturing process, pyroxylin finish makes it possible to obtain a colour finish at a moderate price, and the surface is exceedingly hard and cannot be scratched or chipped easily, while the life of the finish is several times that of a varnish-finished surface.

IV. THE SMALL CAR

Owing to high licence fees (taxes) and the high cost of fuel, European makers after the War paid particular attention to the small car, as a means of reducing the cost of motoring. In the United States in 1926 the smallest car built had an R.A.C. rating of 15·6 H.P. and very few models rated at less than 20 horse-power. Of the 145 British models in production that year six had a rating of less than 10 H.P. and considerably more than one-half rated at less than 15 horse-power. The cars were also built narrower. Practically all American cars, even the smallest, had the standard tread of 56½ in., or at least approached it very closely, while about one-half of the British models had a tread of 50 in. or less, the minimum being about 43 inches. Practice on the Continent resembled that in Great Britain. The average British car of 112–115-in. wheelbase had a H.P. rating of 12, and as the annual tax was £1 per H.P., the saving on this item was quite considerable, as compared with the average American car of the same wheelbase, which had a rating of 22 or 24 horse-power.

With the smaller engine the fuel consumption for the same weight of car is also appreciably less, due to the fact that the load factor of the engine is higher (the average load carried is a greater fraction of the maximum output of the engine), and the efficiency of the engine increases with the load factor. On improved roads very good speeds could be made even with the small engines, which were always of the high-speed type (sometimes called high-efficiency type). Of course, acceleration was not so good, and more of the running had to be done on the lower gears, which involved more frequent gear shifting. Some of the smallest cars, like the Austin 7 H.P., approached a motor-cycle with side-car in power, weight and other characteristics. This vehicle had a four-cylinder engine of 55 mm. bore and 75 mm. stroke and weighed complete with 2-passenger body 790 pounds. The chief demand, however, was for the type of car rating at between 10 and 14 horse-power. Among the most popular smaller cars in 1925 were the Morris in England and the Citroën in France.

Ford Cars.—A unique position in the American motor-car industry has been occupied by the Ford Motor Co., whose annual production for several years constituted about one-half that of the whole industry. This company in 1909 developed a passenger car which sold for the next 17 years without material modifications in design except as regards the body and equipment. This stability of design made possible production on an unequalled scale and at remarkably low cost. In 1925 the price of the two-seater (22.5 H.P., R.A.C. rating) was $260, and that of the open 5-seater $290 f.o.b. Detroit. This, however, was without the self-starter and battery lighting equipment, which were taken by practically all purchasers and which made the cost per car $85 higher. The company operated a plant at Manchester, England, at which 90% of all the work of manufacture on the cars sold in Great Britain was said to be done. It also had a factory in Lyons, France, and assembling plants at Copenhagen, Denmark and Antwerp, Belgium. In 1925 the company stated that it had delivered more than 12,000,000 vehicles, and that it was then producing 7,000 per day.

V. PRODUCTION, STANDARDISATION AND MARKETING

Amazement is often expressed at the enormous capacity of the American market for absorbing cars. Calculations of the limiting market were sometimes made on the premise that a certain minimum income (say $1,500 annually) was necessary in order to enable a person to keep a car, and from income-tax records the supposed number of possible owners was then determined. However, these predeterminations of the so-called "saturation point" practically always erred on the conservative side. Three main factors made it possible for the American people to maintain substantially 20,000,000 cars in 1926—roughly two cars for every three families (1) a great reduction in prices made possible by improved manufacturing processes; (2) the introduction of the time-sales plan and (3) the practice of many

TABLE III. *Statistics of the Development of the American Industry*

	1909	1914	1919	1924	1925
Capital invested	$173,837,000	$407,730,000	$1,802,302,862	$1,691,050,112	$1,888,028,810
Cars and lorries produced[1]	127,731	569,045	1,974,016	3,617,602	4,336,754
Value of products	$249,202,000	$632,831,000	$2,506,834,594	$3,168,588,146	$4,210,174,963
Persons engaged in mfg.	85,359	145,951	651,450	629,563	711,442[2]
Wages and salaries	$58,173,000	$139,453,000	$813,731,856	$547,215,700	$649,668,829[3]

[1] From U.S. Census. Based on statistics of complete car production gathered by National Automobile Chamber of Commerce and on the assumption that the parts and accessories business grew in same proportion. [2] 361,442 in motor-car and lorry plants, the rest in parts and accessories (exclusive of tires) plants. [3] In motor-car and lorry plants alone.

well-to-do motorists of buying a new car every second or third year and trading-in the old machine, which depressed second-hand values to a very low point.

TABLE IV. *Statistics of the American Industry for 1925*[1]

Number of passenger cars produced	3,839,902
Number of lorries	497,452
Number of open cars	1,676,171
Number of closed cars	2,163,131
Wholesale value of passenger cars	$2,523,642,558
Wholesale value of lorries	$454,262,275
Parts sold by motor-vehicle manufacturers	$308,830,130
Replacement parts and tires	$923,440,000
Total wholesale value of vehicles and parts	$4,210,174,963
Number of motor vehicles exported	536,741
Registrations of passenger cars	17,512,638
Registrations of lorries	2,441,709
Total registrations	19,954,347
Number of motor-vehicle dealers	48,555

[1] From *Facts and Figures of the Automobile Industry*, published by the National Automobile Chamber of Commerce. The production figures given apply to the U.S. and Canada combined, practically all of the producing establishments in Canada being branches of U.S. firms.

The large numbers in which particularly the lower-priced American cars were manufactured made possible very economical methods of production. Many parts that were formerly made of sand castings were made in the form of sheet metal pressings or die castings. Both these methods of production are very much more economical, if a large number of duplicate parts is required, although the initial investment for equipment, such as dies, presses, etc., is very high. In drilling the bolt holes in engine blocks, as many as one hundred holes, from top, bottom and both ends, were drilled in a single operation in a multiple spindle drill press. All the cylinder barrels of six or eight cylinder blocks were bored at the same time, and the flat surfaces on the outside of the block were finished in large milling machines, to the tables of which a large number of blocks could be strapped at the same time. Machine tools of the automatic and multiple station type were largely introduced, the latter having indexing tables making it possible to load and unload the machine at one station while work was going on at one or more other stations, so that no stops were required for reloading. All the sheet metal parts, such as fenders, aprons, etc., when finished were hung on a conveyor which automatically dipped them in tanks of japan and carried them through a baking oven, so that the only hand work in the finishing process consisted in hanging the parts on the conveyor and taking them off again.

Assembling of the car also is done on a conveyor, or moving line. The work of assembling begins with the frame, which is pulled along rails by means of the conveyor chain at the rate of 5 or 6 ft. per minute. After the axles, springs and wheels are assembled, the chassis is turned over by means of a hoist, and thenceforward is moved along on its wheels, while the rest of the parts are put on. Some of the major components, such as the engine, transmission, steering gear, etc., are previously assembled on separate lines and brought to the proper point at the side of the main assembling line by means of conveyors. Large use is made of gravity conveyors, that is, inclined planes made up of closely spaced steel rollers, which eliminate the necessity of lifting heavy parts by workmen. This is only a small selection of the methods adopted by American motor-car manufacturers which enabled them to cut down the man-hours required in the manufacture of a complete car from 1,460 in 1904 to 641 in 1914 and to 435 in 1924.

The first two of the foregoing figures are based on U.S. Census reports, while the last is based on statistics of the National Automobile Chamber of Commerce, a work-year in each case being taken equal to 2,500 work-hours. This does not take into account the fact that about one-half of the 1924 cars were of the closed type, as compared with an insignificant proportion in 1904, and all carried much more equipment. The great drop in automobile prices after the War is best illustrated by some figures gathered by the National Automobile Chamber of Commerce according to which the cost of cars at the beginning of 1925 was 71% that in 1913, whereas the cost of living was 167% and the cost of erecting frame buildings 196%.

Standardisation (*see* MACHINE TOOLS; MEASURING INSTRUMENTS).—A great help to the motor-car industry in the United States was the standardisation work of the Society of Automotive Engineers, concurrent with specialisation in the manufacture of parts. One of the first things standardised was fine-pitch screw threads. It was found that the former standard threads, such as the U.S.S., Whitworth, etc., were too coarse for motor-car work, and manufacturers began devising their own fine-thread standards; if this had continued it would have led to the use of many different pitches for screws of the same diameter, which would have been most annoying to the user. In order to obviate this, the S.A.E. screw thread was evolved, and soon came into common use. A great deal of the standardisation work was concerned with the joints or connections between parts made in different factories. Thus the mountings, on the engine, of carburettors, battery ignition units, magnetos, electric generators, starters and tire pumps were standardised, as were flywheel housings, shaft fittings, spring mountings, etc. At the end of 1924 there were more than 200 separate motor-car standards on the records of the S.A.E. Great Britain had a similar technical society, the Institution of Automobile Engineers, but motor-car standardisation work was carried on by a sub-committee of the British Engineering Standards Committee, on which both the Institution of Automobile Engineers and the Society of Motor Manufacturers and Traders were represented. There was also a technical society in Germany, the Automobil und Flugtechnische Gesellschaft, but it had not been active. During the World War engineering standardisation work was begun in Germany by a general organisation covering the whole engineering trade, and after the war motor-car standardisation was continued by the Reichsverband der Automobil-Industrie.

VI. DEPRECIATION AND INSURANCE

A private car naturally is most enjoyable during the first years of its life, while it is still fairly representative of the highest advance of the art, while its finish is unmarred, its mechanism runs smoothly and quietly and while the chances of breakdowns on the road are at a minimum. Therefore, many American motorists "trade in" their cars every second or third year for new ones. The average American automobile built prior to 1920 had a life of about 7 years, so the average depreciation was slightly less than 14%, the car having still some "junk" value at the end of its useful life. However, during the first few years the depreciation was much greater. The "used-car problem" became a great bugbear to the American industry and trade. Very few cars of the better grades were operated by their original owners until worn out, hence in the case of practically every sale of a new car an old one had to be taken in, and in their eagerness to effect a sale, dealers often made a greater allowance than the condition of the car and the state of the market warranted.

This was reflected in the high rate of "mortality" among automobile dealers, which reached 25% in 1922 and 26% in 1923 but declined to 21% in 1924. For the guidance of dealers the Chicago Automobile Trade Assn. published an index of used car values which circulated throughout the country. From this it was found that the values of a car at the end of successive years of service formed substantially a geometrical series and that the value at the end of the year on the average was only slightly more than 50% than at the beginning of the year. After the first few years the higher grade cars depreciated somewhat less rapidly than the lower grades. In the following table are given the valuations of the 1919–24 models of three makes of car—high, medium and low-priced, respectively—during the second quarter of 1925.

Used-Car Values

Year of Manufacture	1924	1923	1922	1921	1920	1919
Original cost	9,000	7,000	7,000	9,000	9,500	..
Value in May 1925	..	2,300	1,700	1,200	850	150
Original cost	965	1,195	1,395	1,795	1,595	..
Value in May 1925	385[1]	275	185	175	75	35
Original cost	510	525	525	525	795	..
Value in May 1925	255	150	90	50	25	10

[1] This exceptionally high depreciation was due to the fact that the particular model was discontinued by the manufacturer. The rate of depreciation in general also was affected by the fact that from 1920 on new car prices decreased materially.

The above table shows that the item of depreciation during the latter years of a car's service is very small.

The life of a car naturally is a matter of considerable moment to both the owner and manufacturer. The assertion has been made that there is no limit to the possible life, as all parts are interchangeable,

and any part that wears out can be replaced by a new one. There is an element of truth in this statement, and it is quite possible to obtain phenomenal mileages if that is desired above everything else. In practice users find that after a car has given a certain amount of service it is best to "scrap" it and get a new one. With increasing age the cost for repairs increases rather rapidly, the car becomes "rattly" and therefore less pleasant to operate, it usually becomes shabby in appearance, and besides, it does not possess the improvements of the newer models making for increased comfort and convenience of the occupants. When a certain state of depreciation and obsolescence has been reached, the car therefore usually goes to the "auto-wrecker," who takes it apart and sells some of the parts for repairs to other old models and the rest for scrap metal.

Since there are available in the United States fairly accurate statistics of annual production, registrations (cars in use), exports and imports, it is possible to calculate quite closely the average age of the cars which have been scrapped. Each year there are newly put into service a number of cars which is equal to the number produced in the country that year, minus the number exported, plus the number imported. If no cars were scrapped, then the total number of registrations would be increased in the course of the year by the number newly placed in service. Actually the increase in registrations will be less, and the difference between the number of cars newly placed in service in any year and the gain in registrations during that year is the number of cars scrapped during the year. The average life is then substantially equal to the interval between the one-year period during which an equal number of cars was newly placed in service and the year during which the cars went out of service. Some correction must be made for the fact that the going into service of all cars does not coincide with the beginning of the year in which they were first registered. By the use of this method it was found that the average life of all cars which were scrapped in the United States during the three-year period ending with 1923 was 6.9 years.

Car Thefts.—After the War the loss of motor-cars by theft became a serious hazard, which is partly accounted for by the fact that by that time cars had become so numerous that practically the whole of the younger generation had the opportunity to learn their operation.

There were two general forms of automobile thievery. One form, indulged in particularly by irresponsible youngsters, consisted in taking a car that was left by its owner at the curb, going for a "joy ride" and leaving it at the roadside wherever the fuel supply ran out, an accident occurred or something else intervened to compel the abandonment of the trip. The more serious form was theft of cars with a view to their sale to the public. The division of the United States into a large number of states, each with its own laws and police powers, facilitated this nefarious business, and there grew up a regular traffic in stolen cars that were driven over the border into a neighbouring state and there disposed of by unscrupulous dealers. The matter became so serious that the Federal Govt. in 1919 passed the Dyer Act, which made it illegal to transport or assist in the transportation of a stolen car from one state into another.

Another measure that hit at the root of the evil was the enactment, by several of the states, of laws requiring an abstract of the title to be filed with the authorities, as in the case of real-estate transfers. All cars were provided with locks, which acted as more or less efficient theft retardants. The ignition type, which came into use first, proved of little value, as a man skilled in electrical work and familiar with the particular car could readily make or unmake the necessary connections to render it ineffective. Locks on the transmission were more dependable, but when these were introduced it was found that owners often failed to lock them, as they were generally rather hard to get at. It was then suggested by the insurance underwriters that "concurrent" locks be fitted, acting on both the ignition switch and on the transmission, which the owner was compelled to lock if he wanted to shut down his engine, and these were coming into use in 1925. In 1924, 10,064 cars were stolen in New York City, of which 7,101 were recovered.

Insurance.—Motor-car insurance had grown to a very large business in 1925. The insurance companies wrote policies covering five principal hazards, namely, fire, theft, collision, liability for personal injury and liability for property damage, but usually several or even all of these were covered by a single policy. Reductions were made on the premium for carrying certain equipment which had been approved by the Underwriters' Laboratories. For instance, a reduction on the premium on fire insurance was granted if a portable fire extinguisher was carried on the car; on theft insurance, if the car had an approved lock and on collision insurance, if it was fitted with approved bumpers. According to *The Insurance Field*, the total premiums paid in the United States under the five principal hazards during 1924 amounted to $297,005,029, and the total losses reported were $123,292,454.

During the period when the "jitney" business was increasing rapidly and many taxi-cabs were operated by individual owners, the operators often caused serious accidents and then were unable to pay the damages awarded by the courts to the injured. Many cities and states then passed legislative measures requiring all operators of public-service vehicles to be bonded or to carry insurance. Later, attempts were made to extend this compulsory insurance plan so as to apply also to drivers of private vehicles, and in 1924 bills to that effect were introduced in the Legislature of six states, but none passed that year. Switzerland and Denmark at that time had compulsory insurance of motor-car operators. In Switzerland any applicant for a driver's licence was compelled to take out first a liability insurance policy for a minimum indemnity of 30,000 fr. to a single person and 100,000 fr. to several persons. For motor-cycles the amount was 20,000 francs. Under the Swiss law the driver and not the owner of the vehicle involved was held responsible for the damage done. However, the burden of proving intention, negligence or imprudence rested with the claimant.

An attempt was made while the bill was under discussion to make motorists directly responsible for all damage done by their cars, the same as in the case of the railways, but this was strongly and successfully opposed by the motoring interests. Tourists when entering Switzerland were compelled to arrange for insurance for the duration of their stay in the country. The Danish law went into effect in 1918 and was amended in 1921. Under it, motorists were compelled to take out a policy for 20,000 crowns and motor-cyclists for 10,000 crowns. The objection was raised to the compulsory insurance scheme that it would have the effect of making drivers careless. Insurance companies opposed it because most of the plans involved the feature of state insurance.

VII. ACCIDENTS AND LEGISLATION

A rather unpleasant chapter in motor-car history is that of accidents. With the constantly growing number of cars on the road and the increasing speed of their operation, it is natural that accidents should have increased, but after the World War the figures became appalling. Many measures were taken to reduce the hazards, and a certain degree of success was achieved, in that the number of accidents in proportion to the number of cars in service decreased, but still the total number increased from year to year. At first a large proportion of the accidents occurred in the cities, as most of the cars were then owned there, and many factors, such as congestion of traffic, lack of playgrounds for children, etc., contributed to the hazards. Means of traffic regulation were introduced which not only tended to prevent accidents but greatly speeded up traffic (*see* TRAFFIC PROBLEMS).

In all of the large cities in 1925 a large proportion of the police force was detailed to traffic duty. They were stationed at all main street intersections, and let the traffic pass alternately in the two directions. Safety zones and isles of safety were marked off by lines painted on the pavement, or by other means, where people could wait safely for tramcars or take refuge in crossing wide streets. Some of the narrower streets were reserved for traffic in one direction only. In the smaller places, where the expense rendered it impractical to station traffic policemen at important crossings, beacon lights were placed on the ground at the centre of the crossing, some of them so arranged that they became extinguished automatically in broad daylight, and later automatic traffic signals were installed which, by showing red and green lights alternately in the same direction and simultaneously in the two directions at right angles to each other, served the same function as the traffic officer and were sometimes referred to as silent policemen. A large number of (usually very serious) accidents occurred at railway crossings, and relief from this hazard was sought by the elimination of level crossings and by providing guards at points of intense traffic and more effective warning signals at others.

Notwithstanding all these safety measures and the institution of campaigns of education the number of automobile fatalities in the United States increased from 9,097 in 1917 to 12,370 in 1921 and to 17,345 in 1924. These figures are of the same order as the American losses in the World War, and the comparison was made use of to bring home the seriousness of the situation. Fatalities per 100,000 cars in service in the three years mentioned were 178, 118 and 98 respectively. Automobile grade-crossing fatalities increased from 1,791 in 1920 to 2,149 in 1924, or at a lower rate than automobile fatalities generally. In European countries there was a similar increase in accidents, although, on account of the lesser density of motor traffic there, the figures are less striking. In Paris, for instance, the number of street accidents increased from 70,715 in 1922 to

126,867 in 1924. An analysis of the causes of accidents involving motor-cars was made by the Motor Vehicle Dept. of the State of Connecticut in 1923. Out of a total of 15,170 accidents, 70·5% were the fault of the operator, 22·8% the fault of other persons, 4% were due to defective equipment and 2·7% to all other causes combined. Of 834 accidents in Connecticut in Jan. and Feb. 1924, for which the operators were held responsible, 36·8% were due to failure to give right of way (disregard of the rules of the road); 13·7% to skidding; 13·5% to inattention; 6·7% to failure to signal; 6% to careless backing; 5·4% to excessive speed for the conditions; 5·3% to allowing too little headway; 3·1% to driving on wrong side of road; 2·4% to confusion; 1·8% to cutting in; 1·7% to inexperience; 1·1% to intoxication; 1% to cutting corners; 1.5% miscellaneous. Dr. C. H. Dickinson of the Bureau of Standards suggested as one rule of safe driving that the speed should never be so high that the car cannot be stopped within the assured clear course ahead.

Legal History.—During the first decade of the 20th century the development of the motor-car industry in the United States was hampered to a certain extent by attempts to enforce recognition of an alleged basic patent on vehicles propelled by liquid hydrocarbon engines, which was issued to George B. Selden, of Rochester, N.Y., in 1895, after having been in the Patent Office since 1877, but in Sept. 1911 the U.S. Circuit Court of Appeals for the Second Circuit held that, although the patent was valid, it was not infringed by the defendant, the Ford Motor Co., which implied that it was not being infringed by any of the car manufacturers in production at that time. The Assn. of Licensed Automobile Manufacturers (A.L.A.M.), consisting of the manufacturers who had recognised the patent prior to its defeat in court, then reorganised as the National Automobile Chamber of Commerce, which came to be recognised as representative of the entire automobile industry, although the Ford Motor Co., the largest manufacturing concern, never joined it. All the national motor-car shows in the United States from that time till 1925 were held under its auspices, and it looked after the interests of the industry also in other ways, particularly through its legal, traffic and patent departments. Patent litigation in the industry was practically entirely prevented by a cross-licensing agreement involving all members of the chamber. Similar organisations in other countries are:—

Great Britain.—Society of Motor Manufacturers and Traders.
France.—Chambre Syndicale de l'Automobile et des Industries qui s'y rattachent.
Belgium.—Chambre syndicale de l'Automobile.
Germany.—Reichsverband der Automobil-Industrie.

VIII. MOTOR RACING AND SHOWS

During the years immediately preceding the World War France had the greatest export business in motor-cars, built up by consistent technical development and skilful sales propaganda, chiefly in the form of road-racing. A series of international races held during the first decade of the century, known as the Gordon Bennett Cup Races, came to an end because the French objected to the stipulation in the Deed of Gift of the cup that in the race each country should be represented by a team of three cars, which gave a country with a small industry practically the same chance of winning as a country with a large industry.

In 1911 began a new series of races for the *Grand Prix* of the Automobile Club of France in which each manufacturer was allowed to enter up to three cars, and there was no limit to the number of manufacturers of any one nation. In fact, the race was not on the basis of national team against national team, but on that of manufacturer against manufacturer. This race was held four years in succession (1911–4) and was revived in 1921. Owing to the continued improvement in engines and the increased speeds made possible thereby, it was repeatedly necessary to reduce the limit on the piston displacement of competing cars. Originally the displacement was limited to that of a four-cylinder engine of 110-mm. bore and 200-mm. stroke (7·6 litres), but in 1921 the limit was 3 litres, in 1923 it was reduced to 2 litres and in 1925 to 1·5 litres (for the 1926 season).

In England and Scotland racing on the public roads was prohibited, and the only road races in the British Is. were held in the I. of Man. In the United States a number of important races were held in the East during the early years of the automobile movement, but owing to frequent fatalities a strong public sentiment grew up against them, and race promoters were compelled to shift the scene of their activities first to the South and then to the Middle West and Far West.

Between 1910 and 1914 a number of racing-tracks with high banking, most of them 2½ m. in circumference, were built in the United States after the model of the Brooklands track in England. The first and most successful of these was the Indianapolis Speedway. It was at first attempted to hold races on these tracks at frequent intervals, but they soon began to pall on the public. Later the plan of a single annual race was adopted, European contestants were secured, and large cash prizes were offered to the winners, and from that time the Indianapolis races have always had an enormous attendance. It is worthy of note, however, that practically none of the large manufacturers of America entered cars in the later races. In earlier years competition in races was regarded as a form of sales propaganda, and the expenses were charged to advertising, but the public gradually came to realise that to win a race at close to 100 m.p.h. required an entirely different car from that needed by the average family, and that it would not be safe to base conclusions regarding the quality of a company's stock cars on the performance of its special racing machines. Track-racing then became a form of entertainment, expenses being met out of gate-money. The Indianapolis Speedway 500-m. race held on Decoration Day, 1925, was won by Peter DePaolo on a 2-litre (122 cu. in.) eight-cylinder-in-line Duesenberg racing car with supercharger, at an average speed of 101·13 miles per hour.

Shows.—An important influence on the rapid development of the motor-vehicle industry must be ascribed to the motor-car shows held annually (except for interruptions due to the World War) in such centres as Paris, London, Brussels, New York and Chicago, under the auspices and control of the motor-car manufacturers' associations of the respective countries. The Paris show, the oldest and for a long time the largest as regards number of exhibitors, was resumed after the War, 1919. But in 1920 the show was suspended, because at the time when preparations would have been made trade conditions seemed to make it unnecessary. It was again suspended in 1925. London shows were held at Olympia. Owing to the fact that Great Britain was one of the greatest markets for motor-cars, importing more than any other country in Europe, the Olympia show always had a strong international flavour. There was a special show for commercial cars at Olympia in 1923, shortly after the passenger-car show. In the United States also, truck shows had been held separately for several years. National motor-car manufacturers' associations previous to the World War had an international federation with headquarters in Paris. In 1920 the original international federation was dissolved, and a new allied federation took its place.

The Automobile Association.—A unique organisation of motorists, the Automobile Association, exists in Great Britain, and in 1925 had over 300,000 members. When the association was organised in 1905, motorists were using their vehicles under considerable difficulties, and the police authorities of practically every county in the United Kingdom made a special point of seeing that the speed limit of 20 m.p.h. was strictly adhered to. Among the services which this organisation rendered to members were the following: free assistance by its patrols, which were found on 20,000 m. of the main highways of the country; free legal defence in proceedings under the Motor-Car Act and the Roads Act in any court of summary jurisdiction in the United Kingdom; free use of roadside telephone boxes at any hour of the day or night; free legal advice on any matter arising directly out of the use of motor-cars or motor-cycles; free advice and assistance by the home and foreign touring departments of the association; access to roadside motor fuel supply stations; engineering advice on matters appertaining to the purchase, repair and maintenance of cars and motor-cycles; officially appointed agents and repairers, as well as hotels, in practically every town in Great Britain, where the facilities and accommodation offered

had been inspected and approved by the association. The uniformed patrols of the A.A., which saluted every passing member (but failed to salute if they wished to give a warning or communicate with the member for any reason) are a familiar sight on British highways. The association also had an industrial vehicle section which, among other services, endeavoured to secure return loads for motor-lorries making deliveries to remote points.

IX. MOTOR TAXATION

In nearly all countries motor vehicles are subject to an annual tax based upon the rated horse-power of the engine. Great Britain did not impose such a tax until Jan. 1 1921. The rate was then £1 per horse-power, determined by the following equation:—

$$\text{H.P.} = \frac{Nb^2}{2{\cdot}5}$$

where N is the number of cylinders and b the bore in inches. The same formula, known in Great Britain as the Royal Automobile Club formula, was used in most states of the United States, where it was known as the A.L.A.M. formula. Since the War the U.S. Govt. levied an excise tax on all cars turned out by the manufacturers as well as on repair parts and tires sold. This tax in 1924 netted the Govt. $101,123,621·75 from passenger cars, $10,335,369·14 from commercial vehicles and $27,742,764·12 from parts, tires and accessories. Vehicles for hire also were subject to a Federal tax, which netted $2,013,839·00, making the total Federal receipts from motor vehicles in 1925, $141,215,594·01. Registration fees, including drivers' licence fees, which were collected by the states, totalled $225,492,252·00 (an average of $12·82 per car). Some of the states collected a tax on petrol.

It was estimated by the U.S. Bureau of Public Roads that personal property taxes on motor vehicles amounted to $90,000,000, and by the National Automobile Chamber of Commerce that municipal taxes of $15,000,000 were levied, making the total taxes derived from motor vehicles by the Federal, State and Municipal governments in 1925, $551,442,336·01. Annual taxes are much higher in Great Britain. For a total of 1,393,000 licences current on March 31 1925, aggregate fees of £13,437,000 were paid, or an average of a little less than £10. This average figure, however, is greatly influenced by the large number of lightly taxed motor-cycles licensed. The average fees paid on public-service vehicles amounted to £31 9s.; for commercial goods vehicles, £21 1s. 6d.; for motor-cars taxed on a horse-power basis, £15 8s., and for motor-cycles, £2 13s. 6d. Several other classes figure in the tax records, including motor-ploughs, and motor-tractors, but they are taxed rather lightly.

X. WORLD COMMERCE

During the early part of the World War the American motor industry furnished large numbers of motor-lorries to the British, French and Russian governments, as reflected by the export returns, which showed an increase in the number of trucks exported from 784 in 1914 to 21,265 in 1916. At the same time the foreign demand for American passenger cars increased greatly, because the belligerent European countries could not make deliveries. In 1918, when the United States threw its full strength into the War, motor-car exports suffered a material decline, but they jumped ahead again immediately after the Armistice, an increase of 79% being shown in 1919. That year the exports of passenger cars, lorries and parts together exceeded $100,000,000 in value, yet the passenger cars exported were hardly 4% of the total production, while the exports of commercial vehicles amounted to 4·9%.

After the War the tide of international motor-car commerce showed great fluctuations. As soon as shipping connections became re-established there was a heavy demand, particularly from the neutral countries of northern Europe. In 1919 only the United States was in a position to export large numbers of vehicles, because it took the motor-car industries of the European belligerents a long time to get back to a peace basis. After a short time, however, the low rates of continental exchange and embargoes on motor-car imports in several countries, including Great Britain, France, Germany, Italy, Denmark and Norway, cut down the exports from the United States. Even when the embargoes were lifted, imports were restricted by high customs duties, as, for instance, 70% in the case of France. The German embargo was lifted on Oct. 1 1925 but imports of cars were subject to an import duty, which, starting with rather high rates, was to be reduced every six months until in 1928 it was to be stabilised at substantially the pre-war rates.

For a number of years previous to 1925 Germany had special agreements with Austria and Italy whereby she allowed a certain number of motor-cars to be imported from these countries in return for permission to export to them German motor-car parts, such as magnetos and ball-bearings. Imports of cars from other countries were made possible by special permits, but permits for only four cars per make per month were issued. Imports into France were rendered practically impossible by the high duty, while Great Britain continued to absorb large numbers of foreign cars even during the period the McKenna duties were in force. The removal of these duties by the Labour Govt. subjected the British industry to a severe strain, especially on account of competition from the United States, but it was observed by German commentators in 1925, who then feared a similar ordeal for their home industry, in view of the contemplated lifting of the embargo, that the British industry had successfully met this competition.

TABLE V. *U.S. Motor-car Exports (including Passenger Cars, Lorries and Parts except Motor-car Engines and Tires)*

Exported to	1924	1919	1914
Belgium[1]	9,472,635	364,004	160,639
Denmark[1]	8,930,388	4,443,302	184,951
France	4,980,144	22,243,042	1,103,481
Germany	2,927,029	..	1,272,600
Great Britain	10,305,752	9,760,430	7,159,074
Italy	2,245,575	215,417	293,275
Norway	545,525	2,102,757	124,083
Russia	167,826	8,292	917,859
Spain	6,322,196	1,426,650	71,024
Sweden	3,432,040	689,998	260,228
Canada[1]	27,824,520	22,062,779	9,583,655
Argentina	17,842,193	4,492,522	1,121,474
Brazil	10,204,507	1,033,831	370,043
Chile	2,313,463	2,606,047	192,342
British India	2,363,963	543,393	439,968
Dutch East Indies	1,399,961	4,498,397	238,322
Japan	5,710,461	6,416,928	137,522
Australia	33,594,710	5,358,336	855,637
New Zealand	5,406,913	2,589,166	1,089,951
Br. So. Africa	7,627,583	2,568,790	1,506,668
Other countries	41,765,611	20,272,577	6,215,990
Totals	205,382,995	113,696,658	33,298,806

[1] Exports to these countries in 1924 consisted largely of parts which were there assembled into cars of which a considerable proportion were exported to neighbouring or politically allied countries.

TABLE VI. *British Motor-vehicle Imports*

	1925	1924	1920	1915	1910
	£	£	£	£	£
Cars	6,322,121	3,028,427	10,490,012	3,128,229	1,440,586

Totals	9,421,739	6,513,566	8,390,742	1,874,277	2,606,403

[1] Exclusive of tires.

The number of motor-cars, lorries, chassis and parts imported into Great Britain in 1925 was 50,339; the number exported 29,051.

According to a report made by the Society of Motor Manufacturers and Traders to the Board of Trade early in 1926, about 1,000 concerns were then engaged in the manufacture and the wholesale distribution of motor-cars in Great Britain, and the amount of capital invested in the British industry was about £50,000,000. The number of retailers was placed at 12,000.

XI. COMMERCIAL MOTOR VEHICLES

Up to 1920 motor-omnibuses were developed chiefly for city transport, and the two largest operating companies at that time were the London General Omnibus Co. and the corresponding

Paris corporation, The Société des Transports en Commun, the former operating a fleet of 2,500 vehicles. Omnibuses for city use are generally of the double-deck type, designed to carry a maximum number of passengers at a moderate speed but to have good accelerating power. In 1926 the London General Omnibus Company, in alliance with the Associated Equipment Company, placed on the streets a new series (200 vehicles) which was fitted into a covered top and was therefore specially designed and sprung to meet the police regulations. This type was 13 ft. 10¾ in. high, 25 ft. long, 7 ft. wide and had a wheel base of 15 ft. 6 in. The vehicles are licensed to carry 50 passengers, 24 inside and 26 outside. In the United States the Yellow Coach Mfg. Co. turned out a double-deck 'bus for 67 passengers, which had a wheelbase of 200 in. and a tread of 73½ in., a chassis weight of 7,313 lb. and carried a four-cylinder 4 by 6-in. engine. Omnibuses with petrol engines and electric drive came into extensive use in the United States in 1925. Two hundred of these were placed in service by the street railway management of Philadelphia, and smaller numbers by operating concerns in other cities.

'Buses and lorries with electric drive without the use of a storage battery had long been made by Tilling-Stevens, Ltd., of Maidstone, England, and in the United States the General Electric Co. had been working on the problem. One disadvantage of the earlier designs was that, owing to the slowness of an electric generator to " pick up," that is, to attain its full voltage, if the throttle of the engine were opened quickly the engine would be without appreciable load for an instant and would race, which would result in vibration very unpleasant to the passengers. This was overcome by providing a separate exciter for the generator, the field of the exciter being supplied with battery current. An advantage of the electric drive in urban omnibus service, where frequent starts and stops must be made, is that acceleration is much smoother, there being no interruption due to gear-shifting. The strain on the driver is much less, as practically all speed control is effected by means of the throttle. Shocks to the mechanism due to " grabbing " of the clutch when shifting gears are avoided, and it was also claimed that better schedule time could be made than with a similar omnibus with mechanical drive.

Development in the United States; New Types.—A great extension took place in rural omnibus services between 1920 and 1925. In the United States this was strongly influenced by the rapid extension of the network of improved roads, which made it possible to operate the vehicles at lower cost, but there were parallel developments in many other parts of the world. The earlier omnibuses generally were shod with solid rubber tires, had stiff chassis springs designed to withstand the shocks sustained on rough roads and generally had a high centre of gravity, which features combined to make riding in them rather uncomfortable. About 1923 a new type of omnibus, referred to as a safety coach, made its appearance. It was mounted on pneumatic tires, had a wide tread and a very low-hung chassis, sometimes was equipped with air brakes and had sufficient power for speeds up to 60 m.p.h. on smooth, level roads. Some of these vehicles were as luxuriously equipped as, and afforded all the comfort of, the finest private closed cars, while others, for a different class of service, were of less pretentious construction.

One development in the omnibus field that came to the front in 1924 was the six-wheeler. These 'buses had double axle rear trucks and were driven and " braked " on the four wheels. Distribution of the total weight on six wheels facilitated the use of pneumatic tires. With the increase in size and speed of the 'buses, increased power was required, and whereas most of the earlier omnibuses in rural service had four-cylinder engines (they were actually, for the most part, adapted lorry chassis), in 1925 more than one-half of the omnibus models offered by American manufacturers had six-cylinder engines, which offered advantages also from the point of view of reduced vibration. The frame height of the loaded omnibus from the ground generally varied between 22 and 26 in., and most of the larger and faster vehicles were equipped with four-wheel brakes. Rural omnibuses were generally of the one-man type, passengers entering through a door at the front and depositing their fare in a coin box near the driver, while entering or leaving. The door was of the safety type which could be opened and closed only by means of a lever within convenient reach of the driver's seat. A mirror in front of the driver enabled him to observe the passengers without losing sight of the road ahead for more than an instant. Electric buttons at the sides of all seats enabled passengers to signal the driver when they wanted to get off, and at night the interior of the vehicle was usually brilliantly lighted. In the ordinary low-fare 'buses the seats were often of the plain, cane-covered type, while those for a more exclusive service generally had deeply upholstered or even air-cushioned luxurious seats and sometimes revolving chairs.

In 1925 it was estimated that there were 60,000 motor-omnibuses in service in the United States, including 31,100 by independent common carriers, 3,250 by tramway companies, 20,000 by schools, 1,500 by sight-seeing and tourist undertakings, 2,900 in various lines of business (real estate, department stores, apartment houses, garages and factories), 1,000 by hotels and 250 by railway terminal companies. The motor-omnibus was responsible for important changes in the educational system. In 1924, 1,424 consolidations of schools took place, and that year some 470,000 pupils were daily carried to and from school in motor vehicles.

Lorries.—Motor-trucks must be equipped with engines able to take them fully loaded up the steepest grades which occur on regularly travelled highways. When operated in comparatively level districts they always have a surplus of power, and it was found advantageous when operating under such conditions to use one or two trailers with the truck. The advantage is greatest where the merchandise to be transported is very bulky. This plan results in considerable economy, as from two to three times as much load can be carried on one trip as with the truck alone, with little extra expense. In continental Europe there was usually a helper on each trailer to look after the load and apply the brakes, but the use of helpers greatly reduces the gain in economy, especially where wages are high, and in the United States it was not usual to employ an extra man.

It was realised that in order to make it possible to stop in an emergency the trailers as well as the truck must be braked; but the problem of braking the trailers from the truck had not been definitely solved although at least one system of air brakes and one system of automatic mechanical brakes applied through the drawbar had been worked out. Another combination for heavy merchandise transportation consisted of a road tractor, which was merely a foreshortened truck chassis, and a semi-trailer. This semi-trailer was a two-wheeled construction, the forward end of which was supported on the tractor frame by means of a swivelling fifth wheel. This end of the semi-trailer could be supported by means of jacks while loading and unloading, and the tractor did not need to stand idle while these operations were going on. A particular form of semi-trailer was the pole trailer—the length of which could be varied—used mainly for transporting lumber, pipes, steel sections, etc.

Electric and Steam Vehicles.—In 1925 electric and steam passenger vehicles formed an insignificant fraction of the whole number in use. Previous to the War the electric passenger car had considerable vogue as a ladies' car, especially in cities with comparatively level streets, like Los Angeles, Chicago, Cleveland and Buffalo in the United States, but the introduction of the electric starter, and, to a lesser extent, the demountable rim, removed the last obstacles to the use of petrol cars by women drivers, and thereafter the electric passed into the background. On the other hand, electric lorries had found a definite place in city haulage, particularly in New York, where at the beginning of 1925 3,274 such lorries were in service. Owing to the low power of their motors the depreciation of these lorries was low and the cost of transportation with them on a ton-mile basis was somewhat less than with petrol lorries, but on account of its greater independence and its materially greater speed, most users preferred the petrol lorry even for city haulage.

A new type of electric commercial vehicle, known in the United States as an industrial truck, but perhaps better described as a

floor truck or a low-wheel truck, came into extensive use, especially during the War period. These industrial trucks take the place of hand trucks on steamship piers and railway-station platforms, in factory buildings and paved yards. Petrol industrial trucks have also been developed, but as they are not admitted to steamship piers on account of the fire hazards, the electric has an undisputed field there. There was great inducement in Europe during the War, when petrol was exceedingly scarce, to develop the electric vehicle for both passenger and commercial traffic. In Germany a scheme was worked out for a system of goods transport in large cities by electric lorries with interchangeable batteries, and a few sample trucks were built, but the Armistice intervened and the scheme was dropped.

The steam vehicle also retrogressed as a factor in transportation. In 1925 the manufacture of steam passenger cars had almost entirely ceased, but considerable numbers of steam lorries were still being manufactured in England. The petrol motor had definitely gained the ascendancy over steam and electric motors, and supplies for it could be found and repairs to it had in almost every town. In the United States, for instance, there were, at the beginning of 1925, 65,674 repair shops (besides 58,206 garages), and all these repair shops were equipped to cater to owners of petrol cars, but only a few to owners of steam and electric vehicles, giving a tremendous advantage to the former.

MOTTA, GIUSEPPE (1871–), Swiss statesman, was born at Airolo Dec. 29 1871. He studied law at the universities of Fribourg and Munich and at Heidelberg and became a successful barrister, establishing an extensive practice in Ticino and the neighbouring cantons. He served on the Great Council from 1895–1911 and was a national councillor from 1899–1911. He led the Catholic Conservative party in the Ticino from 1900 to 1911 and on Dec. 14 of the latter year was elected a member of the Federal Council by the Federal Assembly. In 1915 and 1920 he was president of the Swiss Confederation. He directed the financial administration of the Confederation 1912–9, and in 1920 assumed charge of the Federal dept. of foreign affairs. Motta was chief of the Swiss delegation to the League of Nations in 1920 and presided over the fifth Assembly of the League in 1924.

MOTTL, FELIX (1856–1911), German conductor (*see* 18.931), died at Munich July 1 1911.

MOULTON OF BANK, JOHN FLETCHER MOULTON, BARON (1844–1921), British lawyer, was born at Madeley, Salop, Nov. 18 1844. Educated at Kingswood School, Bath, and St. John's College, Cambridge, he had a brilliant career, becoming senior wrangler and first Smith's prizeman in 1868. He was elected a fellow of Christ's College, and in 1874 was called to the Bar. He specialised in patent law, for which his conspicuous scientific abilities peculiarly qualified him, and rapidly acquired a large and lucrative practice. In 1885 he became a Q.C. and entered Parliament as Liberal member for the Clapham division of London. In the following year, however, he lost his seat and was out of Parliament until 1894, when he succeeded Sir Charles Russell, Q.C. (Lord Russell of Killowen), as member for South Hackney. He was unsuccessful at the general election of 1895, but in 1898 he was elected for the Launceston division of Cornwall, a seat which he retained until his appointment as a lord justice of appeal in 1906. In 1912 he was made a lord of appeal in ordinary with the title of Lord Moulton of Bank. He died suddenly in London, March 9 1921.

Owing to his combination of gifts, Moulton's position at the patent Bar was unique. He had no rival and has had no successor. As a judge his success was less pronounced, perhaps in consequence of the extreme specialism of his career as a practitioner. On the other hand, during his years on the bench, he rendered distinguished scientific service to the country. He was first chairman of the medical research committee under the National Insurance Act (1912) and during the World War he was chairman of the committee on chemical products and high explosives and director general of explosive supplies in the Ministry of Munitions. He also was chairman of the British Dyestuffs Corporation (1919).

MOUNET-SULLY, JEAN (1841–1916), French actor (*see* 18.936), died in Paris March 1 1916. His *Souvenirs d'un Tragédien* was published in 1917.

MOUNTAINEERING (*see* 18.937).—The most important event of the period 1910–25, was, of course, the assault on Mt. Everest, which is the subject of a separate article. Everest, however, did not monopolise the attention of Himalayan explorers. Useful work was accomplished by the Workmans during 1911 and 1912 in the Karakoram, by C. F. Meade in the Garhwal Himalaya and by Kellas who reached a height of 22,700 ft. on Kangchenjhau.

The American continent has witnessed a series of campaigns which for energy and success have seldom been equalled. Outstanding exploits have been the conquest of Mt. McKinley in Alaska (20,300 ft.) by Belmore Browne, A. Aten, M. La Voy in 1925 and H. C. Parker; the conquest of Mt. Logan (19,850 ft.) in 1925 and the ascent of Mt. St. Sandford, the highest peak in the Selkirks by Howard Palmer and Professor Holway with Swiss guides in 1912. In 1924 Canadian climbers registered no less than 30 important first ascents, including Mt. King Edward.

The main exploration of the New Zealand Alps was completed before 1910, but Harold Porter's two expeditions (1923 and 1925) proved that interesting pioneer work still awaits the explorer. The Caucasus have been a closed book to mountaineers since the War. A British expedition in 1914 made a number of new ascents. Norway still offers the prospect of virgin ascents. Stedtind, described by Cecil Slingsby as "probably the most natural obelisk in the world and the greatest prize in all Scandinavia" was climbed in 1910 by C. W. Rubenson and friends. Two Oxford expeditions to Spitsbergen in 1922 and 1923 accomplished some excellent work.

Alpine Climbing.—In the Alps every peak worthy of the name had been ascended by 1910, nearly all of them from various sides. But Alpine exploration is not a closed chapter, and new routes even on well-known peaks may excite as keen an interest as the conquest of peaks in unclimbed ranges. Technically, the best work done in the Alps attains a higher standard of difficulty than elsewhere. The problems which call for solution in great ranges such as the Himalaya, are the problems of exploration rather than of climbing, in the more restricted technical sense of the word. A Himalayan explorer has to organise transport, handle native porters, plan a route through unmapped country, and—in the final stages—struggle against mountain sickness, but cragsmanship and ice-craft of a high order are seldom called into play.

In the Alps, the progressive elimination of unclimbed routes, implies a rising standard of difficulty among those that still resist attack. As an example of the thoroughness of the exploration of the Alps, it is interesting to note that 16 different passes have been made across the range at the head of the Lauterbrunnen Valley on a front of less than eight English miles. The technique of rock climbing has developed more rapidly than the technique of ice-craft. The contrast between modern achievement in the period under review and the period which closed with the seventies, is far more marked in cragsmanship than in ice craft.

Alpine Ascents by Britishers.—Another change is noticeable. The earlier exploration of the Alps was, in the main, the work of Brit-

ish mountaineers with Swiss guides whose technique their employers helped to develop. Since 1910 the prizes have often fallen to continental mountaineers, though no individual climber has a longer list of successes to his credit than G. W. Young. In 1911, with Professor H. O. Jones (killed soon afterwards in the Mont Blanc range), he completed the ascent of the Brouillard ridge of Mont Blanc and achieved the first complete traverse of the great west ridge of the Grandes Jorasses and the first descent of the ridge that stoops to the Col des Hirondelles. With Professor Jones and Todhunter, he made the first ascent of the Mer de Glace face of the Grépon, and just before the War climbed the Gspaltenhorn by the terrible west ridge, perhaps his finest performance. His leading guide on all these climbs was Joseph Knubel of St. Niklaus. Among other first-class climbs by British mountaineers may be mentioned the conquest of the south face of Mont Blanc by Oliver and Courtauld with the brothers Aufdenblatten in 1923, and the first crossing of the north face of the Dent d'Hérens by a guideless party led by George Finch. The direct ascent of this face was achieved by Welzenbach and Allwein in 1925. The guideless conquest by Raeburn and Ling of the north face of the Disgrazia also deserves mention, for the British mountaineers with new climbs to their credit during this period have almost been content to divide the credit with their guides. On the other hand the Everest expeditions were guideless, and some of the work done on the American continent by men of the Anglo-Saxon race has been guideless.

Among other fine Alpine climbs of this period may be mentioned the north Arête of Piz Badile by A. Zurchner, led by the guide Walter Risch, perhaps technically as exposed and difficult a climb as had yet been done. The ascent of the north face of the Lauterbrunnen Breithorn by Chevet and Richardet, and the variation route taken by Lauper and Liniger up the north face of the Mönch, rank among the great mountaineering exploits, involving as they did, difficult work both on rock and ice. Richardet, Lauper and Chervet were members of the Akademisher Alpen Club, Berne. The students of the Berne and Zürich universities have long been known for their mountaineering exploits. One of the last classic problems of the Oberland, the ascent of the Mittellegi ridge of the Eiger, was also solved during this period by a Japanese climber, Yuko Maki, led by the great Grindelwald guide F. Amatter. Artificial aids were employed for this climb.

French Guideless Climbing.—A great feature of post-War mountaineering has been the revival of French guideless climbing. Before the War, French climbers of the type of Fontaine were few. Since the War the "Groupe Haute Montagne" of the French Alpine Club—a guideless group—have to their credit a consistent record of brilliant work, combining the spirit of adventure with the same British tradition. The "Groupe" has been engaged in cairning the last untouched pinnacles of Mont Blanc, and among its most brilliant achievements may be mentioned the ascent of the north face of the Aiguille du Plan by Lagarde, de Lepiney and de Segogne in 1924.

German Mountaineering.—In the Dolomites and the Kaiser Gebirge German and Austrian climbers have done some very remarkable climbs, but their successes have been paid for by an increasing death roll. There is a grave tendency among German climbers to take chances, to risk bad weather and impromptu bivouacs. Their exceptionally heavy death roll is caused by the fact that these young climbers, fired by a spirit of emulation, often forget the penalty for too risky procedure. British climbers, have proceeded with equal skill but with greater circumspection, and if, in the Alps at any rate, they have fewer new ascents to their credit since the War, they have avoided the accidents which have been so common among German and Austrian climbers. The same may be said of rock climbing. There is nothing to choose in severity between the various climbs achieved by the Germans and Austrians and the new routes which have been exploited in Cumberland, but comparatively few lives have been lost on our British hills.

Several of the British climbing clubs have shown great activity since the War. Mention must be made of the imaginative enterprise of the Fell and Rock Climbing Club in purchasing for the nation the summit of Great Gable as a war memorial for those members of the Club who fell in action. Rubber soled shoes have given to the cragsman greater security and made it possible to accomplish more climbs than could ever have been achieved in the nailed boot epoch. During this period, the conquest of the Alps by ski-runners has been practically completed. Scarcely any peak of importance has not been ascended either partially or entirely on ski. The best period for mountaineering on ski is undoubtedly the late spring. Summer ski-ing is growing in popularity and provides mountaineers with the opportunity of making ascents during prolonged periods of snowy weather.

The Canadian Alps.—Exploration of the Canadian Alps has been very active, aided by the Alpine Club of Canada and its very energetic director, Mr. A. O. Wheeler, and the provision of Swiss guides by the Canadian Pacific Railway and later by the Canadian National Railway.

The following are the principal ascents:—

1913. First ascent of Mt. Robson culminating summit in the Canadian Alps (12,972 ft.) by A. H. MacCarthy and W. W. Foster with the Austrian guide Conrad Kain.

1915. First ascent of Mt. Edith Cavell (11,033 ft.) by Professor Holway and Dr. A. J. Gilmour.

First ascent of Mt. Louis (8,800 ft.) the most difficult rock climb in the Canadian Alps by A. H. MacCarthy with Conrad Kain.

1919. First ascent of Mt. King George (11,226 ft.) by V. A. Fynn with R. Aemmer (guide).

First ascent of Mt. Douglas (11,174 ft.), Mt. Joffre (11,316 ft.) by J. W. A. Hickson with E. Fenz, Jr. (guide).

1920. First ascent of Mt. Ferenitz (10,573 ft.) by A. Howard Palmer and Allen Carpe.

1922. First ascent of Mt. Queen Mary (10,600 ft.) and Mt. Birdwood (10,160 ft.) by F. M. Waterman and C. F. Hogeboorn with R. Aemmer (guide).

First ascent of Mt. Apex (10,625 ft.) by Allen Carpe and H. G. Hall.

First ascent of Mt. Barnard (10,780 ft.), Mt. Trutch (10,690 ft.), Nanga Parbat (10,780 ft.) and Gilgit (10,300 ft.) by Howard Palmer and J. Monroe Thorington with E. Fenz, Jr. (guide).

1923. First ascent of Mt. Saskatchewan (10,964 ft.) and North Twin (12,085 ft.) by J. Monroe Thorington and W. S. Ladd with Conrad Kain (guide).

First ascent of Mt. Clemenceau (12,000 ft.) by De Villiers-Schwab's Guideless party.

First ascent of Mts. Brazeau (11,250 ft.), Unwin (10,550 ft.) and Henry MacLeod (10,600 ft.) by Howard Palmer, Allen Carpe and W. D. Harris.

First ascent of Mt. Spring-Rice (10,745 ft.) by J. W. A. Hickson with E. Fenz (guide) and of Mt. Rhondda (10,625 ft.) by the same and A. Geoffrion.

1924. Exploration in the Cariboo group and ascent of eight new peaks ranging from 10,000 to 11,750 ft. by Allen Carpe and R. Chambertin with W. D. Harris and A. L. Withers of Jasper.

First ascent of South Twin (11,675 ft.), Mt. Outram (10,670 ft.) and two other unnamed peaks by W. O. and F. V. F. Field with E. Fenz, Jr. and Jos. Biner (guides).

First ascent of Mts. Oates (10,200 ft.), Kain (10,000 ft.), Hooker (10,782 ft.) and Simmen Peak (10,899 ft.) by J. Monroe Thorington, M. Strumia, A. Ostheimer with Conrad Kain (guide).

First ascent of Mt. Erebus (10,234 ft.) and two other unnamed peaks by L. Coolidge, G. Higginson and J. Johnson.

First ascent of the often attempted difficult Mt. Geikie (10,854 ft.) by the famous Alpine veteran V. A. Fynn, C. G. Water and M. D. Geddes and of Mt. Barbican (10,100 ft.) by the same party.

First ascent of King Edward (11,400 ft.) by H. Palmer and J. W. A. Hickson with Conrad Kain.

1925. First ascent of Mt. Logan (19,850 ft.) by a joint party of Canadian and American mountaineers led by A. H. MacCarthy.

First ascent of Mt. Alberta (11,784 ft.) by Yuko Maki of Tokyo and five other Japanese with H. Fuhrer and H. Kohler, and Mt. Woolley (11,170 ft.) by the same party.

There are still several unclimbed peaks in the Selkirk Range. The following ascents are notable:—

1910. First ascent of Grand Mountain (10,832 ft.) by E. W. D. Holway and Howard Palmer.

1911. First ascent of Mt. Austeritz (10,960 ft.) and Mt. Holway (10,000 ft.) by the same.

1912. First ascent of Mt. Sir Sandford (11,590 ft.) by the same with E. Fenz, Jr. and R. Aemmer (guides) and of Mt. Adamant (10,980 ft.) by the same.

1913. First ascent of Mts. Beaver (10,644 ft.) and Duncan (10,548 ft.) by E. W. D. Holway with E. Fenz and Ch. Häsler (guides).

1917. First ascent of Mt. Moloch (10,198 ft.) by J. W. A. Hickson with E. Fenz, Jr. (guide).
1924. First ascent of Mt. Inconoclast (10,646 ft.) by Dr. Cora J. Best's party with Ch. Häsler (guide).

The Southern group or Purcell range has been much visited since 1910.

1910. First ascent of Mt. Nelson (10,772 ft.) by C. D. Ellis.
1911. First ascent of Mt. Gleason (10,550 ft.) and Mt. Monica (10,060 ft.) by C. D. Ellis and E. W. Harnden.
1913. First ascent of Mt. Sir Charles (10,830 ft.) by E. W. Harnden and party.
1914. First ascent of Mt. Farnham (11,075 ft.), Farnham Towe (10,850 ft.) by Mr. and Mrs. A. H. MacCarthy with Conrad Kain (guide).
First ascent of Delphine Peak (10,975 ft.) by A. A. McCoubrey with E. Fenz, Jr. (guide).
First ascent of Mt. Bruce (11,090 ft.) by E. W. Harnden and party.
1915. First ascent of Mt. Ethelbert (10,450 ft.), Jumbo Peak (11,125 ft.), Commander (10,950 ft.), St. Peter (10,750 ft.), Spearhead (10,500 ft.) and Peacock (10,525 ft.) by Dr. and Mrs. W. W. Stone, the MacCarthys, H. O. Frind with Conrad Kain (guide).
1916. First ascent of Howson Spires (10,900 ft.), Bugaboo Spires (10,250 ft.) by the MacCarthys, Frind with Kain.
1924. First ascent of three peaks of over 10,000 ft. at the head of Hamill Creek by the McCoubreys with E. Fenz, Jr. (guide).
1925. First ascent of Mt. Coppercrown (10,218 ft.) by A. A. McCoubrey with E. Fenz, Jr. (guide).

Generally speaking no mountain in the Canadian Alps approaches in technical difficulty a first-rate expedition in Europe. There is less risk of avalanches and the glaciers are much less complicated—on the other hand long distances have to be traversed, while the arranging of transport and camps is a big and expensive business. There is still much exploration to be done.

Useful work is being done by the Associated Mountain Clubs of America in exploring the less accessible regions, opening trails therein and securing protective legislation for them.

BIBLIOGRAPHY.—The *Alpine Journal* now (1926) in its 69th year continues to chronicle the mountaineering work of the world. The leading technical book is G. W. Young's *Mountain Craft* (1920). Books on special topics are: Himalayas: H.R.H. Prince Luigi Amedeo, Duke of the Abruzzi, *Karakoram and the Western Himalaya.* (1909); Hon. C. G. Bruce, *Twenty Years in the Himalayas* (1910) and *Kulu and Lahoul* (1914); Dr. W. H. and Mrs. F. B. Workman, *Two Summers in the Ice-Wilds of Karakoram* (1917); Filippo de Filippi, *Storia della Spedizione Scientifica Italiana nel Himalaia Caracorum* (Bologna, 1924). *See* also EVEREST. The Alps: Sir Claud Schuster, *Peaks and Pleasant Pastures* (1911); Prof. T. G. Bonney, *The Building of the Alps* (1912); Rev. W. A. B. Coolidge, *Alpine Studies* (1912); A. Steinitzer, *Der Alpinismus in Bildern* (1913); Guido Rey, *Peaks and Precipices* (1914); Walter Larden, *Recollections of an Old Mountaineer* (1919); Sir Martin Conway, *Mountain Memories* (1920); F. F. Tuckett, *A Pioneer in the High Alps* (1920); Douglas W. Freshfield, *Life of H. B. de Saussure* (1920) and *Below the Snow Line* (1923); G. I. Finch, *The Making of a Mountaineer* (1924); Arnold Lunn, *The Mountains of Youth* (1925); W. Lehner, *Die Eroberung der Alpen.* Canada: Belmore Browne, *The Conquest of Mt. McKinley* (1913); Howard Palmer, *Mountaineering and Exploration in the Selkirks* (1914); Leroy Jeffers, *The Call of the Mountains* (1923); J. M. Thorington, *The Glittering Mountains of Canada*; Howard Palmer and J. M. Thorington, *A Climber's Guide to the Rocky Mountains of Canada.* Other Ranges: Malcolm Ross, *A Climber in New Zealand* (1914); Rev. Walter Weston, *The Playground of the Far East* (1918); R. C. Carr and G. H. Lister, *Mountains of Snowdonia* (1925). Mountaineering on Ski: F. F. Reget, *Ski Runs in the High Alps* (1913); Arnold Lunn, *Alpine Ski-ing* (1921); Marcel Kurz, *Alpinisme Hivernal*; The British Ski Year Book (1920, etc.). (A. L.*)

MOUNTAIN WARFARE.—The difficulties attending the prosecution of a campaign in mountains arise primarily from the physical features of the theatre of operations; and secondly, in a marked degree, from the effect those features have in moulding the character of the inhabitants.

Lack of Communications.—A mountainous district is, as a rule, undeveloped; and the means of communications, where any exist, are indifferent or bad. An invader is tied to certain existing roads or tracks as the only method of advance, and has little scope for effecting surprise by means of alternative routes. The observation which the defender can obtain from the hill tops is as good as, and in some ways better than, can be obtained by the invader from aeroplanes. As a result, the invader's intentions can be grasped almost from the start, and the uncertainty common to war in normal theatres is largely discounted. The country is usually barren, and all supplies and stores for the invading force have to be carried into the country. Since communications usually consist of mere tracks, or of some boulder-strewn dry river bed, "pack" is the only possible means of transport. Consequently the invading commander is burdened with the guarding of long lines of slow-moving pack animals, and, owing to the fact that they have to convey their own and their drivers' food, they are able only to carry a relatively small useful load.

The climatic conditions in mountains tend to extremes of heat and cold. Changes in weather conditions are also sudden. The melting of snows or the bursting of a thunderstorm in the mountains may mean the flooding of the valley forming the route of advance, and the washing away of the line of communications "road," which has often been cut out with great labour.

Characteristics of the Inhabitants.—The nature of their surroundings reacts, as elsewhere, on the characteristics of the inhabitants. Their life consists of a struggle with nature. The ease and luxury of the plains is absent. They live scattered in small hamlets close to such patches of ground as will yield to cultivation. Industries are based on the village system, and the local weavers, potters, carpenters and so on supply the needs of the small community. There is no centralised life as in the plains. The inhabitants of a given area (probably emanating from a common stock) usually own a tribal allegiance to each other, but are often again sharply divided into subtribes, the boundaries of which are the valleys which they inhabit. Life is hard, and the only physically fit survive early childhood.

As a result the characteristics of mountaineers are exceptionally sound physique, bravery, great powers of endurance and ability to thrive on the bare necessities of life. They are, moreover, usually intensely patriotic (for it is a curious and almost universal fact that the wilder a man's country the more attached he is to it). Finally, they fight in mountains in their own element, on ground to which they are accustomed, and which confers on them a mobility twice as great as that of the invading plainsmen.

The above are valuable military attributes. But they are to some extent offset by others. The highly individualistic life in mountains, whilst leading to an admirable independence, also leads to a lack of centralised purpose and interest. Whilst patriotism for the clan is great, patriotism for the sub-tribe is sometimes greater. There is consequently a tendency toward absence of cohesive effort if the operations be going adversely. This lack of cohesion renders them peculiarly averse to night operations, the success of which against mountaineers is noteworthy throughout history, though it must be added only when most carefully organised and prepared. Nevertheless, mountaineers have always been difficult opponents to overcome.

Operations of Two Kinds.—The consideration of operations in a mountain theatre falls naturally under two heads. First are operations in an area such as the Austro-Italian frontier. There, though the mountains exist, the area has been considerably opened up. Communications are relatively good; heavy stores can be brought up. The forces on both sides are possessed of all the appliances of war. Better theatres for operations exist on the flanks of the mountains, and it is there that the real struggle will be fought out. Neither attacker nor defender is in reality a true mountain race, for national armies are taking part. As a result, the operations tend more and more to take the colour of normal operations in the plains, modified, no doubt, but lacking most of the characteristics of campaigns against true mountaineers. Second are operations in an undeveloped mountain theatre against semi-civilised inhabitants. It is in such a case that the true attributes of mountain fighting are best brought out. In describing them the theatre of the North West Frontier of India is taken as an instance.

Frontier Warfare in India.—The inhabitants of this area possess all the characteristics noted above. As regards supply during operations, they normally carry seven to 10 days' food on them, and consequently are untroubled by anxiety about their line of communication. They are armed only with rifles and knives. But the rifles are modern for the most part; and it is for consid-

eration whether the power of mobility conferred by such an armament and supply system does not largely compensate for the absence of artillery and other arms. A commander entrusted with the subjugation of a frontier tribe has a difficult task before him. It may be possible to overawe the tribe by air action alone. But targets for aerial attack are limited in such a form of society, and if the opposition of the tribe be determined, air action alone, will seldom suffice; an advance over the ground will, as a rule, be necessary.

Planning the Campaign.—The first difficulty is to select the objective. It can be said at once that the true objective is to bring the enemy to battle. But how is it to be done? Owing to absence of lines of communication, the enemy's strategical mobility is always superior. Owing to his upbringing, his tactical mobility is also superior, except against the best hill troops. Normally, a threat against an enemy's capital forces him to interpose, and brings on a battle. Here, the enemy may not consider any of his hamlets worth defending resolutely. He may prefer to adopt a purely guerilla attitude, to be ubiquitous, and to worry the advance. That is the most difficult problem to deal with. As a rule he is ready to oppose an advance with resolution in measure as his hopes stand high. If defeated, he tends towards more guerilla methods.

A commander therefore has usually to select the line of advance most likely to produce massed resistance. In doing so he can advance as one column, or by several columns up several valleys. The first method has the advantage of simplicity and of inviting the enemy to concentrate. But the larger the force on one track the slower the movement, and so, if the enemy seeks to avoid decisive battle, the less hope there is of achieving it. A move in several columns has the advantage of speed, and gives greater hope of cornering an elusive enemy. But it involves a series of lines of communication, and is attended by all the difficulties of co-operation and mutual support between columns when separated by mountain ranges.

Progress of Operations.—Whatever the plan the method of conducting operations follows a fairly uniform course. The force advances up a valley protected by a strong advanced guard. This advanced guard throws out detachments to seize and hold tactical points on the hills flanking the valley, and so securing the advance of the column below. These detachments (or "piquets") are withdrawn by the rear guard when the column has passed. Since all commanding ground within rifle range must be denied to the enemy, it is clear that piquets often have to establish themselves 2,000 yd. from the column, and to climb 1,000 ft. or more. The process is therefore laborious and slow, and limits the length of march possible in a day.

Defence at Night.—For the night, all-round defence is essential against so ubiquitous an enemy. Arrangements therefore take the form of a central camp, protected by self-contained piquets posted on tactical points round the camp. These piquets must be sufficient in number, and be placed far enough out, to prevent the enemy firing into camp at night. But since complete protection against such sniping is impossible, a considerable amount of protection against fire has to be provided within the camp. The camp itself has also to be designed and organised to resist assault. It will be realised that there is, in consequence, an immense amount of heavy work to carry out at the end of an exhausting day's advance. Moreover, it is of primary importance that all movement shall have ceased and the camp be made entirely secure before dark. Because, though (as stated above) organised night operations frequently prove successful, unorganised movements are disastrous in face of a ubiquitous enemy who holds the initiative.

It is frequently necessary to raid and destroy villages in order to induce the enemy to stand and fight. Such raids need careful organisation in order to insure that the work is efficiently done in the time available. Raids are usually carried out in various directions, radially, from some semi-permanent camp, the force going out early and returning to camp before dark. The retirement is almost always followed up, and it is in harrying a retirement that the enemy is most dangerous. A running fight (with all its disadvantages) is unavoidable, because the enemy has no columns or guns moving on a road to deploy, but merely follows up deployed. The art of conducting such a retirement consists in the careful and timely laying out of troops in successive positions, so that the retreat of the rearmost is always efficiently covered and in the skilful co-operation of fighting aeroplanes.

For the defence of the line of communication the system is a chain of piquets in assault proof posts dominating the route. These posts, often 2,000 ft. above the valley, have to be strongly built of dry stone, wired and the garrisons supplied with food and water for (say) 10 days. It is obvious that the work involved is laborious. At suitable intervals on the line of communication larger posts are established capable of accommodating the convoys passing through. These posts also contain the mobile reserve for their section of the line of communication.

An Example.—Perhaps a small example will best illustrate the difficulties which beset a commander in mountain warfare. A force of four battalions (and attached troops) camps for the night. It is found necessary to use one company per battalion for camp piquets. Next morning the advance continues, but owing to the necessity for an early start it is impossible to relieve the piquets before moving. They must be withdrawn by the rearguard and rejoin units later. So the advance begins with all battalions only three companies strong. "A" battalion gives two companies as advanced guard, one available for piqueting. "B" is allotted entirely for piqueting. "C" heads the main body. "D" finds two companies for rearguard and one as baggage escort. In the advance it is found that piqueting is heavy, that an average of a company to a mile is needed. The force advances four miles (which means that the remaining company of "A" and all "B" battalion are used up on piquet) and is confronted by 1,500 enemy in position. In theory, a brigade is confronted by 1,500 men. In practice 1,500 men are being faced by the two advanced guard companies and the three companies of "C" battalion, perhaps actually some 500 or 600 in all; for that is all that the commander has immediately available. The above crude example is typical of the dispersion of resources inherent in mountain warfare.

Two Lessons.—As regards mountain warfare in general, history appears to point to two main lessons: firstly, that the true subjection of mountaineers can only be arrived at by opening up and developing the country. Short of that, they may be overawed and pacified for a time, but a change in the undeveloped and individualistic conditions of life is essential to their permanent pacification. Secondly, that if the operations for their primary subjugation are to be quickly and successfully carried out, the forces engaged must be definitely trained to the task, and the personnel composing the force should, as far as possible, be composed of men bred in mountains. (J. P. V.-S.)

MOUNT STEPHEN, GEORGE STEPHEN, 1ST BARON (1829–1921), Canadian financier (*see* 18.942), died at Brocket Hall, Hatfield, Herts., Nov. 29 1921.

MOZAMBIQUE (*see* 22.163) has a population (1923) of about 3,500,000, including some 10,500 Europeans (mostly Portuguese and British) and about 6,000 Indians. The country is divided into (*a*) the province of Mozambique, governed directly by Portugal, with Lourenço Marques (*q.v.*) as capital, (*b*) the territory of the Mozambique Company (capital Beira), (*c*) the territory of the Nyassa Company. The companies administer their territories under charter. The charter of the Nyassa Company was for a period ending in 1927. Negotiations for its renewal were conducted in 1926.

History.—Although Portugal had been in nominal possession of the country for some 400 years, it was not until 1912 that fairly effective control was obtained over all the hinterland, while in 1915 there was a widespread revolt in the Zambezi valley. In 1918 the region north of the Zambezi was ravaged by the Germans under Von Lettow-Vorbeck. This region had been marked, before the World War, for exploitation by the Germans. Early in 1914 German capitalists had obtained control of the Nyassa Co., the Anglo-German agreement of 1913 (never signed) having recognised German economic interests as

paramount in that area (*see* AFRICA). The World War put an end to this project. In 1919 the "Kionga Triangle," formerly part of German East Africa, was added to Mozambique—it gave Portugal the right bank of the Rovuma to the sea.

The Portuguese since 1910 have made serious efforts to improve the administration. In 1914 a measure of autonomy, enlarged in 1920, was granted to the province. In general the treatment of the natives was satisfactory, but labour conditions left much to be desired. Compulsory unpaid labour in the province of Mozambique was not abolished until 1925. Early in 1926 the Portuguese Government appointed a commission of enquiry with instructions to see that nothing was permitted which gave colour to the charge that slavery in a disguised form still obtained.

Economic Conditions.—Economic development was considerable in the province and in the Mozambique company's territory. The Portuguese, however, lacked capital to carry out large enterprises, while the constant ministerial changes at Lisbon and the financial embarrassment of Portugal reacted unfavourably on Mozambique. Development was most marked where British interests were concerned and British capital was forthcoming. The transit trade was large, Lourenço Marques serving the Eastern Transvaal, and Beira being the chief port for Rhodesia, Katanga and British Nyasaland. A railway from Beira to the Zambezi completed in 1922, was built with British capital to meet the needs of the Nyasaland protectorate. This railway superseded the route by the Zambezi and in consequence the British concession at Chinde, at the mouth of the river, was given up in 1925. The Beira-Zambezi railway also opened up rich tracts suitable for sugar, cotton and other crops. Moreover it brought a step nearer the exploitation on a large scale of the coalfields on the north side of the Zambezi near Tete. Another railway, from Inhambane to Delagoa Bay (280 m. long), built in sections, was nearing completion in 1926. This line also serves fertile regions. Great progress was made in sugar growing, and sisal, cotton and maize were increasingly cultivated. The chief exports are sugar, copra and ground nuts.

The three administrations have different systems of keeping accounts, but, approximately, the trade figures for the whole country in 1911 were: Imports £8,520,000 (including £6,800,000 in transit); exports £2,720,000. In 1923 the value of trade in the province of Mozambique was, roughly £10,000,000, including transit trade valued at £4,800,000. In the same year the external trade of the Mozambique Company was valued at £11,000,000 including goods in transit £2,200,000. In the Nyassa Company's territory imports in 1924 were valued at £90,000 and exports at £111,000. A valuable export, which does not appear in the trade returns, is that of native labourers to the Transvaal mines.

Revenue is derived mainly from Customs, a hut tax (for which in 1925 a poll tax was substituted) and a tax on labourers who emigrate; the last source is not available in the territories of the chartered companies. In Mozambique province in each year between 1908–9 and 1920–3, except in the first two years of the War, there was a surplus over estimated revenue. In 1923–4 the revenue collected was 50,957,000 escudos. In 1925 the exchange problem was acute and the province suffered severely. In the Mozambique Company's territory, where accounts are kept in sterling, revenue in 1923 was £361,000 and expenditure £281,000. (*See* AFRICA).

MUIR, JOHN (1838–1914), American naturalist and writer, was born at Dunbar, Scotland, April 21 1838. In 1849 he went to Fox River, Wisconsin. When 22 years old he entered the University of Wisconsin, teaching and working on farms during vacation. After finishing his course he began wanderings on foot through the United States and elsewhere. In 1868 he first entered the Yosemite Valley which for many years after formed the base of his continued expeditions. In 1876 he joined the U.S. Coast and Geodetic Survey, and in 1879 discovered the Alaskan glacier that now bears his name. In 1881 he took part in the expedition in search of the De Long party in the Arctic region. It was largely due to his efforts that the Yosemite region was set aside as a national park in 1890. He died at Los Angeles, Cal., Dec. 24 1914.

He published, among other works; *The Mountains of California* (1894); *Stickeen* (1909), the story of a dog; *The Yosemite* (1912) and *The Story of My Boyhood and Youth* (1913). In 1888 he edited *Picturesque California*. The following appeared posthumously: *Unpublished Prose and Letters* (1915); *A Thousand-Mile Walk to the Gulf* (1916); *The Cruise of the Corwin* (1917) and *Steep Trails* (1918).

MULCAHY, RICHARD JAMES (1886–), Irish politician, was born in Waterford, and began his career in the engineering department of the Dublin General Post Office. He took part as a lieutenant in the Irish rebellion of 1916, and was afterwards interned in Frongoch. In Dec. 1918 he was returned as Sinn Fein M.P. for the Clontarf Division of Dublin and retained his seat until 1922. He played a prominent part with Michael Collins in the reorganisation of the Irish Volunteers, of which he had become chief-of-staff in 1918. He sat in the Dáil from 1921–3 as a member for the Northwest Division of Dublin, and after the Treaty of 1922 became minister of defence for the Irish Free State. He succeeded Gen. Michael Collins, after the latter's death in 1922, as commander-in-chief of the Free State forces, and had the chief conduct of operations until the cease-fire order of 1923, in which year he was returned to the Dáil for Dublin city north. He resigned office in the spring of 1924 upon the executive requiring the resignation of three of his principal officers in connection with troubles arising out of demobilisation and reorganisation.

MULHOUSE or MULHAUSEN (*see* 18.960) was restored to France after the World War. The population was 99,226 in 1921, and a later estimate gives 105,000. A busy factory town and port on the Rhone-Rhine Canal, it is thoroughly French in character. The French occupied Mulhouse on Aug. 8 1914, but evacuated it two days later. They were again on the outskirts on Aug. 20, but the reverses in the north compelled a retreat, and the town was ruled as hostile territory by the Germans during the World War. The French re-entered Mulhouse in Nov. 1918.

MÜLLER, HERMANN (1876–), German politician, was born May 18 1876 at Mannheim. From 1899 to 1906 he was editor of the Socialist newspaper the *Görlitzer Volkszeitung*, and from 1906 onwards was a member of the directing board of the German Social Democratic party. From 1916 to 1918 he was a member of the Reichstag. On Aug. 1 1914, he went to Paris with the object of finding out whether international action by the Socialists of France and Germany could be initiated in order to avert the World War. His mission was unsuccessful, and he had great difficulty in making his way back to Germany through the French lines. His report did much to determine the attitude of the German Social Democrats in voting in the Reichstag for the first war credit. On June 21 1919 he was appointed Minister for Foreign Affairs—under the chancellorship of Gustav Bauer—and in this capacity went to Versailles and with the Colonial Minister, Dr. Bell, signed the Peace Treaty for Germany on June 28 1919. After the resignation of the Bauer Ministry, which followed upon the Kapp Putsch (March 1920), Müller was appointed Chancellor of the Reich, an office which he held till the following June, when the result of the general elections for the Reichstag necessitated the formation of a Coalition Ministry with Fehrenbach of the Catholic Centre party as Chancellor. Thereafter Müller continued to play a leading part in the affairs of the Social-Democratic party.

MUMMY: *see* ARCHAEOLOGY: *Egypt*.

MUN, ADRIEN ALBERT MARIE DE, COUNT (1841–1914), French politician (*see* 19.1), died at Bordeaux Oct. 6 1914.

MUNCH, EDWARD (1863–), Norwegian painter, was born Dec. 12 1863 at Löten, Hedemark. He went to Christiania (Oslo) at an early age and studied at the royal school of drawing

under Krohg by whom he was introduced to the naturalistic school of painting. The inborn genius of Munch however reacted against this teaching. He was more inclined to express feelings inspired by a troubled mind than impressions engendered by reality, and did not hesitate to go his own way as an artist. The most famous work of this early period is "Spring" (1899), justly considered one of the gems of the National Gallery at Oslo. In the beginning of the 'nineties, the undercurrent of mental agitation broke through in all its power, and in a number of works (mostly in the Oslo National Gallery), Munch revealed an extraordinary sensitiveness, displayed alike in the subjects of his pictures and the artistic method of execution which he employed. From the beginning of the 20th century Munch's art assumed a more realistic character. This is particularly evident from his landscapes of this period, the outstanding features of which are vigorous plainness and impressive colouring. In 1913 Munch completed the fresco decorations of the University Festival Hall at Oslo; he also established his reputation as an etcher of ability.

MUNDELEIN, GEORGE WILLIAM (1872–), American cardinal, was born in New York City July 2 1872. He received his education at the Manhattan College, and St. Vincent Seminary, Beatty, Pa., subsequently proceeding to Rome and studying theology at the Urban College of the Propaganda in that city. He was ordained priest June 8 1895, at Rome, and became secretary to Bishop McDonnell of Brooklyn, N.Y., being made chancellor of the diocese in 1897. He was appointed auxiliary Bishop of Brooklyn, with the titular see of Loryma, Sept. 2 1909. He became Archbishop of Chicago, Nov. 30 1915, and was created a cardinal by Pope Pius XI, March 24 1924. He was a prominent figure at the Eucharistic Congress held in Chicago in June 1926.

MUNICH (*see* 19.5), the capital of Bavaria, Germany, with a population of 630,711 in 1919, took a prominent part in the revolution of 1918, when Bavaria became a republic (*see* BAVARIA). Housing conditions were very bad after the World War; in 1919 there were 7,919 applications for 23 houses available. A school of infantry is permitted under the provisions of the Treaty of Versailles. The War Memorial was unveiled in 1924; 14,000 citizens of Munich fell in the War. A German museum was opened in 1925, and a transport exhibition was held in the same year. The factory of the Deutsche Werke, formerly artillery workshops of the German Army and subsequently converted to the manufacture of agricultural machinery, has been acquired by the municipality.

MUNICH, UNIVERSITY OF (*see* 19.6).—Between 1910 and 1912 seven new chairs were founded. No further developments took place till 1920, since when 12 new chairs have been created, including those in Egyptology and race hygiene. The number of students averaged 6,800 up to 1914, and remained below this figure till 1916–7, when it amounted to 7,900. It rose in 1918–9 to 9,823, and to 10,333 in the summer of 1921. There has been a decline since that date, and in the summer half of 1925 there were 8,006 students, of whom 938 were women.

MUNICIPALITY: *see* CITY GOVERNMENT.

MUNITIONS OF WAR.—Under this heading the production of munitions during the World War by the United Kingdom and the United States is dealt with.

I. THE UNITED KINGDOM

The Problem.—When the British Army of six divisions took the field in 1914 it possessed about 900 field guns, less than 200 field howitzers, about 60 heavier weapons of 6-in. and upwards and perhaps about 200 obsolescent types, such as the 4.7-in. and the 85-pdr. howitzer, a reserve of ammunition of less than 1,000,000 rounds weighing some 20,000 tons and less than 2,000 machine-guns. By the end of 1918, the army had received 10,000 field guns, 6,000 other light guns, over 3,000 field howitzers and 7,500 heavier guns and howitzers; 217,000,000 rounds of artillery ammunition, weighing 5,500,000 tons and nearly 225,000 machine-guns.

During 1914 the War Office limited its orders to Government factories and the armament firms. In 1915 a few small contracts were placed with other firms, but on the appointment of the armaments output committee at the War Office, and a week later of the Treasury committee under Mr. Lloyd George, further extensions took place. Foreign orders were extensively placed in the U.S.A. and Canada. The passage of the Ministry of Munitions Act in June 1915 and the Munitions of War Act in July 1915 and the transfer Sept. 1915 of the ordnance factory at Woolwich to the Ministry of Munitions placed the Minister (Mr. Lloyd George) in a position to organise effectively production on the largest scale possible—by the most modern means—of the enormous quantities of material required and to deal with labour problems without delay.

Rifles.—The rapid development of the army was impeded by difficulties in supplying rifles—weapons of precision manufactured by highly skilled labour with specialised machinery. Old pattern rifles were repaired and rifles were borrowed from Japan. Orders were placed in America, but the rifles were not available till the summer of 1916 and then needed adjustment. By this time the home supply was adequate.

Guns.—Heavy artillery was needed to break down the German defences, and a programme was drawn up in June 1915 by Mr. Lloyd George on a basis of 100 divisions with proportion to reserves. Wastage was heavier than was expected. Aircraft defence developed; merchant ships had to be armed; tanks (*q.v.*) had to be equipped. Nevertheless at the middle of 1918 the output of guns sufficed to meet all these requirements.

Ammunition.—To provide adequate supplies of shells, with explosives, propellants, fuses, grenades and the score of other elements, national factories were built and proved highly efficient and economical. Large orders were placed in America and Canada. Fitting factories were built, and intensive research at Woolwich produced a satisfactory fuse.

Explosives and Propellants.—Lord Moulton presided over a committee appointed in 1914 to organise the supply of explosives. Cordite was at first a propellant. The supply was fairly ample owing to the foresight and the policy of the Admiralty. The new programme increased the demand for H.E. Trinitrotoluol (T.N.T.) was mixed with amatol (ammonia citrate). Out of about 625,000 tons of explosive supplied, only 210,000 (of which 3,500 tons were imported) was T.N.T., less than 80,000 tons prussic acid and the rest ammonia citrate. The production of cordite was limited by supplies of acetone, and eventually a nitro-cellulose powder manufactured by Messrs. Dupont of America was adopted. The Gretna propellant factory, which cost £8,000,000 to build, made nearly one-fourth of the cordite required at a great saving of cost. Imports and home products are shown below.

Trench Mortars and Trench Ammunition.—The total number of trench mortars delivered during the War period amounted to 19,096, and the output of trench-mortar ammunition to over 17,000,000 rounds. The total number of grenades delivered amounted to 100,103,000, and of aerial bombs to 4,738,000. Of the 5,316,000 rifles manufactured, 3,954,000 were made in Great Britain, and the army was entirely armed with rifles of

TABLE I.

	Trade	National Factories	Imports

TABLE II. *Guns and Gun Ammunition*

	New Guns and Howitzers					Filled Ammunition (in thousands)				
	Light	Medium	Heavy	Very Heavy	Total	Light	Medium	Heavy	Very Heavy	Total
Up to June 30 1915	802	242	6	31	1,081	1,877·3	389·0	26·5	14·0	2,306·8
1915 2nd six months	1,895	493	4	33	2,425	4,461·7	976·7	134·4	74·5	5,647·3
1916 1st six months	1,180	969	205	116	2,470	10,287·1	2,919·2	432·1	213·8	13,852·2
2nd six months	1,045	679	495	258	2,477	25,204·3	8,392·6	2,492·7	1,654·7	37,744·3
1917 1st six months	1,547	408	570	253	2,778	30,004·2	9,887·1	4,480·6	2,145·8	46,517·7
2nd six months	2,488	603	762	450	2,303	22,556·7	9,528·8	6,693·1	2,381·1	41,159·7
1918 1st six months	3,990	966	1,164	264	6,384	18,474·6	8,363·1	6,734·6	1,625·4	35,197·7
2nd six months	3,056	797	875	270	4,998	19,067·7	6,421·0	7,647·3	1,479·5	34,615·5
	16,003	5,157	4,081	1,675	26,916	131,933·6	46,877·5	28,641·3	9,588·8	217,041·2

The classification is that adopted by the Inter-Allied Munitions Council. In the case of Great Britain it includes under "light" field guns (13-pdr. and 18-pdr.), mountain guns (2·75-in. guns and 3·7-in. howitzers), anti-aircraft guns (13-pdr., 3-in. and 4-in.) and tank and other miscellaneous small guns. The medium guns include the 60-pdr. gun and 4·5-in. howitzer. The heavy include the 6-in. howitzer and gun and the very heavy include 8-in., 9·2-in., 12-in. and 15-in. howitzers and guns.

TABLE III.—*Production of Rifles, Machine-Guns, Small-Arms Ammunition, Aeroplanes, Aero-Engines and Tanks*

Totals	5,316,277	239,840	9,172,645	57,931	54,789	2,818

[1] Including 186,000 "Acceptances" of U.S.A. rifles.
[2] Including 154,000 "Acceptances" of U.S.A. rifles.
[3] Including 462,000 "Acceptances" of U.S.A. rifles.
[4] Including 391,000 "Acceptances" of U.S.A. rifles.

home manufacture. A total of 240,000 machine-guns were delivered. The total number of rounds of small arms ammunition manufactured amounted to 9,172,645,000, nine-tenths of which was manufactured in Great Britain.

The number of aeroplanes manufactured amounted to 54,789. The number of aero-engines was 57,931. The first tanks were delivered in the third quarter of 1916 and numbered 110. Owing to changes in design, etc., only 40 were delivered in the following quarter and 100 in the first quarter of 1917. The total number of tanks manufactured amounted to 2,818.

Mechanical Transport, Railway Material, etc.—The Ministry became responsible for the supply of motor vehicles on Sept. 1 1916. From this date to the end of 1918 there were delivered 33,000 heavy lorries, 2,500 four-wheel-drive lorries, 4,000 light lorries, 4,700 motor-cars, 1,700 ambulances, 4,100 Ford cars, 1,400 Ford ambulances, 12,000 Ford vans, 2,200 caterpillar tractors, 27,700 motor-cycles, 7,000 motor-cycle combinations and 185 armoured cars. The Ministry of Munitions from Oct. 1916 supplied 2,300 m. of 75-lb. rails, 4,200 m. of light rails, 750 standard gauge locomotives, 800 locomotives for other gauges, 13,000 petrol tractors and 33,000 railway wagons of various types.

During the War, Great Britain kept Italy and France supplied with coal, with substantial supplies of iron and steel, with benzol, and Italy with T.N.T., picric acid and other explosives. As regards finished munitions there was a certain amount of interchange between the various countries. For instance, Great Britain receiving aero-engines and some anti-aircraft guns from France and motor-cars from Italy, and supplying heavy artillery and ammunition, incendiary and other special small arms cartridges for use in aeroplanes and machine-guns. British assistance to Russia took the form almost entirely of finished products, including machinery.

II. THE UNITED STATES

No accumulation of war materials in excess of the amounts required for the regular army, which numbered 127,588 on April 6 1917, was made by the United States in anticipation of entry into the World War. The national army, 19 months later (Nov. 11 1918), numbered 3,757,624, of whom 2,086,000 had been transported to France.

War Operations of Americans, 1917–8

Men in France fighting	1,400,000
Men in France behind lines	600,000
Men in army in United States	1,700,000
Men in navy	550,000
Men in War work	7,150,000
Women in War work	2,250,000
Men, women and children not in War work	91,350,000
Total	105,000,000

The total number of American troops placed in the field was larger than could have been equipped with material of American manufacture. The European Allies guaranteed their surplus for the use of American troops, and thus ensured an earlier and more numerous American participation upon the firing line.

A large part of the munitions needed for maintaining an army of 4,000,000 men could be produced in the United States without difficulty. Such articles as shoes, socks, uniforms, blankets, food and food containers, camp utensils and equipage required only the drafting of specifications and the speeding-up of industry to produce the requisite amounts.

The Engineer Corps handled 3,225,121 tons of supplies during the 19 months of War; 1,303 locomotives and 18,313 freight cars were shipped to France; 1,002 m. of standard-gauge railroad track were constructed there. Most difficult of all was the problem of manufacture of delicate or heavy ordnance, siege guns, field artillery, machine-guns, rifles, aircraft, tanks and

Clothing, Etc., Produced and Shipped to the A.E.F. Between April 1917 and Nov. 11 1918

	Produced	Shipped
Blankets	19,419,000	3,127,000
Coats	22,603,000	7,294,000
Drawers	71,884,000	14,701,000
Undershirts	69,764,000	15,693,000
Shirts	22,198,000	6,401,000
Stockings	89,871,000	29,733,000
Shoes	26,423,000	9,136,000
Breeches and trousers	17,342,000	6,191,000
Overcoats	7,748,000	1,780,000

motor transport, in which quantity production depended upon slow and painstaking preparation of the preliminary processes, upon the supply of labour and raw materials, and upon the wise selection of designs and types to be manufactured. Considerable experience in the manufacture of ordnance and other munitions had been gained by private firms during the period of American neutrality through the fulfilment of contracts placed in the United States by the Allied belligerents. Most of the private capacity to make explosives, rifles, machine-guns and cannon was in use. The experience thus gained was an asset for the United States, but few of these resources could be diverted to the supply of American armies without endangering the supply of Allied armies already on the firing-line in the common cause.

General Munitions Board.—The advisory commission of the Council of National Defence early recognised that new factories must be erected for the construction of guns, aircraft and other munitions of the elaborate type, and that a preliminary determination of standards must precede this in order that the types put into production should be as few in number and as useful as possible. On March 20 1917 the Munitions Standards Board came into existence to advance this work as a sub-committee of the Council of National Defence. On April 9 it was reorganised as the General Munitions Board. Within a few weeks of the declaration of war numerous special bodies were created to carry on parts of the munitions work.

Ships.—The growth of shipping under the American flag (in vessels of 500 gross tons or over) was as follows:—

	Ships	Gross tons
Strength April 6 1917	1,614	3,569,675
New construction to Nov. 11 1918	704	2,287,034
Ships otherwise acquired to Nov. 11 1918	95	274,366
Enemy ships seized in United States	97	648,894
Dutch ships requisitioned	87	354,278
Total to Nov. 11 1918	2,597	7,134,247
Ships lost April 6 1917–Nov. 11 1918		
By enemy action	103	313,569
By other causes	213	416,578
Strength Nov. 11 1918	2,281	6,404,200

Aircraft.—Prior to April 6 1917 the United States had acquired in all 224 aeroplanes. The appropriations of Congress for military aviation were as follows:—

1912–6	$ 900,000
1916–7 (Urg. Def. bill)	500,000
1917 (Army approp.)	13,281,666
1917 (Milit. aeronautics)	10,800,000
July 24 1917	640,000,000
1917–8 (Urg. Def. bill)	43,450,000

The policy adopted by the air service was to design a standard type of aeroplane engine, put it into quantity production, and have ready for the campaign of 1918 a fleet of 22,000 effective aeroplanes. By July 4 1917 the first experimental "Liberty Motor," as the standard engine was named, had been constructed. After further refinement of design it was turned over for production to the manufacturers of automobiles in the absence of large aircraft industries in the United States. The first finished Liberty engines were delivered in Dec. 1917, and 15,572 more followed within the next year. The first American squadron completely equipped by American production was reported by General Pershing to have crossed the German lines on Aug. 7 1918. The A.E.F. was provided by the French Govt. with 2,676 aeroplanes, and received from the United States 1,379 planes of the De Havilland type. The delivery of aeroplane engines of all types to the Government in the United States began with 66 in July 1917 and rose to 5,297 in Oct. 1918, with a total of 28,509 to the end of 1918.

Heavy Ordnance.—Only six government arsenals and two private plants had had experience in producing heavy ordnance before 1914; by Nov. 1918 there were nearly 8,000 plants at work upon ordnance contracts, light or heavy. Up to the Armistice 1,102 guns (from 3-in. to 9.5-in.) and 14,623 forgings (from which the finished guns are turned and bored) were made in the United States for the Allies. Fifteen additional heavy-gun factories were equipped to meet the American need, and the rate of production for Oct. 1918 was above 24,000 guns per year. In mobile field artillery the French 75-mm. gun was accepted for the standard in quantity production, and its designs, with those for its intricate recuperator, were redrawn to meet American conditions in manufacture. The tolerances, which the French were in the habit of working out in the assembling plant, were reduced to figures and gauges in order to permit the American method of manufacture of separate interchangeable parts. In Oct. 1918 464 complete artillery units (guns, carriages and recuperators) were produced and delivered to the army by American manufacturers, with an accumulated total of 2,058 units to the end of the year. But no 75-mm. guns or 155-mm. howitzers of American manufacture were on the front at the date of the Armistice. The French Govt. provided the A.E.F. with equipment of this sort sufficient for 30 American divisions.

Machine-Guns.—An American gun, invented by Col. I. N. Lewis, "was a revelation when it came to the aid of the Allies early in the Great War," and capacity for its manufacture was developed in private American plants on Allied order. In May 1917 the machine-gun board tested and adopted two newly

designed guns, one heavy and one light, both the work of John M. Browning. During Oct. 1918 the War Department accepted 14,639 heavy and 13,687 light Browning guns. By the end of the year 226,557 machine-guns of all types had been accepted by the United States.

Naval Ordnance.—Much delicate experimentation was done in search for new rangefinders and submarine detectors, various listening devices being brought forward for the latter purpose. The construction of the North Sea mine barrage called for the development of a new mine and anchor. Orders were placed for 125,000 mines, of which 56,611 were laid in the barrage by American mine-layers operating from bases in the north of Scotland, near Inverness. The whole barrage included 70,263 mines, of which 13,652 were British laid, covering a zone of sea from 15 to 35 m. in width, and to a depth sufficient to prevent submarines from diving under it. The complete barrier was in place by July 29 1918, although it was much tightened thereafter. The barrage is known to have destroyed 17 submarines and to have closed the North Sea outlet, particularly after Norway announced a determination to mine her own territorial waters adjacent to the barrage.

MUNSEY, FRANK ANDREW (1854–1925), American publisher and newspaper proprietor, was born at Mercer, Me., Aug. 21 1854. He was educated in the public schools and became a telegraph operator in Augusta, Maine. In 1882 he went to New York City and established *The Golden Argosy*, a magazine for children, later changing this to *The Argosy*, a magazine for adult readers. In 1889 he founded *Munsey's Weekly*, replaced two years later by *Munsey's Magazine*, the first monthly of its class to sell for the popular price of 10 cents. He also founded *The All-Story Weekly* (1904) and *The Railroad Man's Magazine* (1906) and purchased *The Baltimore News* (1908), *The New York Press* (1912) and the New York *Sun*, both morning and evening issues (1916). He merged the *Press* in the *Sun*. In 1920 he bought from the executors of James Gordon Bennett's estate the New York *Evening Telegram* and *The New York Herald*, together with its Paris issue. He combined the *Herald* and the morning *Sun* as *The Sun and the New York Herald*, but in Oct. 1920, changed the name to *The New York Herald*, at the same time continuing the evening paper as *The Sun*, thus perpetuating intact two names famous in American journalism. He died in N.Y. City Dec. 22 1925. By his will, after providing for relatives, he left the residue of his estate, estimated at $40,000,000 to the Metropolitan Museum of Art, New York.

MUNSTERBERG, HUGO (1863–1916), German-American psychologist (*see* 19.12), died in Cambridge, Mass., Dec. 16 1916.

Among his later publications were *American Problems from the Point of View of a Psychologist* (1910); *Psychology and Industrial Efficiency* (1913); *American Patriotism and Other Social Studies* (1913); *Psychology and Social Sanity* (1914); *The War and America* (1914); *The Peace and America* (1915); *The Photoplay: A Psychological Study* (1916) and *Tomorrow: Letters to a Friend in Germany* (1916).

MURAL PAINTING (*see* 19.16).—France more than any other country has maintained a continuous and vigorous tradition of mural decoration in recent years, and this despite economic difficulties and the vagaries of modern art. The annual Salons furnish an index to mural work though the final fruit does not necessarily appear in them.

French Examples.—Nearly every year murals have been among the most admired works of the Salons. In 1910 at the spring Salon it was the "Luncheon" by Aman-Jean, a large panel for a room in the Museum of Decorative Art which attracted all visitors. The autumn Salon of the same year was particularly rich in mural paintings. M. Denis, who had already won with his decorations of the chapel of Vésinet, the position of France's leading decorator, left vacant by the death of Puvis, exhibited a series called "Florentine Evening," in which he combined with the chaste dignity of Puvis a Florentine sensitiveness suggestive of Fra Angelico and Botticelli.

Alongside these decorations hung four ingenious panels by P. Bonnard, with dancing figures in fanciful fountained courts and gardens and with fantastic irregular borders ornamented with silhouetted monkeys and birds. At the spring Salon of 1911 Aman-Jean's exhibit of two more figured panels for the same museum room was overshadowed by a great section of ceiling decoration for the Théâtre-Français in which A. Besnard gave a monumental presentation of the garden of Eden with various subsidiary figures, genii and writers. Even more admired, because of their simple subjects, lucid composition and idyllic charm, were three decorative paintings by Denis: "Sunny Sands," "September Evening," and "First Steps." The following autumn Salon contained two outstanding murals by J. Flandrin, "Summer" and "Fountain," both calm and spacious, and modern in matter as well as manner. The spring Salon of 1912 brought new laurels to Denis and Aman-Jean. The latter eclipsed his previous works with a decoration for an amphitheatre of the new Sorbonne, "The Elements," elaborate in symbolism, clear in pictorial conception and accomplished in execution. Denis filled his five staircase panels. "The Golden Age," with bathers, lovers, dancers, vintagers and the like in a vague enchanting paradise. In these panels he gave pictorial expression to what he has expressed in words: *L'art est la sanctification de la nature.* He revealed here his spiritual kinship to St. Francis of Assisi, whose Fioretti he has feelingly illustrated. In the spring Salons of 1913 and 1914 a series of decorations called "Garden Games" drew attention to another able mural painter, J. P. Laurens.

In 1913 the Théâtre des Champs-Elysées opened. Of its extensive wall paintings the most important are by Denis, though E. A. Bourdelle, E. Vuillard, K. X. Roussel, H. Lebasque, and Jacqueline Marval also contributed. Denis painted the frieze around the dome, consisting of four panels and four medallions. Two of the panels, "Dance" and "Musical Drama," are each more than 50 ft. long, and the other two, "Symphony" and "Opera" more than forty. While these four panels illustrate both the principal forms of music and the successive stages of its history its technical means are shown by four intervening medallions, "Orchestra," "Choir," "Organ," and "Sonata." Of their relation to the large panels it has aptly been said: *ce sont comme des reflexions intimes entrecoupant les grandes affirmations publiques.* The crowning panel directly above the stage, "Dance," distinctly recalls Ingres.

After the interruption of mural painting by the War, the French began again with remarkable precision exactly where they had left off. If any effect of the War on mural painting, other than impoverishment, was observable in the Salons of 1919 and succeeding years, it was a greater emphasis on subject and a greater demand for religious paintings. As before Denis was prominent. In the spring Salon of 1919 he exhibited a glorious "Annunciation," and in the autumn Salon of that year a "Jesus at the House of Mary and Martha." Another religious mural prominent in the autumn Salon was the "Ex-voto to Ste. Geneviève" by G. Desvallières. The following spring Salon contained L. Simon's diptych for the church of Notre-Dame-du-Travail in Paris, conspicuous because it is one of the few successful decorations inspired by the War. The energetic ascent to Calvary and the touching Mass of the dead soldier are modern, but reflect the grand style of religious painting of the 17th century; this adherence to the traditions of religious painting accounts for the compact composition, which makes the diptych seem crowded to eyes accustomed to the usual loose composition of modern murals. The post-War spring Salons were enriched by the decorations for the Conseil d'Etat at the Palais Royal by H. Martin.

The Paris Exposition of Modern Decorative Art of 1925 occasioned much mural painting, which was, however, not representative of all phases of contemporary work. P. Baudoüin's *Corporation de la Fresque* did many frescoes directly on the wall (instead of paintings on canvas attached to the wall, the now all but universal practice), among which "The Poet" by J. Adler and "Music" by L. Toublanc on the Cour Bouchard were outstanding. H. Marret was also represented by two frescoes on the exterior of the Pavillon Ruhlmann, though he commonly works on canvas; his principal contributions among many were four large paintings on the Cour des Métiers ("Traffic," "Sports," "Street" and "Architecture") and an "Annunciation" in the village church, to the decoration of which Desvallières contributed a retable and Denis a great Calvary, which served to reaffirm his supremacy. Deserving of mention also were the murals of G. L. Jaulmes and J. Dupas, who with his followers decorated the Pavillon du Collectioneur.

Photographed in colour from the painting by Ezra Winter

Work in other Countries.—Compared with the French, the murals by artists of other European countries represented in the Paris Exposition were of minor importance; this corresponds to the minor importance of mural painting in those countries. The fervent nationalism throughout eastern Europe has given rise to ambitious patriotic decorations, such as those of A. Mucha for Prague, but not to mural painters of the first rank. East of France the most important figure of recent years was F. Hodler (d. 1018), a Swiss active also in Germany. Among his later works was the dignified "Unanimity" for the Rathaus at Hanover, exhibited at the autumn Salon of 1913.

Thus, while Hodler may be considered an offshoot of the figure tradition of France, Walser seems to be inspired by the luscious sign paintings of the Tyrol. Another interesting eddy somewhat like that of pre-Raphaelitism, is occupied by B. Goldschmitt, who completed in 1911 a droll cycle of frescoes representing the Tyrolese legend of King Laurin's rose garden for the Hotel King Laurin at Bolzano. The vigour of modern Spanish painting is attested by its power to propagate itself across the Atlantic whither two of its most representative mural series have migrated; the decorations by D. Rivera for the Ministry of Education in Mexico City and the 14 paintings of the provinces of Spain by J. Sorolla y Bastida for the Hispanic Society in New York.

An Anglo-American Tradition.—Britain and America have co-operated to such an extent in mural painting that one may speak of an Anglo-American tradition based partly on pre-Raphaelitism, and point to the American, J. S. Sargent (*q.v.*), and the Englishman, F. Brangwyn (*q.v.*), as its exemplars. This Anglo-American mural painting is the closest rival to that of the French school. It makes less use of landscape and poetry than the French and greater use of man and his material achievements. It is local and realistic where the French is idyllic. Its abstract figures are usually allegorical rather than mythological. The last murals by Sargent were those of the stairway and rotunda of the Museum of Fine Arts, Boston.

The decoration of the Missouri State Capitol is the largest current effort in mural painting in America. The following list of painters besides Brangwyn represented there is an indication of the size of the undertaking and of the number of mural painters in America: R. E. Ball, T. P. Barnett, O. E. Berninghaus, A. Blondheim, F. G. Carpenter, C. Hofbauer, R. Kissack, R. E. Miller, F. Nuderscher, R. Ott, H. Reuterdahl, E. Wuerpel and N. C. Wyeth. The paintings of the Wisconsin State Capitol were undertaken about a decade earlier and represent the work of another group of artists mainly older: the sensitive and distinguished stylist, J. W. Alexander, who died in 1915, H. Ballin, E. H. Blashfield, who has been the most prolific of American mural painters, Kenyon Cox (d. 1919), E. E. Garnsey, and F. D. Millet. Quaintly illustrative and very personal are the murals by Violet Oakley in the Pennsylvania State Capitol. (*See* also PAINTING.) (J. Sh.)

MURKLAND, WILLIAM URWICK (1842–99), American divine, was born Nov. 17 1842 in Demerara, British Guiana. When a child he moved with his parents to Petersburg, Va., and later to Richmond. In 1857 he entered Hampden-Sidney College, but on the outbreak of the Civil War enlisted in the Confederate Army. He was captured at Laurel Hill but was paroled, and returned to Hampden-Sidney College, where he graduated with first honours in 1862. Having meanwhile been exchanged, he again entered the Confederate Army. After the close of the war he entered the Union Theological Seminary of Virginia. After his ordination as a Presbyterian minister in 1869, he was pastor of Centre Church, Cumberland Co., Va. In Jan. 1870, he was called as assistant to the Franklin Street church, Baltimore, Md., and the following June was chosen pastor, which position he held until his death, May 13 1899. In 1800 he was a delegate to the World's Peace Congress in London. Dr. Murkland was one of the prominent figures in the Presbyterian Church in the United States.

MURMANSK, Russia, the Russian port on the Kola peninsula, has been connected with Leningrad (St. Petersburg) by rail since 1917. The line runs across the base of the Kola peninsula and along the coast of the White Sea, joining the Leningrad-Vologda line about 75 m. east of Leningrad. Owing to swampy ground, the line is almost unworkable in some parts of the summer months. A British flotilla was stationed at Murmansk in 1917, and after the Russian collapse, in order to maintain a hold on the coast, two cruisers and a battleship and 5,000 troops were sent in 1918. In that year N. Tschaikowsky overthrew the rule of the Soviets, and set up a provisional government with the help of the British forces; but after their evacuation in 1919 Murmansk came again into Bolshevik hands.

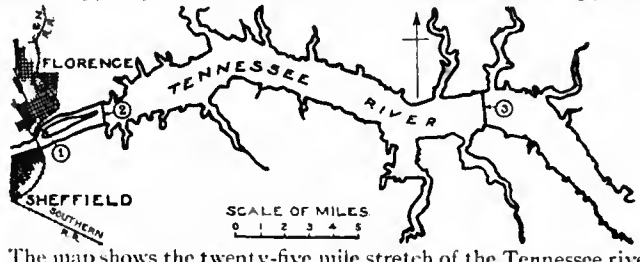
MURPHY, JOHN FRANCIS (1853–1921), American landscape painter (*see* 19.38), died at New York City Jan. 30 1921.

MURRAY, GEORGE GILBERT AIMÉ (1866–), British classical scholar, was born at Sydney, N.S.W., Jan. 2 1866, but left Australia at the age of eleven. Educated at Merchant Taylors' School, London, and St. John's College, Oxford, he at once established his reputation as the most brilliant classical scholar of his day, winning the Hertford and Ireland scholarships (1885), the Craven scholarship (1886), the prize for Latin verse (1886) and the Gaisford prizes for Greek verse and prose (1886–7). He was elected to a fellowship at New College, Oxford, in 1888, and next year to the professorship of Greek at Glasgow University, a position he held till 1809. In 1908 he was appointed regius professor of Greek at Oxford. In 1889 he had married Lady Mary Howard, daughter of the 9th Earl of Carlisle. Professor Murray's sympathies were always strongly shown on the advanced Radical side in politics. He was parliamentary candidate for Oxford University at the general election of 1918 and at a by-election in 1919, but was unsuccessful. During the World War he prominently espoused the cause of conscientious objectors, and later identified himself with efforts to ameliorate economic conditions in the enemy countries. In 1923 he was elected president of the League of Nations Union. He published a *History of Ancient Greek Literature* in 1897, but is more widely celebrated for his incomparable renderings of the plays of Euripides into English verse. Several of his versions were acted in England and America. He also published *The Rise of the Greek Epic* (1907; 2nd ed., 1911, 3rd ed., 1924) and *Four Stages of Greek Religion* (1913). Amongst his works on other subjects are *The Foreign Policy of Sir Edward Grey* (1915); *Faith, War and Policy* (1918); *Religio Grammatici* (1918); and *Problem of Foreign Policy* (1921). *See* GREEK LITERATURE: ANCIENT.

MURRAY, SIR JAMES AUGUSTUS HENRY (1837–1915), British philologist (*see* 19.40), died at Oxford July 26 1915, when *The New English Dictionary* had reached its 10th volume.

MURRAY, SIR JOHN (1841–1914), British geographer and oceanographer (*see* 19.42), was accidentally killed near Kirkliston, Scotland, March 16 1914. In conjunction with Dr. Johan Hjort he published in 1912 *The Depths of the Ocean.*

MUSCLE SHOALS.—The section of the Tennessee river, U.S.A., known as Muscle Shoals, extends from the head of Brown's Island, a short distance below Decatur to Florence, Ala., a distance of 37 m., in the course of which the river falls 134 feet.



The map shows the twenty-five mile stretch of the Tennessee river immediately above Florence, Ala., embracing the shallower section of Muscle Shoals. (1) the small dam affording a navigation approach to the Wilson dam. (2) the Wilson dam, the largest masonry dam ever built. (3) the contemplated third dam, which, when built, will render navigation for commercial purposes feasible at all times.

The depth of the channel varies considerably, but in places the minimum depth at low water is less than two feet, and commercial navigation at such levels has never been practicable. As early as 1827 preliminary surveys were made by the U.S. Govt. with a view to improvement, but nothing of permanent value was accomplished in the 19th century.

War Development.—Various proposals were made for power development between 1903 and 1912, but nothing definite was

attempted till the outbreak of the World War, when the urgent need for nitric acid for use in explosives induced the U.S. Govt. to construct two large nitrate plants at Sheffield near the lower end of the Shoals, to be operated by hydroelectric power. Plans were accordingly prepared in 1916 for a joint navigation-power scheme, involving the construction of three dams on the Tennessee river, and work was commenced early in 1918 on the major feature of the project, viz.: Dam No. 2, officially known as the Wilson dam. The work of construction was started immediately and the dam was completed in 1926.

Details of the Dam.—It is located a short distance above Florence and is a monolithic concrete structure, 4,500 ft. in length, 95 ft. high from the river bed to the crest, 140 ft. high from foundation to the level of the operating bridge and 105 ft. thick at the base. The structure contains about 1,353,000 cu. yd. of masonry, making it the largest masonry dam in the world—the Aswan dam on the Nile, its nearest competitor, having 1,179,000 cu. yards. It is equipped on the north side with two navigation locks, each having a lift of 46 ft. 6 in. at mean stage, and on the south side is the power-house, forming an integral part and continuation of the dam itself. The latter contains a spillway section 2,660 ft. long in the shape of an overfall dam with a heavy concrete apron and 58 steel floodgates to discharge excess water. Each floodgate is 18 ft. high and weighs about 33 tons. These gates are capable of passing a flood of 900,000 cu. ft. per second. On the top of the structure is a concrete arch bridge, supporting the floodgates and carrying a highway and a standard gauge railway track.

Power Installation.—The power-house is 1,250 ft. long, 160 ft. wide, and 134 ft. high, built of concrete with a steel trussed roof and designed for an ultimate installation of 18 hydroelectric units providing 612,000 H.P., the installation in 1926 consisting of eight hydraulic turbines generating 260,000 horse-power. Four units of this latter installation were placed in operation on Oct. 1 1925, the resultant power being leased to the Alabama Power Co. under a temporary contract, terminable on four weeks' notice. The water-power, when the full machinery has been installed and is utilising the natural flow of the river, will produce on an average 700,000,000 kw. hours of primary power per annum, *i.e.*, power which is available every hour of the year, and 1,490,000,000 kw. hours of secondary power per annum, *i.e.*, power that is available a portion of the year only. The total cost of the dam as it stands, including the present turbines, amounted to approximately $51,000,000, and at the peak of construction, 4,500 men were employed on the work.

Navigation Problems.—Dam No. 1, a small work also constructed by the Federal Govt., is situated three miles below the Wilson dam. It is 300 ft. long, having a lock with a lift of 17½ feet. Its only purpose is to provide a navigation approach to the lower lock of the Wilson dam.

These two units of the combined navigation power scheme do not in themselves solve the navigation problem, inasmuch as the Wilson dam only overcomes 96 ft. of the fall of the river at the Shoals, and the navigation pool provided by it only extends about 15 m. upstream. Consequently it does not eliminate the upper stretch of shoal water. To effect this object Dam No. 3 was designed, located 14 m. above the Wilson dam. When constructed it will overcome about 40 ft. of the fall of the Tennessee, provide above it a navigation pool some 84 m. in length and, combined with the Wilson dam, will eliminate the Muscle Shoals as an obstacle to transportation. In March 1926 nothing had been done in regard to this dam beyond some preliminary surveys and borings.

In Nov. 1918, when the Armistice was signed, the nitrate plants had not been completed. Units, however, were ready to start operations in Oct. 1918, temporary power being supplied by the Alabama Power Co. from its plant on the Warrior river, 90 m. south of Muscle Shoals, and the first ammonium nitrate was produced a fortnight after the Armistice. By this time the emergency had passed and the final work was not done till the summer of 1919. They have not been operated since. Their total construction cost amounted to $83,500,000. The future of the whole project was the subject of much discussion in Congress. Finally bids were asked for by the Government. On July 8 1921 Henry Ford made an offer but no action was taken in regard to it and Mr. Ford subsequently withdrew his offer. No action had been taken by March 1926.

MUSEUMS (*see* 19.60b).—The normal progress and development of museums in Europe since 1910 was rudely interrupted and gravely affected by the War. From 1914 to 1918 no government was in a position to spend much money on acquisitions, and many of the usual channels of supply were cut off. Staffs were depleted by the claims of war service; and although museums continued to play a not unimportant part as an element of refreshment in the strain of war, public interest was inevitably diverted from them. In addition, in certain cases, and notably in respect of the great museums and galleries of London and Paris, special measures of precaution had to be taken, which constitute a remarkable chapter in their history.

War Precautions.—The record of these precautions would need an article by itself. It would relate the hurried removal from Paris of a portion of the collections of the Louvre and other museums (principally pictures, but including the Venus of Milo) at the critical time when a German occupation of Paris seemed far from improbable; the measures taken to protect those which remained from the risks of bombardment; the further removals at the time of the German advance in the spring of 1918. In London it would have to record the protection by sandbags and by removal to basements of the chief treasures of the British Museum, the National Gallery, the Victoria and Albert Museum, the Wallace Collection and other galleries during the early months of the War; the closing of certain galleries in 1916 by the Govt. on grounds of economy; and particularly the great removals at the beginning of 1918, when the principal contents of all the great London collections found refuge in an underground tube railway, in the National Library of Wales at Aberystwyth and elsewhere. In Italy it would have to tell of extensive removals and protections at Venice and other northern towns. The experiences of Belgium and of the towns of northeastern France would also have to be recorded. Materials exist for such a record, and it is an episode in museum history of no little interest, one remarkable feature of which is the extremely slight injury caused by the hurried process of dismantling invaluable collections of most fragile objects.

The Functions of Museums

Leaving aside, then, the special subject of museums in war time, the purpose of this article is to trace the principal features of the development of the museum service and especially to indicate the progress that has been made in making the museums perform more efficiently the services which they are intended to render to the public. The main objects of museums are threefold: (1) to preserve the historical and artistic relics of past ages—the acquisition of objects; (2) to render them readily accessible to scholars—adequate housing and the publication of catalogues and reproductions; (3) to educate the general public—arrangement, display, labelling, guide-books, cheap reproductions, lantern slides, lectures.

Museum Extensions.—With regard to the first two of these heads there is not much to say. In spite of the grave financial difficulties in post-War Europe, new museums have continued to be built, and old museums have been enlarged. Among the more important may be mentioned the London Museum, opened at Kensington Palace in 1912, and transferred to Lancaster House in 1913; the Museum of Eastern Art at Cologne (1914); the Wellcome Historical Medical Museum in London (1913); the new wing of the British Museum (1914); the National Museum of Wales, founded at Cardiff in 1912, of which a part has been opened; a new wing of the Fitzwilliam Museum, Cambridge (1921); the Museo Petriano at the Vatican and the Museo Nuovo on the Capitol in Rome (1925). A new Science Museum was in 1926 in process of erection at South Kensington, and in the galleries vacated by it the War Museum was temporarily and inadequately housed. Paris has a Bibliothèque et Musée de la Guerre, besides a special Museum at the Invalides; in other countries more attention appears to have been paid to War Libraries than to War Museums. In Russia several museums and institutions, principally of science but also of ethnology and Russian mediaeval art, have been founded or extended since the Revolution.

In America, unhampered by war expenditure and enriched by the munificence of many private benefactors, new galleries have sprung up like mushrooms; and endowments on a large scale have been lavished, of which the most magnificent was the bequest of some £9,000,000 by Mr. Munsey to the Metropolitan Museum of New York.

Organisation of Expeditions.—Meanwhile, whether in new buildings or in old, the acquisition of fresh objects has gone on continuously. It is quite impossible to give particulars of even the most important; but mention should be made of one branch of collecting activity, namely, the organisation of expeditions by the greater museums for excavation and for natural history research. In this branch of museum work America, with its great pecuniary resources, has led the way. The American Museum of Natural History has continued to despatch expeditions to various parts of the world, the most notable being that to Siberia, which made remarkable discoveries of the eggs of dinosaurs. The Metropolitan Museum of New York has continued its very thorough and elaborate work in Egypt; the Museum of the University of Pennsylvania has had expeditions in Egypt, Palestine and Mesopotamia; the Field Museum of Natural History at Chicago has made large collections of natural history and ethnography; the Heye Museum of the American Indian investigated sites in New Mexico and elsewhere. These are but examples of the fruitful activity of American museums in this direction.

European museums have not been in a position to do so much, nor has the direct conduct of excavations been a common form of activity on the part of continental museums, though, in accordance with the national laws of antiquities, the museums of Italy, Greece and Egypt have profited largely from the researches undertaken, whether by their own countrymen or others, in the soil of these countries. In England the British Museum has undertaken archaeological excavations at Carchemish in Asia Minor and in Mesopotamia; and the Natural History Museum has taken part, in greater or less measure, in expeditions in Australia, East Africa and elsewhere. This is a form of activity which seems likely to increase, owing to the fact that several areas of great importance, especially for archaeology, have been made more accessible in consequence of the War. It has, moreover, stimulated public interest in such research, and may be reckoned as a contributing cause towards the development of public interest in museums generally, which is one of the notable characteristics of the period under review.

It is, in fact, in the relation between the museum and the general public, and in the development of the museum as an instrument in the general education of the nation, that progress has been most marked; and in any consideration of the future of museums this is a point of prime importance.

Educational Uses.—The earlier conception of a museum regarded it as in the first place a storehouse of objects of antiquity for the benefit of the student, and in the second as an old curiosity shop for the amusement and edification of the intelligent visitor. Its value as a means of education for the general public was not realised until late in the 19th century. In Great Britain the recognition of this function at first took the form of a great improvement in the labelling of the collections and the provision of illustrated guide-books suitable for the intelligent reader who was not a specialist, and serviceable even outside the museum as handbooks to the subject with which they dealt. At the British Museum this reform was mainly connected with the names of Sir Edward Bond and Sir Edward Maunde Thompson; and Sir William Flower at the Natural History Museum was a strenuous advocate and exponent of the popularisation of museums.

Museum Lectures.—In America a new departure was made in the provision of oral instruction in the galleries by official guide-lecturers or docents, the example being set by Boston in 1907. It was taken up in England in 1911, when the first official guide-lecturer was appointed at the British Museum; it quickly took root there (and at the Natural History Museum, which is governed by the same trustees); and thence, largely owing to the strenuous and persistent advocacy of Lord Sudeley, it spread to the other national museums and galleries, until now it can be said that the practice of itinerant lectures in the exhibition galleries by highly educated men and women, to chance audiences who assemble to hear them, is thoroughly established as a recognised branch of museum service. In smaller museums, where the attendance is not sufficient to provide daily audiences for a lecturer, similar work is nevertheless frequently undertaken in the form of advertised courses of lectures.

Improved Guide-books and Reproductions.—The educational value of museums has also been greatly increased by the development of methods of photographic reproduction. Guide-books can be made more attractive by plentiful illustration; and photographs, especially in the popular picture-postcard form, can be obtained very cheaply. These can be rendered far more useful for educational purposes if issued, as at the British Museum since 1914, and subsequently elsewhere, in sets dealing with special subjects. Fifteen postcards in monochrome, or six in colours, with a leaflet of information, can be sold profitably for a shilling, and furnish an interesting and attractive introduction to a subject. The danger is lest the productivity of a museum should be diverted overmuch into these popular and profitable productions, at the expense of those contributions to learning which every great museum is rightly expected to make.

This development of the educational and popular sides of museum work is not by any means confined to the great metropolitan collections. It is characteristic of museum work as a whole throughout England and America. Every active-minded curator is anxious to make his museum a living centre of intellectual interest; and the future of m seum development depends mainly on the answers to be give to the question, How can museums be made more serviceable to the nation?

Research and Scholarship.—A distinction must be drawn between the great museums of the largest towns and the most important universities and the municipal museums of provincial towns in general. The former, while never forgetting the service which they owe to the general public, must not sacrifice to it their duty to scholars and researchers. For these, quantity is often as essential as quality. It is sometimes supposed that the great museums contain masses of objects with which they could well dispense, and which could more profitably be distributed among, or at least lent to, the smaller museums. It is, in fact, seldom and to a very small extent that this is true. The scholar who is investigating a particular subject needs to have under his eye, for examination and comparison, a great mass of material. He needs many editions of an author, many examples of the work of an artist, many specimens of Greek vases or Chinese porcelain, of birds, beasts, fishes, insects, fossils, minerals or flowers. His work would be ruined if he had to search for these in many different collections; and it would be exasperating to find that the objects which he had the right to expect to find in a particular museum had been scattered on loan among a score of provincial collections.

What the curator of such a museum has to consider is, not whether he has in his collections a finer example of a certain class, but whether a particular object is needed for the scientific study of the class to which it belongs. At times, no doubt, a specimen once useful may have lost its value and can be dispensed with, but this happens comparatively rarely. Nor is there much danger lest the museum curator should be led away by the lust of acquisition. Purchase grants are not so lavish that he can afford to buy anything that he does not really want; and in most great collections the demands for accommodation are so pressing that he will gladly dispense with anything that is really superfluous.

The Ideal Museums

The need of great museums, then, is proper provision for (*a*) the student, (*b*) the general public. The difficulty here is mainly structural. There was a time—a time when most of the museums in Europe were built—when there was no great difficulty in putting all the collections of antiquities on exhibition without overcrowding. That time is long past, and what is needed now is to apply to antiquities the method which has always been applied to books and prints and often to natural history specimens, namely, to exhibit only a small selection to the public, while providing facilities for students to examine the mass of the collections in convenient circumstances.

The ideal museum—an ideal realised in some of the latest—is a succession of public exhibition rooms in which a small number of the best specimens are well spaced out and adequately labelled, and another series of rooms in which students can sit down to the examination of a large number of specimens, or the intensive study of a few, according to the need of their study. The general public will have a better chance of appreciating without fatigue the charms of Greek vases or mediaeval enamels from 50 good specimens well displayed than from 1,000 ranged in serried rows of shelves. What most of the older museums need, and what architects have seldom been asked to provide, is ample storage accommodation. They would then be able to discharge the double duty—each so important—which rests upon them.

Provincial Museums.—For the provincial museums the balance of responsibilities is different. Although they can often give important aid to research, their first duty is usually to the general public. Here the educational function is paramount. Few general laws can be laid down, because museums differ so greatly in their possessions and their opportunities. A provincial museum can seldom aim at universality, but it can do much by a wise cultivation of its own particular garden. One duty is incumbent on all, to create interest in, and to diffuse knowledge of, the localities in which they are situated. The history of the town, the records of its buildings and its eminent citizens, the geology, fauna and flora of the surrounding country, the principal arts and industries of the neighbourhood—these are subjects which all active museums now regard as their proper sphere, and which they strive to illustrate with all the materials that they can acquire. On these subjects they are entitled to aim at being exhaustive. On more general subjects they can only hope to be able to give partial representations, and each must cut its coat according to its cloth.

One general counsel can be given—to vary the exhibitions as much as possible, to seize opportunities of giving them topical interest, to add to their educational value by lectures, leaflets and photographs, and generally to cultivate an air of alertness and change rather than sameness and monotony.

Loan Collections.—In this connection the question of loans is of importance. It is clear that provincial museums would be much assisted in provoking interest and in spreading education if their permanent resources were reinforced by temporary exhibitions of loan collections. It is here that a gap exists in the museum system which could be filled with great profit. It has already been indicated that not much help in this direction is to be expected from the great national collections. Local museums might help one another, to some extent, by temporary exchanges of exhibitions on subjects in which each happened to be strong. In some cases also permanent exchanges might be arranged.

Central Depository.—But a very real service to the education of any country would be rendered by the creation of a strong central depository of loan collections. In England a service of this kind, designed in the interests of craftsmanship, was a prominent feature of the original plan of the South Kensington Museum. In the department of classical archaeology, experiments in this direction have been made in England, Ireland and America (see H. Browne, *Our Renaissance*, 1917, pp. 184–281). But a stronger, better supplied, state-supported central organisation is required, which need not be costly, since it would receive subscriptions from the local institutions which had recourse to it. Taking the country as a whole, there will be a great economy in a central circulating collection as compared with a large number of local museums, each trying to add to its permanent collections of non-local objects. The central collection would not need to indulge in expensive purchases, since it would not aim at acquiring objects of the first rank; and it would receive such objects as the national museums were able legitimately to spare.

The main needs of the museum service, then, certainly in England and in varying degrees also elsewhere, are: for the greater museums, restricted exhibition to the public and fuller accommodation for the student and for storage; for local museums, centralisation, co-operation and devotion to the education (in the broadest sense) of the local public.

MUSIC (*see* 19.72).—The purport of the present article is not that of a *catalogue raisonné* of modern music; its intention is to put forward certain general principles that seem to have become more clearly manifested since 1910. Any works and composers that are mentioned will be selected merely as the first convenient illustrations of these principles; and the convenience will be avowedly accidental. This method has, in the past history of criticism, always proved to give results far more interesting than those of an attempt to catalogue and estimate contemporary events and works; nor does the dearth of names and titles detract greatly from its interest. The greatest art takes ample time before its impulses reach the main stream of historic tendency, so that the contemporary view of the main stream is naturally, and not unjustifiably, preoccupied with work that will not interest posterity; while, on the other hand, future historians will, as often hitherto, have great difficulty in finding any historic importance in the works which prove immortal.

But we are on solid ground if we fix our attention on prevalent tendencies shown by large bodies of work and of criticism, and on the conditions in which the work is produced and enjoyed. There are periods of artistic transition in which tendencies are too vague or too involved to be distinguished by the contemporary observer. If perhaps this was so in the beginning of the 20th century, things had become clearer by its second decade; and it was possible to draw an emphatic distinction between what is real and what is unreal in the music of the day.

I. INTRODUCTION

Defects of Contemporary Criticism.—It will be convenient first to deal with the unrealities. The most formidable of these arise from the unnatural conditions on which the modern musician acquires his reputation. At no period in history has an artist been able to make his living solely by his highest line of work; but the hardships of the classical artist's life were at all events not unnatural. They were average effects of human nature, and not of an inflated self-consciousness among art critics. It has always been hard to struggle against a depressing prevalence of dull or vulgar tastes and pedantic conventions; but such a struggle is life, and victory in it is health. Far less certain is it that life and health can be found in the struggle for musical reputation under modern conditions; especially for reputation as a composer.

The grounds on which new music is commonly criticised are no longer grounds of healthy and intelligible discussion. The critics, conscious of the proverbial persecution of genius by contemporary pedants and upholders of convention, are now unanimous in condemning all that is under suspicion of being "correct," and are desperately anxious that no *soi-disant* revolutionary tendency shall miss acclamation and that no dangerous outbreak of normality shall escape damnation. The music that is most written about and talked about is the music about which it is the easiest to say clever things. The clever things must be or seem to be intelligible to the general reader; and this means that they must not be musical facts, for musical facts are involved in musical technicalities. Yet the clever sayings must be impressive. The result is a special psychological jargon, mostly unknown to psychologists, which the general public believes to be a musical jargon. The public finds it fairly amusing, especially when the critics, having exhausted their stock of new musical discoveries and revolutions, are reduced to discussing each other. But it may be news to the public that the jargon is almost wholly unintelligible to real musicians, and nowhere more unintelligible to them than where it employs musical terms.

Meanwhile real music struggles into existence, and even occasionally into recognition, while fashion follows the journalists and awards fame without popularity 10 times a year to musicians of perfectly respectable character and intellect who are driven to pose as lunatics lest sanity should earn them the reputation of

prigs. In such conditions it is not surprising that there is more genuine musical life in provincial districts than in the metropolitan cities. The musical life of the provinces is their own; the metropolitan public is so anxiously watching the jumping of the critical cat that even the formation of coteries is conditioned more by diplomacy than by enthusiasm. Popularity and healthily good music are driven to meet on new ground. Theatre music, apart from opera, is in Great Britain still in a state of squalor, which must remain hopeless as long as British theatregoers maintain the habit of drowning the musical *entr'actes* in talk. But the cinema produces a remarkably perfect silence in spectators, and in its not always fresh atmosphere many an excellent player finds a livelihood which he can ill afford to exchange for a good position in a permanent orchestra. The London music hall, especially since the advent of the great Russian Ballet dancers, has drawn into its sphere of influence many a serious musician, among composers as well as performers; and the composers to whom it is still a strange environment may sometimes find that more than a pot-boiler impulse and technique are required of them if they are to distinguish themselves there.

At all ages there have been heartsearchings as to the border lines of "legitimate" art, and the origins of the highest classical art forms have far more often been popular tendencies than critical doctrines. The health and fruitfulness of permanently valuable art demand two conditions: first, that artists shall have the inducement of a living wage for producing it; secondly, that audiences and spectators shall be accustomed to receive it so attentively as to induce the artist to refine his style. Art does not thrive in a state of public opinion and critical jargon in which nothing is allowed a right to exist except works of devastating genius; and genius itself stands less chance of recognition in such a state than in any other. A good period of art is that in which the ordinary styles are so good that the sensibilities of a child of genius are not starved or disgusted by them before he has had time to outgrow them as a genius must. Nothing good can be expected for genius or philistine from a state of art in which every style is ostentatiously paradoxical.

Between the fruitful and the unfruitful tendencies in contemporary music, the questions at issue are not primarily matters of taste or tradition. It may be assumed that vital art has deep foundations of taste and tradition, even if it professes to revolt from them all; but the signs of its vitality are neither in revolt nor in conformity, but simply in the variety and the coherence of the art in itself. And the variety and coherence are matters of discoverable fact. Principles which make for them are likely to be sound; principles which destroy them are, if correctly stated or imputed, certain to be unsound. We must, however, bear in mind that the creation of a work of art is an altogether different process from criticism and analysis. The craziest theory may be accepted by a composer as being his method of work, and it will do him not the slightest harm so long as it keeps his attention so poised that the depths of his mind are free to express themselves. But the same theory will be disastrous to most of his disciples, though some may share his luck with it. The classical art forms were not, in their origin and maturity, crazy theories, but shrewd generalisations from familiar experience. As that experience becomes remote the art forms lose their vitalising expressive power. But there is more vitality in remote experience than in none at all; and a mere arbitrary contradiction of old artistic theories is, one would think, the most obvious sterilising procedure that could be devised for future art.

II. MODERN MASTERS AND THEIR WORK

Scriabin's Harmonic System.—The procedure is seen at its worst when it is applied to some all-pervading category of music, such as harmony. Whatever may be the merits or the fecundity of the composer, we may be absolutely certain that when he explicitly promulgates a new system of harmony he is talking nonsense. Scriabin (1871–1915) began his career as a brilliant 20th century Chopin, with an unmistakable power of composition in large and free form, besides a happy vein in the tiniest of preludes. In time, certain harmonic mannerisms developed: the composer was inspired to write for orchestra; his vigorous talent for composition not only stood the strain of this larger medium but remained traceable in works based each on some single artificial chord of which the original meaning is obviously a Wagnerian progression, but which was expounded to the gasping interviewer as the most perfect chord in music. And so the gasping interviewer went on his way rejoicing in the possession of a profound technical mystery worthy of revelation together with the composer's theosophic doctrines and other matters of popular interest. There is no reason for doubting the composer's sincerity either in his theosophy or in his harmony. Artists are seldom also men of science, and even men of science keep some region of their minds in a state of holiday wherein they may be perfectly arbitrary and self-centred. Art originates from such regions of the mind, but it will be stifled, and those regions will be starved, unless it emerges and forages in the wide world of human life. Egocentric as is the nature of art, the confines of one personal life are not enough for sane self-development; and the personal note of the artist who retires into the recesses of his arbitrary domain will not long retain its power.

The untimely death of Scriabin left his art just at the point where it was beginning to alienate his enthusiastic supporters. Contemporary enthusiasm and hostility on theories of harmonic style may be left to the theosophists. The important fact is that Scriabin did, while he lived, produce compositions with a large flow and climax: nor do we know that his power to do so was likely to fail him. But the lesson of three harmonic revolutions, distributed over five centuries of musical history, is that wherever a composer becomes preoccupied with harmonic ideas his power of composition is in greater danger of dwindling than when his interests lie in other categories of his art. Scriabin himself complained at last that all his harmonic efforts had not carried him essentially beyond the dominant seventh; and herein history repeats itself, for the complaint is substantially that with which Philipp Emanuel Bach refuted the harmonic theories of Rameau, saying to Burney that he could conceive nothing more childish than this notion of the "fundamental bass," inasmuch as it "would reduce all music to a series of full closes." The truth is that all purely harmonic ideas first become intelligible by gravitating towards a full close; just as all verbal ideas gravitate towards the form of a subject, a predicate and a copula.

Nor do harmonic ideas escape their fate by being based on conceptions which deny the aesthetics of classical polyphony and attempt to treat chords as pure sensations without relation to the melodic progression of their individual notes. Sooner or later the composer will awaken to their possible meaning in a polyphonic scheme. Thus Walford Davies has sealed the fate of the "whole-toned scale" (once believed to be the anti-polyphonic backbone of Debussy's art) by pointing out that it is not a scale at all but a chord, which, properly distributed in different octaves, can resolve in six enharmonically different ways, none of which have anything to do with the sceptical and mechanical train of thought which tries to base harmonic systems on the limitations of the equal-tempered pianoforte with its 12 semitones to the octave. It is not worth while attempting to catalogue the systems of harmony evolved at the pianoforte by composers who continue to imagine that chords can be built up in fourths or in other *a priori* ways as rhythmless and unmelodic entities. Whatever the reader's indignation at finding in this article no treatment of the dozens of harmonic and musico-metaphysical topics he hears of to-day, he may comfort himself with the certainty that nobody will have heard of most of them next year. One might as well discriminate between the fashions which dye the hair green and those which dye it blue.

In all the chaos of recent experiment with discord and disordered rhythm, two questions alone are capable of permanently significant and truthful answers: the one concerns the composer and the other the listener. To the composer we may address Brahms' rude query, "Do you find this fun?" Of the listener we may ask, "Can you find a sufficient variety of coherent definite elements, events, qualities and forms in this art, quite irrespective of any question of novelty?" This question must

be answered with regard to all the elements of the art from the oldest to the newest, and it is one of the few sound artistic questions which concerns an artist's whole output as well as individual works, *e.g.*, whatever may be thought of Scriabin's last harmonic obsessions, his smallest preludes, early, middle or late, could not have been created by a composer who could do nothing else. It is an accident that his work made a new sensation: it is an essential fact that he is a composer. Without the power of composition a new sensation cannot last, even if it can make its mark at all. With power of composition everything in art must some day find wide recognition, if it escapes physical destruction; for no composer attains such power without being driven by strong human impulses. Epigrams are not enough. Human experience vividly presented never loses point.

Stravinsky and the Ballet.—But the chances of producing permanently living work are heavily weighted against the composer if he concerns himself only with things which he alone can understand. The Russian Ballet gave abundant vital impulses to music so long as it dealt intelligibly with drama, fairy tale, fable and life; and the young Stravinsky of *L'Oiseau de Feu* found in it inspiration for music that remains brilliant and intelligible apart from the ballet. In *Petrouchka* he still makes rhythmic and instrumental sounds that faithfully follow and enhance the moods of a fascinating pantomime; but the concert-goer who, knowing nothing of the ballet, affects to be moved by the music in an orchestral concert, is little wiser than the man who would rather say he preferred the wrong end of his asparagus than admit that he did not know which was the right end. The ballet is to the composer an easier and therefore more dangerous art form than the opera; in both cases the listener will always give the music credit for all the qualities of the scenario if the composer only manages not to interfere with them.

Self-deception, loss of vitality, decadence and dry-rot set in when the designers of the ballet themselves retire into the arbitrary kingdom of abstractions which they call symbolic, and which common sense calls nonsense. There is a real kingdom of nonsense, and it will have none of your owlish aesthetic solemnity about morbid twists of mind. Lewis Carroll, trained logician, leaves it to later commentators to identify his Snark with the Absolute, or with the company promoter; his and Edward Lear's wonderland of nonsense is a school of manners in the light of which any explicit social satire and many fantastic flights of modern musical imagination appear almost equally convicted of grossness and heavy incongruity. For music, as for all arts, the fruitful path, and that which leads even to the sublime as well as the imperishable, is a path of unselfconscious childlike enjoyment of the matter in hand, with no petulant preoccupation with the stupidity of the outsider. Erik Satie is amusing enough with his *Vraies préludes flasques pour mon chien*, his *Aperçues désagréables*, and all the rest of it; his works are announced with the challenge, as to *les Aplatis*, *les Insignifiants* and other more Rabelaisian nonentities who will not enjoy them, "*qu'ils avalent leurs barbes! qu'ils se marchent sur le ventre!*" English patriotism cannot but feel flattered by this contrast with the perfect manners, perfect scholarship and perfect art with which Holst has made a fairy tale of all the operatic styles in musical history in *The Perfect Fool*.

Gustav Mahler.—Prominent among the eternal questions which agitate the contemporary critics of all arts at all periods is the proportion of means to ends. The modern orchestra grows easily with the demands of the modern composer, for, in spite of local and temporary difficulties, it is to the interest of players that orchestras should increase as well as multiply; but the most extravagant modern composer has never yet faced the problem of designing music for which the band and chorus of a Crystal Palace Handel Festival would really be to the purpose. In other words, the Handel Festival exists; but the music for an organisation of even half that size has never yet been composed.

Here, then, is material for a real aesthetic development; and herein lies the significance of the recent vogue in Holland of the enormous works of Gustav Mahler. That great Viennese orchestral conductor died almost a generation ago, and his symphonies owe much of their recognition to the personal zeal of their apostle, the eminent conductor Mengelberg. It is improbable that the music-lovers of other countries will ever readily receive these huge volumes of naïve sentimentality and boyish grotesqueness. But the works nevertheless demonstrate at least three vital things: first, that it is still possible for a composer to pile up structure of illimitable extent in the most unsophisticated harmonic and melodic style; secondly, that, whereas taste cannot even begin to express itself without some technique, an immense amount of technique may be learnt from work which cannot be said to show any taste at all; and thirdly, that whatever may be objected to Mahler's taste and form in this direction, he undoubtedly fulfilled his set purpose of working out the pioneer aesthetic and technical principles of music designed for 1,000 performers and upwards. And this is no decadent proposition.

Decadence lies rather in the performance of classical music on a scale for which it was never remotely conceived. The real problems of music for 1,000 performers are, as Mahler perceived, problems for a severely disciplined and accurate imagination; and nothing can be further removed from the world of arbitrary artistic egoism. They are not to be mastered by the methods of that kind of extravagance which now and then displays a revulsion in some absurd economy, like Meyerbeer's old trick of thin and inadequate harmony for one voice supported insecurely by one horn and a spasmodic gurgle on a solo violoncello. With much of Meyerbeer's "best-seller" qualities, Mahler nevertheless has none of Meyerbeer's worldly wisdom, and in his special field there is as yet no greater and more masterly idealist. In vocal music he often attains great beauty and purity of style.

Schönberg.—The main stream of music still flows within the Wagner-Strauss limits, and seldom requires 150 instrumental players. Arnold Schönberg's *Gurre Lieder* (a large vocal and choral cycle, the great success of which is held by his disciples to be a serious hindrance to the spread of his later gospel of *a priori* harmonic revolution) requires a huge orchestra; but the very fact that the score often employs 50 staves proves that Schönberg is by no means imagining the aesthetics of an unprecedented scale of performance; the polyphony that requires 50 staves for its notation implies detail rather than bulk.

Max Reger and Classicism.—The life work of Max Reger presents a strange study of artistic vitality working on methods the reverse of vitalising. At first sight his productivity seems enormous; and since Orlando di Lasso in the 16th century we have had no other conspicuous instance of a composer who seems always able to sit down before a pile of blank music paper with a blank mind and work himself up into genuine inspiration by sheer interest in the weaving of rich musical texture. To the present generation of German musicians Reger is the last of the classics; but there are few things in music less classical than Reger's art forms, rigidly orthodox though they seem. They are the direct result of extraordinary docility in the pupil of the most systematic musical scholar of recent times, and anyone who has groaned in spirit at the sight of one of Hugo Riemann's editions of a piece of classical music may easily recognise in Reger the traces of his teaching. Every external feature of the classical art forms is present without any trace of the classical reasons for it. Everything has been worked out from one detail to the next, without any first principles to account for the whole procedure.

A facile contrapuntist, Reger writes untold numbers of fugues, all on one mechanical plan, mostly with some combination of subjects, but never a combination between subjects sufficiently contrasted to give it point. His instrumental works are for the most part cast in sonata forms; except for the incessantly modulating and chromatic style, the whole collection of works contains neither an unorthodox procedure nor the slightest reason for its orthodox procedures. Bach wrote great works for unaccompanied violin, and Reger does likewise. But he shows no sense of the principle that Bach's unaccompanied melody is its own bass; Reger's melodies cry loudly and ambiguously for harmonic support. You might as well cut out with scissors a full-face portrait of a judge in his wig and expect it to be recognisable as a silhouette.

Whatever is to be learnt from Reger, it is not the meaning of classical art forms. And much is to be learnt from Reger. His texture is inevitably thick, for his rigidly systematic completeness vetoes that suggestiveness which is one of the secrets of the greatest art. But it is astonishingly sonorous, and, in its heavy literal-minded way, effects its purpose in the fewest possible notes, numerous though they be. Every instrument is profoundly studied and developed on the basis of its natural technique; and while the player who claims that he can read Reger at sight is probably mendacious, he will enjoy his instrument all the better for playing Reger well. Nor is this the only or the most important non-egotistic reality in Reger's work. The reality of Reger is that he is a consummate and impassioned rhetorician. His unreal art forms hinder and help him no more and no less than the alphabetical acrostic hindered and helped the poet of the *Lamentations of Jeremiah*. He extemporises on paper, and is profoundly attentive to the nature of his instruments and to whatever text he is setting in his vocal music. In the history of art there can be no more conspicuous example of the difference between analytical theory and the practical conditions of creative work.

Bantock, Holst and Boughton.—The only things that matter to the composer and to his posterity are the things that help or hinder him in creating his works. Posterity will not inquire whether Sebastian Bach, Granville Bantock, Richard Strauss, Busoni—whosoever you will—were reactionaries or revolutionaries, whether they followed classical forms, misunderstood them or abolished them. Nor will posterity pay any attention to the questions we so often ask as to whether such and such a composer's work has led to further developments or hindered them. This is a totally different question from that which is often confused with it, the question whether certain principles (such as a revolutionary but disciplinarian theory of harmony) do or do not interfere with a composer's capacity to write coherent and fluent works. On the sane musician the effect of the achievements of Wagner or Strauss is to enlarge his ideas of the range of his art. He is not obliged to cover that whole range himself; and the musician who, not being Wagner or Strauss, dooms himself to failure by working on their huge scale with inadequate resources, does not thereby show that his artistic balance would lead him to better success on a smaller scale. All great art may be accused of "leading to a blind alley," inasmuch as its achievements are always individual and unique. Yet every achievement that lives (and many live, like the works of Domenico Scarlatti and Couperin, that cannot well be called great) is a source of inspiration to right-minded artists. It is not a matter of taste; nor need it be an incitement to handle any particular art form or to imitate the style that has inspired the artist with Correggio's conviction "*Anch'io son pittore!*" It would be difficult, for instance, to name any composer whose style shows the influence of Granville Bantock; just as it is difficult to trace in his style, otherwise than by merely technical measurements, the influence of Strauss and of the schematic purity and brilliance of Russian orchestration. Yet there is probably nowhere in Europe a more radiant source of musical health.

Another striking example of artistic vitality commands attention in the work of Gustav Holst, an English composer whose interest in oriental subjects is (like Bantock's) no whim for *chinoiseries* but a true expression of the nostalgia of the West for the East. In every direction his work is masterly, independent and indisputably real. *Savitri* is an oriental opera written with the slenderest of instrumental resources and with much singing that is not only unaccompanied but unharmonised. Holst has also produced beautiful songs for the strange combination of a solo voice accompanied only by a violin. At the other end of the scale we have his orchestral work *The Planets*, in which he shows his full musical freedom. Probably the work in which his design most accurately and tersely fills its space is his setting of the sublime ancient Byzantine *Hymn of Jesus*. Here the music seems indistinguishable from the text; and its primitive and drastic harmonic logic, which technically could not have been written before the time of Debussy and Ravel, is no more suggestive of the fashions of to-day, or of any day, than the awe-inspiring Eucharistic text which reverberates through it. No modern music is more utterly unsuggestive of outward and technical resemblance to the classics, and none rests on deeper foundations of musical scholarship.

Among the most significant signs of life in English music we must mention Rutland Boughton's remarkable musical festivals at Glastonbury, where (until interrupted by the World War) he produced English opera on a small scale, ranging from Purcell to his own and other contemporary works, several of which have since become famous.

Strauss's Later Work.—It is easy to ask what effect the World War has produced on music. The wisest answer is negative. The ascertainable effects of the War upon the arts are blankly destructive. Few, if any, of the works written avowedly to commemorate the War can possibly succeed in meaning what they say or saying what they mean. And of the losses to music, who shall discriminate between the talents that had been given time just to reveal their promise and those that were cut off yet sooner? What now of Russia, where in 1921 world-famous composers were living in starvation without even paper to write on? If any musical work is destined to impress posterity as a noble expression and reaction of the World War, the choice might fall on Richard Strauss' *Die Frau ohne Schatten*. His *Alpen-sinfonie*, which, designed before the War, appeared in 1915, was a great disappointment, amiably commonplace in "programme" and sentiment, and hardly more than automatic in its characteristic "road-hog" technique.

As regards *Die Frau ohne Schatten*, the style of Richard Strauss is no longer a new sensation, and it cannot be easily proved to be less automatic here than it is in the *Alpen-sinfonie*. The intention of the work as a whole must be ascribed to the poet Hofmannsthal; but this does not minimise the importance of what Strauss can achieve at the height of his power and inspiration. His mastery of composition and texture has never been seriously in dispute, whatever exception may have been taken to the extremes and licences of his style; and as the poet's intention is noble, the composer has made its realisation vivid as no one else could imagine. From the twilight of 19th century and recent erotic art, and from its always selfish and sometimes abnormal sexual preoccupations, *Die Frau ohne Schatten* breaks away, and its plea for love is nature's plea for life. Musically it is, more copiously than any of Strauss' former works, an occasion for beauty; as a dramatic spectacle it is a gorgeous fantastic pantomime, of which the allegorical meaning leaves it hardly less childlike than *Die Zauberflöte*, which it in some points intentionally resembles. It is altogether a noble and heroic work, unassailable by any cavil that does not condemn itself as ignoble.

III. THE FUTURE OF MUSIC

A New Pianoforte.—In the early summer of 1921 a new kind of double keyboard for pianofortes, invented by the eminent Hungarian composer Emanuel Móor, and manufactured by Messrs. Schmitt-Flohr of Berne, was demonstrated in Berne to large audiences. Two things stand in the way of its development as the most important invention in musical instruments since the pianoforte itself; first the commercial difficulty in promoting an improvement that cannot be simply added as an extra apparatus to an existing pianoforte; and secondly, the tendency to expound it as a device that makes existing feats of pianoforte technique nugatory, a policy which merely infuriates the pianoforte virtuoso. The real importance of the invention lies in its entirely new resources. The principle is simple and might just as well have been discovered when the pianoforte was first invented: in which case Mozart's pianoforte-technique would have begun considerably beyond the point where Beethoven's now leaves off. Two manuals are placed, the one so slightly raised above the other that a perfect *legato* in rapid passages is obtainable between them by one hand. The second manual is an octave higher than the first. Thus the normal stretch of one hand is two octaves instead of one; and with the cultivation of a new set of movements of the hand, backwards and forwards as well as laterally, the possibilities of pianoforte-writing already seem

limited only by pure musical aesthetics. But this is not all; the two manuals can be coupled together by a pedal, so that the instrument possesses much of the property of the organ and also of the harpsichord, in the power of doubling a whole mass of harmony or any part thereof in "four-foot tone." The restoration of harpsichord effects is completed by a lever which operates a kind of sordine, producing a somewhat crudely generalised harpsichord tone which later improvement may make very valuable.

There is a vast new technique awaiting long study and exploration; but the merest rudiments of it produce astonishing results in a short time, for the pianist who gave the first public demonstration did so within six days of setting eyes on the instrument. Doubtless it will develop its own vices as well as resources, but it begins by depriving pianists of occasion for four-fifths of their worst habits, and sets a premium upon a Bach-like and Mozart-like cultivation of polyphonic *cantabile*. Many composers use the pianoforte in the act of composition far more than they are willing to admit. They know it to be a bad habit, because it tends to cramp their invention in two directions: it confines phrasing to the obvious sequences that muscular memory best grasps, and it confines part-writing to the compass and convenience of the hands. The second limitation is now removed, and those composers who suffer from "pianistic" habits may learn from it a greater freedom in their writing for other instruments and for orchestra. Thus there is no region of music unrelated to Emanuel Móor's duplex coupler pianoforte, and this instrument should become a very important source of interest and inspiration in the music of the future.

Wireless and the Future.—The development of wireless broadcasting is effecting, in music as in other matters of entertainment and education, changes which only future generations will be able to estimate. The industrial revolution it will create in the lives of musicians will need wise guidance if it is to be beneficial to music. The function of the large orchestra in the public hall will never become obsolete, for the sounds that reach the ear from the dispersal sources of an orchestra have an acoustic perspective which no improvement in "loud-speakers" can impart to a transmitter or phonographic recorder which emits all sounds from one place. The simple experiment of putting the hands around the ears while listening to an orchestra in a concert-room will convince the listener that a "gramophone effect" is little more than the result of cutting off the waves that reach the ear from other than frontal directions. Apart from the improvements of technique that are rapidly making the transmission of timbre and balance of tone more satisfactory, the development of "wireless" music is already arousing millions to attention without arousing the inhibitions and excitements of crowd-psychology. The very defects of transmission are stimulating pianists (whose instrument suffers thereby more than most) to the study and broadcasting of intimate early keyboard music in which the plain melodic and polyphonic sense demands almost nothing from the special character of the instrument, but appeals to fireside audiences who would find it unintelligibly thin in the concert-room. Moreover, a new fact in musical aesthetics is the extraordinary beauty of microphonically magnified tones of very faint instruments, such as the clavichord.

We may be nearer than we think to a still more subversive revolution by means of the microscopic study of the wave-lines of phonographic records. There is nothing to prevent the possibility of producing music directly in terms of those lines. The limitations of music so produced would no longer be those of instruments, but would be determined solely by the precision with which it may become possible to model any sound-wave required. The composer will imagine and prescribe any producible timbre at any pitch he pleases, and will perhaps have no more to do with the craftsman who models the phonographic wave-lines than the violinist has to do with Stradivarius. The crudest beginnings of this new art will be of enormous importance, but its highest development will still leave the human handling of instruments supreme as the inexhaustible source of musical inspiration.

MUSICAL COMEDY (*see* 8.533).—Although musical comedy is one of the most popular entertainments of the English-speaking races, it has always been passed over by writers on music as too unimportant for discussion, and books of reference have hitherto maintained a curious silence on its origin and character. Yet musical comedy and its off-shoot, revue, occupy a distinct place in the history of the modern theatre.

CHARACTER AND ORIGINS

What is musical comedy, and what is its line of descent from the recognised forms of light opera? Clearly it bears no relation to the classical *opera buffa* of Italy. That had no spoken dialogue and its place was taken by *recitativo secco*, a formal and rhetorical delivery of the words, supported by the lightest accompaniment. Mozart's *Figaro* and Rossini's *Il Barbière* are good examples of *opera buffa*. Nor has musical comedy any real connection with the German *Singspiel* except that spoken dialogue was used instead of *recitativo secco*. In France the *singspiel* developed into *opéra comique*. But the French comic opera was not necessarily comic, but was so called merely to differentiate it from grand opera. It was not considered necessary, indeed, that an *opéra comique* should include a single comic scene or character, but whatever the style of its drama might be, its dialogue had to be spoken. Since the dawn of the 19th century *opéra comique* has been a favourite form of composition with French musicians, but one may look to the popularity of the *vaudeville*, after the French Revolution, as being a more direct ancestor of modern musical comedy as far as the style of the play was concerned. But the *vaudeville* was written in verse, and musical comedy employs only lyrics for musical setting, the play itself being carried on by spoken dialogue.

A much closer analogy is to be found in the French *opéra bouffe*, which is not in any way akin to the Italian *opera buffa*. In the former, spoken dialogue alternates with light music, and in the play itself there were generally topical or satirical allusions. It was a kind of *opéra comique* in little. From the *opéra bouffe* and *vaudeville* sprang the operetta: at first, as its name implies, a short opera of one act which was employed to lengthen the evening's entertainment. Gilbert and Sullivan practically founded their operas on the operetta and *opéra bouffe*, but, except at first, they cast them into two acts of sufficient length to fill the bill.

On its formal side, the English ballad opera may be considered one of the models for musical comedy. Sentimental songs are introduced with the same irrelevance. The English ballad operas came into being as a protest against the Italian operas of the 18th century. The English works were even composed in the Italian manner, *recitatives* taking the place of dialogue. But they did not have much success until Gay wrote *The Beggar's Opera*, for which Dr. Pepusch adapted the best English and Scottish melodies that could be discovered. The opera had a great success in 1728, and when a modern version of it was produced at the Lyric, Hammersmith, in 1920, it ran for 1,463 continuous performances, being beaten only by *Charley's Aunt* (1,466) and *Chu Chin Chow* (2,238). *The Beggar's Opera* was afterwards revived and did well. The success of *The Beggar's Opera* led to the production of *Polly* at the Kingsway

Theatre (1922) and of *The Duenna* (1924). This revival of interest in ballad operas suggests that this typically English form of musical entertainment may have a future. A revival of Isaac Bickerstaff's *Lionel and Clarissa* at the Hammersmith Lyric Theatre in Oct. 1925, proved fairly popular. All these 18th-century ballad operas have been retouched and to some extent modernised, but the work has been done so well that they have not lost their antique character. But neither they nor the Gilbert and Sullivan operas have anything in common with musical comedy. Their popularity is evidence, however, that there is a large public interested in music of a light character.

The *genre* of musical comedy, then, is in direct descent from the *opéra bouffe* and the *vaudeville* of the French combined with our own ballad operas. But it must be remembered that in very few instances is one form of art purposely modelled on what has gone before. Makers of musical comedy have not been at pains to imitate and adapt to present needs former works of light music. Sir Arthur Sullivan is, perhaps, an exception, for the earlier examples of the Savoy operas do show that he had taken the French operetta as his model. Musical comedy, as it is known in London and New York, is an expression of a love of boisterous and farcical humour rather than of the high comedy of the operetta. In its present form it is peculiarly an expression of the English-speaking races. Its humour is broader, more farcical and more eccentric than anything to be found in light French or Viennese opera, and the student will find curious evidence of this in the change which French or Viennese light operas undergo when adapted to the British or American stage as musical comedies. André Messager's *Véronique*, for instance, was first performed in London by a French company (1903) as a light opera. When it was produced, shortly afterwards, in an English version, the comedy part of the florist was developed by Mr. George Graves into an eccentric low comedian. This had the effect of changing the character of the piece, although, of course, the original music remained.

Much the same change had happened to the Viennese light operas which, from 1910 almost to the present day, gradually ousted English musical comedy from the London and New York stage. The public patronises musical comedy because it is fond of music, and it soon became fascinated by the finish and skilfulness of the compositions by Oscar Straus, Leo Fall, Jean Gilbert and Franz Lehar. But to all the light operas of those composers the farce of recognised musical comedy had to be added. This is a relic of the old-fashioned Gaiety burlesque. Those burlesques were more in the nature of what afterwards came to be known as *revue* in London and New York than of the musical comedy with a plot and sentimental scenes. Gradually the Gaiety burlesque developed into the Gaiety musical comedy, the music written by Lionel Monckton, Howard Talbot, Ivan Caryll, Paul A. Rubens and others. These musical comedies always contained big parts for the low comedians, and in the second half of the entertainment the plot was held in abeyance while the low comedy was developed. The gradual popularity of Viennese light opera, adapted to the London stage as musical comedy, with big parts for the low comedians, swept all before it down to 1914. The plots of the foreign light operas gave better opportunities for sentimental scenes and their composers were able, by superior musicianship, to make the best of their ideas through clever orchestration and skilful ensembles. Occasionally light musical pieces which are neither light operas nor musical comedies are produced on the London American stage. The British *Maid of the Mountains* (1917) is but described as romantic melodrama combined with musical comedy. *Lilac Time*, first produced in America as *Blossom Time* (1921), is a light opera founded on Schubert's songs and instrumental pieces. Such pieces are, however, exceptional.

The Rise of Revue

Musical comedy for some years suffered severely from the rivalry of the revue. In Paris the revue had a special character of social satire and topical interest. Very few attempts have been made to acclimatise the French revue to the London stage, the most successful being Mr. C. B. Cochran's series of intimate revues, beginning with *Odds & Ends* in Oct. 1914, at the Ambassadors Theatre. The revue, as we have known it, has been a *mélange* of songs, sketches, low comedy, ballets and pageants strung together without any apparent aim. Many of them have begun with a satirical idea, but the satire has never been carried out. The secret of making a successful revue is known only to those who achieve success. It appears to be based, however, on an instinctive sense of contrast between the different "turns" of the entertainment.

It is often stated that the haphazard style of disconnected "turns" was sympathetic to the war-mind. That may be a reason for the popularity of the revue during the World War and immediately afterwards, but it must be pointed out that this form of entertainment had become popular at least a couple of years before the War. Mr. George Grossmith, who had taken such a large part in the Gaiety musical comedies, was the first to adapt the revue from France. In 1910 he had made a great success in Paris in a Folies-Bergères revue with *Ip-i-addy-i-ay* from one of the Gaiety pieces. In Oct. 1912, he produced the first English revue at the Alhambra. It was entitled *Kill that Fly*, and the music was written by Melville J. Gideon. This was followed at the same theatre in May 1913 by *Eightpence a Mile*. In Nov. 1912, we find that a specimen of the new entertainment, *From Broadway to Paris*, had found its way to the New York stage. Long before the War, the revue was seriously affecting musical comedy in London. Soon after war broke out it became even more the staple musical entertainment in London, for the reason that all the most successful composers of musical comedy were enemies and their works were no longer performed on the stage. Mr. George Edwardes was interned in Germany and could not exercise direct control of the Adelphi and Gaiety theatres. By the end of 1914 only two musical comedies were to be seen in London: *A Country Girl* at Daly's theatre, and *The Earl and the Girl* at the Lyric theatre. Revues became more and more spectacular, and gradually the best of these entertainments included ballets and pageants of great beauty. In a sense, that type of revue was a throw-back to the masque. With the popularity of revue, syncopated or "jazz" music found its way to the stage from the variety halls. From revue it gradually crept into musical comedy, and the long continuance of the War, which automatically put an end to the domination of the Viennese school of musical comedy or light opera, gave this modern musical fashion full scope.

How far foreign musical comedy had gradually come to dominate our stage may be seen from the following list of the principal musical comedies produced in London and New York from 1910 to a few years after the outbreak of the War. The nationality of the composer is placed in brackets, but it must be remembered that in all cases the musical plays were very freely adapted for the countries in which they were performed. But however much low comedy may be imported into them, a foreign musical comedy always retains something of its original character. It is impossible to mistake a musical comedy by Leo Fall for one by Cuvillier, although in every respect the "book" and characters may have been Anglicised or Americanised.

The following list is not, of course, exhaustive, but it is sufficiently complete to show the different fashions of pre-War musical comedy.

1910. London: *The Balkan Princess* (British), *The Girl in the Train* (Viennese), *The Chocolate Soldier* (Viennese), *The Quaker Girl* (British).
New York: *The Arcadians* (British), *The Girl in the Taxi* (Viennese), *King of Cadonia* (British), *Madame Sherry* (American), *Our Miss Gibbs* (British).

1911. London: *Peggy* (British), *The Mousmé* (British), *Nightbirds* (adaptation of Johann Strauss's *Die Fledermaus* (Viennese).
New York: *The Slim Princess* (British), *The Balkan Princess* (British), *A Country Girl* (British, revival), *The Dollar Princess* (Viennese), *Girl of My Dreams* (American), *Gypsy Love* (Viennese), *The Kiss Waltz* (Viennese), *Little Boy Blue* (German, original title Lord Piccolo), *The Quaker Girl* (British).

1912. LONDON: *Princess Caprice* (Viennese), *Gipsy Love* (Viennese), *The Girl in the Taxi* (Viennese), *The Dancing Mistress* (British), *The Sunshine Girl* (British).
NEW YORK: *The Count of Luxembourg* (Viennese), *The Merry Countess* (Viennese, *Die Fledermaus*), *Oh, Oh, Delphine* (British-American), *Peggy* (British), *The Wedding Trip* (American), *The Charity Girl* (American), *Tantalising Tommy* (Viennese).

1913. LONDON: *The Pearl Girl* (British), *The Girl from Utah* (British), *The Girl on the Film* (German), *The Laughing Husband* (German), *The Marriage Market* (Viennese), *Oh, Oh, Delphine* (British-American).
NEW YORK: *Sweetheart* (American), *The American Maid* (American), *The Beggar Student* (German), *The Doll Girl* (Viennese), *Lieber Augustin* (German), *The Marriage Market* (Viennese), *Sunshine Girl* (British).

1914. LONDON: *A Country Girl* (British), *The Earl and the Girl* (British), *The Cinema Star* (Viennese), *Toy Ride Lady* (Viennese), *M'selle Tra-la-la* (Viennese).
NEW YORK: *The Belle of Bond Street* (British), *The Girl from Utah* (British), *The Girl on the Film* (German), *The Only Girl* (American).

1915. LONDON: *The Only Girl* (American), *Betty* (British), *To-night's the Night* (British, founded on *The Pink Domino*), Revivals of *Floradora*, *Véronique*, *The Arcadians*, *Chinese Honeymoon*, *The Dairy Maids* and *The Girl in the Taxi*, Big spectacular revues, produced by Albert de Courville and Wal. Pink.
NEW YORK: *Princess Pat* (American), *Alone at Last* (German), *The Blue Paradise* (Viennese), *To-night's the Night* (British), *Watch your Step* (American jazz musical comedy), Several big American revues.

1916. LONDON: *Chu Chin Chow* (British), *High Jinks* (British adaptation of French farce *Les Dragées d'Hercule*, Music by various British composers and Rudolph Friml), *The Happy Day* (British), *Mr. Manhattan* (British), *My Lady Frayle* (British). At end of the year no fewer than 9 theatres were devoted to *revue* and only 3 to musical comedy.
NEW YORK: *Betty* (British), *Follow Me* (American), *The Girl from Brazil* (German-American), *Katinka* (Viennese), *Miss Springtime* (German), *Step This Way* (American), *Very Good, Eddie* (American).

1917. LONDON: *The Maid of the Mountains* (British), *The Boy* (British), *The Beauty Spot* (British).
NEW YORK: *Canary Cottage* (American), *Chu Chin Chow* (British), *Leave It to Jane* (American), *May-time* (German), *Oh, Boy* (American).

1918. LONDON: *The Lilac Domino* (French), *Going Up* (American), *Yes, Uncle* (American), *Very Good, Eddie* (American).
NEW YORK: *The Grass Widow* (American), *Going Up* (American), *The Maid of the Mountains* (British), *Oh, Lady, Lady* (American), *Oh, My Dear* (American), *The Rainbow Girl* (American).

1919. LONDON: *Who's Hooper?* (British), *Baby Bunting* (British), *His Little Widows* (American), *Afgar* (French), *Monsieur Beaucaire* (French), Revival of Gilbert and Sullivan's operas.
NEW YORK: *The Royal Vagabond* (German-American), *Apple Blossoms* (Viennese), *Good Morning, Judge* (*The Boy*, British), *La, la, Lucille* (American). A number of other musical comedies of American origin were produced.

It will be seen from the foregoing list that after 1914 the stage had to rely for the most part on British and American musical comedies, until peace was declared, but towards the end of the War some works of enemy origin were produced. One of the most successful of these American musical comedies was *Irene*, produced at the Empire Theatre in 1920. There has been no great change in the type of musical comedy since the War, except that towards the end of 1925 American musical comedies, (of which *Na No Nanette*, *Mercenary Mary* and *Rose Marie* are the chief examples) with their efficient production and lively syncopated music, gradually took the place of British musical comedies.

In Paris, the home of revue, the musical comedy of the English-speaking races was always an alien form of entertainment. The differences between the operetta and opéra bouffe and musical comedy are slight, but nevertheless very real. They consist partly of the kind of sentiment expressed, of the general character of the music, and, especially, of the type of humour. The light opera of the modern Viennese school, when adapted as American or British musical comedy, had, and, to some extent, still has a vogue in Paris, but even before the War Parisians had grown tired of it, and during and since the War it has never regained the popularity it once had. (E. A. B.)

MUSICAL INSTRUMENTS, MECHANICAL.—In the history of mechanical musical instruments the years 1910–26 are significant chiefly because of the remarkable advance made in reproducing the touch of the human performer. Most of these keyboard instruments are known as reproducing or re-enacting pianos, and a discussion of their mechanical details necessarily concentrates largely upon the field of the modern pianoforte (*see* 21.573).

THE PLAYER PIANO

By 1910 the foot-pumped player piano had already reached a high point of development, and there were a number of elaborate devices for lending expression to its music. Ways had been found of emphasising the melody and subduing the accompaniment, at the pleasure of the player. The control of tempo had also undergone various improvements. Some of these devices had brought about an elaborate system of controlling levers, which the human player could operate with considerable skill. But the chief source of expression still rested in the feet, with most of the shading secured through the varying rapidity and suddenness of the actual foot-pumping. The foot-pedalled player piano permits its "pedipulator" to enjoy the feeling of being actually an interpretative, perhaps even a creative, artist.

The principle of the player piano rests upon the laws of atmospheric pressure. William Braid White, in his authoritative book on *Piano Playing Mechanisms*, gives a fairly simple explanation of what happens when a mechanical piano is made to play. He first shows how "a state of reduced pressure, or, as it is called, 'partial vacuum,' is induced in a small bellows called a 'pneumatic,' one of which is attached in some operative manner to each section of the action of a piano." He continues: "When some of the air has been pumped out of such a pneumatic, the outside pressure pushes up its moving wall, and the motion of this wall constitutes the movement required to set in motion the corresponding action and hammer on the piano." He further explains that "the velocity of motion of the pneumatic in thus collapsing will depend upon the difference between the exterior, or atmospheric pressure, and the reduced pressure inside the pneumatic. The greater the difference between the two, the more effective will be the work of the atmosphere, and the higher the velocity of the pneumatic's motion. Thus it appears that the power exerted on the piano hammer (corresponding to the work of the fingers on the keys) by the pneumatic varies as the rapidity of reduction of air-pressure inside it. It is therefore plain that if we can keep this process of pressure-reduction under control we can vary our tone-strengths as required. Control of this sort is, of course, essential to the artistic rendering of music."

Refinement of Control.—The up-to-date reproducing piano has gone far beyond the ordinary player or pianola in the gradual refinement of such control. The difference is vastly greater than the mere substitution of electric power for foot-pumping. By various methods of controlling pressure-reduction, represented by different instruments, the human touch has generally been approximated, and in a few cases actually duplicated. The ideal of all experimentation with the reproducing piano has been to strike any note at any time with any degree of force used by the actual pianist. Fundamentally this becomes a problem of weight and pressure, which is all that we really mean by "touch." But it was discovered long ago that in attaining subtlety of expression and "tone-colour," the pedalling (soft, damper and sostenuto) was a very important element, and that certain effects depended not only upon such blending of tone but upon the actual overlapping of the tones themselves, and the smooth passage from one to another, in the course of a "crescendo" or "diminuendo," with a scarcely perceptible difference in volume.

The reproducing piano of the highest type permits the duplication of every detail of expression as recorded by the great pianists. (This instrument, however, still allows the amateur to experiment with his own ideas of expression by eliminating the

mechanical control and substituting the manipulation of levers or buttons under his own control.) With the discovery that the human touch could be duplicated came the invention of various recording machines, so that by 1926 every pianist of note could be heard through his records as well as in concert performance.

Recording Processes.—Processes for recording are, by most manufacturers, veiled in absolute secrecy, for obvious reasons. The results, however, depend not so much on the method of recording as on the ability of the reproducing mechanism to duplicate the effects indicated by the artist. Some records made in Europe in the early days of the reproducing piano have been successfully adapted to the later perfected instruments, and actually give a far finer performance than would have been possible when they were first made. In general the recording pianist simply sits at a regular keyboard and plays in his usual style. Electrically connected with his piano, and invisible to him, is a recording machine carrying an endless roll of paper, on which both the notes and the expression are marked as he plays the instrument.

The old player-pianos had their rolls made by mathematically following the sheet-music and with no attempt at variety of expression and interpretation. Some of the newer recording machines also perforate directly from the playing of the artist, but in these cases a careful system of editing is required before the record can be heard in public. The opportunity for editing is offered also in those machines which do not perforate immediately, but in which the start and finish of each tone are clearly indicated by pencil marks, with the exact action of the pedals and every slight variation of pressure. In fact, the possibility of revision and editing is most important in the creation of completely satisfactory recordings. There are always some mistakes to be corrected, and an artist generally finds various details which he wishes to emphasise or subdue, so that the final recording may truly represent his playing at its best.

Some Reproducing Pianos

The pioneers in the manufacture and marketing of the modern reproducing piano were M. Welte & Son, of Freiburg, Germany, and Ludwig Hupfeld, of Leipzig, both of whom were active as early as 1904. The name of Welte-Mignon, which originated at that time, was by 1926 best known in America through pneumatic actions distributed under a license issued by the owners of the Welte patent rights. The inventions of Charles Fuller Stoddard were developed independently, and the instrument which he perfected put on the market by the American Piano Co., under the trade name of the Ampico. Another type of reproducing piano was subsequently developed by the Aeolian Co. from the pianola, and given the name of Duo-Art. The latter may be attached to the Steinway, Weber, Steck and Stroud pianos, while the Ampico may be had in the Chickering, Knabe, Mason & Hamlin, Haines, Fischer and Marshall and Wendell pianos, besides the Willis in Canada, and the Broadwood and others in England. The Welte mechanism is used with the Steinway and other instruments in Europe, and (as licencee) in a great number of American pianos.

Features of Mechanism.—The mechanism of each of these types deserves separate consideration. All three are alike in the general arrangement of pneumatics and in the division of the keyboard, for convenience, into two halves, treble and bass, each controlled by special expression pneumatics. All three possess a device for automatically rerolling a record, and repeating it by the setting of a lever if desired. They also permit the elimination of recorded expression and the substitution of human control. In every case the piano can be used as such, even while a record is in progress.

The Welte.—The original Welte first appeared as a cabinet containing a separate action, operating on the keys of the piano, but by 1926 was generally found as an interior action in grand and upright pianos. The power plant consists of an electric motor and a suction pump. Including "on" and "off," 18 holes in the tracker bar are devoted to expression purposes, ten on the right side and eight on the left, the rest sounding the notes. The bass and treble sections of the action are controlled by separate expression pneumatics, each closing at two definite rates of speed, slowly for crescendo, and fast for accents. There are also pneumatics to lock the expression pneumatics in a mezzo-forte position and other details for increasing expression.

The Duo-Art.—The Duo-Art Pianola differs from other reproducing pianos of the grand type by having its note-sheet driving mechanism and tracker bar placed behind the fall-board, directly over the keys themselves, the case being extended to make the necessary room. Its expression system is divided into a melody or "theme" regulator and an accompaniment regulator, with the melody always slightly stronger. Two sets of four pneumatics each, known as the "accordion dynamics," permit as many as 16 degrees of volume.

The Ampico.—The Ampico has both a crescendo pneumatic system and an instantaneous accent pneumatic system, which it can use in combination to control the air-tension behind the hammers. These systems may be operated independently for their separate effects, or concurrently for their combined effects, thus producing an unusual smoothness in crescendo and diminuendo, as well as a delicate shading. There is also an "amplifier" for special effects of volume, and the extended perforations in the music-sheet produce the greatly desired "singing" quality of tone. Seven holes on each side of the tracker bar control expression, with an extra one on the right for the re-roll. In the Ampico grand, the note-sheet mechanism is in a drawer, while the electrically driven pump is slung under the body of the piano.

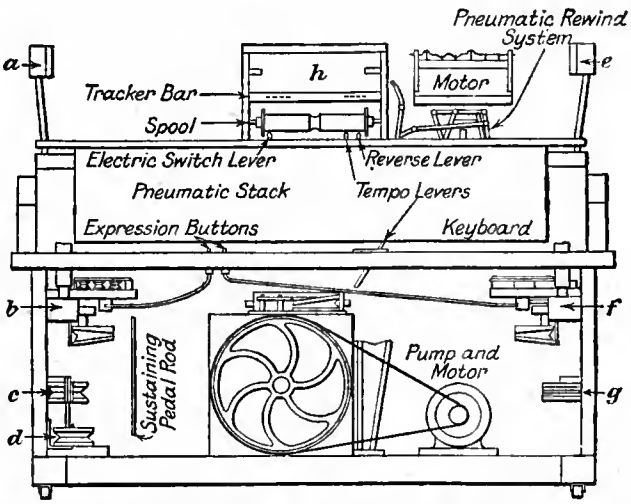

FIG. 1.—Reproducing Piano, showing the principal features of the mechanism, which are described at length in the text.

From a drawing by H. S. Smith, C.E. in Piano Playing Mechanisms, by W. B. White, Ed L. Bill, Inc. N.Y.

Ampico Upright.—A typical reproducing piano (Ampico upright) consists of (*a*) bass equaliser; (*b*) bass regulator system, connected by tube with (*c*) crescendo pneumatic and (*d*) soft pedal pneumatic; (*e*) treble equaliser; (*f*) treble regulator system, connected by tube with (*g*) crescendo pneumatic (right side) (fig. 1).

The recording sheet is hung in place at *h*; it has a metal ring at the end of the paper caught by a pin upon the spool, so that the perforations in the note-sheet will pass over the holes in the tracker bar, which is connected by tubes with the pneumatic stack and the expression system. When the pump and motor are electrically started, air is sucked through the holes in the tracker bar, causing the individual pneumatics to set the corresponding hammers in motion exactly as by the touch of the pianist on the keys. At the same time the crescendo, accents and various pedals are similarly set in operation through special "expression holes" in the tracker bar, corresponding to perforations on the edges of the note-sheet. The expression buttons in front of the keyboard permit the human manipulator to introduce his own ideas of shading. He can also vary the tempo at will, and do his own pedalling, if desired, the automatic expression being in that case temporarily turned off. A small motor serves to keep the note-sheet in motion and to rewind it rapidly when the playing of a record has been completed.

Research Work.—All the companies manufacturing these instruments publish instruction books for mechanicians, and the mechanically inclined reader is referred to these publications for further information. An elaborate research laboratory has been for some time in operation in New York, under the direction of Mr. C. F. Stoddard, and here the minutest details of musical expression, including dynamics, pedalling, touch, tone quality and tempo, have been scientifically analysed, so that a beauty of mechanical playing is possible that was formerly undreamt of. In this laboratory also have been developed scientific methods of recording the performance of a pianist to a degree of accuracy which permits not only the determination of the audible loudness of every note struck, but shows differences in touch that are indistinguishable by the human sense of hearing. This work has made it possible to measure scientifically the technical ability of a pianist.

Practical Uses.—The place of the reproducing piano is now fully established in the field of music on educational as well as aesthetic grounds. Distinguished artists have used these instruments in public performance, directly comparing their own playing with that of their recordings, sometimes alternating with the latter in most astonishing fashion; and recorded accompaniments have proved most valuable for singers, violinists, etc., in concerts as well as for private practice. Schools, colleges and conservatoires of music are coming to recognise the reproducing piano as an indispensable part of their equipment, particularly for teaching the appreciation of music; and teachers of the pianoforte welcome its authoritative recordings as models for their pupils.

Some Other Instruments

Concerning other mechanical keyed instruments little need be said. There are, of course, coin-operated electric pianos, which have proved themselves adequate for entertainment in restaurants and taverns, and often these are reinforced with organ pipes, drums and other orchestral effects. Essentially they are built on the principle of the player-piano, although the need of expression can practically be disregarded.

The Pipe Organ.—The pipe organ itself is thoroughly adaptable to mechanical playing, for its effects have little to do with the human touch, and can be produced at will by the electric control of stops and pipes. All the great organs can be played with the help of rolls, which are either entirely mechanical in their control of expression or permit a human agent to manipulate the stops, while the tones themselves are mechanically produced.

In conclusion, no matter how perfect a mechanical musical instrument may be, the fascination of personally producing tonal beauty will never be entirely lost, and human performance will continue to be popular, with its amazing duplication by scientific means in no sense a discouragement to personal endeavour, but rather a priceless ally to the cause of music on those occasions and in those places where individual skill and talent are not always available (*see* also Phonograph).

Bibliography.—William Braid White, *Piano Playing Mechanisms*, a most valuable and comprehensive treatment of all the mechanical essentials (1925); *Modern Piano Tuning and Allied Arts* (1917) and *The Player-Piano Up-to-date* (1914); H. C. Van Atta, *A Treatise on the Piano and Player-Piano* (1914); Alfred Dolge, *Pianos and their Makers* (1911); Gustav Kobbé, *The Pianolist* (1907) and *The Aeolian Pipe Organ* (1913); G. A. Audsley, *The Organ of the Twentieth Century* (1919); G. L. Miller, *The Recent Revolution in Organ Building* (1913); Manuals of instruction for mechanics issued by such manufacturers of reproducing and re-enacting pianos as the Aeolian Co., the American Piano Co., the Welte-Mignon Corp., the Auto-Pneumatic Action Co., etc. (S. Sp.)

MUSIC HALL: *see* Variety Theatre.

MUSSOLINI, BENITO (1883–), Italian statesman and journalist, was born July 29 1883 at Dovia, in the commune of Predappio (province of Forlì). His father, Alessandro Mussolini, was a blacksmith of internationalist revolutionary and anti-religious opinions, and played an active part in the local Socialist movement, while his mother, Rosa Maltoni, was a school teacher of deep religious convictions; the views of both parents affected young Mussolini in different ways at different stages of his career. He was sent to the Salesain college of Faenza, where he showed considerable intelligence but a passionate, insubordinate spirit. Later he went to the normal school at Forlimpopoli, and eventually qualified as a school teacher at the age of 18, obtaining an appointment at Gualtieri (province of Reggio Emilia). As a youth he developed a love of literature and read widely, and soon became interested in the Italian Socialist movement. But he tired of teaching, and determined to go to Switzerland to improve his education. There he earned a precarious livelihood by manual labour of various kinds, but managed to attend the courses at the Universities of Lausanne and Geneva, and secured a diploma as teacher of French. He lived mostly among the working classes, and, born organiser as he was, he founded trade unions and even promoted strikes, with the result that he was expelled from one canton after another, and finally from the Confederation. After performing his military service in the Bersaglieri, he returned to teaching, but found time to improve his knowledge of the classics. In 1908 he was involved in the political agrarian conflicts in Romagna, was arrested, tried and condemned to 10 days' imprisonment, and afterwards was under police surveillance as a dangerous revolutionary.

At the end of 1908 he went to Trento, where he had been summoned by the local chamber of Labour as secretary, and he also joined the staff of the local Socialist paper *L'Avvenire*. But when he realised that the Trentino Socialists, in their loathing for the national idea, took their cue from the Vienna Govt., Mussolini went over to the *Popolo*, a paper edited and founded by Cesare Battisti, also a Socialist, but above all an Irredentist patriot who was afterwards to serve in the Italian Army during the War, be captured by the Austrians and hanged as a traitor. Here Mussolini took up the study of German literature, and became deeply interested in philosophy, especially in that of Nietzsche. His association with Battisti first inspired him with Irredentist ideas, and after publishing an article stating that "the Italian frontier does not end at Ala" he was arrested and expelled from Austria. On returning to Italy he published an essay of Irredentist tendencies on "The Trentino as seen by a Socialist" in *La Voce*, a periodical printed in Florence which gathered around it some of the most brilliant young *littérateurs* of the day.

The Tripoli Campaign.—The next period of Mussolini's life was wholly devoted to Socialist activity. In 1910 he founded and edited a paper at Forlì called *La lotta di classe*, but while he vigorously supported the ideals of Socialism, he deplored the materialism, as he considered it, of the bourgeois spirit into which the Italian Socialist party had degenerated. He drew further and further away from Marx and Lassalle, feeling more sympathy with the ideas of Baboeuf, Blanqui, Prudhon, and above all with the syndicalism of Sorel. An opponent of parliamentarianism, he reproved the Italian Socialists for compounding with the bourgeois parties in order to secure seats in the Chamber and lucrative contracts for bogus co-operative societies; he not only advocated direct action, but also put it into practice whenever he saw a chance of securing real advantages for the proletariat thereby, and, unlike other Socialist leaders, he was ever ready to lead his followers and run personal risks.

When Giolitti's Government decided to send a military expedition to Tripoli, although not rejecting the idea of war in general, Mussolini opposed this policy because, as he said, unlike the Nationalists, who wanted a vast Italy, he preferred an Italy that should be well cultivated, rich and free. On Sept. 25–27 1911 he therefore organised a popular movement at Forlì against the Tripoli expedition, inciting the mob to resist the authorities. He was in consequence arrested and condemned to five months' imprisonment. At the congress of Reggio Emilia in 1912, when Bissolati and Bonomi were expelled from the party for supporting the Government's African policy, Mussolini remained one of the die-hard revolutionaries, and in December of that year was made editor of the *Avanti!*, the official organ of the party. Under his able editorship the circulation rose from 40,000 to 100,000, and his vigorous leaders gave the paper an entirely new character. He insisted particularly on the necessity for improving the

economic and social conditions of the southern provinces, which other Socialist leaders neglected because their inhabitants gave few votes to the party. During the so-called "Red Week" in the Marche and Romagna (June 7–14 1914), Mussolini was one of the most active leaders of the outbreak. It was on this occasion that he lost many illusions concerning his fellow Socialist leaders, whom he found ever ready to incite the mob to violence while taking good care for the safety of their own persons. He also realised that the masses were anything but ripe for revolution.

The World War.—The great crisis of Mussolini's life came with the outbreak of the World War. From the first he strongly opposed Italy's intervention on behalf of the Central Powers. After Italy's declaration of neutrality he still hesitated, for the conflict was raging within him between the Socialist and the Italian; but it was as a Socialist that he favoured war in the belief that it would end war and re-establish the principles of right and justice, while as an Italian he doubted if his people were ready to enter the fray. In the autumn the tendency in favour of intervention had gained ground, and he wrote that Italian unity must be completed; later he gave his approval to the Government's military measures, as he realised the danger of keeping Italy alone unarmed amid the general conflagration. But he felt that his views were ever less in harmony with the official creed of his party, and he expressed the hope that if Italy did intervene her international status would be raised and an economic and social revolution promoted. He deemed it necessary to resign the editorship of the *Avanti!*, and on Oct. 25 appeared before the Socialist assembly at Milan to justify his conduct. The audience howled at him, with imprecations of "traitor, hireling, assassin!"; but instead of defending himself he violently attacked the other Socialists for their *petit-bourgeois* spirit and insincerity. He ended by confirming his belief in Socialism, and saying, "You hate me because you still love me."

He now founded a new paper of his own, *Il Popolo d'Italia*, and his enemies spread about the rumour that Mussolini had received money from the French Embassy to support the Allied cause, whereas the sole capital of his new venture was 4,000 lire advanced by advertisers. The *Popolo d'Italia* first appeared on Nov. 15 1914, and in the leading article Mussolini asked: "Do we wish to drag out a miserable existence under present conditions, content with the *status quo* of the monarchy and the bourgeoisie, or do we wish instead to break up this wretched combination of intrigue and cowardice?" He concluded with a stirring appeal in favour of war. The paper led a precarious existence in miserable premises, and was hardly able to pay the staff. But it gathered around it a number of brilliant young writers fired with enthusiasm for the national cause, although many were Republicans and Socialists.

Audacity was its keynote, and while the *Idea Nazionale* and D'Annunzio appealed to the older and more intellectual middle classes, Mussolini influenced the younger generation and the workers, and he reached the less educated masses through his friend the Syndicalist Filippo Corridoni (afterwards killed in action), editor of the weekly *Battaglie sindacali*. But he still believed in revolution, and in April 1915 he was arrested for advocating his views at a public meeting; ten days later he was slightly wounded in a duel with the orthodox Socialist Claudio Treves. When on May 24 war was declared he wrote in the *Popolo d'Italia*: "From to-day onwards the nation is called to arms. From to-day onwards we are all of us Italians and only Italians. Now that steel has to meet steel, one single cry issues from our breasts, *Viva l'Italia!*"

In the Trenches.—In Sept. 1915 Mussolini was called up, and served as a private in the Bersaglieri in the trenches along the Isonzo and on the Carso. He did his duty gallantly until he was seriously wounded by the explosion of a trench mortar on Feb. 23 1917. He spent many months in hospital, and on recovery returned to his work on the *Popolo d'Italia*. He wrote a graphic account of his war experiences in his *Diario di Guerra*. As early as the beginning of 1917 he realised the gravity of the propaganda which the Socialists and neutralists were able to conduct owing to the feebleness of the Government, especially of the Minister of the Interior, Signor Orlando, and after resuming his editorial chair he uttered warnings which were disregarded, as were those of Gen. Cadorna. After Caporetto he was one of the few who, in the depths of national depression, never lost heart and in the columns of his paper he issued daily messages of encouragement.

After the Armistice Mussolini opened a campaign in favour of a dignified foreign policy at the Peace Conference, and of adequate recognition for the services of the demobilised men. In reply to the first manifestations of Bolshevism in which the Socialists indulged in consequence of the relaxation of the censorship, Mussolini founded the first "Fascio di Combattimento" on March 23 1919 at Milan (*see* FASCISM); and although the first programme of the new group contained many demagogic demands, the patriotic note was predominant, and Mussolini continued to combat Bolshevik doctrines. With regard to Fiume, he insisted that its Italian character must be secured. When D'Annunzio occupied Fiume the *Popolo d'Italia* lent him its full support.

Mussolini was now bitterly hated by the Socialists, and when at the elections of 1919 he stood as a candidate for Milan, he secured only a few votes and was described by the *Avanti!* as a corpse to be buried in a ditch. A few days later Nitti had him arrested on a charge of "armed plotting against the security of the State" (in connection with his support of D'Annunzio), but did not dare to maintain the arrest, and he was soon liberated. Mussolini now worked harder than ever at his paper, whose circulation increased rapidly; his relaxations were writing plays and playing the violin, and he also took to motoring and aviation, in which sports he showed the same disregard of danger as in war and politics.

Fascist Discipline.—The seizure of the factories by the workmen in the autumn of 1920 did not meet with Mussolini's disapproval, as one would have expected; he regarded their action as a form of practical syndicalism breaking away from the pusillanimous policy of the official Socialist party. But when the Communists proceeded to organise political murders at Bologna, Modena and Ferrara, Mussolini and his Fascists became the nuclei of the national anti-Bolshevik reaction; it is due to him that the whole Communist-Socialist domination collapsed, first in the Po valley and then throughout Italy. But Mussolini was now coming to the conclusion that it was not enough to defeat and disperse the Reds. The Italian people, he argued, were to be made free to recover, to work and produce undisturbed, to fulfil their higher destinies; the incompetent governing caste, ready to compromise on everything, must be swept away and its place taken by the virile youth of the country who had won the War. Fascism was spreading rapidly, and in Nov. 1921 it was organised into a political party, but its discipline still left much to be desired. Mussolini now proceeded to reorganise it and establish it on a strictly hierarchical basis, until its discipline surpassed that of any other organisation in Italy. All ranks of society he regarded as necessary, for he did not wish to repudiate the past. He was, moreover, becoming ever more keenly interested in foreign politics. "I hold that, having broken the pride of Bolshevism, Fascism should become the watchful guardian of our foreign policy." But the movement was extending to every sphere of national life—internal affairs, finance, labour, industry, agriculture. At the elections of May 1921 Mussolini and 37 other Fascist candidates were returned, and together with their allies the 10 Nationalists played an active part in the debates.

During the next 12 months Fascist influence consolidated itself throughout Italy, and the obvious breakdown of the old political parties convinced Mussolini that the time for bold action was fast approaching. At first he thought only of the possibility of a coalition Government comprising Fascist elements, but by the summer of 1922 he felt that a predominantly Fascist Govt. was conceivable and indeed necessary. The strike of Aug. 1 1922, promoted by the revolutionary Alleanza del Lavoro, was broken by the Fascists, and this fact showed the increasing weakness of Signor Facta's Govt., which was no longer able to resist any really energetic action from the right

or from the left. In the meanwhile, Mussolini had been shedding the last traces of demagogic ideas, and at a Fascist gathering at Udine on Sept. 29 he openly pronounced himself an upholder of the Monarchy, thereby securing the sympathy of many non-Fascists and of the army. He now made no secret of his intention of seizing power, and said so openly at the Fascist meeting in Naples in October. The march on Rome (*see* ITALY, *History*) was organised and directed by Mussolini, and indeed it shows the Mussolini touch in every phase. When the Facta Cabinet resigned the King first sent for Sig. Salandra, who tried to form a coalition Government, but Mussolini refused to lend the scheme his support, and Salandra threw up his mandate, whereupon the task was entrusted to Mussolini himself. He formed his Ministry within seven hours, a record for Italy, where, especially during the post-war years, every cabinet crisis had lasted for many days and even weeks. He chose several non-Fascists as Ministers, but refused to contract an alliance with the parties to which they belonged.

His Reforms.—From the moment he assumed office he set to work with his accustomed energy to overhaul and reform the whole administration, to eliminate inveterate abuses, and infuse a new spirit into the State. He himself assumed the portfolios of Foreign Affairs and the Interior, although the work of the latter he left largely to the under-secretary Aldo Finzi. In June 1924, after the Matteotti affair, he appointed Sig. Federzoni Minister of the Interior, but in the following spring, on the resignations of Gen. Di Giorgio and Adml. Thaon di Revel (April 3 and May 5), he assumed the portfolios of War and Marine, and also that of the new Air Ministry; while leaving great latitude to the under-secretaries, he gradually welded the three ministries into a single department of National Defence. He also kept in close touch with all the other departments, and many questions of great national interest, such as the development of public works in southern Italy, for the purpose of bringing that area up to the level of the more progressive north, the so-called "battle for wheat" engaged to intensify wheat production, the reformed electoral law, the various reforms of a constitutional character, etc., are due to his initiative. As a Socialist Mussolini was an anti-Parliamentarian, and even later did not regard the Parliament as the sole organ of national life. His object was to make Italy powerful, prosperous and efficient, in as short a time as possible. But in order to make these reforms lasting he determined that the whole body politic shall be imbued with the Fascist spirit—*fascistizzare la nazione*, as he described it—and he therefore inserted Fascism into every activity of the country.

As a Minister, Mussolini's activity was prodigious. Even when he was seriously ill in the spring of 1925, he surprised his friends and disconcerted his adversaries by continuing very largely to conduct his business of government from his bed, and by his quick recovery. While he was immensely popular with the great majority of the people who appreciate the far-reaching benefits of his rule, he had many enemies among the members of the old governing caste, the Socialists, Communists and Republicans and the anti-national freemasons, whose influence he destroyed. At the end of Oct. 1925, a plot to murder him was discovered by the police, and the would-be murderer, the Socialist ex-deputy Tito Zaniboni, was arrested in the very act; other persons were arrested in connection with the affair, notably Gen. Capello, a leading freemason. The news of the plot aroused general indignation, and Mussolini received a plebiscite of enthusiastic congratulations. On April 7 1926, as he was leaving the Capitol, where he had inaugurated a surgical congress, an Irishwoman, the Hon. Violet Gibson, fired at him with a revolver, slightly wounding him in the nose. The would-be murderess appeared to be demented. The wound did not prevent him from sailing for Tripoli the following day according to programme.

Mussolini is not a finished orator in the classical sense; he has no rounded periods and he seldom introduces apt quotations. But every speech bristles with facts and ideas, each sentence is like a hammer-stroke on the anvil emitting vivid sparks, and each phrase, seemingly independent of the others, contributes to build up the central idea which he wishes to assert. On innumerable occasions an apparently difficult, even insoluble, situation has been solved by one of his vigorous speeches. Besides innumerable articles in *Il Popolo d'Italia*, *Avanti!*, *Gerarchia*, etc., he has published *Il mio Diario di Guerra 1915–7* (Milan, 1923), and his speeches have been collected in several volumes. A selection of them has been published in English edited by Baron Quaranta, *Mussolini as revealed in his political speeches, Nov. 1914 to Aug. 1923* (1923). His biography was published in English by Margherita Sarfatti (Butterworth, 1925). See also Antonio Beltramelli's *L'uomo nuovo* (18). (L. V.*)

MUSTAFA KEMAL (1880–), Turkish soldier and statesman, was born in comparatively modest circumstances in Salonika. His father was a customs officer who afterwards entered the timber trade and died when Mustafa was yet a small child. The boy was brought up and educated by his mother, who appears to have been a woman of character and ability. He completed his primary education in Salonika and entered a secondary school in the same place; but, having been maltreated by his Arabic teacher, he left school, against his family's wish, and secretly entered the military preparatory school.

There he proved to be an exceptional student, especially in mathematics, and attracted the attention of his fellow-students and teachers. His teacher in mathematics, who was also named "Mustafa," gave him the distinctive surname of "Kemal" (an Arabic word meaning "perfection"), as a tribute to his unusual ability. The extent to which he won the esteem and affection of his companions while at the military academy is indicated by the fact that, although he already took an active interest in politics and bitterly criticised the despotism of Abdu 'l-Hamid, he was never denounced.

In 1904 he was gazetted a lieutenant, but on the same day he was placed under arrest, taken to Yildiz Palace, and detained there for weeks under cross-examination. Finally he was banished to Damascus. In this provincial capital he had an opportunity to observe the deplorable condition into which the civil and military organisation of the Empire had fallen. He also found followers here, and founded in 1905 the secret political society "Vatan" ("Fatherland"). From Damascus he was transferred to Jaffa, and from there with the help of his friends, he made his way secretly to Salonika in order to organise a similar political movement in the European provinces. The association which he founded at Salonika was afterwards affiliated to the Union and Progress Society. By this time the Constantinople Govt. had got wind of his secret activities, and it sent orders for his arrest both to Salonika and to Jaffa. With the help of his friends at Salonika, Mustafa Kemal was smuggled on board a steamer sailing for Jaffa, and at the same time the military commandant at Jaffa reported to Constantinople that Mustafa Kemal was on duty on the Egyptian frontier. For a time he was forgotten by the Government in Constantinople. In 1907 he was promoted and sent to Salonika, where he again devoted himself to the work of revolutionary organisation.

When the revolution of 1908 re-established the constitution of 1876, Mustafa Kemal found himself in serious disagreement with the leaders of the Union and Progress Party who were now in power. His political views were more radical than theirs and he protested, though in vain, against the participation of the army in politics. In consequence he abandoned politics for the time and turned his whole energy into his military career. From this time onwards, he was appointed to a number of important military posts, in each of which he gave evidence of his ability and his powers of leadership. In 1910 he was sent to France to follow the army manoeuvres. He was loved and respected by the younger officers, but some of his superiors looked askance at him on account of his uncompromising attitude. In 1911 he went to Tripoli *incognito* in order to take part in the war against the Italians, and there he was promoted to the rank of major. He was still in Tripoli when the first Balkan War broke out in Oct. 1912 (*see* BALKAN WARS). He started at once for Turkey, but the news of his country's defeat and the fall of Salonika reached him in Egypt. In July 1913, however, during the

second Balkan War, he was appointed chief of the staff to the newly-organised army corps on the Gallipoli Peninsula, and here for the first time he made a detailed first-hand study of the problem of defending the Dardanelles. After the restoration of peace between Turkey and Bulgaria in the same summer, he was appointed military attaché at Sofia, with the rank of colonel, and held this post until after the intervention of Turkey in the World War in the autumn of 1914.

Mustafa Kemal believed that Turkey had entered the War prematurely and that Germany was doomed to eventual defeat. Possibly it was on this account that his desire to return to active service was not encouraged; but, on his insistence, he was appointed commander of the forces at Rodosto, and afterwards (in 1915) at the Dardanelles. He was the moving spirit on the Turkish side in the defence of the straits against the British attack; and it would not be an exaggeration to say that the situation was saved through his personal skill, insight and bravery when the Turkish high command had actually lost hope. During the final British assault he was struck by a splinter of shell right over the heart, but the splinter was intercepted by his watch and he thus escaped with his life.

After the evacuation of the Gallipoli Peninsula by the British, Mustafa Kemal was sent to the Caucasus front, where he was promoted to the rank of Pasha and recovered Bitlis and Mush from the Russians. In 1917 he was posted to the Hejāz, but after stopping at Damascus to study the general situation, he proposed to recall all the forces in the Hejāz in order to reinforce the Syrian front. This prudent proposal was not carried out, but later in the same year he was appointed to the command of the VII. Army Corps in the force which the German general Von Falkenhayn was organising with a view to the recovery of Baghdad. At this time Germany's intervention in the internal affairs of Turkey had reached its height, and Mustafa Kemal Pasha put himself at the head of the opposition to it. He sent in a succession of reports adverse to the Baghdad expedition, which he thought would end in another disaster, and when his advice was ignored he resigned. He was then transferred to the Second Army Corps, but abstained from taking up his command owing to his disagreement on questions of principle with General Headquarters. While on leave in Constantinople he was sent on a mission to the German G.H.Q. with the heir apparent Vahydu'd-Din Efendi. There, in the presence of Generals Hindenburg and Ludendorff, he expressed outspokenly his pessimistic views regarding the outcome of the War. In 1918 he yielded to the insistance of Vahydu'd-Din Efendi, who had meanwhile succeeded to the throne as Sultan Mehmed VI., and accepted the command of the VII. Army Corps in Palestine, but by this time all chance of taking the offensive, or even averting disaster, had disappeared. Mustafa Kemal again distinguished himself, however, in keeping together the remnants of his corps on the retreat which followed General Allenby's great victory, and before the end of Sept. he was appointed Commander-in-Chief of all the corps constituting the so-called Yildirim group.

When the Turkish Govt. negotiated the armistice of Mudros (Oct. 30 1918), Mustafa Kemal was opposed to the policy of complete surrender, and after the signature of the armistice he retired to Constantinople and began studying the new situation at his leisure. There was nothing to be done in Constantinople, but his opportunity was given to him by two events: the Greek landing at Smyrna on May 16 1919, which reawakened the Turkish nation, and his own appointment by the Ottoman Govt. in Constantinople as Inspector of the IX. Army Corps in north-eastern Anatolia. His mission, as conceived by the Sultan and the Grand Vizier, Damad Ferid Pasha, was to execute the armistice terms by superintending the disarmament and demobilisation of the Turkish army in this remote district. Mustafa Kemal's intention was to create a nucleus of national resistance against the partition of the country, and he therefore accepted with alacrity the position offered him by the unsuspecting Government. As soon as he landed at Samsun he began to organise his new movement locally at Amasia, Tokat and Sivas, and to correspond secretly with other parts of the country. The Sultan's Govt., awaking too late to what he was doing, recalled him to Constantinople, but instead of obeying he went on to Erzerum and sent in his resignation to Constantinople. He next convened two congresses, one at Erzerum in July, and the other at Sivas in Sept. 1919. Both congresses endorsed his programme of fighting for national existence to the bitter end, and they appointed a standing executive committee under his chairmanship. Thereupon he was outlawed by the Constantinople Govt., and relations between the capital and the interior of Anatolia were broken, but all the efforts of the Constantinople Govt. and the Allied Powers to frustrate Mustafa Kemal's activities were unavailing. They simply strengthened his conviction, and that of the people round him, that he had taken the right path.

The political and military history of the new Turkish Nationalist movement, commonly called the "Kemalist" movement, after its founder, is given elsewhere (*see* GRECO-TURKISH WAR; LAUSANNE, TREATY OF; TURKEY), and in this article it can only be touched upon in so far as Mustafa Kemal's personal career is directly concerned. Mustafa Kemal was in favour of the Nationalists participating in the general election at the close of 1920, but decidedly opposed to the meeting of the Assembly at Constantinople, and his judgment was borne out after the event by the high-handed action which the British military authorities and the Sultan's Govt. took in March and April 1920 respectively. On April 23 1920 Mustafa Kemal gathered together at Angora the Nationalist members of the late Parliament who had escaped from Constantinople, and was elected unanimously as president of this new National Assembly.

During the 2½ years which followed, Mustafa Kemal was the heart and soul of the Turkish national resistance, in circumstances in which all but the most determined characters would have despaired. He knew how to make the most of the fact that this time the nation was fighting for its homeland, and not for some distant alien province like the Yemen or Albania. He succeeded in evoking the utmost powers of his followers, and his firm conviction of final victory, his exceptional military ability, his keen intellect and his persuasive oratory carried his countrymen through their ordeal. During the summer campaign of 1921, which was the supreme crisis of the Greco-Turkish War, the Angora assembly appointed Mustafa Kemal generalissimo of the Turkish forces, with unlimited power, and he took personal charge at the front during the 22 days' and nights' fighting of the battle of the Sakaria. During the battle his horse was wounded and the general broke a rib in falling, but he never left the front. After this battle the assembly gave him the rank of field-marshal and the traditional title of "Ghazi" (the victorious).

The great events which followed—the destruction of the Greek army, the peace settlement at Lausanne, the abolition of the Sultanate, the declaration of the Republic and the abolition of the Caliphate—were the direct work of Mustafa Kemal. On Oct. 29 1923, the date on which the Republic was proclaimed, the great national assembly unanimously elected Mustafa Kemal as the first President of the Republic. The wide constitutional powers which he thus received were enormously enhanced by his personal force of character and by the unique hold which he had obtained over the hearts and minds of his countrymen through the astonishing services which he had rendered to the national cause. Indeed, Mustafa Kemal became a dictator in fact, though not in constitutional theory, and this fact dominated the political situation of Turkey as she emerged from the War. In some ways Mustafa Kemal's virtual dictatorship was advantageous and perhaps even necessary to Turkey, since the period of reconstruction which now began was hardly less critical than the foregoing period of war and revolution. Undoubtedly Mustafa Kemal displayed the same energy, audacity and radicalism in setting out to "win the peace" as he had displayed in winning the War.

On the other hand, after the external menace to the existence of Turkey had been removed, the internal unity of the nation

naturally began to relax, and different parties arose with different policies for securing the national welfare. This was a healthy symptom, and an outside observer would be inclined to criticise Mustafa Kemal, during this phase of his career, for not allowing sufficiently free play to these opposition elements. His somewhat repressive policy towards his political opponents had the unfortunate effect of depriving Turkey of certain talents and abilities which she could ill afford to spare, and there was a perceptible increase of factiousness and embitterment in the internal politics of the country. Nevertheless, at the time of writing, President Mustafa Kemal's position in Turkey remained substantially unimpaired. (A. J. T.)

MUTSUHITO (1852–1912), Emperor of Japan (*see* 19.100), died at Tōkyō July 30 1912. He was posthumously styled the Emperor Meiji, according to the custom of Japan.

MYCOLOGY (Gr. *μύκης*, a mushroom; *λόγος*, discourse): the scientific study of fungi. The two decades from about 1890 to 1910 were remarkable in the history of mycology, for the many interesting discoveries made in the morphology and physiology of the fungi, especially in regard to their reproductive processes and the problems of sex and nuclear fusions. The results obtained have been since then exhaustively investigated, and have been, in large measure, confirmed, and upon the foundations thus laid our knowledge of the fungi has, during recent years, been extended in all directions.

Many new aspects of study have been opened up, life histories have been more fully elucidated, the study of pure cultures has added much to our knowledge of the physiological activities involved in parasitism, saprophytism and symbiosis; and the physiological effects of light, heat and the chemical and other changes taking place in the substratum during the growth of a fungus are more clearly understood. Knowledge of plant diseases (*see* PLANT PATHOLOGY) has, especially in the tropics, been vastly increased; and the establishment by the Govt. of an "Imperial Bureau of Mycology" has already, in conjunction with the valuable mycological work carried on at Kew and the British Museum, profoundly influenced phytopathological research in the empire.

Classification.—In the classification of the fungi, although much has been done to elucidate the life histories of a large number of different forms, there are still so many gaps in our knowledge that anything like a satisfactory natural classification is impossible. Many new schemes have been proposed, but so far the most useful classification is that which maintains the three great classes with their subdivisions: (1) Phycomycetes (Zygomycetes, Oomycetes), (2) Ascomycetes (including Laboulbeniaceae) and (3) Basidiomycetes (Ustilaginaceae, Uredinae and Basidiomycetes proper), together with the *Fungi Imperfecti*, the members of which are probably stages in the life histories of forms belonging to the Ascomycetes and Basidiomycetes, and the lichens, the majority of which are Ascolichens, a few being Basidiolichens. As regards phylogeny, evidence is gradually accumulating that the derivation of the primitive fungi such as the Chytridineae is to be traced to a protozoan ancestry (*see* PROTOZOÖLOGY).

Many of these primitive forms, and notably that curiously interesting species *Polyphagus euglenae*, have much in common with Protozoa, and we have also to consider, in this connection, the mycetozoa and bacteria, which, although they have some of the characteristics, are not regarded as true fungi. As regards the higher fungi, notwithstanding our increased knowledge of their structure and reproduction, any conclusions as to their algal ancestry, although not impossible, cannot at present be substantiated.

Recent Investigations.—Among the more generally interesting investigations of recent years are those on the symbiotic relationships of the fungi to higher plants, as exemplified by the endotropic mycorhiza of *Calluna vulgaris*. Evidence has been brought forward to show that the presence of the fungus is so necessary to the well-being of this plant that no development of the seedling can take place unless it is infected by the fungus, and this infection is brought about by hyphae in the seed coat. Further, although seedlings may be satisfactorily infected from artificial cultures, yet, if the culture is too vigorous and the seedling weak, the fungus behaves as a parasite. This raises important problems still under discussion concerning the relations of mycorhiza and symbiosis to parasitism and saprophytism.

Many new observations have been made upon the cell contents of the fungi. Among these may be mentioned metachromatin, chromidia, mitochondria, coenospheres or coenocentra and elaioplasts. The distribution and staining properties of these bodies have been carefully studied, but we are still far from a clear understanding of their significance.

Some attention has been paid to the colouring matters of the fungi. The orange coloured fatty globule in the zoöspores of Chytridineae probably plays the part of an eye spot. Most of the brilliant colouring of the fungi is due to colouring matters in the cell walls, or in the mucilaginous layers of the cell membrane. Many of these when extracted in water and alcohol exhibit a beautiful blue or blue-green fluorescence.

The stimuli of light and gravity play an important part in the orientation of the fungi. Light exerts not only a directive but also a formative influence on their growth. Positive heliotropic response occurs in many of the Agaricineae, in the asci of certain Discomycetes and in the sporangiophores of various Mucorineae, by which they are brought into the best position for the discharge of their spores. Response to the stimulus of gravity is shown during the growth of the fruit bodies of the Hymenomycetes, and is on all-fours with what takes place in higher plants. The perceptive region is located in the stipe, the upper part being the most sensitive. The gills show a very pronounced positive response to gravity.

There is very little to add to our knowledge of the sexuality and nuclear fusions in the fungi beyond what was known in 1910. In the Phycomycetes functional sexual organs and the fusion of male and female nuclei have been discovered in many species in which they had not previously been found, and the presence of functional sexual organs has been definitely established in the Saprolegniaceae. In the Ascomycetes and Basidiomycetes the significance of the nuclear fusions in the ascus, teleutospore and basidium is still not understood, and the existence of two nuclear fusions in the life histories of certain Ascomycetes is still a matter of controversy. Very conflicting accounts are given of the nuclear behaviour in such classical species as sphaerotheca and pyronema, and until some quite definite agreement as to the facts is forthcoming it seems impossible to arrive at anything like a satisfactory explanation. In that interesting group the Laboulbeniaceae, there is evidence that sexual fusion takes place by a method somewhat similar to that described for the lichens by means of a trichogyne and spermatia. The fusion has not actually been observed, and the fate of the spermatia is unknown.

In the Basidiomycetes proper a number of observations have been made to show that the phenomena of heterothallism and homothallism, as in the Mucorineae, occur here also. The criteria for this conclusion are the behaviour of cultures of monosporous mycelia as contrasted with those of bisporous or polysporous mycelia in the production of fruit bodies; and the formation of clamp-connections. Thus, *Coprinus fimentarius* is stated to be heterothallic on the following grounds: in a monosporous culture no clamp-connections were found, the nuclei remained unpaired and the mycelium was sterile. When two monosporous cultures were brought together clamp-connections were formed, the cells became binucleate and fruit bodies were produced. The presence of clamp-connections is stated to be "invariably associated with the conjugation of the nuclei." It is suggested that this criterion affords a means of determining whether a species is homothallic or heterothallic.

These conclusions are so important that the data on which they are based should be subject to the most critical confirmation, especially in view of the facts that contradictory statements concerning them have been made, and that they have been used as a basis for important conclusions upon the Mendelian segregation of sex in these forms. It is essential that we should have definite confirmation of the function suggested for the

clamp-connections, and of the transference of nuclei from one cell to another in the anastomoses that take place in the mycelia, before any satisfactory advance can be made in this new field of study. (H. W.*)

MYSLBEK, JOSEF VÁCLAV (1848–1922), Czech sculptor, was born at Prague July 21 1848. He was a pupil of Václav Levý and worked under Trenkwald at the academy of fine arts in Prague. He sprang into prominence when in 1871 he carved two symbolical figures for the exterior of the National Theatre in Prague. The statues are distinguished by a Slav lyricism and delicacy, combined with a masculine strength and a monumental feeling. After a brief residence in Paris he was in 1885 appointed professor at the school of arts and crafts in Prague, of which he became a director in 1893. All Myslbek's work presents a blend of idealism with a precise and balanced realism and exhibits his endeavour to cope with the fundamental problems of art. His statues "Devotion" (1884, Modern Gallery, Prague), and "Steadfastness" (1884, Vienna Parliament) notably unite a powerful idea with a complete mastery of the material. His "Crucifix" (1888–9), installed in the Sacré Coeur at Paris, bears comparison with the works of old masters, although it is conceived in the modern spirit, expressing human suffering and divine resignation. The statue of Cardinal Schwarzenberg (1895) is a masterpiece of portraiture, but the highest attainment of Myslbek's art is the monument to St. Václav, a work of 30 years, in St. Václav's Square in Prague, which embodies all his monumental qualities as an artist and attains a level which entitles it to a place among the great works of European statuary. Myslbek died at Prague in 1922.

MYSTICISM (*see* 19.123).—The 20th century has seen a remarkable revival of interest in mysticism. Several causes have contributed to this. First, the inevitable reaction against 19th century rationalism, with its excessive emphasis on the ethical and neglect of the transcendental in religion. Next, the disturbance of traditional theology by textual criticism and historical and scientific research, forcing many religious minds to look elsewhere for the grounds of belief. Thirdly, the application of the comparative method to records of religious experience, especially that intensive form which claims direct intuitive apprehension of God (and this is the kernel of mysticism) disclosed remarkable unity between them; and the development of psychology brought within the range of that science many "mystical phenomena" which had formerly been dismissed unexamined, as the products of superstition or of mental disease.

The fresh material brought in from the study of Oriental religions has also supported the claim of mysticism to be regarded as a genuine form of human experience. Finally, in opposition to the merely moral and humanitarian view of Christianity popularised by Liberal Protestantism and social reformers, this century has produced a number of records of contemporary mystical experience. Thus there have been both additions to the material accessible to students, and advances in the proper arrangement and understanding of facts. No well-informed person now identifies the substance of mysticism with trances, ecstasies or other psychophysical phenomena, or regards it as necessarily hostile to dogmatic theology.

Modern Study.—Modern study of the subject may be said to begin with Dean Inge's Bampton Lectures on Christian Mysticism (1899). It has since been pursued along the parallel routes of psychology, history and philosophy of religion. These aspects of mysticism cannot rigidly be separated, or indeed understood in isolation; each being of vital importance to the rest. The peculiar triumph of the greatest modern writer on mysticism, Baron Friedrich von Hügel, consists in the synthesis effected between the historical, philosophical and intuitive aspects of man's experience of God.

The Psychology of Mysticism

The serious study of mysticism, especially from the psychological point of view, and attempt to discover its relation to other forms of consciousness, originates in William James's epoch-making Gifford Lectures on *The Varieties of Religious Experience* (1902). Although based on material chosen from too restricted a field, the publication of this book revolutionised the attitude of students towards religious psychology. The conception of the subconscious was now first used to provide an explanation and sanction for the ecstatic and other abnormal phenomena found in connection with mysticism, and an attempt was made to distinguish the accompaniments of genuine religious apprehension from their pathological imitations.

These researches have continued vigorously, especially in America and France. Pratt's *Religious Consciousness* (1921) represents the matured result of the movement started by James. Considerable advance has been made towards the correlation and better understanding of such types as the prophet, visionary and religious revivalist, in all of whom a strong mystical impulse is commonly at work. The hostile study of mysticism from the psychological standpoint has its chief exponent in J. H. Leuba; whilst an approach midway between the philosophical and psychological is provided by Bucke's *Cosmic Consciousness*, a curious work which has exercised considerable influence.

Realisation of the close correspondence between the abnormal phenomena of mysticism and those connected with other forms of mental exaltation, healthy and diseased, has caused an attempt to distinguish the essence of mysticism—intuitive experience of absolute reality—from the ecstatic states often accompanying it. This may be the line along which the apologetic of the future will move. Characteristic of the revival is the important part taken by French writers. Effective criticism of mystical phenomena has come from experimental psychologists such as Pierre Janet. Delacroix's sympathetic but penetrating analyses of the evolution of the great mystics have shed much light on the psychological characteristics of religious genius. Valuable studies of the nature of mystical contemplation, and restatement in modern terms of its processes, have been produced by Roman Catholic scholars; the best being those of Père Poulain, S.J. These works have a practical as well as a scientific objective. On the whole, the general result of the application of psychological criteria to mystical experience has been to establish the claim of psychology to explain the special methods and characteristics of the mystic, and disestablish the claim of certain schools of psychology to explain away the reality of his experience.

The History of the Movement

The modern psychological study of mystical phenomena has illuminated many historical problems; especially those connected with prophecy and the origins of religious movements. It has also stimulated interest in the records of empirical religion in its intensest form—the lives and writings of mystical seers and saints. The contribution of mystical experience to the religious outlook of such apparent intellectualists as, *e.g.*, St. Augustine or Aquinas is beginning to be understood; together with the great part played in religious history by mystics and their articulation to the corporate religious life. The treatment of the subject in such works as Heiler's *Das Gebet* and *Der Katholizismus* or Bréhmond's monumental *Histoire du Sentiment Réligieux en France*, is symptomatic of the changed outlook. Material available for students of historical mysticism has been much enriched. Good texts and translations of many masterpieces of European mysticism have appeared, with valuable studies such as those of Abbot Butler and Rufus Jones, based on the historical method. Sūfi mysticism, once only known to Oriental scholars, can now—thanks mainly to the work of Reynold Nicholson—be compared with that of the West. Such studies are seen to have an important bearing on the history of ideas; and the substantial identity of experience which they reveal has proved that mysticism must be regarded as an enduring type of human apprehension.

The changed outlook of physical science, the new understanding of its limitations and the marked revolt from 19th-century materialism, have brought about a *rapprochement* between mysticism and philosophy. There is a tendency alike in monists, critical realists and exponents of the "philosophy of value" to consider seriously the claims and findings of the mystic, which are congenial to the pantheistic temper of modern religious

thought. On the other hand, those hostile to pantheistic doctrine find in the mystic's intuition of God a warrant for transcendentalism; and even show some willingness to reinstate in suitable disguise the ancient concept of Supernature. Inge's *Philosophy of Plotinus* (1918) and Otto's widely discussed essay *Der Heilige* (The Idea of the Holy, 1924) show different aspects of the reaction of philosophy to mysticism. But this is also felt in the pure metaphysics of Wittgenstein, and in the inimical attitude of Croce and his school. The greatest and ultimately most influential expositions of the place of mysticism in theistic philosophy, and its limitations and rightful relation with other aspects of knowledge, are Von Hügel's *Mystical Element of Religion* and *Eternal Life*. These books have affected all modern religious thinkers, and may provide the starting-point of a critical realism harmonising the mystical, moral and intellectual approaches to reality. In America, Hocking's *Meaning of God in Human Experience* is probably the most important philosophic contribution to this subject.

Modern Mystics.—The first quarter of the 20th century saw, especially in France, a revival of genuine Christian mysticism; possibly the beginning of what later historians may recognise as a "mystical epoch." Its most impressive document is the *Spiritual Journal* of the lady known as Lucie-Christine (1844–1908), a record which bears comparison with the historical classics of mysticism. Its most striking product is the career of the hermit saint of the Sahara, Charles de Foucauld (1858–1916). These stand up among a number of more obscure personalities, such as Elizabeth de la Trinité (1880–1906) and Madeleine Sémer (1874–1921), all of whom claim and describe with a conviction and sobriety compelling respect the characteristic mystical experience and certitude. From India, the autobiography of the saintly Hindu theist Maharshi Devendranath Tagore (1817–1905), and the experiences of the Christian convert Sadhu Sundar Singh (born 1889), whose career and personality have made a widespread impression, provide unspoilt examples of first-hand mysticism, and deepen the sense of unity in the spiritual intuitions.

The revived interest in mysticism has had popular results in several directions. It has seemed to endorse the shallow eclecticism in which many escape the difficulties of belief. Its superficial peculiarities have been exploited by theosophists and other apostles of eccentric religiosity. It has produced numerous bastard cults, mostly hailing from America though often wearing Oriental disguise; cults mainly compounded of pantheism, quietism and crude autosuggestion, and offering a "mystical religion" to those seeking a spiritual home full of modern conveniences and devoid of discipline. On the other hand, its spirit has affected for good the literature and activity of the organised Churches; shifting the emphasis from tradition to experience, and bringing back into focus those mysterious realities which religious symbols and institutions seek to express.

NAIROBI, the capital of Kenya Colony, British East Africa (*see* 10.155). In 1923 the population was: Europeans 3,071, Asiatics 8,356, Africans 12,666, total 24,093. Nairobi is the seat of the Kenya Legislature and the headquarters of most of the European organisations in the colony. Nearly all the whites are British, and the town has most of the amenities of a European city. Both the standard and the cost of living are high. Laid out on a large scale, Nairobi was still in the transition stage in 1926, but had many fine private and public buildings. The main thoroughfares are Government road, in which numbers of shops and offices are owned by Indians, and Sixth avenue. Parklands is a residential suburb for Europeans. A Natural History Museum, in Kirk road, was opened in 1922. The Indian bazaar covers nine acres. The natives occupy a separate location. A branch railway runs to the foot of Mt. Kenya. Nairobi is governed by an elected municipality, with separate franchise rolls for Europeans and Indians.

NAMUR, Belgium (*see* 19.159), with a population in 1923 of 31,044, has been called the Sheffield of Belgium, because of its large cutlery industry. Tanning and glass-making are also carried on, and the town has a considerable trade, and six lines of railway. An athletic sports ground was laid out and a fine open-air theatre built before the World War in the park on the Citadel Mount. Namur was bombarded for two days in 1914, before it was taken by the Germans, and after their entry a number of houses were burnt and looted. The Place Leopold and Place d'Armes suffered severely in the bombardment and the town hall was destroyed. The forts were repaired by the Germans after the capture of the town, which formed their cavalry headquarters during the War. The railway station was bombed by the British shortly before the Armistice (*see* BELGIUM, INVASION OF).

NANKING, China (*see* 19.162), had an estimated population of 380,900 in 1923. Since it became the terminus of a railway line to Shanghai, and the line to Tientsin, terminating at Pukow, on the opposite bank of the Yangtze Kiang river, was opened, the trade has increased, but the city has little commercial importance. A short railway line has been opened to Hsiakwan, the port of Nanking a few miles to the south. A grand industrial exhibition, the first in China, was held in the city in 1910, and again in 1921. Only a portion of the ground enclosed by the 20-mile circuit of the walls is inhabited, but the area has been opened up by roads and shops, offices and government buildings in Western style have been erected. The city possesses a naval college, an arsenal, an agricultural experimental station, a Government mint and a university. The last was formed by the union of three independent mission schools in 1911, and includes a college of arts and sciences and one of agriculture and forestry; a hospital and library; senior, junior and primary schools, etc. Two-thirds of the surplus from the American China Relief Fund was presented to the university in 1922 for research, particularly in connection with famine prevention. Good work has also been done in the production of silkworm eggs immune from disease. A number of the large silk stores in Nanking were burnt and looted by Chinese soldiery in 1924, and American marines had to be landed to protect the foreign population.

Nanking was the scene of much fighting during the revolution of 1911, and the Tartar city was burnt. It became the seat of a provisional Government, which hoped to make it the capital city, but in 1913 an armed rebellion took place and the city was bombarded for a fortnight by the troops of the Government. Hsiakwan was burnt down, but was rapidly rebuilt with new and wider streets.

NANSEN, FRIDTJOF (1861–), Norwegian scientist, explorer and statesman (*see* 19.162). After Dr. Nansen's return from the North Polar expedition in 1896 a professorship of zoology was established for him at the University of Christiania. Here he was engaged in working up the results of his expedition and in general scientific research, especially in physical geography and oceanography. In the summer of 1900 he took part in an Arctic oceanographic expedition in the S.S. "Michael Sars," headed by Dr. Johan Hjort, and became director of the International Central Laboratory in Christiania for the Research of the Sea. In 1902 he published *The Oceanography of the North Polar Basin*, and in 1904 *The Bathymetrical Features of the North Polar Seas*. In 1905 Nansen actively intervened in politics for the first time. He issued a manifesto and many articles in connection with the crisis between Norway and Sweden. His attitude may be summarised by the last words of a short work published later in the year: "Any union in which the one people is restrained in exercising its freedom is and will remain a danger" (*Norway and the Union with Sweden*, London, 1905). On the establishment of the Norwegian monarchy Nansen was appointed minister to England (1906), and in the same year was created G.C.V.O. In 1908 he retired from his post and returned to his scientific work as professor of oceanography at Christiania University. He devoted all his time to oceanographic research, and in co-operation with his friend Professor Bjorn Helland-Hansen, of the Bergen Museum, wrote *The Norwegian Sea, its Physical Oceanography* (*Report* on Norwegian Fishery and Marine Investigations, vol. 2, 1909).

In 1910 Nansen made an oceanographic cruise in the "Frithjof" through the northeastern North Atlantic from Ireland to Iceland and back to Norway, and published the results in *The Waters of the Northeastern North Atlantic* (*Internationale Revue der gesammten Hydrobiologie und Hydrogeographie*, Leipzig, 1913). In 1911 he published *In Northern Mists* (2 vol.) on the exploration of the northern regions from early times up to the beginning of the 16th century. In 1912 he made a further oceanographic cruise to Spitsbergen and the waters to the north in his yacht the "Veslemoy," and described it in *En ferd til Spitzbergen;* the scientific results of the cruise are contained in *Spitzbergen Waters* (Society of Science, Christiania, 1915). The following year he made an expedition through the Arctic and the Kama Seas to the mouth of the Yenisei river and through Siberia and the Amur region, recounted in *Through Siberia, the Land of the Future* (London, 1914).

In 1914, jointly with Professor Bjorn Helland-Hansen, Nansen made an oceanographic expedition in the eastern North Atlantic to Portugal, Madeira and the Azores and back to Norway, the important scientific results of this expedition being published by the two scientists in *The Eastern North Atlantic* (Geophysic Publication, Academy of Science, Oslo). During the World War further oceanographic expeditions—Nansen's absorbing interest—were impossible. In 1917 he was appointed head of a Norwegian Govt. commission to the United States, and secured a satisfactory agreement with the American Govt. in regard to the import into Norway of essential supplies. After the Armistice (1918) Nansen threw himself with vigor into the work of repatriating prisoners of war, and under him, as Commissioner of the League of Nations, and with the executive assistance of the national Red Crosses, about 500,000 prisoners of war were repatriated from Siberia, China and other parts of the world. This work was financed largely by the governments participating in the International Committee for Relief Credits, Paris, of which Lord Bradbury was chairman.

In 1919 Nansen conferred with Hoover regarding the possibilities of assisting the Russian people, and suggested to President Wilson and the members of the Supreme Council an organisation for Russian relief on the lines of the Belgian Relief Commission. The Supreme Council supported the proposal on the condition that all hostilities in Russia cease. As this was at the time when Kolchak in the east and Deniken in the south were advancing towards Moscow the project was abandoned. In 1921 Nansen was asked by an international conference in Geneva of delegates of 48 Red Cross societies and 12 governments to put himself at

the head of the relief work for famine-stricken Russia, and on Aug. 27 in the same year he signed an agreement in Moscow with Chicherin, the Soviet Foreign Minister, regarding the method of furnishing relief on an important scale, and visited the areas of famine. In Sept. Nansen endeavoured unsuccessfully to induce the League of Nations to assist the starving millions in Russia by raising, under safeguards, an international governmental relief loan. Failing here, he visited the chief capitals of Europe, and as a result largely of his intensive propaganda the European Red Crosses fed and clothed at one time at the peak of the Russian famine over 1,600,000 inhabitants of the Volga and South Ukraine regions. His publicity campaign undoubtedly had influence in America, which under Hoover's inspiration and direction fed at one time 10,000,000 Russian sufferers. Nansen's mission in Russia continued to conduct two agricultural demonstration estates in the former famine areas. In 1923 Nansen published *Russia and the Peace* setting out the economic position of Soviet Russia. As high commissioner for refugees to the League, he accepted responsibility for the protection and settlement of Russian, Armenian and Greek refugees, and the following is the appreciation of the Assembly of the League of this work:—

The Assembly feels it its duty to pay a whole-hearted tribute to the high commissioner, Dr. Fridtjof Nansen, both for his unceasing devotion, of which for more than four years he has given proof, in assisting refugees of every nation, and for the high qualities which he has displayed in the carrying out of his onerous duties. The Assembly would record the fact that with the very limited means at his disposal Dr. Nansen has saved from misery and often from death hundreds of thousands of human beings, and would render him the grateful thanks due to him as a benefactor of humanity.

In 1923 Nansen was awarded the Nobel Peace Prize, which he gave to the furtherance of the Nansen agricultural demonstration estates and model farms in Saratov and Ekaterinoslav Governments, Russia. In his early manhood Nansen was a great athlete, and by his writings was largely responsible for popularising ski-ing in the Alps, and evidence of his enthusiasm for sport is his work on *Sport in the Polar Regions* and *Wild Norway* (1925). Nansen, as delegate for Norway to the League of Nations, made an impassioned intervention protesting against the occupation of Corfu by Italy in 1923, and at the Fifth Assembly in 1924 he conducted the first informal negotiations that took place concerning the entry of Germany into the League of Nations. Nansen's interest in education has been evidenced by his campaign in favour of Russian professors and universities. In 1925 he was elected Lord Rector of Aberdeen. (*see* POLAR REGIONS; REFUGEES.) (J. H. Go.)

NAOROJI, DADABHAI (1825–1917), Indian politician (*see* 19.167), died at Versova, near Bombay, June 30 1917.

NAPLES, Italy (*see* 19.178), the second largest city in Italy, had a population of 772,405 in 1921. To improve the sanitary condition of the city an opening has been made through the squalid Pendino quarter, and a new approach to the castle from the Strada San Carlo. The quarter of Santa Lucia has grown largely. A fine art collection was presented to the city in 1925, and will be housed in the Villa Floridiana.

The museum, which houses the Pompeian collections, shaken by the building of a tunnel, was found to be in danger of collapse; the walls were temporarily shored up pending its repair. Excavations in 1913 led to the discovery of the old port of Pompeii, and further discoveries in Pompeii itself were opened to the public in 1915. The Neapolitan University was closed in 1925, owing to riots between Fascists and non-Fascists. A metropolitan electric railway was opened in 1925, with seven stations, the terminus being at Pozzuoli; another station will be built at Bagnoli. The work on port improvements was temporarily suspended in 1924. Fears were expressed in 1925 lest the Orient Line would cease to use Naples as a port of call, owing to the new regulations for third-class passengers. Naples is now the third port of Italy: the number and tonnage of vessels entering the harbour are greater than at Genoa, though the amount of goods is less.

NAQUET, ALFRED JOSEPH (1834–1916), French chemist and politician (*see* 19.236), died in Paris March 12 1916.

NARES, SIR GEORGE STRONG (1831–1915), British explorer (*see* 19.240), died at Surbiton, Surrey, Jan. 15 1915.

NAREW, BATTLES OF THE.—The battles on the river Narew, northeast of Warsaw, in July and Aug. 1915, were a part of the great offensive planned by Falkenhayn against Russia. (*See* EASTERN FRONT and map.) During May and June, Mackensen had driven the Russian armies in Galicia from Tarnów on the Dunajec to the east of Lemberg (*see* DUNAJEC-SAN; LEMBERG). In July the group of armies under his command was directed northeast towards Brest-Litovsk against the communications of the Russian forces which still held the Warsaw salient (*see* BREST-LITOVSK). Hindenburg, who commanded the group of armies on the northern part of the Eastern Front, was now ordered to strike a blow on the north side of the salient. Falkenhayn hoped thus by driving in the flanks of the salient to cut off large numbers of Russians in its apex about Warsaw. The realisation of this hope depended of course on the rapidity with which the flanks could be forced.

Rival German Plans.—The operation against the Narew line is of interest because of the controversy it provoked between the two men who had most influence on German strategy during the War, Falkenhayn and Ludendorff. The former was at this time chief of the German Great General Staff, and thus responsible for the supreme direction of the War; the latter was chief of staff to Hindenburg. Ludendorff had long cherished the idea of a Napoleonic manoeuvre against the Russian rear by Kovno and Wilno on Minsk, and considered the proposed Narew offensive as timid and ineffectual, Falkenhayn, with heavier responsibilities on his shoulders, mistrusted both the feasibility and the expedience of the Wilno adventure. He could not afford to become so deeply involved in the Eastern theatre as to be unable to withdraw formations to meet the coming offensive in the West. After a discussion of the alternative plans held in the presence of the Kaiser, Falkenhayn's views were approved; and Hindenburg was ordered to carry out the Narew attack.

A formidable water barrier protects Russian Poland against invasion from East Prussia. From Kovno to Grodno it is formed by the Niemen; from near Grodno it is continued by the Bobr, the Narew and the lower course of the Bug to the fortress of Nowo-Georgiewsk (Modlin); thence the Vistula flows northwest to the frontier. The Russians had fortified this river line. Besides the fortresses of Kovno and Grodno on the Niemen, Osoweic on the Bobr, Lomza on the Narew and Nowo-Georgiewsk at the confluence of the Bug and Vistula, there were fortified bridge heads on the Narew at Ostrołęka, Rozan, Pultusk and Zegrze. Though the river was fordable in the summer at many points, marshes along its length increased its effectiveness as an obstacle.

The German Attack.—Gallwitz's army, which was to make the attack, comprised six corps (14 divisions). It extended from the river Szkwa, northeast of Ostrołęka, to the Vistula. Opposite to it, from Jednorozec, on the river Orzec, to near Płoçk on the lower Vistula, lay the Russian I. Army (Litvinov) with three corps and a cavalry corps.

The tactical details of the fighting are not of any special interest. On July 13 Gallwitz delivered his first attack on the approximate line Przasnysz-Ciechanów, aiming at Pultusk. The Russians, over-weighted both in numbers and heavy artillery at once fell back more than half-way to the Narew line. They were attacked again on July 15, and during July 18 and 19 withdrew across the river, the Russian XII. Army on their right conforming to the movement. Reinforcements had now arrived and resistance stiffened. Though the Germans stormed the bridge-heads of Pultusk and Rozan on July 23, and secured crossings over the river, their further progress was limited by violent Russian counter-attacks, and they were unable to reach the line Wyszków (on the lower Bug)–Ostrów, at which they were aiming. An attempt to force a passage further east at Ostrołęka on July 30 failed, and it was not until Aug. 4 that this bridge-head fell. Losses were heavy on both sides; but the Russians had secured time and space sufficient to evacuate the Warsaw salient without danger.

Hindenburg and Ludendorff naturally claimed that the result the battle vindicated their opinion on the mistaken strategy of e Supreme Command. Falkenhayn retorted that the operaons would have had the desired effect of intercepting the ussian retreat had Hindenburg used the full force available id given Gallwitz 20 divisions instead of fourteen. It seems oubtful, however, whether the communications would have llowed the effective employment of so large a force.

(A. P. W.)

NAROCZ, BATTLE OF LAKE.—Lake Narocz, in Lithuania, 2 m. E.N.E. of Wilno (Vilna), gives its name to a great offenive by the Russian II. Army in the spring of 1916 (*see* EASTERN RONT and MAP).

General Situation on the Eastern Front.—The river Pripet ormed the dividing line between the German and Austrian comands. At the beginning of March there were 42 German and wo Austrian divisions on the front north of the Pripet, the total ength of which was about 250 miles. The Russians had organsed their armies into three groups: the Northern (XII. and V. Armies) on the Dvina, the Western (I., II., X., IV., III. Armies) extending to south of the Pinsk marshes and the Southwestern VIII., XI., VII., IX. Armies) up to the Rumanian border. Their main strength was concentrated on the Northern and Western fronts, where it had been decided that the principal efforts of the year should be made. The losses of 1915 in men and material had been made good; guns and munitions were available on a larger scale than previously, though still insufficient for the requirements of trench warfare.

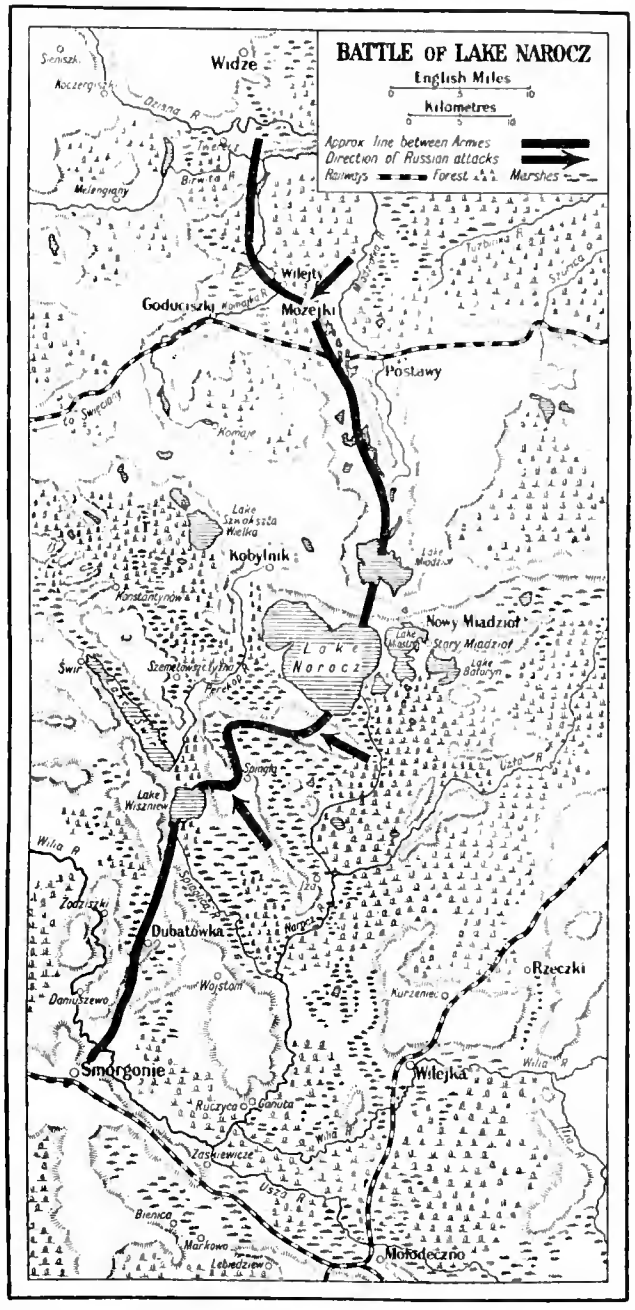
Plan of Operations.—The general idea of the battle was for the II. Army to attack on either side of Lake Narocz, where the German line formed a slight salient; the two wings were eventually to join at Swieciany and to continue their advance westwards to Panevežys (some 80 m. north of Wilno (Vilna) and 100 m. west of the original line), where the V. Army, which was to attack from the Jakobstadt bridgehead on the Dvina, was to join them. The operation seems to have been planned originally to take place later in the year, when all the Allies proposed to attack simultaneously. But on Feb. 21 the German assaults on Verdun began, and the Russians chivalrously hurried on their preparations and attacked to relieve the pressure on the French, at the worst possible time of the year, when the annual thaw, which renders all communications practically impossible for a period, might be expected at any moment.

Description of the Terrain.—Lake Narocz (eight m. by six m.) is the largest of a whole series of small lakes in which the tributaries of the Wilia and the Dzisna rise. It drains into the river Narocz, which flows south to join the Wilia east of Smorgonie. The greater part of the trench line between Dvinsk and Smorgonie (over 100 m. in a straight line) was protected by lake, stream or marsh, and stretches of dry ground wide enough for a large scale offensive were few. On either side of Lake Narocz, however, were gaps of four m. or so in the water line, where the terrain was comparatively favourable for attack, though communications were poor. The northern gap was 10 m. to the north of Lake Narocz, between the villages of Wilejty and Możejki; the southern was between the lake itself and Lake Wiszniew.

Dispositions of the Opposing Forces.—The II. Army, which was to carry out the attack, was divided into three groups: the right group, under Gen. Plyeshkov, opposite the northern gap, consisted of three corps and a cavalry corps; the centre group, under Gen. Sirelius, of two corps; and the left group, under Gen. Baluev, of three corps. Four corps were available behind these groups to exploit any success gained. The right and left groups were to attack the north and south faces of the salient respectively, while the centre group assisted by minor assaults and demonstrations. The army commander, Smirnov, went sick just before the battle and his place was taken by Gen. Ragoza.

The II. Army was opposed by Von Eichorn's X. Army, which extended from the river Dzisna to Krewo, south of Smorgonie, a front of some 85 m., and comprised 11 divisions and two cavalry divisions. The Germans were aware of the Russian concentration. Just before the attack, Gen. Von Hutier, commanding the XXI. Corps opposite the Lake Narocz front, was reinforced by one division, and other reserves were held in readiness to support him.

The Russian Attacks.—A thaw set in on March 17, but the offensive was nevertheless begun on the 18th. After a bombard-



ment of several hours, massed infantry attacks were made both by Plyeshkov's group north of Lake Narocz and by Baluev's group in the south. In the thickly wooded and enclosed terrain the insufficiently trained Russian infantry soon lost cohesion, and their assaults were ill-timed and disjointed. Though the German first-line trenches were in several cases occupied, they could not be held under the concentrated fire of the German artillery, which was extremely skilfully handled. By nightfall the Russians were back in their original positions, having suffered very heavy casualties without result. After two days of further

artillery preparation and minor attacks intended to mislead the enemy, renewed heavy assaults were made on the nights of March 19–20 and 20–21.

On Plyeshkov's front no ground was permanently gained, in spite of terrible losses, but Baluev's group in the south had some measure of success, and made an advance of over a mile on a front of about 2½ miles. The weather conditions were by now terrible; it thawed from the 17th to the 22nd, and the whole area of operations became a sea of mud. The battle was, however, continued till March 27, when the Russians at last desisted from their fruitless and costly attacks. In April a German counter-stroke retook all the ground gained by Baluev. Meanwhile, the attacks of the V. Army from Jakobstadt, March 21–6, were equally unsuccessful and almost equally wasteful of life.

Results of the Operations.—The operations resulted in a complete and disastrous failure for the Russians. Their losses were over 100,000 and they accomplished nothing. The offensive did not cause the Germans to move a single man from the Western Front, and so brought no relief to the French. The operation was mismanaged in every way. Both time and place were ill-chosen; the staff work was bad; and the artillery, in spite of a greater concentration of heavy guns on a narrow front and a more liberal expenditure of ammunition than ever before, failed to give proper support to the infantry, who as usual paid the price in terrible losses. The result was, in fact, a bitter disillusionment to the Russian high command, to the Russian soldier and to the Russian people.

NASH, PAUL (1889–), British painter, was born in London May 11 1889, and educated at St. Paul's School and at the Slade School. His first exhibition was given in 1911, but he was comparatively little known until an exhibition of his Western Front war pictures (1918), the fruit of his work as an official artist 1917–8; several of these are in the Imperial War Museum, London. He then attracted attention as a landscape painter of individuality and charm, a somewhat mannered technique giving way gradually to a freer expression; he gave an important exhibition in London in 1924. He also produced some interesting woodcuts and book illustrations, such as the wood engravings, "Genesis" (1924). He was instructor of design at the Royal College of Art, South Kensington.

His brother, JOHN NORTHCOTE (1893–), worked on similar lines, and was also an official war artist during 1918.

NASHVILLE, Tenn., U.S.A. (*see* 19.246), had a greater business development between 1910 and 1925 than is indicated by the growth of its population within the city limits: 1910, 110,364; 1920, 118,342 (of whom 35,633 were negroes and 2,412 foreign-born, both of these groups being smaller than in 1910); 1925, 136,220, as estimated by the Census Bureau, and probably 150,000 if suburban population which is a part of the economic unit, were included. The value of products manufactured within the city limits increased from $29,650,000 (1909) to $83,041,583 (1923); postal receipts and bank clearings increased threefold, savings deposits and the value of new buildings constructed even more. During the World War the U.S. Govt. established the "Old Hickory" powder plant in the wilderness across the Cumberland river, constructing a village for 30,000 residents. Plant and village were bought after the War by a local corporation formed for the purpose of salvaging the property for an industrial centre. By 1925 a large factory for the production of rayon (artificial silk) was in operation on this site, and the location of other industries was assured. Vanderbilt University, with grants of $8,000,000 from the General Education Board and the Carnegie Corp. thoroughly reorganised its medical school (1919–25) and built for it an adequate modern plant, which was occupied in 1925. Nashville, Davidson county, and the State of Tennessee united in erecting a beautiful memorial building in honour of the men of the state who lost their lives in the War. In 1913 Nashville adopted the commission form of government.

NATAL (*see* 19.252), the smallest and most densely populated province of the Union of South Africa. Its area (including Zululand) is 35,284 sq. m. and the population (1921) 1,429,398, of whom 136,838 were whites, 141,649 Asiatics, 1,139,804 Bantu and 11,107 of mixed or other race. Since 1911 the white inhabitants had increased by nearly 39,000; the Asiatics by 8,210, the Bantu (natives) by 186,000. The density of population per sq. m. was 40.51. The chief towns are Durban and Pietermaritzburg (*qq.v.*). Next in size is Ladysmith with (1921) 6,783 inhabitants (3,221 whites).

The change from the status of a self-governing colony to a province of the Union affected Natal politically more closely than any other province, since in it alone were the great majority of the white inhabitants of British descent. The firm attachment of Natalians to the British connection continued an unchanging factor in the South African situation. Provincial administration was, however, largely carried on upon non-party lines. The first administrator, Mr. C. J. Smythe, had previously held office as Colonial Secretary and as Prime Minister of Natal. Mr. Smythe, who was reappointed for a second term in 1915, died in 1918 and Mr. (later Sir) G. T. Plowman succeeded to the post, which he still held in 1926. Revenue, derived chiefly from transfer duties and licences, increased from £118,000 in 1912–3 to £413,000 in 1922–3, the subsidies from the Union Govt. rising from £361,000 to £563,000. About 70% of the total expenditure was on education, the sums spent for that object rising from £169,000 in 1912–3 to £695,000 in 1922–3.

The Indian Problem.—Natal was deeply interested in the question of Indians in South Africa. Of the 161,339 British Indians in the Union in 1921, no fewer than 141,336 lived in Natal, where they had rendered possible the development of the sugar, tea and wattle industries, as well as provided labour for the coal-mines, railways and other public works. Besides labourers, there were many Indians engaged in professions and commerce. White South Africans in general opposed the further increase of Asiatics in the Union; while, in 1911, the Indian Govt., long dissatisfied with the attitude of Natal to Indians, prohibited the recruitment of indentured coolies. The Indians both in Natal and the Transvaal complained of many grievances, and their cause was championed by M. K. Gandhi, then resident in South Africa. Arising out of the agitation, riots and disturbances occurred in Natal in 1913. In 1914 the Union Govt. passed legislation intended to prevent Indian immigration into South Africa and to prevent Asiatics already in the Union leaving the province in which they lived. The so-called Smuts-Gandhi agreement of the same was designed to guard the vested interests of Indians already in the Union. The attitude of the white inhabitants of Natal was shown by the Borough Ordinance passed by the provincial council in Jan. 1924, debarring Indians in future from acquiring the municipal franchise. This ordinance was held up by the Union Govt. for consideration, but in Dec. 1924, assent to its operation was given. The parliamentary franchise was, with a few special exceptions, already confined to whites. In 1925 there were 38,547 parliamentary electors, of whom only 24 were Indian.

A notable element in the progress of Natal has been the development of coal-mining. The output, which in 1910 first exceeded 2,500,000 tons, had increased to 4,302,000 tons in 1923. Natal coal is of excellent quality. The quantity of coal bunkered and exported in 1924 exceeded 2,700,000 tons.

The Offical Year Book of the Union of South Africa (Pretoria) gives list of government publications dealing with the Asiatic question and provincial administration. *See* SOUTH AFRICA, UNION OF. (F.R.C.)

NATHAN, ERNESTO (1845–1921), Italian politician, was born in London, the son of an Englishman, Joseph Nathan, and of an Italian mother, Sara Rosselli, both Jews. In 1858 he settled in Pisa with his mother and attended the university there. Soon afterwards they had to repair to Switzerland on account of Sara Nathan's republican sentiments; it was then that Ernesto Nathan became acquainted with Mazzini, whose views became thenceforth his chief inspiration and cult. A violent anti-clerical,

soon joined the Freemasons and was elected "Grand Orient" of Italy in 1899, but resigned in 1905 owing to internal disagreements. He became an Italian citizen, and although he had been a republican in his early years, he gradually accepted the monarchy as the best *régime* for Italy. He showed great activity in organising the "Unione dei partiti popolari" in 1900, a *blocco* of the various radical and anti-clerical parties in Rome, and when at the municipal elections of 1900 the clerical administration fell, Nathan was chosen as mayor. Re-elected in 1910, he fell when the *blocco* broke up in 1913. On the outbreak of the World War, in spite of his 70 years, he volunteered for the army and actually served as a lieutenant of infantry for a time. He was editor of the national edition of Mazzini's works. Nathan died in Rome April 9 1921.

NATIONAL DEBT: *see* DEBTS, INTER-ALLIED; GREAT BRITAIN: FINANCE.

NATIONAL PARKS AND GAME PRESERVES.—Under the influence of President Roosevelt's great interest in outdoor life and faith in the value to the people—moral, physical and educative—of contact with nature, the early years of the present century saw in the United States a wonderful advance in the movement for national parks and nature conservation. The momentum gathered was not lost when the administration of President Wilson came, but passed into a new constructive period under his Secretary of the Interior, Franklin K. Lane, a man of imagination and high enthusiasm for the public service and under the latter's friend, Stephen T. Mather, the inspiring head of national park accomplishment in recent years in the United States.

The National Park Service.—At the creation in 1916 of the National Park Service the separate park units created by the Federal Govt. were gathered into a logical system whose aims were clarified and placed upon the highest basis, and a foundation was established on which the future could be safely built. Its establishment, with the unified control it gave, marks the most important advance made since 1910 in national park development in America, whose influence has been widely felt.

Since 1910 a change fundamentally altering the national park problem and incalculably increasing its importance has come into the life of the American people. From being relatively stationary they have become to an extraordinary extent a nation in movement, owing to the automobile, multiplying many times the travel to the national parks and their opportunity for service, but presenting, equally, new difficulties in the organisation and care of motor-camps, the building of roads and the provision for great multitudes of visitors. The aim of the National Park Service as it has crystallised has been to have each recreationally important feature of the country's landscape typically represented in the national system, so that a traveller visiting in turn the various parks may see the country illustrated through supreme examples and learn of the characteristic life—plant and animal—inhabiting its regions.

To this educational aspect of the national parks constantly greater emphasis is being given. They form wonderful natural exhibits and outdoor museums, illustrating, in each section where they lie, the regional life and landscape. With the wide travel to them which the automobile is causing they are becoming also conservational factors of prime importance in arousing interest in the preservation of the nation's irreplaceable wild life inheritance and native beauty.

Parks Established.—During and since 1910 the following national parks, a magnificent group supplementing in extraordinary variety the earlier units, have been established by Congress in the United States: Glacier National Park (1,534 sq. m.) in Montana in 1910; Rocky Mountain National Park (397 sq. m.) in Colorado in 1915; Hawaii National Park (186 sq. m.) in the territory of Hawaii in 1916; Lassen Volcanic National Park (126 sq. m.) in California in 1916; Mount McKinley National Park (2,645 sq. m.) in Alaska in 1917, in its present stage a game preserve and mountain reservation rather than a park in the true sense; Grand Canyon National Park (958 sq. m.) in Arizona in 1919; Lafayette National Park (12 sq. m.) upon Mount Desert I. off the coast of Maine in 1919; and Zion National Park (120 sq. m.) in Utah in 1919; while a bill to create two others in the Great Smoky Mountains of Tennessee and North Carolina and in the Blue Ridge Mountains of Virginia was before Congress in 1926 and was being strongly urged.

National Monuments.—Intimately related to the national parks in the United States are the national monuments, whose first establishment in 1906 was one of the farsighted conservational acts of President Roosevelt's administration. Created by presidential proclamation for the preservation of outstanding features of historic, antiquarian or scientific interest, their number has steadily increased since 1910, until in 1926 they constituted, supplementing the national parks and administered in connection with them or with the national forests, a true museum of the out-of-doors, preserving battlefields and historical sites, prehistoric dwellings, fossil forests, rare botanical exhibits and striking geologic features.

Parks in Canada.—In Canada the older national parks—the Rocky Mountains National Park (2,751 sq. m.) in Alberta, by Banff; the Yoho National Park (476 sq. m.) in British Columbia; Glacier National Park (468 sq. m.) in the Selkirk Mountains; Jasper National Park (4,400 sq. m.) in northern Alberta; and Waterton Lakes National Park (220 sq. m.), adjoining across the national boundary the United States Glacier Park, have all been extensively added to since 1910, and the following have been created: Revelstoke National Park (100 sq. m.) in British Columbia, dedicated in 1919 and the westernmost in the chain of Canadian National Parks; and Kootenay National Park (587 sq. m.), created in 1920, on the western slope of the Rockies, adjoining the Yoho and Rocky Mountains National Parks.

In South America.—In South America plans for an international park centring about the celebrated cataract of L'Iguazu on the boundary between Argentina and Brazil were in 1926 under consideration but had not then been embodied in definite shape. Far to the south in Argentina, near the Chilean boundary in the Andean region, lies the Nahuel-Huapi National Park amid lakes and snow-clad mountains of the Cordillera range, the first of actual establishment south of the United States.

In Europe.—In Europe, Switzerland led the way in national park creation by establishing in the years before the World War a national park and botanical reservation among the Alps that lie between the Lower Engadine and the Italian border, in the Canton of the Grisons, rich in alpine flowers and in scenic beauty. Italy, since the War, has followed with the establishment of a national game preserve, Il Gran Paradiso, in the Alps of Piedmont, for the protection of the few remaining ibexes, and of a national park in the Apennines, northeast from Rome: the National Park of the Abruzzi. Originating in a royal hunting park established for Victor Emmanuel when united Italy became a kingdom, it includes the highest mountain in the Apennine range, Il Gran Sasso d'Italia, and ancient woods of beech and oak that also are the refuge of wild life in vanishing species. But it is a park still in the making, for the future to develop.

One other area in Europe claims attention as the scene of activity in national and international park creation—the Eastern Carpathian and High Tatra mountains, along whose summits lies the boundary between Czechoslovakia and Poland, where extensive parks were planned in 1926, culminating in the Tatra International Park, cresting the range in a magnificent domain of wild and rugged scenery.

In Australia.—In Australia no Federal park system has yet been established, but state reservations, notably Centennial Park, Sydney, N.S.W., have been made which the Commonwealth may make the basis for one later, as wealth and population grow. The unique flora and fauna and continental character of the country make the opportunity remarkable. New Zealand, also, has opportunity for the creation of a wonderful park system in the southern hemisphere and is moving fast toward it through the development of her sea-borne tourist trade.

Game Preserves.—The swift destruction of wild life now taking place in the United States and Canada through increasing population, the ready invasion by the motor-car of regions till now the secluded habitats of wild life, and the drainage of marshlands, has led to a widespread movement for the enactment of protective Federal legislation and the increased establishment of national game preserves.

To these the United States has largely added, both in extent and number, since 1910, and, national park areas apart, which are absolute sanctuaries, has now the following: Wichita National Game Preserve (91 sq. m.) in Oklahoma; the Grand Canyon National Game Preserve (1,384 sq. m.), co-extensive with the Kaibab National Forest, in Arizona; the National Bison Range (29 sq. m.) in Montana; the Elk Refuge National Game Preserve (4½ sq. m.) in Wyoming; the Niobrara National Bird and Wild Life Reservation (25 sq. m.) in Nebraska; the Pisgah National Game Preserve (120 sq. m.) in North Carolina; the Cherokee Federal Game Reserves in Georgia and Tennessee; and an extensive area bordering the Upper Mississippi, in process of acquisition in 1926 under a congressional appropriation, for a national bird and wild life reservation.

In Canada since 1910 the following national game preserves, bearing the name of parks, have been established in addition to the one, Buffalo National Park (161 sq. m.), which then existed; Elk Island National Park (51 sq. m.) in northern Alberta; Nemiskam National Park (8½ sq. m.), an antelope preserve in southeastern Alberta; and Point Pelee National Park (4 sq. m.) jutting out into Lake Erie from Ontario, a bird sanctuary at the most southerly point in Canada, which is an important resting-place for many migratory birds.

Elsewhere, apart from the big game reserves of Africa and seal protection areas, little has been done for game protection through national preserves. Much, however, has been done besides, in Anglo-Saxon lands, by Federal states and provinces, and much by associations, of which outstanding examples for bird protection exist in Louisiana, administered partly by the state and partly by the National Audubon Society, and in New Zealand, where Stewart I. (665 sq. m.) has been set aside as a sanctuary, while it is to be remembered that all game protective laws, Federal or State, have the effect, if enforced and well conceived, of creating reservations to the extent of the territory they cover and the protection they afford, and are complementary in this sense to special game preserves.

In Great Britain the constant vigilance and activity of the Royal Society for the Protection of Birds and the Selborne Society have secured legislative and administrative protection for birds. Sanctuaries have been established on properties of the National Trust and in scheduled public parks and commons. The Selborne Society provides nesting boxes for private gardens. The Farne Islands have been purchased and given to the National Trust as a sanctuary for sea birds. The Royal Society for the Protection of Birds has established a Watchers' Committee which does invaluable work against depredations by collectors, by pollution of the sea by oil, by overhead wires and rat plagues. The bird nests and perches at four selected lighthouses have been the means of saving many migratory birds. The Society keeps constant watch for evasions of the Plumage Act (1921) and develops its propaganda by lectures to schools, by competitions and by the issue of a special journal, *Bird Notes and News*. (G. B. D.)

NATURALISATION (*see* 19.275).—In the period 1910–26 there were many and important changes throughout the world in the laws respecting naturalisation, owing in part to the growth of national feeling, in part to the World War.

The consolidation and amendment of the British law of nationality and naturalisation was recommended in 1901 by a departmental committee of the Home Office, but it was not until 1914, just before the outbreak of the World War, that the principal recommendations of the committee were embodied in an Act of Parliament. This was the British Nationality and Status of Aliens Act, 1914, subsequently amended by Acts of the same name passed in 1918 and 1922, which, while not disturbing the general principles of the Act of 1914, contain important supplementary provisions. These statutes, as their title implies, are comprehensive and deal with the law as to natural-born British subjects, British subjects by naturalisation and aliens within British jurisdiction. In the second of these categories, the new statutes make three important innovations, viz.:

1. They abolish all legal distinctions between natural-born and naturalised subjects. A naturalised British subject, so long as his certificate remains in force, has the same rights and duties as if he were natural-born.

2. A certificate of naturalisation may be revoked by the Secretary of State upon proper cause appearing to his satisfaction.

3. Without prejudice to the power of the self-governing Dominions to grant local naturalisation on such terms as they may see fit, the statutes lay the foundations of a scheme of Imperial naturalisation by providing for the adoption of Part II of the principal Act (as amended) by the Dominions. Part II has (1926) been adopted by Canada, Australia and South Africa.

Grant of Naturalisation.—In respect of the conditions precedent to the grant of a certificate of naturalisation to an alien, the Act of British Nationality and Status of Aliens Acts 1914, 1918 and 1922, do not substantially depart from the provisions of the Naturalisation Act, 1870. The applicant must satisfy the Secretary of State (a) that he has either resided in His Majesty's dominions for not less than five years, or has been in the service of the crown for not less than five years within the last eight years before the application, (b) that he is of good character and has an adequate knowledge of the English language, and (c) that he intends to reside in His Majesty's dominions or to enter or continue in the service of the crown. The residence required is at least one year's residence in the United Kingdom immediately preceding the application, and previous residence for four years, either in the United Kingdom or some other part of His Majesty's Dominions within eight years of the application. These conditions as to residence, however, do not apply to a British-born woman who has become an alien by marriage and who, after the death of her husband or the dissolution of her marriage, seeks re-admission to British nationality; and the Secretary of State may also in his discretion grant a certificate of naturalisation to a minor who has not complied with the prescribed conditions.

But a certificate of naturalisation is not a matter of right. The Secretary of State may grant, withhold or postpone it in his absolute discretion and there is no appeal from his decision. A certificate does not come into effect until the oath of allegiance to His Majesty has been taken. The names of minor children of an applicant for naturalisation may be (and in practice usually are) included in the certificate. The children thereby become British subjects, but on attaining their majority they may divest themselves of their allegiance by a declaration.

Revocation of Certificate.—Under the Naturalisation Act, 1870, a certificate once granted was irrevocable, even if it afterwards appeared that the grant had been obtained by fraud. The Act of 1914 cured this defect by giving the Secretary of State a discretionary power to revoke a certificate obtained by false representations or fraud, and the Act of 1918 converted the discretion into an obligation to revoke and considerably extended the principle of revocation. Section 7, as amended, is as follows:—

(1) Where the Secretary of State is satisfied that a certificate of naturalisation granted by him has been obtained by false representation or fraud, or by concealment of material circumstances, or that the person to whom the certificate is granted has shown himself by act or speech to be disaffected or disloyal to His Majesty, the Secretary of State shall by order revoke the certificate.

(2) Without prejudice to the foregoing provisions the Secretary of State shall by order revoke a certificate of naturalisation granted by him in any case in which he is satisfied that the person to whom the certificate was granted either—

(*a*) has during any war in which His Majesty is engaged unlawfully traded or communicated with the enemy or with the subject of an enemy state, or been engaged in or associated with any business which is to his knowledge carried on in such manner as to assist the enemy in such war; or (*b*) has within five years of the date of the grant of the certificate been sentenced by any court in His Majesty's dominions to imprisonment for a term of not less than twelve months, or to a term of penal servitude, or to a fine of not less than £100; or (*c*) was not of good character at the date of the grant of the certificate; or (*d*) has since the date of the grant of the certificate been for a period of not less than seven years ordinarily resident out of His Majesty's dominions otherwise than as a representative of a British subject, firm, or company carrying on business, or an institution established, in His Majesty's dominions or in the service of the crown, and has not maintained substantial connection with His Majesty's dominions; or (*e*) remains according to the law of a state at war with His Majesty a subject of that state; and that (in any case) the continuance of the certificate is not conducive to the public good.

(3) The Secretary of State may, if he thinks fit, before making an order under this section refer the case for such inquiry as is hereinafter specified, and in any case to which subsection (1) or paragraph (*a*), (*c*) or (*e*) of subsection (2) of this section applies, the Secretary of State shall, by notice given to or sent to the last-known address of the holder of the certificate, give him an opportunity of claiming that the case be referred for such inquiry, and if

the holder so claims in accordance with the notice the Secretary of State shall refer the case for inquiry accordingly.

(4) An inquiry under this section shall be held by a committee constituted for the purpose by the Secretary of State, presided over by a person (appointed by the Secretary of State with the approval of the Lord Chancellor) who holds or has held high judicial office, and shall be conducted in such manner as the Secretary of State may direct:—

Provided that any such inquiry may, if the Secretary of State thinks fit, instead of being held as aforesaid be held by the High Court, and the practice and procedure on any inquiry so held shall be regulated by rules of court.

A committee appointed under this section shall have all such powers, rights, and privileges as are vested in the high court or in any judge thereof on the occasion of any action, in respect of the following matters: —

(*a*) the enforcing the attendance of witnesses and examining them on oath, affirmation, or otherwise, and the issue of a commission or a request to examine witnesses abroad; and

(*b*) the compelling the production of documents; and

(*c*) the punishing persons guilty of contempt;

and a summons signed by one or more members of the committee may be substituted for and shall be equivalent to any formal process capable of being issued in any action for enforcing the attendance of witnesses and compelling the production of documents

The revocation of a certificate of naturalisation, however, does not affect the status of the wife or minor children of the person concerned unless the Secretary of State so directs, and no such order can be made against a British-born woman unless the Secretary of State is satisfied that if she had held a certificate in her own right it could properly have been revoked under section 7. It is to be observed that no distinction is made between minor children who have acquired British nationality through their father's naturalisation and minor children who are natural-born subjects. The anomalous result follows that the British-born children of an alien are in a better position than the British-born children of a naturalised person.

There are other difficulties involved in the construction of the Act of 1918, the language of which is in many places very obscure, but they have never been the subject of judicial discussion. The committee constituted has, however, given certain rulings which have a quasi-judicial force. Thus, it has been held that innocent misrepresentation is "false representation" within the meaning of section 7 (1). Again, the use of the present tense in paragraphs (a) and (e) of sub-section (2) have been interpreted to mean that action under these paragraphs can only be taken during the continuance of a state of war. (D. Ca.)

II. THE UNITED STATES

In the Fourteenth Amendment to the Constitution of the United States it is provided that "All persons born or naturalised in the United States, and subject to the jurisdiction thereof, are citizens of the United States and of the State wherein they reside." This Amendment was proclaimed July 28 1868, but the method of naturalisation had been prescribed previously.

Only a natural-born citizen may become President of the United States, but naturalised citizens may hold every and any other office. The practice in naturalisation is set forth in the Naturalisation Act of June 29 1906 and its amendments; that of expatriation in the Expatriation Act of March 2 1907.

Naturalisation has two stages. The first is a declaration of intention on the part of the alien to become a citizen of the United States, the second is a petition for admission which must be filed not less than two years nor more than seven years after the declaration of intention. Every applicant must reside five years within the jurisdiction of the United States, although an occasional absence with intent to return does not break the continuity of residence. The last year of the residence must be in the state or territory in which naturalisation is to be acquired. Two witnesses are required to the fact of residence and of good character.

The general statute dealing with naturalisation applies only to white persons and persons of African race, hence the nationals of other races are not held eligible to citizenship under the naturalisation laws of the United States. (*United States v. Bhagat Singh Thind*, 261 U.S. 204; *Ozawa v. United States*, 260 U.S. 178.)

Naturalisation is perfected by the decision of a judge of a Federal or state court of record, the applicant taking an oath of allegiance to the Government and renouncing absolutely and forever all allegiance to the foreign country of which he was a citizen or subject.

The advantage of a declaration of intention was supposed to lie in testing the applicant's devotion to American institutions. The disadvantage is in the disagreeable, if not equivocal position in which he finds himself in the interval between the declaration of intention and final naturalisation. The government of origin naturally loses interest in such a person, who, if he wishes a passport, must apply to its representative in the United States. Congress, however, has been unwilling to drop the provision, although frequently requested to do so by the Executive Department of the Government. To obviate the disadvantages of the situation, the Secretary of State was authorised by the Expatriation Act of 1907 to grant temporary passports to foreigners who had declared their intention to become citizens, under such regulations as he should prescribe. This portion of the Act was repealed June 4 1920.

The Act of 1906 expressly mentions the intention on the part of the applicant to reside in the United States as an essential to legal naturalisation, and the absence of the intention may be proved as a fact in legal proceedings, or presumed from leaving the United States within five years. In the case of *Luria v. United States*, 231 Reports, 9 (1913), it was decided, however, that the intent was presumed in previous statutes.

The Govt. of the United States persistently maintained the right of expatriation, interpreting it, however, rather as the right of a foreigner to become a citizen of the United States without the consent of his government, than as a right of an American citizen without the consent of his own government to become a citizen or subject of a foreign nation. The first statute of expatriation affecting American citizens as well as foreigners was the Expatriation Act, passed March 2 1907. It provides that an American citizen, natural or naturalised, renounces his American nationality by becoming naturalised in a foreign country, or by taking an oath of allegiance to a foreign state. This became important in the World War when many American citizens enlisted in foreign armies, arrayed against the Central Powers. They had in all cases been obliged to take an oath of allegiance on entering the military service, and upon their return to the United States they were held to have ceased to be American citizens. To remedy this situation a statute was passed on May 9 1918 allowing such individuals to become American citizens upon taking an oath of allegiance to the United States.

The United States has been a party to treaties by which it was provided that a naturalised citizen might forfeit his American citizenship by residing a certain number of years in the country of his origin. The Expatriation Act generalises that provision by stipulating:—

When any naturalised citizen shall have resided for two years in the foreign state from which he came, or for five years in any other foreign state it shall be presumed that he has ceased to be an American citizen, and the place of his general abode shall be deemed his place of residence during said years.

The Act also stipulated that an American woman marrying an alien acquired his nationality, and that a foreign woman marrying an American citizen acquired American nationality. It further provided that minor children became naturalised through the naturalisation of their parents. Finally, the Act permitted American citizens who had returned to the land of their origin to overcome the presumption of renunciation of American citizenship by registering in the American Consulate; and also required that Americans born in foreign parts should register in an American Consulate.

The statutes provide easy terms of naturalisation of persons serving in the land and naval forces of the United States, provisions which were amplified during the World War. The great change, however, was made in the law of citizenship by the Cable Act of Sept. 22 1922, which provided that a foreign woman marrying an American citizen did not become an American citizen by the act of marriage; and that an American woman marrying a foreigner did not, by the act of marriage, lose her American nationality. It facilitated the reacquisition of American nationality by American women who had married foreigners before the passage of the Act, be reducing residence in the United States to one year before taking an oath of allegiance. From this privilege, however, was excluded the American woman who had married a foreigner who could not become a citizen of the United States under its naturalisation laws. The Act is in accordance with the tendency to recognise the personality of married as well as of single women, but it occasions inconvenience in the absence of treaties with foreign countries in the matter of passports from countries where the nationality of a wife depends upon and follows that of the husband.

III. GERMANY

The German Imperial and State Citizenship Law of July 22 1913 which went into effect Jan. 1 1914 has been much criticised. It contains two sections, 13 and 25, which have been considered generally objectionable to non-German countries. In view of the importance of the articles they are quoted:—

Sec. 13. A former German who has not taken up his residence in Germany may on application be naturalised by the state (of Germany) of which he was formerly a citizen, provided his case fulfils the requirements of Nos. 1 and 2 of paragraph 1 of Section 8; the same applies to one who is descended from a former German or has been adopted as a child of such. Prior to naturalisation a report must be made to the Imperial Chancellor; if he raises objections, naturalisation does not take place. (The text of section 8 of the law referred to in the section just quoted is as follows: "1. If he is legally

competent in accordance with the laws of his former home or would be legally competent in accordance with the laws of Germany; or if the application is made by his legal representative or with the latter's consent in accordance with the second sentence of paragraph 2 of section 7. 2. If he has led a blameless life . . ")

Sec. 25. Citizenship is not lost by one who before acquiring foreign citizenship has secured on application the written consent of the competent authorities of his home state to retain his citizenship. Before this consent is given the German consul is to be heard.

The Imperial Chancellor may order, with the consent of the Federal Council, that persons who desire to acquire citizenship in a specified foreign country may not be granted the consent provided for in paragraph 2.

The only comment necessary on provisions of this kind is the statement that by Article 278 of the Treaty of Versailles of June 28 1919, Germany was obliged to declare the provisions in question as null, void and of no effect.

IV. OTHER COUNTRIES

An examination of the laws of other countries dealing with naturalisation shows that there have been many and important changes since 1910, because the provisions were either in themselves deemed to be inadequate, or not in accord with the newer conditions of the century. In the next place, new states had come into existence, and as they were without legislation on the subject, it was necessary that laws should be passed regarding the acquisition and loss of nationality. Instead of attempting a summary of provisions which are in their nature local and therefore diverse, the principal constitutional and statutory provisions on the subject since 1910 are set forth:—

Argentine Republic.—Law of Nov. 27 1911, granting nationality to alien officers, etc., by virtue of law of July 14 1911; *Annuaire*,[1] 1911.

Austria.—Law of Oct. 17 1919, *Annuaire*, 1920:266; Decree of Aug. 20 1920, relative to acquisition of nationality by option, *BFS*[2] 113:879; Constitution, 1920, *BFS* 113:883, 886, Arts. 6, 11 (i).

Belgium.—Law of May 26 1914, on renunciation of Belgian nationality by persons who have acquired the same under law of 1909, *BFS* 107:587; Law of May 11 1918, granting fresh term for acquisition of nationality by descendants of inhabitants of territories ceded in 1839, *BFS* 111:652; Law of Oct. 25 1919, concerning right of option, *BFS* 112:989; Law of May 15 1922, concerning acquisition and loss of nationality, *BFS* 116:643.

Bulgaria.—Constitutional amendment, 1911, *BFS* 107:619, Art. 55; Law of Dec. 8 1911, amending law of Dec. 31 1903, *Annuaire*, 1911:765.

China.—Law of Nov. 18 1912, *Annuaire*, 1912:625; Law of Dec. 30 1914, *BFS* 114:667.

Costa Rica.—Constitution, 1917, Arts. 40–44, 60, 99 (10), 105; *La Gaceta*, June 13 1917.

Denmark.—Law of Nov. 27 1916, providing for naturalisation of persons of no nationality, *BFS* 110:838; Law of Sept. 5 1920, *BFS* 114:705; Constitution, 1920, Art. 50, *BFS* 114:715.

Dominican Republic.—Constitution, 1924, Pan American Union, *Law and Treaty Series No. 1* (1925), 6, 8, 10, 19, 21, Articles 8, 18, 21, 55, 63; Naturalisation law of Oct. 31 1924, Clunet, 1926:243.

Ecuador.—Law of Oct. 18 1921, *BFS* 114:731.

Finland.—Constitution, 1919, Art. 4, McBain and Rogers,[3] 468.

France.—Decree of Sept. 16 1910, regarding registration of citizens abroad, *Am. Jour. Sup.*[4] VI:92; Law of Oct. 3 1910, to facilitate acquisition of French nationality by Tunisians, *BFS* 106:953; Decree of May 26 1913, on acquisition of French citizenship by natives of Indo-China, *BFS*, 107:771; Decree relative to acquisition of foreign nationality by natives in some of French colonies, Nov. 25 1913, *BFS* 107:776; Law of March 25 1915, *BFS* 109:922; Law of April 7 1915, on withdrawal of naturalisation decrees with respect to former subjects of enemy states, *BFS* 109:923; Decree of April 24 1915, concerning withdrawal of naturalisation, *BFS* 109:925; Law of June 18 1917, *BFS* 112:1025; Law of July 3 1917, concerning option in case of sons of foreigners born in France, *BFS* 112:1029; Law of April 9 1920, concerning foreigners resident in French zone in Morocco, *BFS* 113:1008; Law of Nov. 8 1921, *BFS* 114:753; Law of Nov. 8 1921, relative to French nationality in regency of Tunis, *BFS* 114:755; Law of July 5 1925, concerning descendants of foreigners (not Germans) in Alsace-Lorraine, Clunet, 1925:1187.[5]

Germany.—Law of July 22 1913, on Imperial and State nationality, *BFS* 108:473. Constitution of German Republic, 1919, Arts. 1, 6(3), 110, *BFS* 112:1064, 1082.

Greece.—Constitution, 1911, Art. 3, *BFS* 108:483; Decree of Oct. 19 1922, concerning naturalisation of refugees, *Annuaire*, 1922:314.

Haiti.—Constitution, 1918, Arts. 3, 6, *BFS* 112:1113, 1114.

Italy.—Law of June 13 1912, *BFS* 106:1071; Decree of Aug. 2 1912, concerning enforcement of Law of June 13, *BFS* 106:1076; Law of June 30 1918, *Annuaire*, 1918:169; Decree relative to registration for nationality, Dec. 28 1919, *Annuaire*, 1919:76; Regulations of Dec. 30 1920, *Rev. dr. int. pr.*,[6] 1921:416; Decree of Aug. 21 1921, *BFS* 114:846; Decree of Aug. 31 1921, authorising aliens to make declaration for Italian naturalisation suspended during the War, *Annuaire*, 1921:40; Decree of Sept. 10, 1922, *Annuaire*, 1922:35.

Japan.—Amendments of Aug. 1 1916, to Law of Nationality of 1899, *BFS* 110:920.

Mexico.—Constitution, 1917, Arts. 27(1), 30, 37 73(16) *BFS* 111:787, 792, 794, 804.

Monaco.—Constitution, 1911, Art. 5 (3), *BFS* 105:737, 738; Ordinance of April 13 1911, *Annuaire*, 1911:382, 389.

The Netherlands.—Law of Feb. 10 1910, regulating status of Netherland subjects of population of Netherland East Indies, *BFS* 103:600; Law of July 15 1910, amending nationality law of Dec. 12 1892, *Annuaire*, 1910:321; Law of Dec. 31 1920, modifying law of Dec. 22 1892, *Annuaire*, 1920:116; Constitution, 1922, *BFS* 116:863, Art. 6.

Nicaragua.—Constitution, 1911, Arts. 7–11, 111 (17), *BFS* 107; 1039, 1051–52. New Constitution of 1913 contains same provisions.

Peru.—Constitution, 1919, Arts. 60, 64, *BFS* 113:1142.

Portugal.—Decree of Dec. 2 1910, *BFS* 103:619; Decree of March 28 1911, amending naturalisation law of Dec. 2 1910, *Annuaire*, 1911: 366; Constitution, 1911, Art. 74, *BFS* 105:779.

Rumania.—Naturalisation law of Aug. 31 1918, *Annuaire*, 1920: 305; Decree of Dec. 29 1918, granting certain rights to nationals, *Annuaire*, 1920:306; Decree of May 22 1919, *Annuaire*, 1920:310; Law of Feb. 23 1924, Clunet, 1925:838, and 1926:300.

Russian Socialist Federated Soviet Republic.—Constitution, 1918, Art. 20, Martin and George, *Constitutions*,[7] 231; Nationality decree of Oct. 29 1924, Clunet, 1925–548.

San Marino.—Decree of Jan. 21 1910, regarding citizenship law of Sept. 12 1907, *Annuaire*, 1910:236.

Serbia.—Constitution, 1913, for annexed provinces of Old Serbia, Arts. 6, 29, 144 (9); *BFS* 110:934, 936, 939–40.

Siam.—Law of May 18 1911, *BFS* 105:793; Decree of Aug. 7 1911, regulating execution of law of May 18 1911, *Annuaire*, 1911:918; Law of April 10 1913, *BFS* 108:585.

Spain.—Decree of Nov. 6 1916, *BFS* 110:946.

Sweden.—Law of June 11 1920, amending law of June 1 1912, *Annuaire*, 1920:220; Law on acquisition and loss of Swedish nationality, May 23 1924, Clunet, 1925:1192.

Switzerland.—Law of Jan. 29 1918 concerning cantonal naturalisation (Tessin), *Annuaire*, 1918: 239; Law of June 26 1920, modifying Law of June 25 1903, *BFS* 113:1187.

Turkey.—Law of April 3 1917, concerning Article 6 of nationality law, *Annuaire*, 1919:262.

Venezuela.—Law of May 24 1913, *Annuaire*, 1913: 586; Constitution, 1922, Arts. 10, 11, *BFS* 116:1038. (J. B. S.)

NATURAL RESOURCES, CONSERVATION OF.—The term conservation came into common use and was given special significance about 1908, when President Roosevelt inaugurated a movement in the United States to check the destructive exploitation and wasteful use of many of the most important natural resources. The underlying purpose of the movement was to make the resources render their highest service in the economic, industrial and social upbuilding of the nation. Productive use of agricultural land, continuous production of forests, economy in the use of mineral resources, skilful development of waters coupled with the protection of their sources, the building up of fisheries, the increase of useful wild life and the proper handling and safeguarding of recreation resources are examples of conservation. Use of natural resources without waste, economic development to secure from them a maximum service, continuous production of renewable resources and permanence of industries and of community life lie at the basis of the conservation principle.

The National Conservation Commission.—The idea of handling all natural resources with a view to their highest economic and public service in the long run was new in the United States. The great destruction of the American forests by fire and wasteful exploitation brought the question to the front, and it was Gifford Pinchot, then Chief U.S. Forester, who enlisted the interest of the President in this problem and the broader aspects

of conservation of all natural resources. The first important step taken by President Roosevelt was to call a conference of governors of the states, which assembled at the White House in May 1908. This was the first time the governors of the states had met in conference. As a result of the meeting, a National Conservation Commission was appointed by the President, and 42 states appointed state commissions to study the problems of natural resources, to assemble data regarding their quantity and condition, and to formulate a policy for their conservation. In 1909 the National Conservation Commission made its report to Congress. In the same year President Roosevelt invited the governor-general of Canada, the governor of Newfoundland and the president of Mexico to appoint commissioners to discuss, with commissioners representing the United States, the principles of conservation as applied to the continent of North America.

Legislative Action.—The movement inaugurated by President Roosevelt led to a radical change in public policy with reference to the resources owned and controlled by the Government. Not only were the National Forests and Parks placed on a permanent basis of protection and administration, but legislation was later enacted providing for the proper use under Federal control of the lands still under public ownership which contained coal, oil, phosphates or potash or which were valuable for water-power development. The movement led further to action ensuring the conservation of fisheries, game and bird life. The influence of the conservation movement has spread far beyond the handling of Federal properties. It has been the factor leading to action by many individual states. The greatest progress has been made by them in the protection of forests from fire, although many of the states are not yet doing what is needed to attain this end.

Since the World War there has been increasing appreciation of the significance of natural resources as a primary factor in the industrial strength and prosperity of nations. The older countries have by very force of economic conditions been obliged to give attention to the careful husbanding of their resources. Many of them have already been through the process of wasteful exploitation and have learned the lesson of conservation. The newer countries are still exploiting their forests without proper measures of replacement, still using wasteful methods of developing oil, natural gas and coal, still overstocking the cattle and sheep ranges, still using crude methods of agriculture, still failing to protect their natural supply of useful wild life.

Exhaustion of Resources.—In many countries, as the United States, which have been naturally endowed with an abundance of natural resources, the most accessible and most cheaply produced of the raw materials are rapidly being exhausted. Vast resources still remain, but the difficulties and cost of their exploitation are constantly mounting. This situation is of very real importance to those nations which have to look abroad for raw materials. The exhaustion of the accessible bodies of virgin softwood timber in North America will be felt by importing nations which will be obliged to pay higher and higher prices for this class of material or go without. Necessarily there will be in the near future a world shortage of softwood timber of the better grades (*see* FORESTRY). In the same way the wasting of oil, coal and minerals in one country becomes a matter of international consequence.

Government Action.—Since the War the conservation of natural resources has been given larger attention in many countries. Great Britain has embarked on an ambitious plan of reforestation and has already held two imperial conferences to discuss problems of timber supply and forestry as affecting the entire empire. The forthcoming World Forestry Congress at Rome is an event of very great significance in international conservation. Various countries are adopting a liberal policy of developing their water-power resources with a view to greater independence in power for manufacturing, transportation, heat and light, and already there has been an important water-power conference of an international character in London. The Institute of Agriculture at Rome is a vital force in the development of the resource of greatest importance in most countries, and its work is directly in the interest of conservation. Very gratifying also is the increased interest in the conservation of game and other wild life in those countries which heretofore have given little attention to the value of wild life. This is evidenced by the projects to conserve the big game in Africa and elsewhere, the progressive steps in many countries to stock the streams and lakes with fish, and the new interest in European countries to protect the native insectivorous birds which are so important to agriculture.

Agriculture.—In agriculture it is usually recognised that private ownership of farms is from every standpoint desirable. The objective is to develop a nation of small land proprietors. Government, however, gives assistance to farmers in a great variety of ways—through loans on liberal terms, through aid in co-operative buying and selling, through highway development, through research and education, through help in securing seed at reasonable cost, etc. On the other hand, it is generally recognised that the public should have control of as large an area of forest land as possible, particularly those areas in the mountains where the forests should be well handled in order to protect the watersheds and to conserve the sources of streams. Most countries early in their history adopted a policy of distributing their forest lands to private individuals, and what they now own represents the residue after this policy of distribution was stopped; and most of them are endeavouring to recover by purchase what they once owned and never should have disposed of. In France 34·5% of the forests are publicly owned; in Germany 52·7%; in Sweden 23·6%; in Great Britain 3·6%; in the United States 21 per cent.

Some countries are obliged to impose restrictions upon private owners to prevent public injury to watersheds and to insure productive use of the land. As a rule, also, the public co-operates with private owners in forestry. In some cases, as in Great Britain, a subsidy is actually given for reforestation. The United States has adopted a policy of retaining control of the publicly owned water-power sites, with a view to ensuring full development and use, and of preventing possible abuse through monopolies. The United States is retaining also in public control the coal, oil, phosphate, potash, sodium and certain other resources which are located on the public domain. How far the public will go in regulating the privately owned coal in the United States remains to be seen. The present system results in great wastage, at least in the bituminous fields; and the interruption of service to the public through strikes and other causes has resulted in serious public injury. Other countries, as Great Britain, are facing a similar problem (*see* COAL). Broadly speaking, government takes part in conservation as far as may be necessary to prevent public injury. Where such control is not necessary the aim is to secure the desired results by co-operation, education and research.

Scientific Research.—A factor of very great importance and significance in conservation is scientific research. Never in history has there been such a clear recognition of this fact; never has there been such liberal support of research by Federal and State Legislature, by the industries, by the great universities of the country and by contributions from benevolent foundations and private individuals. The foundations of conservation rest upon sound scientific research, and the work now being done holds out high promise for the future. The co-operation of nations in research in matters relating to natural resources is likely to lay the foundations for consideration of the problems of distribution of raw materials and many other problems of mutual economic interest. The countries which adopt an effective policy of conservation of their natural resources are strengthening the foundations of their industrial progress and national strength and they are rendering a service to the whole world.

See D. Drake, *America Faces the Future*, chap. 23 (1922); also COAL; FORESTRY; OIL; etc. (H. S. G.)

NAURU or PLEASANT ISLAND, an atoll in the South Pacific, midway between the Marshall and Solomon Islands, with an

area of about 5,400 acres. The population in 1923 was 110 Europeans, 603 Chinese and 1,296 Nauruans and other South Sea Islanders. The island is valuable on account of its phosphate deposits, which were worked before the War by a German company the rights of which were sequestrated during the War and vested in an English company. A German possession, placed under the German administration of New Guinea, the island surrendered to the Australian Navy in Sept. 1914, and was placed by the Supreme Council under British mandate on May 7 1919. Side by side with the mandate assigning the island to the British Empire arrangements were made for Australia and New Zealand to share with the United Kingdom in the administration and the products of the phosphate industry, which together were to supply the necessary funds for the exploitation of the island resources. The first administrator was to be appointed by the Australian Government. The Nauru Agreement Act was ratified by the three Parliaments concerned, and received the royal assent on Aug. 4 1920, subject to the provisions of Art. 22 of the Covenant of the League of Nations.

The Phosphate Deposits.—The deposits were discovered in 1900, and were worked by the Pacific Phosphate Co., which also worked the deposits on Ocean Islands. The deposits in these two islands were estimated at about 100,000,000 tons. The interests of the company in these two islands were bought out in 1919 by the British, Australian and New Zealand Govts. according to the terms of the Agreement at a cost of £3,500,000 subscribed in the proportions 42, 42 and 16. The deposits are worked by a phosphate commission of three members appointed by the governments and the output is divided in proportion to the investments of the parties. The pre-War output (1913) was 350,000 tons; the output in the first 10 years of the commission's management was over 360,000 tons a year. Though the islands do not compete in quantity with the enormous output of Northern Africa, 2,000,000 tons, or of Florida and other United States yields, 4,000,000 tons, the deposits are of exceptionally high quality

See the *Reports on the Administration of Nauru* issued by the Australian Govt.; particulars of the Mandate are given in the *Year Book of the Commonwealth of Australia* (1923).

NAVAL ACADEMY (*see* 27.736).—The expansion of the Naval Academy in the period 1910–25 began before the entry of America into the World War. In 1912 the six-year course (including two years at sea as midshipman) was discontinued, and midshipmen were commissioned ensigns immediately upon graduation from the academy. By Acts of Congress in 1916 and 1917, the number of annual appointments to the academy allowed to each senator, representative and delegate in Congress was increased from two to five; presidential appointments from 10 to 15, and appointments of qualified enlisted men from 15 to 100. Thus the total number of authorised appointments reached 3,126; and the number of midshipmen increased from 758 in 1910 to 1,230 in 1916 and in 1923 to about 2,500. The Naval Appropriation bill of 1924 provided for the pay of three midshipmen for each senator, representative and delegate in Congress in lieu of the five authorised by law. After 1920 physically qualified candidates were allowed to enter either by examination or by certificate from a recognised school. Commencing with 1925 candidates for admission by certificate were required to pass a brief examination in mathematics and English.

As a war measure, the class of 1917 was graduated in March of that year, and the class of 1918 in the following June. The course was reduced to three years; but by cutting down examination periods, holidays and reviews, and increasing the academic year to nine months, practically the same work was covered. In 1919 the four-year course was resumed. Between Sept. 1917 and Jan. 1919 five reserve officer classes, composed chiefly of former enlisted men who were graduates of technical schools, were quartered at the academy for periods of about three months' training. In this way 1,622 officers were added to the service as temporary ensigns.

The post-graduate school for officers, established in 191 in the former marine barracks near the Academy, was suspended during the World War, but reopened in 1919 with about 50 student-officers. These spend a half-year or year at the post-graduate school before continuing their studies in civilian technical institutions. In 1918 two wings accommodating 1,100 additional midshipmen were added to Bancroft Hall, an extension to the Marine Engineering building was completed in 1919 and a new Seamanship building in 1920. In 1919 the civilian corps of instructors was reorganised with increased pay and systematic promotion. The staff of the academy increased from 146 officers and civilian instructors in 1910 to nearly 300 in 1921 with a subsequent reduction to about 218 in 1925. In 1925 aviation training was included in the curriculum of the academy.

(L. McC. N.)

NAVIGATION (*see* 19.284) has progressed considerably in some departments since 1910, as the result of scientific discoveries and inventions. The advance made in the science of wireless telegraphy has been of considerable assistance to navigators; and it is probable that when directional wireless telegraphy is further developed, the methods whereby the position of a ship can be fixed by this means will come into more general use. Astronomical navigation, that is the fixing of the position of a ship by observations of the heavenly bodies, alters little, and during the period 1910–25 no new methods were introduced. The use of position lines, however, came into more general use, and calculations have been simplified by the compilation and publication of special tables for finding the zenith distance.

Old and New Methods Compared.—The accuracy of the position of a ship obtained from observations of heavenly bodies depends almost entirely on the accuracy of the time shown by the chronometers carried on board the ship. To enable the exact error of the chronometer to be obtained and the daily rate deduced, it was formerly necessary to obtain the accurate time at ports where a visual time signal was installed, or by a series of observations made with sextant and artificial horizon at places the longitude of which was accurately known. In those ships which are fitted with wireless telegraphy wireless time signals enable navigators to obtain accurate time daily in most parts of the world. At the end of 1925 there were over 50 stations working on various wave-lengths and situated in different countries for transmitting the time daily. The majority of these signals are sent by means of an automatic arrangement operated by the pendulum of a standard clock which is electrically connected with the transmitter. Greater reliance can be placed on the accuracy of signals transmitted in this manner than on those which are sent by hand. The signals are, in many cases, transmitted according to the international system; it is, however, desirable to refer to the relevant publications for details of procedure.

The term Greenwich mean time (G.M.T.) is considered to be the standard time of the meridian of Greenwich commencing at midnight and reckoned throughout the 24 hours. Both civil and astronomical time are, therefore, reckoned from midnight instead of from midnight and noon respectively. In the Nautical Almanac (abridged for the use of seamen) for 1925, and following years, the elements which prior to 1925 were given for every 2 hours of the astronomical day, which then began at noon, are given for every 2 hours of G.M.T. commencing at midnight.

To avoid confusion a system of time zones for time-keeping at sea is in force in the navies of most countries. This system has been adopted so that vessels at sea, within certain defined limits of longitude, shall keep the same time as that used on land. The world is longitudinally divided into 24 zones of 15° each, the centre of the system being the meridian of Greenwich. This centre division lies between the meridians of $7\frac{1}{2}°$ East and $7\frac{1}{2}°$ West and is known as the Zero Zone, or Zone 0; the zones lying to the eastward being numbered in sequence with a minus (−) prefix; those to the westward being similarly numbered with a plus (+) prefix. The limits of the zones on land are modified somewhat according to the geographical configuration of the country concerned. By this system the same time is kept whether on land or sea throughout each zone except during the periods of summer time.

Directional Wireless.—Determining the position of a ship at sea by means of directional wireless telegraphy (*see* WIRELESS) became of importance during the World War and is of inestimable value to ships in thick weather, when approaching the land. The bearing of the shore station from the ship can be obtained either by means of a directional receiving apparatus carried in the ship, or by the system whereby the bearing of the ship is determined by one or more directional receiving sets on shore; the result being communicated to the ship. Owing to the cost of the installation and the necessity for great skill on the part of the operator, the former method is seldom used. To enable the latter method to be of use to ships wireless direction finding (D/F) stations are established in many parts of the world. The procedure varies to some extent for different stations and in different countries. A ship requiring a bearing calls up the station or stations concerned and finally receives her bearing from one or more of these stations. The position of the ship can thus be determined.

The accuracy with which the bearing can be taken depends on several factors; bearings have sometimes been found to be unreliable at night and when the direction runs approximately parallel with the coast-line. Experiments have been made with a wireless beam which revolves in a similar manner to the beam from an ordinary lighthouse, the beam revolving through 360° at a constant rate in a definite time. Wireless waves travel along the arc of a Great circle, this being the shortest distance between any two points on the surface of the earth. It follows, therefore, that the true bearing of the ship from the station, or *vice-versa*, must be corrected for convergency to obtain the mean mercatorial bearing which is required if a chart on Mercator's projection is in use. A simple formula given in text-books enables this to be done. On a chart constructed on the gnomonic projection D/F bearings can be laid down without any correction for convergency, since Great circles appear as straight lines on this projection. If, however, a compass "rose" is used it is necessary to have one on the chart for each D/F station, to compensate for the angular alteration of the projection at that station.

Other Systems in Use.—Sound ranging (*see* SOUND RANGING) also enables the position of a ship to be determined with accuracy at a considerable distance from the land. The pressure wave generated by the detonation of a submerged explosive charge is received in hydrophones placed along a base line. This distant explosion affects the hydrophones in turn, and with the aid of time-recording instruments the position of the explosion can be deduced. To obtain accuracy at great distances it is necessary for two or more stations to co-operate. Although this method was used with success during the War no stations at the close of 1925 had been installed as aids to general navigation. It was not at that time considered probable that this method would come into common use, partly owing to the expense of installing and maintaining the stations, and partly on account of the necessity for ships to carry explosive depth charges. The combination of D/F and sound ranging would be of considerable value to navigation, especially when approaching the coast in thick weather.

The Leader system assists vessels to enter or leave harbour or to pass through narrow channels in thick weather. A submarine electric cable is laid along the channel, the shore end being connected to a station producing an alternating current. A simple and inexpensive receiving apparatus on board the ship enables the signals to be heard in telephones, or other form of amplifier, placed at or near the position from which the ship is usually conned. Two sets of coils are fitted, one on either side of the ship out of the water, and so arranged that they can each be connected up to the receiving telephones. By connecting first one set of coils and then the other, to the receiving telephones, it is an easy matter, when within range, to determine whether the cable is to port or starboard. With practice the distance of the cable can be estimated with comparative accuracy, because the signals become stronger as the cable is approached, the maximum intensity of the signals occurring when the ship is close to, but not vertically over, the cable.

The same cable enables one ship to enter and one to leave harbour at the same time, provided of course the navigable channel is of sufficient width; it is a simple matter for each ship to steer to keep the cable a reasonable distance away on her port side, so that the two ships pass safely port to port. If space permits it is possible to lay two cables, one for entering and one for leaving, the signals produced in each cable being distinctive by their note and character. This system, which proved of value during the War, had not come into general use in 1925, owing presumably to the somewhat heavy initial cost and the cost of maintenance. In channels where frequent dredging is necessary to maintain the depth the presence of a submarine cable would of course cause some inconvenience.

Echo sounding (*see* SOUNDING), by which the depth of water is obtained by the acoustic method, is of value in cases where the depth of water, or the speed of the ship, makes sounding by direct measurement unreliable. To obtain an accurate sounding by this method, complete and sensitive apparatus is required. The apparatus consists of two microphones, one of which registers the emission of a sonic signal and the other the arrival of the echo reflected by the bottom of the sea. A specially constructed time recorder capable of reading to one-thousandth part of a second is connected to the microphones and enables the depth to be deduced. Sound travels through sea water at an average velocity of 4,900 ft. per second. Consequently, by the acoustic method, very great depths can be reached in a brief space of time and the depths normally required for navigational purposes will be reached in a small fraction of a second.

The Gyro compass (*see* GYROSCOPES) is used in many ships. Owing to the masses of iron and steel used in the construction of modern ships and the presence of dynamos and other electrical machines, the position in which to place a magnetic compass in a ship requires careful consideration, to avoid undue loss of directive force and the consequent large errors which would require correction. The gyro compass does not depend for its action on the earth's magnetic field, but on gravitation and the earth's diurnal rotation round its axis. A suitable position below is selected for the master-gyro; and repeater dials, connected with the master, can be placed in any desired position in the ship. These repeaters need not be placed with the dials horizontal, they can be fixed vertically or in any other desired position. The introduction of the gyro compass has made automatic steering possible. An efficient automatic steering apparatus will keep a ship on a fixed course with greater regularity than can be accomplished by a skilled helmsman. For the navigation of the air *see* AIR NAVIGATION.

NAVY (*see* 19.299).—The most constant factor in naval affairs in modern times has been the predominance of the British Navy in relation to the forces of other maritime countries, as they have successively risen and declined. But in the evolution of national policies a counterpoise has always existed, with the result that the British Navy has seldom been, in fact, supreme. In the closing years of the 19th century the balance of power was maintained by France and Russia, while, in the Pacific, the United States and Japan, which were then emerging as naval Powers of the first rank, supplied an additional check on British predominance.

I. GREAT BRITAIN AND GERMANY

German Navy Acts.—These were the conditions which existed when the first German Navy Act was passed in 1898, to be replaced by a more ambitious measure two years later, which became known as "the Navy Act." This measure introduced a new factor in the situation. It provided for the creation of a fleet of 20 battleships, supported by eight coast defence ships,

12 large cruisers and 29 small cruisers, with a second line of older ships. Whereas British policy had always been based on the maintenance of exiguous military forces, but a strong fleet on the two-power standard, Germany already possessed an army, if not larger, at least reputed to be more formidable and efficient, than that of any other country. France and Russia, with frontiers running parallel with those of Germany, were already making the maximum effort their finances and man-power permitted to neutralise the strength of Germany as a military Power, Austria-Hungary, with not inconsiderable military resources, being Germany's "brilliant second." Neither France nor Russia, though each was vitally concerned to keep open its ocean communications and to defend its territories from invasion by sea, was in a position to make an adequate rejoinder to the menace which the German Navy Act suggested; Japan was rendered increasingly nervous as to her position in the Far East, in view of German political and economic activity, while the United States was anxious to avoid any embarrassment in the Pacific, in order that she might watch events in Europe (*see* GERMANY: *Naval Policy*).

Effects of German Expansion.—In these circumstances the whole naval situation gradually underwent a complete change. A widespread feeling of nervousness led to "understandings," or treaties, by which each country which considered itself threatened by the growing naval strength of Germany re-insured its interests. An alliance was concluded between Great Britain and Japan in Jan. 1902 which was strengthened three years later; Great Britain and France began to draw closer together towards the close of 1903 and eventually these two countries, in association with Russia, formed "a diplomatic group," which led to discussions between the several naval staffs with a view to the possibility of common action by sea and eventually also by land; and the United States and Japan signed a treaty pledging each country to respect the other's territorial interests.

It thus came about that as amendments to the Navy Act were carried in the Reichstag in subsequent years, all of them authorising further expansions of the German Navy than had hitherto been provided for, as well as of its resources for repair (of which the creation of the dockyard at Wilhelmshaven, the enlargement of the Kiel Canal and the development of Krupps's establishments at Essen, were the most notable), the tendency was for the other naval Powers to pool, in some degree, their naval interests. This movement reacted powerfully on the British Navy. A concentration of forces in the North Sea was begun at the expense of the squadrons in the Mediterranean, the Pacific and other distant seas, and British shipbuilding policy was adapted to the new situation which was rapidly developing; while France withdrew most of her ships from her Channel ports in order to increase her strength in the Mediterranean; Russia at the same time improved her position in the Baltic.

Coming of the Dreadnought.—By 1910 the rivalry between the navies of Great Britain and Germany had become the dominating factor not only to those two countries, but to every other country. Since Germany, though not neglecting the building of cruisers, was concentrating her attention on the creation of a great battle fleet, obviously, from the limited radius of action of the vessels, intended for service in the North Sea, the British Admiralty had also for some years turned its attention increasingly to the perfection of battleship design. Germany was rising to a condition of parity in modern ships of the line in 1905, when, on Lord Fisher's initiative, the all-big-gun ship—commonly known as the "Dreadnought"—was evolved, being of two types—the battleship and the battle cruiser. Germany, her policy thrown into confusion, felt herself compelled to follow the new policy, but as dreadnoughts were of greater beam than the ships of about 14,000 tons displacement which she had hitherto been building, she became involved in a complete reconstruction of the Kiel Canal, entailing an expenditure of £11,000,000, while further large sums had to be spent on deepening her shallow harbours.

The German naval authorities had assumed that the British forces would continue to be dispersed over the seas and oceans of the world. When that assumption proved unfounded, the German plans for naval expansion were repeatedly varied; the final development taking place in 1912. This amendment of the German Navy Act, providing for a large fleet always in commission, was interpreted by the British Govt. as a direct challenge to British naval power. Mr. Winston Churchill, the First Lord of the Admiralty, made a speech which revealed the anxiety with which the British Cabinet, reflecting public opinion, regarded the situation. He stated that the two-power standard no longer accorded with the conditions at sea which were rapidly developing and that in future the Admiralty intended "to develop a 60% superiority in vessels of the 'Dreadnought' type over the Germany Navy on the basis of the existing Fleet Law," with "other and higher standards for the smaller vessels." He also let it be known that for every additional keel laid down in Germany, over and above those already provided for, two would be placed in position in British yards. It was revealed later on that the British naval authorities, having already discarded the 12-in. gun, which was mounted in the original "Dreadnought," in favour of the 13·5-in., had decided to introduce a new 15-in. gun, firing a projectile twice as heavy as the 12-in. weapon. Germany, which had for many years been satisfied with the 11-in. gun, had in recent designs provided for nothing more powerful than the 12-inch.

These and other developments revealed the intensity with which the contest between the two countries was being pursued. Informal conversations in Berlin with a view to a "naval holiday" had proved fruitless. In the succeeding two years there was consequently no slackening of activities, either in the dockyards or at sea, in anticipation of a war, which Lord Fisher, studying the progress of the enlargement of the Kiel Canal, prophesied would not occur at any rate until 1914. On that calculation, as was subsequently revealed, British plans of naval development rested. The following statement shows the number of ships built and projected from the introduction of the dreadnought design.

TABLE I.

Year		Capital Ships	Protected Cruisers	Destroyers
1905–6	Great Britain	4	..	18
	Germany	..	..	..
1906–7	Great Britain	3	..	14

	Germany	2	2	12

[1] Germany also laid down an armoured cruiser—the "Blücher."
[2] No provision had been made in the programme for protected cruisers or destroyers.

II. THE NAVIES OF OTHER COUNTRIES

During the years when the two naval protagonists were strengthening their fleets in feverish haste, the older navies of Europe suffered a decline of relative strength which in the circumstances was inevitable. France, Italy and Russia, even if they had had the will to do so, could not, owing to the necessities of the military situation which occupied the minds of their Governments, keep pace with the rapid and costly developments which were taking place on either side of the North Sea.

France.—From the time when, in 1908, Admi. Germinet left the Ministry of Marine, the naval policy of France lacked definite purpose and continuity. There were frequent changes of ministers, at the rate of about one a year, and each one, being a civilian, became the instrument of one or other of the rival schools of naval thought, while in the Chambers, senators and deputies increasingly lost confidence in the administration of the naval service, both ashore and afloat, with the result that supplies demanded by the expert advisers were repeatedly denied. Gradually the naval policy of the country became more and more based on defensive ideas. The *guerre de course* gained an ascendancy over the minds of those concerned with naval defence, with the result that the offensive ideal of warfare no longer dominated policy, and attention was concentrated on small craft.

The French Navy, which had ranked for many years as second only in strength to that of Great Britain, was consequently surpassed in strength, first by Germany, and then by the United States, although sums had been voted for its support (1896–1911) which were 50% larger than the amounts spent on the German fleet. In 1909, as the result of an inquiry carried out by a Parliamentary Committee, an organic law was at last adopted for the expansion of the French naval forces. But it came too late to change the situation, and on the outbreak of the World War the navy, though inspired by a new purpose, was still suffering from lack of continuity of policy, and in consequence all new construction was frequently delayed by repeated changes of design.

Russia.—Simultaneously with the decline of French naval prestige, the Russian fleet also suffered. The recently constituted Duma, established in 1905, refused to approve of measures for strengthening the navy on the ground that the Admiralty and all the naval departments urgently required reorganising. When a building scheme was at last adopted, the decision that new vessels, instead of being built in foreign yards as had hitherto been the custom, should be constructed in Russia, and as far as possible of Russian materials, proved a further handicap to progress. In these circumstances, the Russian fleet, which had sustained heavy material losses in the war with Japan, failed to recover either its prestige or its material strength. Though naval expenditure was maintained at a high level, the Russian fleet continued to decline owing largely to the failure to carry out reforms in the naval administration, which were recognised as being essential if a higher standard of efficiency was to be attained.

Italy.—In contrast with the misfortunes which sapped the strength of the allied fleets of France and Russia, the Italian naval authorities pursued a consistent and methodical policy. The increased attention which the Austro-Hungarian Govt., on the urgent representations of Germany, was devoting to naval affairs, was responsible, in no slight degree, for the energy displayed in Italy, which had ceased to evince any enthusiasm for the Triple Alliance, of which she was nominally a member.

Navies in 1914.—In these circumstances the balance of naval power in European waters underwent a dramatic change as the Anglo-German contest for naval power pursued its course, larger and larger sums being devoted each year by these two countries to ship construction, the maintenance of bigger fleets at sea, and manoeuvres for the training of officers and men. Whereas British naval expenditure had been £26,000,000 in 1900, in the spring of 1914 the House of Commons voted nearly £44,500,000. The outlay in Germany over the same period rose from £8,000,000 to over £23,000,000. A new standard of naval efficiency was set up in these two opposing fleets, and the deficiencies of the French and Russian fleets became more conspicuous in contrast, while Italy, watching with growing suspicion the course of naval events in the Austro-Hungarian Empire, occupied an ill-defined position between the two groups of naval Powers. In 1914 the strength of the fleets in Europe was as follows, the letters G.B. representing Great Britain, G. Germany, A.H. Austria-Hungary, I. Italy, F. France and R. Russia. The abbreviation Bt. indicates "built"; the abbreviation Bg. indicates "building."

A leading naval authority—Count Reventlow—who was in close touch with the naval authorities in Berlin, afterwards stated that when the War broke over Europe in 1914 the German fleet was not ready. "In 1906," he stated, "came the dreadnought revolution in shipbuilding which quickly rendered worthless all ships built before that time (pre-dreadnoughts) and compelled tremendous enlargements of wharves, harbours and canals, gigantic extensions of organisations, etc. The work of completing the German fleet would have extended far beyond the year 1920 under these conditions." British policy in this respect, as well as in regard to the political "understandings" with France, Russia and Japan, which enabled the main British squadrons to be concentrated in the North Sea, completely upset all the calculations on which German naval policy had been based in the early years of the 19th century.

Eastern Waters.—During these years naval conditions in the Pacific and adjacent waters also underwent marked changes. Great Britain and the other European Powers reduced their forces to the lowest level compatible with the naval plans of Germany. While neglecting the Mediterranean and Atlantic, these plans embraced a powerful cruiser squadron in China waters, which, in view of the high standard which it achieved in gunnery, became a considerable factor in the naval situation in the Far East. Public sentiment in Japan and the United States having been somewhat reassured by the treaty of non-interference with each other's territorial interests, these two countries continued to increase their naval forces, but the movement was marked by no such political unrest as was being exhibited on the two sides of the North Sea.

The Japanese Govt., which had placed reliance upon the Anglo-Japanese alliance for the preservation of the *status quo* in the Pacific, slowly adjusted itself to the new conditions which British preoccupation in the North Sea had made inevitable, while the United States, occupying a position of complete detachment from the troubles which were coming to a head in Europe, began to occupy a position of some importance at sea. The world cruise of the American fleet, which had begun at the end of 1907 and lasted 14 months, had given the American people a new conception of their concern with naval affairs. Rear-Admi. Sperry, when his ships had made their furrow of 45,000 m.

in the seas and oceans of the world, had stated that " this cruise marks an epoch in our naval annals, for the fleet has found itself—being welded into a unity." Events in later years were to supply ample confirmation of this statement.

III. THE WORLD WAR AND AFTER

During the years of the World War, both the United States and Japan embarked upon schemes of naval expansion.

United States.—In 1916 Congress adopted an Act " for the purpose of further increasing the naval establishment of the United States," which, in its methodical character, somewhat resembled the successive German Navy Acts. It provided for the construction of the following vessels: 10 first-class battleships, six battle cruisers, 10 scout cruisers, 50 torpedo boat destroyers, nine fleet submarines, 58 coastal submarines, three fuel ships, two destroyer tenders, two ammunition ships, two gunboats, a repair ship, a transport, a hospital ship and a fleet submarine tender. Provision was also made for improving the Navy Yards at Puget Sound, Philadelphia, Norfolk, New York, Boston, Portsmouth, Charlestown and New Orleans, the work to be completed within five years. This Act provided for nothing less than the construction of a new American fleet and foreshadowed an expenditure far larger than any country had hitherto contemplated. It also contained clauses which attracted little attention at the time outside the borders of the United States, though the words pointed to ambitious hopes for the limitation of naval armaments.

It is hereby declared to be the policy of the United States to adjust and settle its international disputes through mediation or arbitration, to the end that war may be honourably avoided. It looks with apprehension and disfavour upon a general increase of armament throughout the world, but it realises that no single nation can disarm, and that without a common agreement upon the subject every considerable Power must maintain a relative standing in military strength.

In view of the premises, the President is authorised and requested to invite, at an appropriate time, not later than the close of the War in Europe, all the great Governments of the world to send representatives to a conference which shall be charged with the duty of formulating a plan for a court of arbitration or other tribunal to which disputed questions between nations shall be referred for adjudication and peaceful settlement, and to consider the question of disarmament and submit their recommendations to their respective Governments for approval.

The Act also laid down that, if a conference succeeded in attaining the purposes for which it had been called, the constructive plans might be varied in accordance with any engagement into which the United States had entered. The War in Europe was to continue for upwards of two years after the passing of this measure, and consequently keels were laid in American shipyards in accordance with the terms of the Act, and the United States was definitely committed to this great programme of naval expansion before the Treaty of Versailles had been signed.

Japan.—The course of events at sea confirmed the importance of sea-power to an island state. Japan had for several years entertained the project of building 16 capital ships, eight battleships and eight battle cruisers, none of which should at any time exceed eight years in age. On the assumption that such vessels possessed an effective life of about 24 years, Japan contemplated having at her disposal, in time, 16 capital ships of the latest design and constructions and 16 bordering upon obsolescence, with a similar number occupying a position midway between these two groups. The plan embraced the expansion of the dockyards and other establishments ashore, as well as provision of the necessary trained personnel. With the approval of the Imperial Diet, this programme of expansion was taken in hand in 1916. At that time Japan was spending £15,000,000 annually on her navy; it was estimated that the votes might rise to nearly £60,000,000 by 1920, although the Government declared that whatever other nations might do Japan would not exceed the eight-eight programme, which it was proposed to carry out gradually as the financial position of the country might render possible.

A New Rivalry.—In place of the rivalries in naval armaments which had persisted in Europe for so many years, a new race for naval power had begun between the United States and Japan while the World War was still in progress. Even after the United States had intervened in the struggle, the activities in the government and private yards continued with unabated energy, while, on the other side of the Pacific, the Japanese people settled down to the task of building up their fleet to the eight-eight standard, with all that was implied in cruisers, destroyers, submarines and other auxiliaries. Not only was the American programme really more ambitious than that of Japan, but the United States possessed within her own borders practically all the raw material necessary for the creation of a fleet, while Japan was confronted with the problem of obtaining from overseas no mean proportion of the steel and other material which she needed. On the other hand, the Japanese, in virtue of their conscriptive law, were in a position to obtain all the officers and men which the larger fleet would require, drawing freely upon a seafaring population, but the United States was faced with the problem of competing in the labour market for recruits, which experience had proved were not always forthcoming in adequate numbers.

Post-War Situation in Europe.—When the World War came to an end, the whole naval situation in Europe had undergone a complete change. The German Navy, by the surrender of all its modern units, had been reduced to the status of a third-class sea Power, and denied the possession of either submarines or aircraft of combatant types. The Russian fleet, after the revolutions, had, to all intents and purposes, ceased to be of any importance. France and Italy had been so preoccupied in supporting their armies, tasks which necessitated the concentration of all their industrial activities on the provision of military munitions, that neither country had had either the man-power or the material available for the construction of new ships. The British fleet, which had borne the main burden of the War on the Allied side, had been forced by the compelling circumstances of the naval situation to pursue a policy of expansion embracing capital ships, cruisers and every type of auxiliary craft. It emerged from the struggle, in spite of the heavy losses which had been sustained, as the only first-class naval force in European waters.

Limitation of Armaments.—When President Harding in the year following the signing of the Peace of Versailles issued an invitation to the leading naval Powers to a conference at Washington to discuss the possibility of limiting armaments, the United States was already potentially the leading naval Power of the world. All the battleships, battle cruisers and scout cruisers of the 1916 programme, as well as no mean proportion of the auxiliaries, including five destroyers, five fleet submarines, and 37 smaller submarines, were under construction. The British naval authorities had inherited from the War a great fleet, but, except for the battle cruiser " Hood," none of the battleships embodied any of the lessons enforced by the struggle at sea, while the cruisers had for the most part been designed for service in the North Sea, and, owing to their limited radius of action, were unsuited for ocean work. In these circumstances the British Admiralty, urged to economy, had entered upon a vigorous scrapping policy, one firm alone buying 113 war-ships, on the understanding that they should be broken up. At the same time provision was made in 1920 for laying down four new battleships, to displace 45,000 tons, as well as a submarine and a minelayer. Japan had in hand three of her new battleships, as well as two battle-cruisers, eight cruisers, 10 destroyers and 15 submarines.

A new phase in the competition in naval armaments had begun, involving the United States, Great Britain and Japan in vast expenditure. The Washington Conference (*q.v.*) arrested this movement, so far as the principal battle fleets of the world were concerned. The United States Govt. suggested that all the battleships then under construction should be forthwith scrapped. As the result of discussion, the American scheme was slightly varied. Japan made good her claim to retain two

post-Jutland ships of the latest design, and the same liberty was accorded to the United States, while freedom was accorded the British naval authorities to lay down two new capital ships of 35,000 tons, which on completion should replace four older vessels. It was stipulated that no other capital ships should be laid down before 1931, and that gradually the British and American battle fleets should be brought to a condition of parity with a standard of displacement of 525,000 tons, Japan being allotted 315,000 tons and France and Italy 175,000 tons, a balance of power calculated on the same proportions applying to aircraft carriers. The treaty also provided that no capital ships built in replacement of older vessels from 1931 onwards should exceed 35,000 tons or carry a gun with a calibre in excess of 16 inches. While no restrictions were placed on the number of cruisers which might be built, it was also stipulated that no vessel of this type should exceed 10,000 tons displacement or mount any weapon of larger calibre than eight inches. No limits were placed, on the other hand, on the building of destroyers or submarines.

Strength of Navies.—In these circumstances the Naval Treaty was signed at Washington and was subsequently implemented by the Governments of the United States, Great Britain and the British Dominions, Japan, France and Italy, the French Govt. making sundry reservations. In subsequent years great activity developed in the construction of cruisers, destroyers and submarines in all the shipyards of the world. At the beginning of 1926 the strengths of the fleets in completed ships were as follows (vessels building or projected are shown in parenthesis), the letters B.E. representing the British Empire, U.S. the United States, J. Japan, F. France and I. Italy:—

TABLE III. *Ships Built and Building*

	B.E.	U.S.	J.	F.	I.
Battleships	18 (2)	18	6	9	7
Battle Cruisers	4	..	4	..	..
Cruisers	47 (15)	32 (8)	31 (8)	15 (9)	14 (5)
Cruiser Minelayers	.. (1)	..	3	.. (2)	..
Armoured Coast Defence Vessels and Monitors	3	1	..	..	..
Aircraft Carriers	8 (1)	1 (2)	2 (2)	.. (2)	1
Flotilla Leaders	17	..	..	2 (20)	11

Torpedo Boats	..	..	..	..	54
Submarines	56 (10)	120 (8)	53 (26)	45 (58)	42 (20)
Sloops	34	..	..	8	..
Coastal Motor Boats	6	..	2	2	12
Gunboats and Despatch Vessels	.. (4)	12	6	49	12
River Gunboats	18	6 (6)	8	6	2
Minesweepers	61	44	4 (2)	29	40 (6)

All the naval Powers were maintaining in 1926 a large measure of secrecy as to the designs of the cruisers, destroyers and submarines which were being built, and everything pointed to a continuation of an active policy of construction. In the summer of 1925 the British Admiralty announced details of a five-year shipbuilding programme (1925–30) embracing nine cruisers of 10,000 tons displacement, seven cruisers of smaller size, 27 destroyers, 24 submarines, five gunboats, four motor launches, two submarine depôt ships, a net-layer and a repair ship, as well as a large floating dock to be stationed at Singapore, on the development of which work had been begun the previous year.

NAVY DEPARTMENT (*see* 1.201).—Since 1910 the U.S. Navy Department has been reorganised to some extent in accordance with requirements found necessary to meet fully the demands of the World War, and likewise as a result of lessons learned during that war. On Aug. 29 1916, closely following the U.S. Govt.'s ultimatum of April 18 to the Imperial German Govt. with regard to unrestricted submarine warfare, an Act of Congress established a naval flying corps, a naval reserve force, reorganised the navy on a basis of immediate preparation for war, and authorised the construction of 10 battleships, 6 battle cruisers, 10 scout cruisers, 50 destroyers, 9 fleet submarines, 58 coast submarines, 2 gunboats and 12 auxiliary ships.

The naval consulting board, composed of leading scientists and inventors, was provided for on the same date. Not directly concerned with the reorganisation of the Navy Dept., but affecting the mobilisation of U.S. military power, was the authorisation by Congress, also on Aug. 29, of the Council for National Defence, with the secretaries of War, Navy, Interior, Agriculture, Commerce and Labour as members, for the purpose of correlating the factors of preparedness for war.

The Navy After the War.—Since the World War, the U.S. Navy has been reduced to a peacetime basis. Its limitation as to strength was prescribed in certain respects by the Washington Treaty for the limitation of naval armament. The Washington Treaty was ratified by the five great naval Powers concerned on Aug. 17 1923, following a conference of representatives of the United States, the British Empire, Japan, France and Italy, which was convened Nov. 12 1921 at the invitation of the American President in Washington, and which ended on Feb. 6 1922, after the representatives had signed the terms of the treaty. The efforts of the representatives of the United States were directed towards the limitation of total tonnage in each type of combatant naval craft.

The treaty as finally ratified limited the total tonnage of capital ships (battleships and battle cruisers) and large aircraft carriers; restricted the individual tonnage displacement of warships; fixed a limit to the size of naval guns; prohibited reconstruction of capital ships and aircraft carriers except as provided by treaty; fixed the *status quo* with regard to fortifications and naval bases of certain outlying possessions of the United States, the British Empire and Japan; specified the capital ships that each of the five Powers could retain; provided a schedule of replacement of capital ships; and indicated the capital ships which were to be scrapped. (*See* WASHINGTON, TREATY OF.)

Plans of Navy Department.—Certain other changes subsequent to the Armistice in 1918 affected the plans and organisation of the Navy Department. On May 28 1919 the General Board of the Navy recommended that the 1916 building programme for new ships be completed. This recommendation was carried into effect until the restrictions imposed upon new construction by the Washington Treaty were ratified. The joint army and navy board, established July 17 1903, was reorganised to some extent in July 1919. This board, composed of three naval and three army officers, confers upon and reaches conclusions regarding problems in all matters calling for the co-operation of the two services, and has direct power of approval of reports submitted by the joint planning committee, the joint aeronautical board and the joint munitions board. The bureau of aeronautics was added to the Navy Dept. by authorisation of Congress, July 12 1921. It is of interest here to note that the national advisory committee for aeronautics, which supervises and directs the scientific study of aviation in the United States, was established through the Naval Appropriation Act of March 3 1915. The latest contemplated change of any importance in the reorganisation of the Navy Dept. is the addition of an assistant secretary for naval aviation.

Organisation.—The U.S. Navy in 1926 may be considered to consist of the following: the Navy Dept. at Washington, the U.S. fleet and detached naval forces, and the naval shore establishment. The Navy Dept. at Washington is the directing

agency, operated, under the direction of the President of the United States, by the Secretary of the Navy. In deciding upon details of naval policy, the Secretary is advised by the assistant secretary of the navy, the joint army and navy board, the chief of naval operations, the general board of the navy, the major-general commandant of the marine corps and by the chiefs of the following technical bureaux: navigation (personnel), engineering, ordnance, construction and repair, aeronautics, supplies and accounts, yards and docks, medicine and surgery. The judge-advocate-general furnishes legal advice. The chief of naval operations is by virtue of his position the senior admiral of the navy (*see* STAFF, NAVAL).

The office of naval operations, which was established under Act of Congress March 3 1915, operates the fleet and detached naval forces, develops and maintains the plans for their use in war, and in general co-ordinates under the direction of the Secretary the work of the eight technical bureaux in the development of the navy. The general board makes recommendations on important questions of naval policy. The marine corps is operated by its major-general commandant. The assistant secretary supervises the preparation of the annual estimates, administers the navy yards and performs such other duties as may be assigned to him by the Secretary of the Navy. During the absence of the Secretary of the Navy from Washington, the assistant secretary becomes the acting Secretary, and in the event of the assistant secretary's absence, the chief of naval operations becomes the acting Secretary of the Navy.

Divisions of the Navy.—The fleet and detached naval forces, other than those assigned to naval districts, are organised as follows: the U.S. fleet, the naval transportation service, the Asiatic fleet, naval forces in European waters and the special service squadron. The U.S. fleet comprises the greater part of the naval forces based on home ports. This fleet is divided into four parts—the scouting fleet in the Atlantic, the battle fleet in the Pacific, the control force in the Atlantic and the fleet base force in the Pacific.

The duties of the U.S. fleet are confined to training for the development of the fleet to its maximum strength as a fighting force. The naval transportation service carries the fuel and other supplies from supply ports to the theatre of operations, where its cargoes are turned over for use or distribution to the fleet base force. The Asiatic fleet is composed of a cruiser acting as flagship, some destroyers, submarines, gunboats and a small air force; this fleet protects U.S. interests in the Far East. The naval forces in European waters protect American interests in Europe and the Near East. The special service squadron protects U.S. interests in the Central and South American republics.

The third component part of the navy, the naval shore establishment, consists of 14 naval districts, each of which has a commandant, who, as a representative of the Navy Dept., has general supervision over all naval activities in his district. These 14 naval districts include in their territory the United States proper and its outlying possessions. Each district has a navy yard, naval base or naval station, where the commandant has his headquarters and staff. These yards and stations carry out such important repairs and alterations to ships as are not performed by the forces afloat. (C. D. Wi.)

NEAL, DAVID DALHOFF (1838–1915), American painter (*see* 19.320), died in Munich, Germany, May 2 1915.

NEBRASKA (*see* 19.323) had in 1925 a population of 1,355,371 (U.S. Census Bureau estimate); in 1920, 1,296,372; in 1910, 1,192,214. The increase from 1900–10 was 11·8%; from 1910–20 8·7%. In the decade 1910–20 the foreign-born whites decreased from 176,662 to 149,652. In 1920 the urban population (in places of 2,500 or more) was 405,306 or 31·3% of the whole; in 1910 310,852, or 26·1%. The rural population in 1920 was 891,066, or 68·7%; in 1910 881,362, or 73·9%. The drift of population to the larger cities has continued strongly during the period 1920–5. The five cities having in 1920 a population over 10,000 are given in table in next column.

	1920	1910	Increase %
Omaha	191,601	124,096	54·4
Lincoln	54,948	43,973	25·0
Grand Island	13,947	10,326	35·1
Hastings	11,647	9,338	24·7
North Platte	10,466	4,793	118·4

In the decade 1910–20, 33 out of 93 counties showed a decrease in total population, and 43 (chiefly the older counties) showed a decrease in rural population. The irrigated districts in the Platte valley and the cities of 10,000 or more have absorbed practically all the increase in population from 1910–25.

Agriculture.—The number of farms in 1925 was 127,731; 67,764 were operated by owners, 669 by managers, and 59,298 or 46·4% by tenants. The farm acreage was 42,024,129, of which there were 23,109,624 ac. of improved land. The average acreage per farm was 329. The value of farm land and buildings was $2,523,306,303 in 1925 as compared with $3,712,107,760 in 1920; the average per farm was $19,755 in 1925, $29,836 in 1920. In 1920 Nebraska ranked sixth among the States in area of cultivated lands. It was first in production of hay, second in winter wheat, third in corn (maize), third in combined production of wheat, oats and maize. About 1,000,000 ac. were in woodland, of which half or more had been planted by settlers. Production of principal crops for the years 1920 and 1925 is shown in the following table:—

	1925		1920	
	Ac.	Bu.	Ac.	Bu.
Maize	9,100,000	236,600,000	6,699,450	160,391,314
Wheat	2,676,000	34,150,000	4,429,156	57,843,598
Oats	2,699,000	73,953,000	2,029,740	59,819,545
Barley	233,000	5,662,000	211,242	4,405,323
Rye	205,000	2,552,000	359,926	3,259,390
	(tons)	(tons)	(tons)	(tons)
Hay	4,648,000	5,867,000	4,798,363	5,307,702
Sugar beets	61,000	816,000	54,486	554,646

Domestic animals on farms in 1925, 1920 and 1910 included the following:—

	1925	1920	1910	Jan. 1 1925
Horses	863,152	961,396	971,279	857,000
Mules	119,874	99,847	79,652	116,000
Cattle	3,314,342	3,154,265	2,567,392	3,301,000
Swine	4,279,824	3,435,690	3,435,724	4,545,000
Sheep	..	..	..	726,000

Industries.—Slaughtering and meat-packing, the chief manufacturing industry, in 1919 employed 10,122 wage-earners in 16 establishments, and the products were valued at $303,849,000. Wage-earners employed in all industries numbered 36,521, as compared with 24,336 in 1909.

Minerals.—Of the pumice produced in the United States 97% is mined in Nebraska. Production of limestone, sand and gravel for cement industries and road building increased rapidly. Potash is found in alkali lakes in the sandhill region of western Nebraska. The World War shut out importation from Germany, and commercial potash rose to 10 times its former price, with the result that a new industry sprang up, but died out after the War, when importation from Europe was resumed.

Finance.—By Act of the Legislature (1921), assessment of property was changed from one-fifth to full value. In 1925 the assessed value was $3,156,307,123. Total levies for all State purposes (1925) were 2·35 mills. Total State and local taxes for all purposes (1924) were $53,447,375, about $41 *per capita.* There is no State debt. The total debt of all sub-divisions of the State on Jan. 1 1926 was $107,000,000. The revenue in 1924 was $12,498,432 and the disbursements $12,890,046.

Roads and Transportation.—The amount expended on roads from 1920 to 1925 was approximately $8,000,000. In 1925 there were 5,960 m. State roads and 3,514 m. improved State roads. In 1925 farm-owned motor-cars were 122,910, or 40% of the whole number in the State, 301,716; farm-owned motor-trucks were 16,112, or 43·5% of the whole, 37,003. One of the great

changes since 1920 has been the entrance of motor-buses and motor-trucks into rivalry with railways. This began actively in 1923 and has rapidly expanded, and railways have since noted a large falling off in local business. In 1924 there were 6,441 m. of steam and 215 m. of electrical railway track.

Education.—Nebraska is second in literacy among the States. The 1920 U.S. census found 13,874 persons over 10 unable to write in any language. The Nebraska law requires attendance of all children between seven and 16. In 1924 there were 7,120 schools, with 327,417 enrolled pupils; teachers, 14,284; total school expenditure, $32,508,108. Foreign languages in the schools became a political issue as a result of the World War. About 200,000 Nebraskans were German-born or children of parents born in Germany. Through the efforts of the German-American Alliance, the Mockett law was enacted in 1913, providing for teaching the German language in the common schools upon petition of school patrons. After the declaration of war, the Mockett law was repealed, and the Siman law passed forbidding the use of any foreign language as a medium of instruction. On appeal to the U.S. Supreme Court, the Siman law was held unconstitutional.

History.—The chief political issues were the introduction of prohibition, woman suffrage, initiative and referendum and the reconstruction of the State government, all of which were adopted in 1920. The Legislatures of 1919–25 granted $9,000,000 for the construction of a new State Capitol. The governors since 1910 were Chester H. Aldrich (Rep.), 1911–3; John H. Morehead (Dem.), 1913–7; Keith Neville (Dem.), 1917–9; Samuel R. McKelvie (Rep.), 1919–23; Charles W. Bryan (Dem.), 1923–5; Adam McMullen (Rep.), 1925– .

NEBULA: *see* ASTRONOMY.

NEGRO (*see* 19.346).—The Negro population of the United States as enumerated in 1920 was 10,463,131, an increase of 635,368, or 6·5% over 1910. The rate of increase was less than in any preceding decade and less than three-fifths of that between 1900 and 1910, the smallest up to that time. As in the white population the rate of increase between 1910 and 1920 was less than in any preceding decade, it might be thought that the fall in the increase among Negroes conformed to the trend of population change. But this would be an error. The rate of increase of Negroes in 1900–10 was about ·5 and in 1910–20 about ·4 of that of the whites. That this deviation in the rates of increase had been maintained for a long period appears from the following figures:—

Period	Increase				Ratio of Negro per cent of increase to White (100)
	Amount in thousands		Per cent		
	Negro	White	Negro	White	
1800–20	770	3,560	76·8	82·7	93
1820–40	1,102	6,329	62·2	80·5	77
1840–60	1,568	12,727	54·6	89·7	61
1860–80	2,139	16,481	48·2	61·2	79
1880–1900	2,253	23,289	34·2	53·9	64
1900–20	1,629	28,012	18·4	41·9	44

Increase.—The numerical increase of Negroes was larger in the later periods, rising to a maximum in the last 20 years of the 19th century. The rate of increase, on the contrary, diminished steadily. At each period the rate of Negro increase was less than that of the white. Apparently the immediate result of the Civil War and emancipation was to raise the relative rate of Negro increase between 1860 and 1880 from ·6 to nearly ·8 of that of the whites. But since 1880 the rate of Negro increase has fallen rapidly, and Negroes, who in 1800 were 18·9% of the country's population, in 1920 were only 9·9%. If each race should increase through the present century as it did between 1900 and 1920, the population of the country in 2000 A.D. would be over 400,000,000, of which about 20,000,000, or one-twentieth, would be Negro. The rate of increase of each race is likely to fall, but the difference in favour of the white race is not likely to diminish.

Areas.—The region in which the increase of Negroes since 1900 has been greatest is shown by the following facts. The five states with the greatest amount of Negro increase between 1900 and 1910 were all southern states. The increase in them was nearly one-half (49%) of that of the whole country. The five states which occupied a similar position between 1910 and 1920 were Pennsylvania, Ohio, Illinois, North Carolina and New York, four of them northern states, and the increase in them was nearly three-fifths (58%) of the whole. These four northern states are highly urbanised. The facts suggest a migration to industrial centres. The conjecture may be tested by computing the percentage of increase of urban population both negro and white. From 1900 to 1910 the whites in cities having 2,500 inhabitants or more increased 39·1% and the Negroes 34·2%; from 1910 to 1920 the percentage of increase decreased for each race, but among the whites it fell by 10·5% to 28·6%, and among Negroes it fell by 1·6% to 32·6%, so that between 1910 and 1920 Negroes in cities increased at a higher rate than the whites.

Migration.—The large amount of Negro migration to northern cities between 1910 and 1920 and the comparatively slight migration in 1900–10 appear from the following table:—

City	Negro population in 1900	Increase of Negroes	
		1900–10	1910–20
Chicago	30,150	13,953	65,355
New York	60,666	31,043	60,758
Philadelphia	62,616	21,846	49,770
Detroit	4,111	1,630	35,097
Cleveland	5,988	2,460	26,003
St. Louis	35,516	8,444	25,894
Total	199,047	79,376	262,877

The preceding figures are for the cities in which the Negro population increased by 25,000 or more between 1910 and 1920. All lie outside of the southern states. The Negro population of these six cities increased between 1900 and 1910 by 39%, and between 1910 and 1920 by 95%. As the increase of Negroes in all northern states between 1910 and 1920 was 444,635, nearly three-fifths (59%) of that increase was in these six cities.

Births and Deaths.—The remarkable fall in the rate of Negro increase and the rapid distribution of Negroes to other parts of the country than the South, especially to certain northern cities, are the striking changes revealed by the fourteenth census. How is the fall in the rate of increase to be explained? Has it any connection with the growth of interstate migration? These questions are elucidated by turning from the census figures of living population to the registration figures of births and deaths. The following table shows the registered births and deaths of Negroes in each of 30 states arranged in the order of increasing proportion of deaths to births:—

States with a Natural Increase of Negroes

State	Period covered by registration	Negro births	Negro deaths	Deaths to 100 births
North Carolina	1917–22	143,367	77,758	54
Mississippi	1921–2	44,940	24,574	55
South Carolina	1919–22	95,110	53,372	56
Virginia	1917–22	119,435	77,775	65
New Jersey	1921–2	6,779	4,771	70
Maryland	1916–22	45,871	40,245	87
Massachusetts	1915–22	8,846	7,870	89
Wisconsin	1917–22	657	597	91
New York	1915–22	34,502	32,126	93
Delaware	1921–2	1,248	1,200	96
Michigan	1915–22	7,603	7,453	98
Connecticut	1915–22	3,890	3,868	99
New Hampshire	1915–22	86	85	99
Total		512,334	331,694	65

States with a Natural Decrease of Negroes

State	Period covered by registration	Negro births	Negro deaths	Deaths to 100 births
Illinois	1922	3,704	3,786	102
Pennsylvania	1915–22	45,311	48,207	106
Ohio	1917–22	21,719	23,940	110
Rhode Island	1915–9 and 1921–2	1,522	1,684	111
California	1919–22	2,688	3,054	114
Indiana	1917–22	8,758	10,377	119
Nebraska	1920–2	564	685	122
Kansas	1917–22	5,956	7,286	122
Utah	1917–22	128	158	123
Kentucky	1917–22	24,180	30,343	125
Vermont	1915–22	29	38	131
Oregon	1919–22	100	154	150
Minnesota	1915–22	913	1,388	152
Washington	1917–22	424	738	174
Montana	1922	20	40	200
Wyoming	1922	17	39	229
Maine	1915–22	84	194	231
Total		116,117	132,111	114

If Negro deaths had exceeded births in the 17 states of the last table between 1910 and 1920, and if there had been no immigration of Negroes to this group of states, the number of resident Negroes would have been less in 1920 than in 1910. In fact, it increased from 852,120 to 1,113,940, or 30·7 %. The total immigration to these states for the decade was probably not less than 300,000.

There are seven southern states for which we have births and deaths reported, and all but Kentucky had an excess of births over deaths. The Negro population of these states increased between 1910 and 1920 about 1%. On the basis of the figures for 1919 and 1920 there was a natural increase of about 35,600 annually, or 356,000 for the decade. As the decennial increase of Negroes was about 40,000, these states must have lost by emigration more than 300,000.

The bureau of the census has supplied figures of Negro births and deaths between 1915 and 1923 in the urban and rural districts. They are as follows:—

	Births	Deaths	Deaths to 100 births
Urban	266,380	269,631	102
Rural	517,945	309,243	60

These show that during these eight years in the cities of the United States for which the facts are known there were 3,251 more Negro deaths than births, but that in the country districts there were 208,702 more births than deaths. The figures of each class are given separately below for North and South.

	Births	Deaths	Deaths to 100 Births
Northern urban	155,972	151,118	97
Northern rural	33,245	40,294	121
Northern total	189,217	191,412	101
Southern urban	110,408	118,513	107
Southern rural	484,700	268,949	55
Southern total	595,108	387,462	68

Conclusion.—These figures show that the rural districts of the North are least suitable for Negro increase, that the urban districts of the South are almost as unfavourable, that the cities of the North show a slight excess of Negro births, and that the great reservoir for Negro increase is the rural districts of the South. The cause for the low rate of increase between 1910 and 1920 is found in the migration from the country districts of the South both to the North and to southern cities, and to their exposure to conditions climatic or economic which raised the death-rate and lowered the birth-rate. Urban conditions in the South as well as in the North bear far more lightly upon the whites, who thrive and multiply in American cities. In this regard urban Negroes in the United States are in a position like that of European and American whites living in cities a century or more ago, when cities were parasites upon the adjacent country districts, at whose expense alone they could maintain their population.

NEGRO LITERATURE: *see* AMERICAN LITERATURE; FRENCH AFRICAN LITERATURE.

NENOT, PAUL HENRI (1853–), French architect, was born in Paris, and when only 13 years old was placed in the studio of M. Lequeux as architectural pupil, coming there under the influence of J. L. Pascal. Thence, when 15, he went to the École des Beaux-Arts. After serving in the Franco-Prussian War of 1870, in which he gained the Military Medal, he continued his course at the Ecole des Beaux-Arts, and in 1877 gained the Grand Prix de Rome. While holding this prize in Rome, he competed for the Victor-Emmanuel monument in that city, receiving for his design the premium of 50,000 fr., the work itself being entrusted to an Italian. On his return to France he entered for the great competition for the rebuilding of the Sorbonne, in which he was successful, and commenced in 1885 a work that was to occupy him for the next 17 years. The building forms a parallelogram of over 900 ft. in length by 325 ft. in width, and its plan is brilliantly conceived, taking as its dictating condition the retention of Richelieu's chapel of the Sorbonne. Nenot relied steadfastly on the assistance of the sculptor and the painter, and the grand amphitheatre gave him the opportunity he absolutely insisted on of employing for its decoration Puvis de Chavannes, whose mural painting of the "Sacred Grove" is his masterpiece. The hall itself, used as a *salle des conférences*, is an admirable example of the D-plan carried by a series of alcove recesses to an ultimate development. His other buildings, mostly in Paris, include the Institut Océanographique, the offices of the Compagnie Générale and those of the Compagnie Nationale des Wagons-Lits. He received many distinctions, becoming a member of the Institut in 1895, and being later elected president of the Société des Artistes Français. He was awarded the gold medal of the Royal Institute of British Architects in 1917.

NEPAL (*see* 19.378).—The relations between the British Govt. and Nepal were for more than a century regulated by the Treaty of Segowlie of 1815, which, among other provisions authorised the appointment of a British Resident at Katmandu. On Dec. 21 1923 a fresh treaty of friendship was signed between the two countries, confirming the old treaty and making certain fresh provisions, the most important of which (at any rate from the Nepalese point of view) is the recognition by the British Govt. of the complete independence of Nepal. The old quinquennial mission to Peking has fallen into desuetude.

Slavery, which was an institution in the country from the time of the Gurkha conquest, has now been abolished by the Nepal Govt. and all slaves have been manumitted with the general consent of the slave owners and of the population of the country generally. This liberal measure was due to the initiative of the Maharajah, Sir Chandra Shamsher Jang.

Services in the World War.—During the World War, Sir Chandra Shamsher Jang gave signal proofs of his loyalty and friendship to the British Empire. Immediately after the outbreak of the War he placed the whole resources of his country at the disposal of the Allies. From March 1915 to the end of the War a force of some 10,000 men of the Nepalese Army served in India and on the Indian frontier. The normal number of Gurkha battalions (20) in the Indian Army was doubled, and it is estimated that over 200,000 Nepalese subjects left Nepal to serve with the Indian Army during the course of the War.

The Nepalese Govt. contributed sums amounting in all to 13,500,000 rupees (nearly £1,000,000) for various war funds, etc. (exclusive of the Maharajah's numerous subscriptions to

military hospitals and charitable funds in connection with the War), cardamums to the value of 130,000 rupees; tea to the value of some 32,000 rupees; over 8,000 hill blankets, and other articles of clothing; various gifts of timber, including 200,000 broad-gauge sleepers for the Indian railways, and 31 Vickers-Maxim machine-guns—a magnificent contribution from a small and poor country. Many decorations were bestowed upon the troops who served with the Indian Army, and upon the various members of His Highness' family who organised and commanded them. During the short Afghan War in 1919, the Maharajah dispatched a force of 2,000 men of the Nepalese Army, which assisted the Indian Govt. in guarding the Northwest Frontier stations.

Route into Nepal.—The only portion of Nepal (with the exception of some portions of the tarai country which lies at the foot of the hills), ever visited by Europeans is the Valley of Katmandu, and even this can only be entered by special permission of the Nepal Government. The road to Katmandu starts from Raxaul, a small junction on the Bengal North Western Railway situated close to the frontier, due south of the capital, in the district of Champaran in Northern Behar. Hence to Katmandu is a distance of 75 m., the first 50 of which lie across the alluvial plain of the tarai and through a sal forest to the foot of the hills, whence the road follows the beds of rivers and across low ridges till the small hamlet of Bhimpedi is reached. Up to this point the road is practicable (at least during the cold weather) for wheeled traffic, and it is indeed possible to drive a motor-car over it, and it is gradually being improved and rendered fit for wheeled traffic all through the year. From Bhimpedi there is only a mountain track, which crosses two bridges (elevation about 8,000 ft.), and reaches the valley of Katmandu some seven miles from the city, whence a fair carriage road is available. A ropeway has been constructed from near Bhimpedi to the Katmandu valley, and will be operated by electricity from the power station in the valley, which also supplies electric light to the city. (*See* INDIA.) (W. F. O'C.)

NERNST, WALTER (1864–), German physicist, was born on June 25 1864 at Briesen, West Prussia. He studied at the universities of Zürich, Berlin, Graz and Würzburg and became an assistant at the University of Leipzig, subsequently going in this capacity to Göttingen, where he later became a professor. In 1905 he was appointed ordinary professor of physics in the University of Berlin. He became known through a technical invention in the sphere of electric lighting, which falls within his Göttingen period. In the glow-lamps named after him, the filaments are made of the rare earths, arsenate of zirconium, thorium, magnesium and others, which, in the cold state, do not conduct electricity (second-class conductors) but do so if heated to a temperature of 600–700° Centigrade. In comparison with the carbon filament lamps that were generally used at the time these Nernst lamps offered the advantage of a considerably lower consumption of current, but the complication of the heating device soon reduced their popularity, especially as it was about this time that Auer succeeded in producing glow-lamp wires out of osmium, which after further development led to the metal filament lamps of to-day. Nernst is further known for the statement of the so-called third law of thermodynamics. In 1920 he received the Nobel Prize for physics.

He is the editor of the *Jahrbuch der Elektrochemie*, the *Zeitschrift für angewandte Chemie*, and the *Zeitschrift für Elektrochemie*. His *Experimental and Theoretical Applications of Thermodynamics to Chemistry* appeared in English (1907).

NETHERLANDS (KONINKRIJK DER NEDERLANDEN) (*see* HOLLAND, 13.587), a kingdom of Western Europe. The land area is 12,618 sq. m. and the population (Dec. 31 1924), 7,298,043.

I. POLITICAL HISTORY

Although she did not take part in it, the World War was the greatest event in Holland's history between 1910 and 1925.

Neutrality.—The fact itself of her having succeeded in maintaining her neutrality seems little short of a miracle. Holland's situation has always been a perilous one, not only because she is surrounded on all sides by the nations whose wars convulse Europe, but because important waterways, on which her neighbours' trade depends, flow out into the sea across her territory. In the years before the War, when it was already casting its shadows ahead, more than one acute controversy between the two opposing groups of European Powers had centred round the position of Holland. First, Belgium had been used in an attempt to make Holland give up her attitude of detachment. The Dutch-Belgian *rapprochement*, which was so much talked about in those years, did not proceed from the Dutch-speaking Flemings, but from Francophile circles. It never went very far, and it was forgotten in the outcry raised over the proposal to fortify the mouth of the Schelde which was submitted by the Dutch Govt. to the Chamber in 1910. The contention, however, that Holland was obliged, or even that it had the right, to allow Entente forces to use the Dutch part of that river in case of a German threat to Antwerp was quite untenable. The Entente Governments tacitly recognised the correctness of Holland's behaviour, and in 1911 and 1912 official visits of President Fallières to The Hague and of Queen Wilhelmina to Brussels and Paris made it plain to the World that there was no ill-will between Holland and the Entente.

Probably, indeed, a desire to allow Germany no possible pretext for an attempt to occupy the Dutch ports in case of an Anglo-German conflict had as much to do with the decision to fortify the mouths of the rivers as any idea that the fortifications might ever actually be used against Great Britain. While English and French newspapers were protesting against this scheme, Holland was also remodelling her system of land defence to excellent effect. The German general staff were so much impressed with these reforms that they thought it necessary to rearrange their plan of operations for the event of a war with France. From Von Moltke's memoirs it appears that at the time of his predecessor, Von Schlieffen, the German staff intended to violate Dutch as well as Belgian territory, trusting that when they rushed their armies westward through the Dutch province of Limburg (which juts out to the south, covering part of the eastern frontier of Belgium), the Dutch Army would remain inactive behind the "water line," the inundated area, which protects only the western part of the country, the most densely populated part, including the provinces of North and South Holland, in which all the largest and economically and politically most important towns are situated. Von Moltke, realising that the Dutch Army was made mobile and would be used to strike, even if only the outlying province of Limburg were violated, decided to respect Dutch neutrality, although the détour necessitated would delay the German advance from Crefeld by some precious days.

Holland's attitude, then, in those crucial years was strictly and impartially neutral. The sympathies of the public could less easily be controlled. The memories of the Boer War had already lost much of their bitterness, largely owing to the grant of self-government to the late Boer Republics and the consequent appeasement in South Africa itself. The economic prosperity of the country was to a certain extent bound up with the tremendous development of the German hinterland since 1870, but the Dutch people felt oppressed by the militarist temper and the blatant imperialism which appeared to possess their powerful eastern neighbour. On the outbreak of war in 1914, it was the violation of Belgian neutrality and the subsequent acts of repression in the occupied territory which made the deepest impression and determined the attitude of Dutch public opinion. Only when the pressure of the British blockade began to be severely felt could the small group of German sympathisers command some attention, without, even then, ever swaying public opinion.

The Government at once proclaimed, and rigidly maintained to the end, strict neutrality. Inevitably there were times when each group of belligerents felt Holland's neutrality, however impartially administered, as a burden. The British Navy was able to see to it that Holland did not provide Germany with the food and other materials she wanted from overseas, but the enforcement of the blockade gave rise to a good deal of friction. Moreover, Holland's neutrality undoubtedly had the effect of

covering Germany's right flank. On the other hand, the closure of the Schelde, once Antwerp had fallen, was all to the advantage of Great Britain, as Germany was thus prevented from using Antwerp as a submarine base.

Disputes about particular points were practically continuous, but the sincerity and reality of Dutch neutrality were recognised on both sides, and neither attempted to use violence against Holland. The efficiency of Holland's defence forces contributed to this. The army, 450,000 strong, had been mobilised without a hitch in the last days of July 1914, and was kept on a war footing, at a great cost financially and morally, till 1918. It had to cope with no serious incidents. Some thousands of Belgian and British troops were interned after the fall of Antwerp. German and British aeroplanes sometimes strayed on to Dutch territory. The naval forces occasionally had to intern a submarine or a destroyer, and to them fell the dangerous work of mine-sweeping along the Dutch coast. The Government carried out its international obligations as a neutral with consistent firmness and moderation. Mr. Loudon, the Minister for Foreign Affairs, had from the first adhered rigidly to international law, and he strove honestly to see that all the Government's actions in the carrying out of the decree of neutrality were guided by its precepts.

The Blockade.—Unfortunately, frequent cases arose in which the vague principles of international law could be variously interpreted. Great Britain, for instance, protested when Holland excluded armed merchantmen from her harbours, contending that the article in Holland's original proclamation of neutrality to which Mr. Loudon appealed had been drawn up at a time when Germany's resort to unrestricted submarine warfare could not be foreseen; and it was in reply to those utterly illegal methods that Britain had started arming her merchantmen. In this case Holland maintained her attitude. The sand and gravel dispute, which dragged on throughout 1917 and 1918, was more acrimonious, and at one time endangered Holland's neutrality. The Entente Govts. protested against Holland allowing the Germans to use her waterways for the transport of sand and gravel to Belgium for use in the construction of a new kind of ferroconcrete dugouts. Both belligerents put the severest pressure on Holland, Great Britain penalising her for concessions to Germany, Germany threatening her for concessions to Britain. Mr. Loudon at last consented to ration this traffic on the footing of pre-War statistics; but in the spring of 1918, when Germany was making her final offensive, Ludendorff wanted this arrangement to be used as a pretext to overrun Holland and make a dash for the Dutch ports. An ultimatum was actually presented, and only the determined intervention of representatives of the civil power in Germany prevented Ludendorff from having his way.

The most real difficulties, however, were economic; and these began to be of the most tragic importance to the Dutch people in 1915. For Holland international commerce is not a luxury but a necessity. It directly supports an important part of the community, Dutch industries are dependent on it for most of their raw materials and their coal, while four-fifths of the grain supply comes from abroad. Seaborne trade was gradually extinguished as the War went on. The Germans began by laying mines in front of the English ports. The British retaliated by laying a minefield in the North Sea. In order to make their blockade of Germany effective they exercised an ever more stringent control over imports into the adjacent states, regardless of the provisions of the Declaration of London.[1] They proscribed to neutral traffic a route along the south coast of England, so as to be able to examine cargoes at leisure. The Germans then proscribed the route round the North of Scotland, and declared the Channel area an area of war. In March 1915 the *Entente* Powers did away with all distinctions between legitimate and contraband trade, and prohibited the import into Holland of all goods, whatever their nature, which could be suspected of being destined for transmission to Germany. All goods imported into Holland had to be consigned to an unofficial body (the Netherlands Oversea Trust), which possessed the confidence of the *Entente* authorities and undertook that they should go no further.

[1] This declaration has never been ratified.

The Allies gradually assumed control of the entire economic life of Holland, allowing her the bare necessities of life, withholding anything that could be used to replace goods sent to Germany. Even Holland's trade with her own colonies was subject to this control. As Holland depends on Germany for certain indispensable articles, *e.g.*, coal, she was driven to export food which she really could not do without, in order to obtain them in exchange. Meanwhile in 1915 Dutch vessels had begun to fall victims to German U-boats. After the unrestricted submarine war had been proclaimed early in 1917, practically all overseas traffic ceased. Food scarcity became almost as serious in Holland as in Germany itself, certainly more serious than in England. Bread was severely rationed. Meat was very scarce, as the lack of imported fodder had necessitated the slaughtering of stock. Factories began to close down in 1917 for lack of raw materials and coal. In the last stages of the War Holland's industrial life was at a complete standstill.

Holland greeted the Armistice with relief; but the peace had many disappointments in store for her, and Mr. Van Karnebeek, who had become Minister for Foreign Affairs when a new Government was formed shortly before, was not to have a much easier task than his predecessor.

One big surprise was the discovery that Belgium proposed to advance at the Peace Conference certain claims involving Dutch sovereignty. In the first months of the War, when the Germans advanced through Belgium, a stream of Belgian refugees, which swelled to a flood when the invaders reached Antwerp, had sought safety on Dutch soil, where they were hospitably received. At one time their number exceeded 1,000,000, and their support, the provision of food and shelter, was an exceedingly heavy charge. Hundreds of thousands went back to their country when things had settled down under the occupation. Hundreds of thousands remained till the end of the War, and the way in which they were cared for by a nation which was itself soon to suffer very heavy privations is one of the redeeming features of the history of the War. But all this kindness and generosity seemed to have been forgotten, and Holland found herself decidedly unpopular in some of the Allied countries. The firm refusal of the Dutch Govt. in 1920 to surrender the ex-Emperor William, who had taken refuge there in Nov. 1918, gave rise to excited denunciations of Holland's alleged tenderness for the Hohenzollerns. Holland's attitude in the War was widely represented in the most unfriendly light.

The Question of the Schelde

On this matter Belgium declared that Holland's claim to sovereignty over the Schelde mouth, and her action in closing it against the Allied forces, had made the defence of Antwerp impossible, while her possession of the province of Limburg had hindered the defence of Belgium's eastern frontier, which ought to have been based on the River Maas. It has been argued above that Holland's action in the War had really benefited the Allied cause, but the opposite contention was made by the Belgian "*Comité de politique nationale*," which advocated annexation of the disputed regions. It claimed that Belgium should be given sovereignty over Dutch Flanders, on the left bank of the Schelde, and over Dutch Limburg, on the ground that the treaties of 1839, guaranteeing the neutrality of Belgium, having lapsed, these territories were necessary for her protection and development. With the same object in view, exaggerated complaints of an economic nature were made against the Dutch régime on Antwerp's waterway to the sea. The relations between the *Comité* and the Belgian Govt. were intimate, and Belgium initiated a discussion of these questions at the Peace Conference in Paris, claiming they arose out of the discussion of the treaties of 1839. Holland claimed that this revision should not in any case prejudice Dutch interests, and that any discussion of claims involving Dutch sovereignty was inadmissible, as Holland had not been a party in the War and had honourably fulfilled her obligations as a neutral. Mr. Van Karnebeek consented, however, to go to Paris to explain this point of view to the Supreme Council, who heard M. Hymans on May 20 and Mr. Van

Karnebeek on June 3 1919. The Powers created an international commission to deal with the question, asking them to submit "proposals which involve neither transfer of territory nor international servitudes." The question was eventually referred to direct negotiations[1] between the two countries.

These negotiations on new arrangements for the régime on the Schelde, on the Ghent Terneuzen Canal, etc., were, however, carried on in a somewhat unfavourable atmosphere. Dutch public opinion was greatly irritated. The populations of Limburg and Dutch Flanders protested their loyalty to the Dutch fatherland. Meanwhile the annexationist agitation in Belgium went on, and was still supported by the Government, as was proved when a secret circular, emanating from the Belgian Foreign Office to "Belgian agents" in Dutch Limburg, was disclosed by Flemings friendly to Holland. Yet the Dutch Govt. was prepared to go far to meet Belgian wishes. Although not admitting that the régime of 1839 had been harmful to Belgian interests, and maintaining that she had always administered it in a fair and friendly spirit, Holland declared her readiness to make important economic concessions, which she looked on as the price to be paid for good political relations.

Early in 1920 a treaty in which several Dutch concessions were laid down was ready for signature, when a new dispute arose, about the sovereignty of the Wielingen Channel, which connects the Schelde estuary with the open sea. Although that channel runs along the Belgian coast within the three-mile limit, Holland had exercised sovereign rights over it since mediaeval times, and the two delegations at the beginning of the negotiations had agreed to leave the Wielingen question on one side. When agreement had been reached on other matters it was arranged that each side was to present its case with regard to the disputed point in order to safeguard its claims for the future, but without any intention of arriving at a solution for the time being. Yet when the Dutch Note embodying the case of Holland with respect to sovereignty over the Wielingen was handed in, the Belgian Govt. regarded it as a new and unacceptable claim, and used it as a pretext to break off the negotiations; or such was the view taken in Holland, where it was believed that M. Hymans at the last moment shrank from facing annexationist criticism with a treaty containing nothing but economic concessions. When conditions everywhere grew more stable, and the annexationist programme of the *Comité de politique nationale* looked less capable of realisation, M. Hymans, who had again become Belgian Minister of Foreign Affairs after a period out of office, approached Mr. Van Karnebeek, and the treaty of 1920, was, without Holland having changed her attitude towards the Wielingen question, signed at The Hague on April 3 1925.[2]

Its ratification by Holland was, however, delayed by the prolonged political crisis; and meanwhile it was subjected to lively criticism. In 1919 and 1920 Holland had been willing to make economic concessions to avoid a threat to her sovereign rights; and Mr. Van Karnebeek's conduct of the delicate negotiations had been generally admired. When in 1925, however, the treaty was at last published in its entirety, the danger which loomed so large five years before seemed altogether negligible, and the proposed concessions were scrutinised entirely on their merits. The result was widespread dissatisfaction with the one-sided character of the treaty.

Criticism centred round two main points. Firstly, there are the provisions for a new Dutch-Belgian *régime* on the Schelde. The prosperity of Antwerp during the last years appears the best reply to the suggestion that Dutch control of the lower course of the river threatened Antwerp with ruin. Yet public opinion in Holland admits that the machinery provided by the 1839 treaty for carrying into practice the mixed commission's recommendations is cumbrous. It is greatly disturbed, however, at the provision in the new treaty by which Holland's obligations with respect to the works for keeping the river in a navigable state are defined afresh. It is feared that Holland may have to spend millions in technically unsound attempts to keep the elusive Schelde channel in the same place. A clause exempting vessels bound for Antwerp, during their transit of the Dutch part of the Schelde, from any examination or delay upon any ground whatever arouses criticism as an infringement of Holland's sovereign rights. The provision, by which pilots' fees from the open sea to Antwerp are expressly limited to the amount payable from the open sea to Rotterdam, although the first distance is three times the latter, while nothing is said to prevent the Antwerp fees from being fixed at a lower level, is thought to favour Belgium unduly.

The second point criticised is that containing Holland's consent to the construction over her territory of canals from Antwerp to Moerdyk and from Antwerp to Ruhrort. These canals are obviously intended to deflect part of the Rhine trade from its natural course down the river to Antwerp; a plan which is naturally deeply resented in Rotterdam. It is argued further that the treaty would not eliminate all matters for dispute between the two countries; but that it contains the germs of endless new quarrels. Furthermore, the Flemings, who play an increasingly important part in Belgian political life, are friendly towards Holland and will, it is hoped, understand her refusal to be bound by arrangements made during the ascendancy of the *Comité de politique nationale*, although at the same time the interests of Antwerp, the Flemish metropolis, are very particularly involved. Certain points were discussed afresh between the two governments, and at least interpretative concessions on the part of Belgium were expected.

Domestic History Since 1910.—In 1907, for the second time in the century, a Cabinet was formed out of the coalition of the parties of the Right, that is, of the two Protestant parties, the Anti-Revolutionaries and the Christian Historicals, and the Roman Catholic party. This coalition, which may at first sight appear an unnatural one, sprang from the fact that Catholics and orthodox Protestants were equally opposed to the ruling Liberalism, and in particular to the educational system developed by the Liberals. Only the State's own schools, which were strictly "neutral" as regards religion, received grants of public money. The orthodox Protestants and the Catholics both complained that as taxpayers they had to help in supporting schools to which conscience forbade them to send their children, while as parents they had also to maintain their own private denominational schools. This situation at length, and in spite of the traditional enmity between the two creeds, led to a coalition of the Calvinist parties and the Roman Catholic party.

In 1910 Dr. Abraham Kuyper formed the first Coalition Government. Himself a Calvinist, chief of the anti-revolutionary party, he succeeded in finding "one root of faith" from which both Catholics and Protestants sprang, and divided the Dutch nation into "Christians" and "Paganists." But the political situation in 1907, when the second Coalition Govt. was formed, did not permit Dr. Kuyper's strong personality to be included, and when in 1909 the general election led to further disaster for the Liberals he nevertheless remained discarded. Mr. Heemskerk was the leading member of this Government, which was somewhat too moderate in its religious policy for the more fanatical Kuyperians, whose zeal for social reform was gratified by the grandiose scheme for state disability and old age insurance on which the Minister of Labour, M. Talma, worked strenuously. The scheme, however, had not yet been carried into effect when the defeat of the Coalition at the polls in 1913 hung it up indefinitely.

The parties of the Left proved unable, in 1913, to assume the responsibilities of government. The once powerful Liberal party was now broken up into several sections, of which one was really anti-clerical conservative, while another was radical. Moreover, the Socialist party, which made a big advance in 1913, now claimed a large proportion of the forces of the Left, and there was little sympathy between it and the so-called Old Liberals. An attempt was made, nevertheless, to form a coalition of the

[1] See H. W. V. Temperley, *History of the Peace Conference in Paris*, vol. ii., pp. 192 *seq.* (London, 1920).

[2] In spite of the signature of the Convention, neither side abandoned the original contention with regard to the Wielingen Channel, the Belgians basing their claim on the three-mile limit, the Dutch on ancient rights of possession.

Left, under Dr. Bos, the Radical leader, on a programme that included universal suffrage. The Old Liberals agreed to this programme, but the Socialists, although their leader, Mr. P. J. Troelstra, was in favour of accepting, refused to co-operate.

In this difficulty an extra-parliamentary Cabinet was formed by Mr. Cort van der Linden. In conformity with the verdict of the electors it bore a decidedly "Left" character, but it attempted to find final solutions for both the questions which had long paralysed Dutch political life. Mr. Cort van der Linden and his colleagues proposed to bring about a revision of the Constitution (for which purpose a two-thirds majority of the Chamber is required) by an agreement of all parties. In it the Clerical groups would find the solution of the school problem and the Liberals, Radicals and Socialists the final extension of the suffrage.

Although faced with the problems arising out of the World War, the Government persevered with this task, and indeed the quickened sense of national solidarity helped it rather than otherwise. In 1917 its programme was carried out. Universal suffrage and proportional representation were introduced; at the same time, the principle of absolute equality with regard to the public exchequer of "public," undenominational or a religious education and "private" denominational education, was conceded in full and written in the Constitution.

The first elections held under the new suffrage law (June 1918) resulted in further disaster for the Liberal groups. The Cort van der Linden Administration resigned and another Calvinist-Catholic Cabinet was formed. The Premier, Mr. Ruys de Beerenbrouck, was a Catholic, a thing without precedent in Dutch history. This Government's mandate was confirmed by the elections of 1921, when the Coalition parties increased their number of seats to 60 out of the 100 which constitute the Second Chamber. At the elections of 1925 they lost some ground, but still retained the majority, and when Mr. Ruys retired, Mr. Colÿn, leader of the Calvinist anti-revolutionary party, formed another Coalition Cabinet. In Nov. 1925 internal disagreements compelled that Government to resign. Each of these elections since proportional representation came into force meant a further stage in the disintegration of the Liberal parties, of which only the Radical group held its own. The Socialists, on the contrary, made a big advance in 1918, and although they suffered a setback in 1921 they more than retrieved their fortunes in 1925. They then numbered 24 members and were the second largest party in the Chamber after the Catholics with 32. The 1921 election was the first at which women's suffrage was in full working order. Six out of the 100 seats were occupied by women in the Chamber of 1925.

The years of Coalition Govt. through which Holland passed after the Armistice can be divided into two very distinct periods. The years 1919 and 1920 were feverish ones, when a fallacious sense of prosperity stimulated enterprise in business and politics alike. It is not perhaps unfair to connect the zeal for social reform which characterised those days with a certain nervousness which remained after the "November days" of 1918. Mr. Troelstra, the Socialist leader, his imagination fired by the spectacle of the German revolution, toyed with the idea of imitating it among his own people. The attempt was a ludicrous failure. The Government took strong measures and the people rallied to them, and after an excited week quiet was restored on Nov. 21 1918. The Socialist party, which had been far from unanimous about this adventurous policy, re-entered the path of constitutionalism, and Mr. Troelstra, who resigned the leadership in 1925 owing to ill-health, never regained his old prestige. Yet the affair probably helped to create the spirit in which the Government tackled social problems. Mr. Talma's insurance scheme, of which the Cort van der Linden Cabinet had carried out only a small part, was taken up again, and in Dec. 1919 a comprehensive Disability Insurance Act was passed. Large sums of money were voted in aid of building societies and building schemes of municipal bodies. Not only were housing conditions greatly improved, but as architecture has again become a living art in Holland, and the best architects were called in, the new quarters of many a Dutch town afford fine examples of modern building, and have been studied and admired by the experts of other countries. A piece of legislation with which Holland was in advance of all other countries was an Act restricting the hours of labour to 45 a week.

But the fictitious prosperity was succeeded by a severe depression. Shipping and shipbuilding particularly felt the effects, and no place suffered more from the occupation of the Ruhr area and from the preference granted by France to her own and Belgian commerce than the great port of Rotterdam. When international conditions improved in 1924, economic conditions in Holland soon felt the effect. Yet unemployment remained still a drain on Dutch resources. The one really bright spot in the picture was the prosperity of the East Indian "cultures."

Meanwhile, the stress of the times occasioned a radical change in the Government's policy. Economy came to be the cry. The building subsidies were cut down. In order to enable Dutch industry to compete with the countries with debased currencies, dispensations from the Act restricting the hours of labour were freely granted. On yet another point a revulsion of feeling manifested itself against legislation passed almost without opposition a few years previously. The new Cabinet of the Right had to carry into practice the general provision of financial equality for denominational education which their predecessors had written into the Constitution. It was now felt that the multiplication of small State-subsidised schools, which resulted from Dr. De Visser's (the Minister of Education 1918–25) measures, overburdened the taxpayer.

During the years 1922–4 Dutch politics centred round the financial situation. In the early summer of 1923 the Government strengthened itself with a new Minister of Finance, Mr. Colÿn, who two years later was to succeed Mr. Ruys in the premiership. Mr. Colÿn, a strong personality, was expected to carry out a programme of ruthless economy. All salaries paid by the State were indeed cut down by one-fifth, a measure which naturally occasioned a good deal of discontent. Socialist and Radical critics complained that economies in other directions were neglected, while at the same time, by the raising of the general import tariff from 5 to 8% *ad valorem*, the introduction of a tax on bicycles (which are more numerous in proportion to population in Holland than in any other country), and the raising of the duty on tobacco, the burden of taxation borne by the mass of the community was not inconsiderably increased. The object of Mr. Colÿn's policy, at all events, was reached: in the course of 1925 the budget was balanced. An improvement in the yield of direct taxation, as a consequence of the economic revival, contributed towards this event.

In spite of this success, Mr. Colÿn's Govt. soon was unable to carry on. It was freely predicted at the time that the elimination of the education grievance would soon bring about the dissolution of the Coalition, and that thus the way would become clear for a more natural grouping of parties on economic and political lines. In Oct. 1923 it was thought that the knell of the Coalition had been sounded when 10 Catholics joined the parties of the Left and the bill for the strengthening of the naval defences of the Dutch East Indies, which the Government, in spite of their zeal for economy, and in spite of the effect which the Washington treaties might be supposed to have on the situation in the Pacific, considered indispensable, was rejected in the Second Chamber by 50 to 49 votes (Oct. 26 1923). After a crisis of several months, however, the Coalition was patched up and the elections of June–July 1925 were fought on the old lines. Mr. Colÿn formed a new Government in July. The new crisis was occasioned by a question of far less intrinsic importance, but more serious as a sign of the progressing disintegration of the Coalition.

In spite of the prolonged comradeship in office, one at least of the two Protestant parties, the Christian Historical party, never ceased to look upon the Roman Catholics without a certain watchful suspicion. Of late years, owing to their excellent organisation and also to their constant participation in the government of the country as a consequence of the Coalition,

the growth of Catholic influence and self-confidence, which started in the 19th century, had been accelerated, inducing a certain uneasiness and irritability in Protestant circles, which the Christian Historical party, for all its loyalty to the Coalition, could not ignore. In those circumstances a motion, introduced by an independent Christian Historical member of the Chamber, to abolish diplomatic representation at the Vatican, which had been introduced during the War by the Cort van der Linden Govt., assumed an importance quite out of proportion to its intrinsic merits. The whole Christian Historical party voted for it, and the motion was carried. The Liberals, Radicals and Socialists, while caring little for the question itself, had voted for the motion in order to show up the unreality of the Coalition. The Catholic Ministers in Mr. Colÿn's Cabinet resigned on Nov. 11 1925, and the next day the Premier offered the resignations of himself and all his other colleagues.

Co-operation between the Christian Historicals and the Roman Catholics had now become exceedingly difficult, but the hopes of those who wanted to see the Coalition give way to a new grouping of parties were disappointed. Radicals and Socialists have long aspired to an alliance with the Catholics, among whom democratic tendencies are strongly, although by no means exclusively, represented. An attempt (Nov. 24–Dec. 1 1925) on the part of the Radical leader, Mr. Marchant, to form a democratic Ministry, however, met with a unanimous refusal from the Catholics, in spite of Mr. Marchant's offer to rescind the vote against the Vatican legation. The result was that Dutch parliamentary politics appeared to have reached an absolute deadlock. After a crisis of unprecedented duration, Jonkheer de Geer, therefore, on March 3 1926 formed a non-parliamentary Cabinet with a programme of all-round economy, including reductions in the army and navy and productive state works for the unemployed. He announced his intention of resigning as soon as a parliamentary majority had been formed.

II. ECONOMIC AND FINANCIAL DEVELOPMENT

Although Holland remained neutral during the World War, the War itself and the subsequent years left their impress upon its economic and financial development. Some of these influences were of a temporary nature, such as the effects of the crisis of 1920–1 upon Dutch economy. The permanent changes chiefly regarded public finance. In the economic sphere the War accelerated the expansion of national industries and the process of banking concentration. The foreign capital holdings of the people were affected by the loss of Russian securities, representing an estimated value of £100,000,000, and by the realisation of a considerable number of American securities. Against these losses, there was a large increase in the extent and value of the Dutch capital invested in the Dutch Indies, and further a large increase in internal investment within the country.

Population.—The War had little effect on the growth of the population, which increases by approximately 100,000 per annum, a relatively high figure as compared with other countries, the result of a persistently favourable birth-rate (24·1 per 1,000 in 1925) and an extremely satisfactory death-rate (9·6 per 1,000 in 1925). It was only in the influenza year 1918 that the death-rate increased to 17·2 per 1,000. The population was 5,945,115 in 1910; 6,865,314 in 1920; and approximately 7,400,000 in 1925.

Agriculture.—A sound adaptation of the various branches of agriculture and cattle-breeding to the nature of the soil, the advantages of cultivation by the individual owners and an increasingly marked preponderance of small holdings, favourable market facilities and technical skill stimulated by co-operation and State encouragement—all have contributed to the development of agriculture.

The home production was only 154,000,000 kg. of wheat or about 21·8% of the total consumption (708,000,000 kg.); on the other hand 32·5% of the total output from dairy-farming was available for export. After the War the export trade recovered quickly. Exports of butter, which had ceased entirely during the last years of the War, attained their pre-War figure in 1924 (£5,800,000); cheese exports actually increased threefold (£6,200,000); whilst meat exports during the same year amounted to £6,300,000 or 30% more than in 1913.

Industry.—A number of new industries are increasing in importance, for example, the chemical and electric lamp industry. The first blast furnace was started at Velzen near the North Sea coast. The coal mining industry, whose beginnings date from the end of last century, now satisfies two-thirds of the requirements of the country. The output of coal rose from 300,000 tons in 1900 to 1,000,000 tons in 1910 and 6,800,000 tons in 1925. An approximate idea of the industrial position in 1923 can be derived from the statistics of production.

	Yield of the various branches of industry in Holland £
Foodstuffs	25,000,000
Textile industry	20,800,000
Metal industry	19,600,000
Luxury articles	8,300,000
Clothing and boots	5,400,000
Wood industry	5,200,000
Chemical industry	5,200,000
Miscellaneous	18,800,000
	£108,300,000

The value of the total agricultural output in this year was £87,900,000.

The unemployment figures showing the percentage of workers unemployed among trade unionists give an idea of the general economic situation in recent years. Whilst in 1913 the highest figure was 8·8 (Dec.), the summer average 4·1 and the winter average 8·0, the corresponding figures for 1924 were respectively 19·7 (Jan.), 5·8 and 10·5. Generally speaking the highest level was reached in 1923. Since then the figure has fallen, but was still unsatisfactorily high in Dec. 1925—13·8.

Trade and Shipping.—Trade statistics were reorganised and improved in 1917. As a result, however, no comparison of figures of values is possible while even figures of quantities before 1917 can only be used with great reserve.

	1913	1925
	kg.	kg.
Imports	21,302,000	25,500,000
Exports	5,848,000	12,336,000

The direction of Dutch trade has changed considerably:—

	Germany		England		United States		Belgium		France		Dutch East Indies	
	1913	1925	1913	1925	1913	1925	1913	1925	1913	1925	1913	1925
Imports	28·9	24·2	8·7	15·9	1·31	11·2	9·01	11·1	0·8	4·4	3·5	5·6
Exports	27·9	25·9	22·2	25·9	3·9	3·8	11·0	9·0	1·0	4·7	5·3	7·4

(The figures represent percentages of the total)

The system of virtual free trade—duties of 5% being levied on a number of "finished articles"—remained practically unchanged during the War and even during the subsequent period of currency disorder in several states of Europe; only in the case of the shoe and cigar industries special temporary prohibitive measures were introduced with a view to restricting dumped imports. The tariff was increased to 8% on July 1 1925, and the list of dutiable commodities was somewhat extended, principally on revenue grounds. In 1925 47% of the total exports of £146,200,000 consisted of foodstuffs and 35·7% of manufactured goods. The total imports in that year amounted to £204,200,000.

The importance and development of shipping can be gauged from the following figures for ocean-going shipping in the port of Rotterdam:—

Loaded ships, net tonnage registered: 1900	5,452,000
Loaded ships, net tonnage registered: 1910	8,898,000
Loaded ships, net tonnage registered: 1913	11,638,000
Loaded ships, net tonnage registered: 1925	13,903,000

The amount of Dutch high-seas shipping in 1925 was 1,319,534 net tons registered, so that Holland took the seventh place in the high-seas shipping of the world, being only surpassed by Norway in the tonnage per head of population. In 1913 the tonnage amounted to 687,635, and Holland then also stood seventh on the list.

The Monetary System and Banking.—The following figures show the extent of banking transactions:—

	1913	1920	1924
Capital and reserves	£ 12,600,000	£ 37,700,000	£ 82,400,000
Other assets . .	32,200,000	133,300,000	83,200,000
"Debtors" . .	15,600,000	75,900,000	47,900,000

Throughout this period the Dutch guilder (florin), thanks largely to the policy followed by the Netherlands Bank, maintained its position as one of the highest-valued currencies of Europe. The gold standard was officially re-introduced on April 28 1925 when the prohibition on the export of gold was cancelled. On the same day similar steps were taken by Great Britain and by the Netherlands East Indies. The amount of bank notes in circulation at the end of 1925 was £72,900,000, as against £25,900,000 at the outbreak of the War. The gold reserve increased during the same period from £13,000,000 to £37,000,000. In addition to the bank note circulation the "giro" systems of transfer through the intermediary of the Netherlands Bank and of the Post Office are becoming increasingly important. But the cheque and clearing system of the large banks has not developed much in Holland.

State Finances.—Before the War the state finances were satisfactory. The total of "ordinary" expenditure had increased from £12,400,000 in 1900 to £16,400,000 in 1910 and £18,300,000 in 1913. The increase is evidence of the tendency in Holland, as elsewhere, towards increased state activities: but it should be remembered that the general rise in prices during the period 1900–13 amounted to 16%, and the increase in population to 19%.

The position of the Dutch public debt was very satisfactory before the War. In 1840, after the end of the war with Belgium, it amounted to approximately £117,000,000. By Jan. 1 1914 it had fallen to £95,700,000, although large public works (railway construction) had been undertaken in the interval. The war and subsequent years made very high calls upon the state funds. Mobilisation cost £101,400,000; the supply of the population with material necessities during the War—the system of distribution involved subsidies from the public funds—cost £47,100,000; and the housing subsidies which were charged against the extraordinary budget cost £54,700,000. The ordinary expenditure also increased considerably as a result of increased state activities and rising prices: the highest figure reached was £52,700,000 in 1924. The deficit for the period of crisis, which terminated in 1924 as far as the state finances are concerned—after deduction of such exceptional taxation as the tax on war profits—was £183,500,000. Of this amount £175,000,000 have been funded. Although the sinking fund continued to operate in the interval, the debt rose to a record figure on Jan. 1 1925 with £244,100,000, falling to £239,300,000 on Jan. 1 1926. The ordinary expenditure for both 1925 and 1926, which can again be regarded as normal years, amounted in round figures to £50,000,000 and is wholly being met out of the revenue. 36·2% of the total expenditure was met out of the proceeds of direct taxation in 1925 as compared with 23·7% in 1913.

The above-mentioned increase of expenditure is reflected in the position of the Treasury. Whilst before the War it was very rare for more than £4,000,000 to be required for Treasury needs, the floating debt amounted on Jan. 1 1922 to not less than £71,500,000 (consisting chiefly of Treasury bills). Against this amount there stood £40,000,000 of claims, composed for the most part of advances made to the colonies. It was only owing to the exceptionally liquid state of the money market that the State was able to raise such sums. The floating debt was reduced by Jan. 1 1926 to £25,500,000, owing to various funding operations undertaken in successive years; but against this figure there are claims of the State amounting to £24,100,000, mostly against foreign countries.

The burden of taxation—viz.: of all taxes, including those of the provinces and communes—increased from £3 5s. per head in 1913 to £13 4s. in 1921 (including tax on war profits), but had been reduced by 1924 to £7 12s. per head of the population.

	Index Numbers Wholesale Prices	Imports £ million for home consumption	Exports £ million of domestic produce	Netherlands Bank Yearly average

(G. W. T. B.)

NEUILLY, TREATY OF.—The Bulgarian Treaty was signed at Neuilly on Nov. 27 1919, and came into force on Aug. 9 1920. In the main it is the same as the Austrian Treaty. But there were important differences in the military and naval clauses, and also in regard to reparation and finance.

As regards the territorial clauses, the only serious changes were to the west and south. The Serb-Croat-Slovene kingdom obtained several strategic ratifications. The two most important are that the Strumitsa salient in the extreme south-west has been flattened out, the western half being ceded to the Serbs; also, and more important, in the Nish-Pirot area the town of Tsaribrod has been taken from Bulgaria and a line drawn whereby an advance on Nish would be rendered more difficult. The frontier, however, confers no offensive advantage on the Serbs, and is thus a sensible one. A loss more serious in another sense is that to Greece of the district of Western Thrace, lying between Xanthi and the Maritsa river. This was ceded to Greece on her obtaining Eastern Thrace and Adrianople. Bulgaria, for ethnic reasons, received a slight extension of territory west of Adrianople. The expulsion of Greeks from Adrianople and East Thrace by the Turks has, however, not caused the Allies to change their minds about Western Thrace, which remains annexed to Greece and is denied to Bulgaria. But, though these losses are humiliating to the pride of the Bulgars, it cannot be said that they seriously injure their strength or prosperity. Dedeagach, which she lost to Greece with the whole of Western Thrace, is really unsuitable as a port and also at a great distance from Sofia.

With the view of giving Bulgaria access to the Aegean, Veniselos offered, during the negotiations, to build a railway connecting the fine Greek harbour of Kavalla with the Salonika-Constantinople railway, which now runs to Sofia up the Struma valley, though with a break of gauge. This offer, though doubtless quite sincere, has never been acted upon, though in article 48 the Principal Allies undertake to ensure the economic outlets of Bulgaria to the Aegean Sea.

Bulgaria had always asserted claims to that part of Macedonia now in Serbian hands, and also to Eastern and Western Thrace. In the former area her ethnic pretensions are better founded than in the latter. But Serbian Macedonia is in the hands of a formidably armed and militarily strong nation. Greek Macedonia and Thrace are now populated by hundreds of thousands of Greek refugees from Asia, and contain over 80% of a purely Greek population. It would seem, therefore, that both districts are irrecoverably lost to Bulgaria, and that her strength must rest purely on her own resources. In population, she has only lost some 300,000 persons, of whom some are not Bulgars.

Part IV. The military, naval and air clauses have some special points. Bulgaria is allowed 20,000 regulars, 10,000 gendarmes and 3,000 frontier guards, or 33,000 in all. This number is insufficient to maintain order in a turbulent Balkan State, and the subsequent serious disturbances in Bulgaria are due directly to this fact. It is increased by the difficulty of applying the voluntary long-service system of 12 consecutive years to a nation of peasants. In an agricul-

tural country it is practically impossible to get men to leave their farms for 12 years, and the army is always likely to be dangerously below strength, and the less regular formations dangerously above it. The naval clauses do not differ from those of the German or Austrian Treaty. All Bulgaria's navy has now been destroyed, and she is left with four torpedo-boats, of which three are damaged, and six motor-boats, of which four are damaged.

Part V. (*Prisoners of War and Graves*) and .

Part VI. (*Penalties*) are the same as in the Austrian Treaty (*see* ST. GERMAIN, TREATY OF).

Part VII. (*Reparation*). This contains the most novel and interesting feature of the Treaty, and is, in fact, the only serious attempt to get reparation on to a business basis. It contained three features of great interest.

(*a*) Contrary to the practice in the German, Austrian and Hungarian Treaties, there was no attempt made to seize or distribute the Bulgarian commercial fleet on the "ton-for-ton" or "class-for-class" principle.

(*b*) It fixed the amount to be paid at the lump sum of £90,000,000.

(*c*) It created a Reparation Commission consisting of French, British and Italian representatives, with power to reduce this amount by a simple majority vote (not by unanimity as is the systematic rule), on the suggestion of the inter-allied Commission.

The general scope and powers of the Reparation Commission are drawn in such a manner as to control the finances of the country sufficiently to obtain reparation, without offensive interference. In the end, the Reparation Commission, after examining the question on the spot, has practically remitted three-quarters of the total of £90,000,000. The annual sum now required to meet the charges on the 550,000,000 gold francs of the debt is well within the capacity of the new Bulgarian State, and is being punctually paid. None of the remaining clauses of the Bulgarian Treaty have any special features of interest or importance.

Conclusion.—Viewing the Bulgarian Treaty as a whole, it is the fairest and most practical of all the Treaties imposed on the enemy Powers. There has been little diminution of territory or population, and no vindictiveness shown. Bulgaria was protected by the Principal Allies, first from occupation of her territory by Serbs or Greeks, next from the seizure and distribution of her commercial fleet, and finally from the financial anxieties and confusion consequent upon an unfixed liability, and from the difficulties of a too-powerful and too-obtrusive Reparation Commission. The reason is that the Principal Allies, while not strong enough to withstand the public demand for severity in the German, Austrian and Hungarian treaties, were strong enough to resist the Serb, Greek and Rumanian claims in the Bulgarian Treaty. The result is that Bulgaria is more relatively prosperous than any other ex-enemy state, and has been able to pay her liabilities without making the League her receiver and manager, like Austria and Hungary, or adopting a disguised form of this liquidation like Germany under the Dawes scheme. Bulgaria has shown herself more willing to accept new conditions, and it is not impossible that she may enter ultimately into some form of alliance with the Serb-Croat-Slovene kingdom. NEUROMUSCULAR SYSTEM (*see* 19.44).—Briefly, recent contributions have dealt largely with the anatomical nerve-supply of the striate (so-called "voluntary") skeletal muscular system, the discrimination of the different functions of muscle substance, and the integration of neural and muscular activity. From consideration of the action of the simplest neuromuscular unit, prosecution of the subject leads us by consecutive and logical steps to matters of deep interest and significance in relation to the function of the nervous system as a whole and to age-old questions such as the meaning of "the will." The problems of the neuromuscular system may be approached from various viewpoints; it is natural to commence with that of morphology.

Anatomical Considerations.—The striate skeletal muscular system is supplied by efferent motor nerves from the anterior or ventral horns of grey matter in the spinal cord; the course and distribution of these nerves, and, conversely, the representation of individual muscles in the nerve-cell groups of the anterior spinal horns, are all well known. When a motor spinal nerve enters a skeletal muscle at its so-called "motor point" its fibres divide up and ramify to the various component muscular fibres of the muscle, ending on these latter structures by "motor-nerve end-plates." According to the views of Langelaan, each motor nerve-fibril is in communication with the sarcoplasm of the muscle fibril which it is supplying.

In addition, however, to this accepted spinal nerve supply, close study has been given in the period under review to the question of a sympathetic nerve supply to the skeletal musculature (apart, of course, from the familiar sympathetic innervation of non-striped, visceral muscles). Suspected long ago by Ranvier and others, and held in more recent times by Fano, Botazzi and Pekelharing, the notion of the duality of nerve-supply to the "voluntary" muscles has been set on a firm histological basis especially by the work of Boeke, Kulschitsky, Dusser de Barenne, Agduhr, Hunter, Latham and a number of other investigators. Even so, we are still confronted with the question whether spinal and sympathetic motor nerve fibrils end in the same, or in different, muscle fibrils. On the determination of this point much will depend. While Boeke and others claim that both kinds of nerve end in the same muscle fibre, Hunter and his collaborators contend that as there is a double neural supply, so there are two distinct sets of muscle fibres, each having its specific function, and they maintain, in consequence, that each skeletal or "voluntary" muscle is anatomically and physiologically a couple, a doubled structural and functional unit, and that by experiment or by disease one of these may be destroyed and the other left. Their theories of muscle function are based on the histological claim that the actual innervation of muscle fibres is single, not dual, the sympathetic system sending its fibrils to muscle fibres *not* linked to the spinal motor system, that is, not furnished with spinal motor-nerve end-plates. In his most recent work, on the other hand, Langelaan takes the view that the sarcoplasm of one and the same muscle fibril is reached anatomically from *both* spinal and sympathetic sources, though he distinguishes the function of the two. Since the question has an obvious physiological bearing, it may also be approached from that standpoint.

Physiological Considerations.—Among the problems of the functions of muscle substance one has emerged more definitely in recent years as being of fundamental significance, viz., the relation of the function of contraction to that of maintenance of muscle tone. We owe largely to the work of Sir Charles Sherrington our current conceptions of muscle tone, according to which it is commonly understood as being that condition of contraction of a resting muscle which exists without "voluntary" innervation and is also present though the limb is passively supported, since the muscles do not then "sag" or hang flaccid. Tone gives a shape to muscles, and is in evidence both in resting (static) and in moving (kinetic) states of the musculature. Sherrington has shown that tone is in reality postural contraction, that is, it is a mild contraction of muscle-fibres produced reflexly by sensory excitations arising in peripheral sensory end-organs substantially those of the muscles themselves, the impulses passing therefrom by sensory paths to the spinal grey matter and back to the muscles by spinal motor nerves. This is he proprioceptive reflex arc of Sherrington, and interruption of it at any point is followed by loss of tone in the muscle concerned. In virtue of this reflex contraction, further, a muscle can adapt itself to its varying length; in other words, whether its fibres are as a fact in a shorter or longer anatomical state the reflex contraction is maintained. This property was described by Sherrington as "plasticity," whence the term "plastic tone."

Plasticity.—The exact sense in which the expression "plasticity" is employed is of importance, for others have understood it somewhat differently. When an ordinary nerve-muscle preparation is taken from such an animal as the frog it must by definition be absolutely toneless, since it is separated from the tone-maintaining proprioceptive arc, and cannot therefore exhibit that quality of tone described as "plasticity." In his recent communications, however, Langelaan states that the preparation, though contraction-less, possesses "plasticity," signifying thereby a property of having its form modifiable slowly by external force. Most physiologists and neurologists follow Sherrington in regarding "plasticity" as being a muscle property derived solely from somatic proprioceptive arcs in a condition of integrity.

Movement and Posture.—It is now commonly declared that a distinction is permissible between "contractile tone" and "plastic tone"; more especially during the last decade a hypothesis has gradually taken shape, to the effect that movement can be legitimately distinguished from posture, that these are subserved by different mechanisms, and that whether initiation of movement and maintenance of posture are "active" ("voluntary"), or "reflex" ("involuntary"), each is the expression of a neural activity different from that of the other. In respect of reflex activity, the form the hypothesis takes (according to the late Irvine Hunter, one of its chief supporters) is that "postural tone"—the mild postural contraction defined above as being of reflex proprioceptive origin—is in reality compounded of two subvarieties, acting together but distinct, viz., "contractile tone" and "plastic tone." When in response to suitable stimuli a muscle or muscular group in a limb contracts reflexly, that is, when the limb or a limb-segment changes from one posture to another, this is effected by the contraction of muscle fibres which are innervated by the spinal (somatic) nervous system; such fibres are considered to be responsible for "contractile tone," the tone that is in evidence during contraction. When, next, a posture reflexly assumed comes into being at the end of a reflex movement, that posture is held or maintained by the action of a different set of muscle fibres, whose postulated function, in Hunter's view, is to remain at a given fixed length, once movement of the contractile fibres has ceased, thus immobilising the muscle for as long as may be. These are thought to be responsible, therefore, for "plastic tone." At this point we revert to the considerations in the first section, since Hunter argues that it is the sympathetically-innervated fibres which develop "plastic tone," and the spinal fibres which underlie the manifestations of "contractile tone." Further, he states that the former are essentially *non-contractile;* he assumes their length is passively altered during the contractions of the contractile set.

Dual Theory.—The dual theory of the neuro-muscular system, as it may be termed, has had in recent years various other exponents whose views by no means harmonise with those of Hunter outlined above. Reference may be made to one or two pertinent considerations. Re-examination by Langworthy of Vulpian's phenomenon (1862) would seem to show the possibility of muscular contraction via the sympathetic nervous system. Langworthy has found that stimulation of the lingual nerve (containing bulbar autonomic fibres) leads to slow, wavy contractions of the tongue muscles after complete degeneration of the hypoglossal nerve end-plates by previous section of that nerve. It is more than doubtful, therefore, as regards Hunter's theory, whether *non-contractile,* sympathetically-innervated muscle fibres actually exist. Not a little can be said in favour of the view, however, assigning some function connected with the tension of muscular tissues to a sympathetic innervation, seeing that the actuality of a sympathetic supply to striped muscles cannot be gainsaid. Langelaan, for instance, considers that the sympathetic supply to muscle sarcoplasm maintains the latter in a state of appropriate tension such as to facilitate within it the passage of an innervating current of somatic motor-nerve origin.

Movement Analysed.—Other arguments go to show that a rigorous and schematic differentiation as between movement and posture can scarcely be sustained. Movement is in reality a continuous series of changes of posture, and Sherrington has demonstrated that no clear-cut distinction can be drawn physiologically between reflexes of posture and reflexes of movement. From still another standpoint, experiments with the string-galvanometer have proved that an action-current exists in a healthy muscle when at rest and in a state of normal tone, and that no *qualitative* difference can be detected between it and the action-current when the same muscle is either actively ("voluntarily") innervated or passively moved (Von Weizsäcker, Wachholder, Mann and Schleier). Such data favour the view that tone and contraction are identical and that no fundamental or essential distinction is to be drawn between them; and they militate against any conception of neuromuscular activity which entails the existence of completely separable neural mechanisms for posture and for movement.

Automatic Action.—A second aspect of the problem furnished by the activities of the neuromuscular system concerns reflex or automatic action. Speaking generally, "voluntary" action has always been thought, for seemingly cogent reasons, to contrast specifically with "involuntary" action. The experimentalist and the clinician have long been familiar with so-called spinal automatisms, with co-ordinated grouping in action of neuromuscular units, forming a "pattern" which has an apparent meaning or purpose. In the "spinal animal," for example, following transection of the neuraxis at the level of the junction of medulla and spinal cord, numerous reflex activities can readily be demonstrated, of which the "scratch reflex" is a classical variety. Similarly, in suitable cases in man (of which the War furnished us with many instances) it is quite simple to demonstrate that the isolated spinal cord can live by itself and that it possesses capacities for activity in a co-ordinated form, primitive neuromuscular mechanisms usually hidden in health but capable of expressing themselves in the form of release-phenomena when the cord is separated by disease from higher physiological levels.

The apparently purposive character of many of these reflex activities (automatic emptying of the bladder, attempts at spinal walking or stepping, biologically old reflexes connected with the genital apparatus, etc.) is of considerable importance and significance, for they are entirely independent of conscious control and of intelligent guidance, since in the given circumstances (gunshot wounds of the cervical cord, experimentation) the cord with its neuromuscular patterns is physiologically severed from the brain. Thus muscular action of a strictly reflex kind, produced solely by appropriate stimuli at the same low physiological level, may, and does, exhibit outward characters which render the discrimination from "voluntary" action not a little arduous—as far, that is to say, as externals are concerned.

Neuromuscular Functions at Higher Levels.—Pursuing this line of investigation, the physiologist is led to examine the neuromuscular functions of the animal in which transection is performed at higher levels than the spinal. During the last few years a whole series of apparently purposive reactions superficially indistinguishable from combined movements of the order usually called "voluntary," have been demonstrated by Prof. R. Magnus, of the University of Utrecht, and his colleague, Prof. de Kleijn, and other collaborators, to occur in the higher animals through the agency of mechanisms that are purely and rigidly automatic. Magnus and de Kleijn's method has been to study the reflexes and reactions of the "spinal" animal; then to take the "midbrain" animal (transection at the level of the corpora quadrigemina of the mesencephalon) and observe what additional functions it is capable of executing; they next take the "thalamus" animal (separation from cerebral cortex and corpus striatum at the level of the internal capsule) and investigate its functions. They then argue for the localisation of the mechanisms underlying these respective additional functions within the corresponding limits of the respective additional areas of the neuraxis above the upper spinal cord. They have thus been able to demonstrate with precision that a large group of seemingly purposive movements, by which man and the higher animals balance their bodies, maintain normal postures and adjust themselves to forces disturbing equilibrium, are as a fact nothing else than reflex actions of ascertained neuromuscular mechanisms.

Static and Stato-kinetic Reflexes.—Under the former are included: (1) Standing reflexes. The head influences the posture of the body by means of tonic neck-reflexes acting on the limbs. When the position of the head in relation to the body is passively altered, specific corresponding changes take place in the attitude of the limbs. If the head is fixed in its relation to the body, and then its position in space altered, the musculature of body and limbs is correspondingly modified by means of tonic labyrinth-reflexes. (2) Eye reflexes of compensation. For each position of the head in space there is an appropriate reflex setting of the eyes in the orbits, effected both by tonic neck-reflexes and labyrinth-reflexes, acting on the eye musculature. (3) "Correcting" or "righting" reflexes. Animals whose midbrain is intact are capable of reassuming correctly a

normal attitude, through reflex action, from which they have been passively deflected. The machinery for this reflex "righting" is complex, there being at least four different sets of reflexes.

The discoveries of Magnus and de Kleijn have made a large addition to the long series of automatisms of which the physiologist has been cognisant. Into them no element of choice enters. Activities hitherto considered intelligent must be relegated to the category of automatisms, of reflexes, almost, indeed, of tropisms.

Cerebral Motor Cortex.—Finally, in respect of the cerebral motor cortex itself, recent investigations indicate that revision here also is required. Classifying in a general way as belonging to the "old motor system" the motor reactions of infracortical physiological levels (*cf.* supra), the neurologist has been in the habit of regarding as the "new motor system" that comprised in the electrically excitable motor area of the cortex with its corticospinal prolongation to the motor cells of the anterior cornua of the spinal cord. This corticospinal system (with its analogues) is usually understood to be the "voluntary" motor system and to exercise a controlling influence on infracortical motor centres. In some respects it is unquestionably the master system, yet in other respects this is no more than a *façon de parler*. The writer has shown (Croonian Lectures before the Royal College of Physicians of London, 1925) that many of the "involuntary" movements of diseased conditions, *e.g.*, those of chorea, are as a fact identical in all essential respects with "voluntary" movements of cortical origin, except that the patients' "volition" neither initiates nor is able to inhibit them. They constitute cortical reflexes, the expression of activity of neuromuscular mechanisms whose anatomical site reaches to the cortex and which are nevertheless outside "volitional" control. Other recent work points in the same direction. Monakow, for example, has come to the view that the function of the pyramidal areas seems to be in the class of reflex activity. Lashley, who has done much experimental work on cerebral function, concludes that the conception of "volitional" activity is too vague to have any scientific value, while years ago Hughlings Jackson taught the neurological world that, in respect of movements, "voluntary" and "automatic" were not terms of differentiating quality, that gradations existed between the two, and that the progression is in reality from "least automatic" to "most automatic."

Conclusions.—The conclusion from this very brief survey of recent developments in the field of the neuromuscular system cannot, however, be expressed in any definite form. On the one hand, some will hold that these accretions to knowledge widen the gap between intelligence and automatism, even though they appear to bring that gap higher up in the scale of motility. Others will argue that if some part, at least, of cortical motor activity is shown to be "non-volitional," then "volition" is driven further back, physiologically, to a transcortical level, and that it can be little else than transcortical inhibition.

(S. A. K. W.)

NEUVE CHAPELLE, BATTLE OF.—The German failures at Ypres in Oct.–Nov. 1914 had caused them to alter their strategy. They abandoned the effort to obtain a decision in the west, adopting a defensive attitude there, and concentrated their strength on crushing the Russians, who were isolated, short of equipment and munitions, and in consequence unable to utilise fully their vast resources in men. In the west the Germans could profit by all the factors which so greatly favour the tactical defensive in modern warfare, barbed wire and machine-guns in particular; they could hold their lines lightly and yet keep occupied Allied forces much stronger than their own.

The Allies, to whom the expulsion of the Germans from France was an urgent necessity, economically as well as politically, were impelled to pit themselves against the German defences before adequate measures could be devised for neutralising the special sources of the defensive's strength. In selecting the locality of their attacks they were directed to Artois by the fact that the German lines in Artois covered the main railways by which the German armies on the Western Front were supplied at their most vulnerable point, the plain of Douai. A break through in Artois therefore offered special advantages.

The Various Plans.—While the winter months saw incessant local fighting, at the Allied Headquarters more ambitious projects were being contemplated. Neither Sir John French nor Gens. Joffre and Foch would admit that the German lines could not be broken, and both entertained hopes of a substantial strategic success. Joffre's chief project was the recovery of the Lorette and Vimy ridges as a preliminary to an advance in force into the plain of Douai. Sir John French was particularly keen on recovering the Aubers ridge and so getting his right centre out of the water-logged Lys valley; success here, moreover, would threaten the German hold on Lille and might open the way to effective co-operation with French operations nearer Arras. Actually, owing to the diversion to the Dardanelles of the 29th Div. which had been earmarked for relieving French troops at Ypres, the first serious offensive of 1915 was undertaken by the British alone, the French X. Army being unable to co-operate unless this relief could be carried out.

Opening of the Attack.—The British offensive took the shape of an attack on Neuve Chapelle, where a nasty salient had been driven into the British line when the Germans captured that village in Oct. 1914. To recapture Neuve Chapelle would greatly improve the position tactically, and might lead to gaining a foothold on the Aubers ridge, an indispensable preliminary to any major operation on the I. Army's front. The attack delivered on March 10 began well. The Germans, far from expecting it, had thinned their forces opposite the British and had only three battalions on the frontage attacked. The bombardment had been effective and, except on the extreme left, the wire was well cut. The centre of the attack reached and captured Neuve Chapelle without much difficulty, but the uncut wire on the extreme left held up the flank of the 8th Div., which only secured its final objective after several hours' delay. On the extreme right also one battalion of the Indian Corps lost direction and found itself separated from the rest by a stretch of untaken trenches in which Germans were resisting. Here also there was delay, and the diversion of supports and reserves to help overcome the obstacle.

Meanwhile the centre was held up until the flanking brigades could get up level, though had it pressed on at once, regardless of its exposed flanks, it seems doubtful if there was anything at hand to stop it. But it was considered essential that there should be no advancing with unprotected flanks and the centre had to wait. When at last the flanking brigades came up, the opportunity had gone, for sufficient German reinforcements had arrived to man the redoubts in their half-finished second line. On the right two Gurkha battalions reached the Bois de Biez about nightfall, but being too much in advance of other troops were withdrawn, and on the left the leading brigade of the 7th Div. passed through the 8th, but too late to make much progress before darkness stopped its advance. One main cause of delay had been difficulties in transmitting accurate information from the front line to the higher commanders and in forwarding orders back to the front; another was the holding back of reserves until the situation was accurately known.

Second and Third Days.—Next day (March 11) saw efforts made to push on, but with little success. Mist hindered the observation of artillery fire, the interruption of communications with the front line hampered co-operation between artillery and infantry and caused much of the precious ammunition to be ineffectively expended. German reinforcements arrived in sufficient numbers to secure the second line and even to counter-attack in force early on March 12. There was very heavy fighting, ending in the repulse of the Germans with great slaughter, and the 7th Div. profited by this chance to storm a strong redoubt north-east of Neuve Chapelle. Elsewhere, however, no progress could be made and on March 13 it was decided to suspend the attack. The advantage of surprise was lost, the Germans were

[1] It was calculated that in May 1915 the Germans had under 2,000,000 men on the Western Front, a force considerably inferior to the French alone, while the British then numbered nearly 500,000.

now in force on the front, the ammunition expenditure had exceeded expectations and used up the available supply.

Sir Douglas Haig was anxious to renew the offensive without delay and to recover the advantage of surprise by attacking at a new point. Unfortunately, the ammunition shortage forbade this and postponed any renewal till a fresh reserve had been accumulated, and the delay allowed the Germans to strengthen their defences greatly, and remedy defects in them which the battle had revealed. (*See* WORLD WAR: BIBLIOGRAPHY.)

(C. T. A.)

NEVADA (*see* 19.450), a State of the United States of America. The population in 1920 was 77,407, a decrease of 5·5% compared with 1910 as against an increase of 93·4% for the preceding decade. The native white population in 1920 numbered 55,897; foreign-born whites 14,802; Indians, 4,907. The density of population in 1920 was 0·7 per square mile. The urban population (in places of more than 2,500 inhabitants) was 19·7% and the rural 80·3 per cent. Reno, with a population of 12,016, an increase of 10·6% over 1910, was the only town having more than 5,000 inhabitants.

Agriculture.—The number of farms in 1920 was 3,163. The value of farm property increased in 1910–20 from $60,399,365 to $99,779,666. The value of crops more than doubled between 1915 and 1920, largely owing to higher prices. Since 1919 the value of agricultural products has surpassed that of mineral production. Sheep and cattle are Nevada's chief assets. The average wool clip from about 1,000,000 sheep is 7,500,000 pounds. The chief crops are hay, potatoes, wheat, barley and corn. Turkeys are raised, and cantaloupes (melons) are grown extensively on the Truckee-Carson Irrigation Project, while dairy-farming is the chief industry near Reno.

The better utilisation of the water supply for irrigation and power is one of the most pressing needs, as the old laws gave vested rights in water to those who used it for irrigation; but marked progress has been made, through court decisions, in the adjustment of water rights for the Truckee, Humboldt, Carson and Walker river systems. The next step is the development of storage projects, of which the Newland Irrigation District is the first unit. The Walker River Irrigation District is a state project which has reclaimed over 150,000 acres. An appropriation was made by Congress in 1925 for the Spanish Springs Reclamation Project, near Reno.

Minerals.—From 1907 metal production steadily increased until it reached its peak in 1917, in which year gold, silver, copper, lead and zinc were produced to the value of $54,424,580. From 1918 to 1921 production steadily decreased, the decline of 1919 being more than 50% of the figure of 1918. A further fall took place in 1919 and again in 1921, in which latter year the mineral output was only valued at $12,137,000. Increased operating costs and low prices for metals because of accumulated war stocks, together with exhaustion of ore and scarcity of labour, were the prime causes. The Pittman Silver Purchase Act of Congress kept the silver industry in better condition until the expiration of the Act in June 1923. In 1922 the output increased in value to $18,374,023; in 1923 and 1924 metal production again showed an increase, reaching about one-half the normal output.

Production for 1924 was valued at $23,800,000 and the output gradually improved, the production of base metals—copper, lead and zinc—becoming the most important. Nevada contains valuable tungsten deposits which were not at first profitably worked because of foreign competition, but which, in 1925, were advantageously operated in several places. Other minerals commercially developed are quicksilver, antimony, manganese and platinum. The production of non-metals, such as gypsum, borax, lime, fluorspar, diatomaceous and fuller's earth, alum, potash, sulphur and other rock products has increased. Large quantities of pure rock salt exist. A shale-oil plant near Elko produces oil and a large number of by-products. Opals and turquoises of value are mined.

Industries.—Manufacturing industries are of little importance. The value of all manufactured products increased by 77·5% between 1909 and 1919, but the value added by manufacture in 1919 showed a decrease from 1914 of 5·7%, due to the decrease in the smelting and refining of copper. The most important works are for grist, flour, dairy products, the making and repairing of cars and the smelting of ores.

Transport.—Since 1910 the Western Pacific Railroad has acquired a part of the Nevada-California Oregon line and has altered it to broad gauge, thus making connection with Reno. In 1925 a new line was completed from the Idaho line to Wells, where it connects with the Southern Pacific and the Western Pacific. In 1924 there were over 2,000 m. of railway in the State. The Las Vegas and Tonopah Railway discontinued operation from Beatty to Las Vegas in 1918: the Legislature of 1919 designated the line as part of the State highway system, and the Highway Dept. converted the road bed into a modern highway. Between 1916 and 1925 Nevada expended over $7,000,000 on road building.

Government, Education and Finance.—State social service has been extended through numerous commissions and a few new departures, such as the industrial school and the grant to the Florence Crittenton Home. Nevada was one of the first States to have industrial insurance. Counties are permitted to arrange for mothers' pensions and old-age pensions. An extensive building programme for state institutions was begun in 1917, and included new prison and asylum buildings, a Heroes' Memorial Building, additions to the Orphans' Home and the Nevada School of Industry and several new buildings at the University of Nevada.

State recreation grounds are being developed on the sites of the prehistoric cities in Clark and Nye counties, at the Chloride Cliffs near Beatty, at the Lehman Caves and other points of interest in White Pine county, and at the Valley of Fire in southern Nevada. Illiteracy, mainly among the Indian population, was reduced from 6·7% in 1910 to 5·9% in 1920. In 1924 there were 319 elementary public schools and 46 public high schools in the State. The bonded debt on Jan. 1 1925 was $1,660,000, and state-owned bonds had a value of $3,055,357. The total assessed value of taxable property in 1924 was $201,292,000.

History.—In 1912 the Progressive party polled a vote second to that of the Democrats. The Democratic party continued in undivided power until the election of 1920 gave many important offices to Republican candidates. Emmet D. Boyle, Democrat, was elected governor in 1915 and was re-elected in 1919. James G. Scrugham, Democrat, was elected to the same office in 1923. The most important amendments to the constitution of Nevada were those of 1911 and 1913 for the recall and for female suffrage. A state prohibition law was enacted, pursuant to a direct vote of the people cast Nov. 5 1918. The legislature ratified the 16th Amendment (income tax) to the Federal Constitution in 1911, the 17th (direct election of senators) in 1913, the 18th (prohibition) in 1919 and, in 1920, the 19th (woman suffrage).

(J. E. W.*)

NEVILL, LADY DOROTHY FANNY (1826–1913), British writer, was born in London April 1826, the daughter of Horatio Walpole, 3rd Earl of Oxford. She married in 1847 Mr. Reginald Henry Nevill (d. 1878), a grandson of the 1st Earl of Abergavenny. She travelled widely, and had a very large circle of acquaintances, including Disraeli, of whom she was a great admirer, Richard Cobden and Joseph Chamberlain. She was noted for her amusing conversation and powers as a hostess, was a member of the first committee of the ladies' branch of the Primrose League, and was the author of various volumes of entertaining reminiscences; *Reminiscences of Lady Dorothy Nevill* (1906); *Leaves from the Notebooks of Lady Dorothy Nevill* (1907); *Under Five Reigns* (1910); *My Own Times* (1912). She died in London March 24 1913. Her daughter, Meresia Dorothy Augusta Nevill (1849–1918), was born Dec. 14 1849 and was also a devoted and energetic worker for the Primrose League. She died in London Oct. 26 1918. The *Life and Letters of Lady Dorothy Nevill* (1919), were edited by her son Ralph, author of *Sporting Days and Sporting Ways.*

NEWARK, N.J., U.S.A. (*see* 19.460), began in 1914 to develop its waterfront on Newark Bay as a shipping terminal and industrial centre. About 1,100 ac. of meadow land on the west shore of the bay were bought, an approach channel was dredged from the government channel in the bay, which leads out through the Kill van Kull into New York Bay, and the adjacent land was reclaimed: On the entrance of the United States into the World War in 1917 the War Dept. leased 133 ac. of the newly filled land for one of its largest army supply bases, spending $12,000,000 on docks, warehouses and equipment for handling freight; and the U.S. Shipping Board established here a $30,000,000 shipyard, employing 17,000 workers, where 150 steel cargo vessels were constructed by the Submarine Boat Corporation. At the close of the War the army base (including nine warehouses with 2,000,000 sq. ft. of floor space) became a commercial terminal, and the city resumed its original programme. With aid from the Federal Govt. the channel was deepened to 31 ft. and widened to 400 feet. Additional land was reclaimed, making available over 200 industrial sites.

The aggregate value of the products manufactured within the city limits was $201,888,000 in 1909; $577,609,000 in 1919; $336,809,458 in 1921; and $448,172,394 in 1923, when there were 1,863 plants, with 70,056 wage-earners. The leading industries, measured by value of output in 1923, were electrical machinery, apparatus, and supplies, leather, jewellery and chemicals. Ninety new factories were established in the Newark industrial district in the year ending Oct. 1 1925. Important improvements in the city's equipment include the public service terminal at Park Place, opened for street railway operation April 30 1916; a trunk sewer, constructed in co-operation with Paterson and 13 other municipalities, to collect the sewage of towns in the Passaic valley, carry it across Newark Bay, and discharge it in upper New York Bay; doubling of the water supply by development of the Wanaque watershed, a new public market and a city stadium, seating 12,000. A magnificent group of bronze statuary, "The Wars of America," by Solon Borglum was placed in Military Park in 1925. At a special referendum election held Oct. 9 1917 the commission form of government was adopted. Population (1910), 347,469; (1920) 414,524, of whom 16,977 were negroes and 117,549 foreign-born; (1925), according to Census Bureau estimate, 452,513.

NEW BEDFORD, Mass., U.S.A. (*see* 19.462), took first place in 1919 in the manufacture of cotton goods, as measured by value ($177,058,520), ranking above Fall River. The aggregate value of all its manufactured products rose from $53,238,000 in 1909 to $210,773,000 in 1919; dropped to $110,014,358 in 1921; and rose to $149,998,694 in 1923. The number of wage-earners in factories was 26,566 in 1909; 41,630 in 1919; 37,917 in 1923. The population increased to 121,217 in 1920; but in 1925 was 120,494 according to the Massachusetts state census, indicating that the loss during the period of depression had not yet been recovered. The proportion of women and children employed was exceeded in 1920 only by Washington and Fall River respectively. Housing conditions, severely taxed during the War, were studied by a special commission in 1919. A thorough survey of the public-school system was made by its own personnel (1921–2) under the direction of an expert, resulting in a programme of "principles, policies and plans," which was adopted by the school committee. A state pier, 750 ft. long, with 25 ft. of water on all three sides, was an important addition to the harbour facilities. New Bedford is the spot cotton market of the north.

NEW BRUNSWICK (*see* 19.464), a province of the Dominion of Canada. The population in 1921 was 387,876, an increase of 35,987 since 1911. Of the total 70% was rural; 30% was of French extraction. The towns having over 5,000 population in 1921 were St. John (47,166), Moncton (17,488) and Fredericton (8,114). The Government consists of a lieutenant-governor and a legislative assembly of 48 members; an executive council consisting of the Premier and eight other ministers is formed from the legislative assembly. The province is represented in the Federal Parliament by 10 senators and 11 members of the House of Commons.

Education.—Primary education is free and undenominational, being supported by legislative grants supplemented by local taxation. In 1924 there were 2,195 schools, 2,305 teachers and 72,713 pupils. A noteworthy fact, however, is that in 1921 12·46% of the population were illiterate, the highest percentage of any province in the Dominion.

Production and Industry.—Agriculture is limited chiefly to the production of potatoes, hay and clover, oats, turnips and buckwheat, this order representing production value in 1924. The area under wheat showed a steady decline between 1920 and 1925. The total area under crops in 1925 was 900,033 ac., as compared with 1,335,118 ac. in 1919, the highest on record. The total value of field crops in 1925 was $25,681,100. Farm livestock greatly decreased during the years 1922–3, the number of horses falling from 70,152 in 1922 to 50,644 in 1923, cattle from 303,115 to 212,901, sheep and lambs from 236,031 to 157,808, and swine from 85,260 to 66,182. From 1923 to 1925 numbers remained steady. The total value of livestock in 1924 was $15,390,800. The production of butter and cheese is relatively unimportant, the total value of both in 1924 amounting to $592,605.

The forest area of the province comprises about 15,000,000 ac., one half of which are crown lands. Of the timber cut in 1924, amounting to 362,000,000 superficial ft. 27% consisted of fire-killed spruce, cedar and fir, and 20% of spruce and fir killed by the bud-worm. The average annual value of the lumber output in the years 1917–21, not including wood used by settlers, was $13,235,128: in 1924 lumber production was valued at $12,407,262. Reseeding of the burnt-over lands was commenced in 1924. There were five pulp-mills in 1923, with a production of 111,126 tons valued at $6,986,208. The first paper-mill was put in operation in 1923.

The total value of the fisheries in 1923 was $4,548,535, as compared with $6,298,990 in 1918. The province possesses some mineral resources, coal, gypsum and oil being the most important. The manufacturing industry of New Brunswick has shown sustained progress. In 1922 there were 885 establishments with a capital of $81,789,934, employing 14,199 persons and having a total production valued at $64,614,137. In 1923 the total value of manufactures had increased to $70,114,006. Of the 120,000 H.P. available some 45,000 H.P. had been developed by 1925. The development of Grand Falls, the largest undeveloped water power in eastern Canada, was postponed owing to a change of government.

Communications.—There was a marked improvement in the roads of the province during the post-War period: 1,100 m. out of a total of 1,763 m. of main road were reconstructed. The policy followed in 1924 involved an expenditure of $860,000 or $2.20 *per capita* on roads. The province had 1,947 m. of railway in operation in 1923, most of which is controlled by the Canadian National Railways. St. John is the eastern terminus of the Canadian Pacific Railway. (*See* CANADA.) (S. LE.)

NEWCASTLE-UPON-TYNE, England (*see* 19.472), with a population of 275,009 in 1921 and an area of 8,452 ac. (including the town moor of 927 ac.), maintained a large output of ships, guns and munitions during the World War, but suffered subsequently from trade depression. Since 1918 the city has returned four members to Parliament. The port is constantly being improved; the channel from Newcastle to the sea has been dredged to a depth of 30 ft., and to 25 ft. for a distance of 11 m. westward from Northumberland dock. A quay extension, providing three berths, was opened in 1924. In 1925 schemes for further quay extensions, for a new road through the centre of the city, for the purchase of the Tyneside tramways, and for lifts from the quay to a new bridge across the Tyne (then in course of construction), were submitted to a vote of the ratepayers, but only the last mentioned scheme met with approval. A large extension of the Royal Victoria Infirmary was opened in 1920, and the Princess Mary maternity hospital in 1923. A War Memorial in Eldon Square, and a monument at Barras Bridge to commemorate the raising of several battalions, were unveiled in 1923. A memorial to men of the 6th Battalion Northumberland Fusiliers was erected in 1924 (*see* DURHAM, UNIVERSITY OF).

NEWFOUNDLAND (*see* 19.478), a Dominion of the British Empire. The area of the Island is 42,734 sq. m., and its population at the census of 1921 was 259,259. The total population

of the colony, including its dependency of Labrador (*q.v.*), which has an area of about 120,000 sq. m., was 263,259.

I. POLITICAL HISTORY

The inauguration in 1912 of the Fishermen's Union, which established large trading stores in all the principal outposts and had as its political object the safeguarding of the interests of the fishermen by means of representation in the Legislature, was the outstanding political event of the immediate pre-War period. In the elections of Nov. 1913, although the Government of Sir Edward Morris was re-elected, the candidates of the Fishermen's Protective Union (F.P.U.) won all the constituencies in the north and northeast. On the outbreak of the War a Newfoundland regiment was formed and served overseas in Gallipoli, Egypt and France. Altogether some 6,500 men joined up for service during the War. In 1917 the Morris Government was enlarged into a National Government by the inclusion of the opposition, in order to expedite measures dealing with war requirements. At the end of 1917 Sir Edward Morris resigned, and was succeeded by Mr. (Sir) William Lloyd, the former leader of the Opposition.

In 1919 Sir William Lloyd attended the Peace Conference as the representative of the Colony. During his absence his Government was destroyed by internal dissensions, and Mr. (Sir) Michael Cashin became Premier. The elections of Nov. 1919 were marked by extreme bitterness, religious feeling being introduced to a great extent. A considerable turnover of votes resulted, and the Government was defeated by a party led by Mr. (Sir) Richard Squires, consisting of his own supporters and those of Mr. (Sir) William Coaker, the leader of the Fishermen's Protective Union. The year 1920 was marked by a dispute with Quebec over the Labrador boundary, and the question was finally referred to the Privy Council.

The Government was re-elected in 1923, but shortly afterwards Sir Richard Squires resigned as a result of grave charges preferred against him in the Legislature, including, amongst others, the receipt of money from private corporations and the diversion of Government funds to persons occupying high official posts. Subsequently these charges were investigated by Mr. T. Hollis Walker, K.C., Recorder of Derby, England, who was obtained to act as a commissioner for this purpose, and his finding was adverse to Sir Richard Squires on certain points. Thereupon a criminal indictment was preferred against the latter in the Supreme Court, but the grand jury found "no bill," and the Crown did not pursue the matter further. The Attorney-General, Mr. William Warren, had assumed the leadership, but on the opening day of the legislative session of 1924 his ministry was defeated. It was reconstructed, but without avail, and then Mr. Albert Hickman, with the backing of the F.P.U., formed a ministry and went to the country. The leading political issues were the reorganisation of the public services and a greater honesty in the Government, and the election resulted in a victory for the party led by Mr. Walter Monroe, which assumed office in 1924.

II. ECONOMIC AND FINANCIAL HISTORY

The colony enjoyed considerable prosperity between 1910 and the outbreak of the War. Fishing, mining, paper-making, etc., made marked progress, but after 1914 the financial difficulties of the European countries in which these products were marketed, coupled with difficulties of transport, brought about a serious depression, which was followed by a financial crisis. Later the food requirements of Southern Europe sent the price of codfish to a record figure, and the war demands for timber and fish resulted in a period of great prosperity, which continued until 1920. A reaction then set in, with disastrous consequences to the whole commercial community and to the economic stability of the island. In the effort to overcome this, the Government attempted a policy of control over the marketing of colonial fishery products in foreign markets, but it could not be enforced, and ultimately had to be abandoned after severe monetary losses. Sales of iron ore were likewise hampered by the economic poverty of customers, and the depression in the paper market compelled wage reductions, which were followed by labour troubles which seriously affected the output of the mills. After 1923, however, a slow but sure recovery was being made to pre-War conditions of industry and trade.

Fisheries.—The cod fishery continued to be the chief industry, and the years 1924 and 1925 were marked by fair catches and good prices. The seal-hunt, owing to over-fishing, yielded not much more than 100,000 pelts annually, against twice that number annually before 1914. The lobster fishery, for the same reason, suffered such decline that a "close season" for three years was put in effect in 1924. The herring fishery considerably improved during the post-War period. The salmon fishery also yielded better returns, and the whale fishery showed a slight improvement. Efforts are being made to improve the curing and marketing of these products, to develop the canning industry and encourage the fishing for other species, heretofore neglected, but which it is believed could substantially augment the annual catch. The total value of the fishery products exported during the fiscal year ending June 1924 was $10,867,496.

Forest Products.—The development of the forest resources was very marked during the period 1910–25, notably in paper-making. The mills of the Anglo-Newfoundland Development Co., at Grand Falls, first designed to produce 200 tons of newsprint paper daily, were enlarged to produce another 75 tons, the additional mechanical pulp required being pumped through underground pipes from a subsidiary mill at Bishop's Falls, 9 m. distant. In 1923 still larger mills were begun at Corner Brook on the Humber river, with a capacity of 400 tons of "newsprint" daily, by the Newfoundland Power and Paper Company. These mills were completed and officially opened in Aug. 1925. A third mill of similar capacity, to be located on the Gander river, on the east coast, was projected by the Reid Newfoundland Co. in 1925. Mills for the manufacture of mechanical pulp were also projected, and the island seems destined to develop into a great paper-producing centre. Lumbering on a small scale, entirely for local consumption, is also practised. The total value of the exports of paper, pulp, etc., in 1923–4 was $5,955,725, as compared with $428,459 in 1909–10.

Minerals.—Mineral development has been mainly connected with iron ore. The mines at Bell Island, which are estimated to contain 15% of the world's total available supply, were only partially operated during the War years, and during the post-War period, owing to chaotic financial conditions in Europe, suffered considerably in their sales. After 1922, however, the export exceeded 1,000,000 tons annually, four-fifths going to Germany and the remainder to Nova Scotia. The total value of the mineral export in 1923–4 was $1,281,929. Mining otherwise has been on a small scale and without any substantial results.

Finance and Trade.—With its population only slightly increased since 1911, while its burdens have been almost doubled by War outlays and post-War reconstruction, Newfoundland has realised the necessity of encouraging other industries in order to avoid the former dependence on the fisheries. Hence the efforts to stimulate paper-making, mining, etc., and the adoption of tourist and other policies. Substantial success is being attained, so that emigration from the Island, which was very great in the immediate post-War period, had virtually ceased by 1925, while a surplus revenue and swelling bank deposits attested the greater prosperity of the resident population. Trade has considerably improved since 1921–2, as is shown by the table below. The increase in the value of imports for the year 1924–5 was due

Year	Funded Debt	Revenue	Expenditure	Imports	Exports
	$	$	$	$	$
1919–20	43,033,035	10,597,561	9,247,005	40,533,388	34,865,438
1920–1	49,033,767	8,438,039	10,949,053	28,909,727	22,441,267
1921–2	55,030,027	8,269,680	9,127,542	18,209,853	19,478,417
1922–3	54,957,765	8,876,772	9,552,301	19,321,824	20,956,863
1923–4	60,456,965	8,401,669	10,022,137	27,677,182	21,071,571
1924–5[1]	68,964,665	9,783,188	9,436,185	36,374,674	23,590,186

[1] This amount includes an issue of $2,500,000.00 in Dec. 1925.

to the great demand for raw materials for development schemes, including the Corner Brook paper mill, the extension and repairs to the dry dock at St. John's, and the re-laying of a section of the railway.

Communications.—The railway system, over 900 m. in length, with 10 subsidiary steamers covering in-bay and coast routes, proved a great boon to trade during the War, but ceased to be profitable after hostilities ended because of the increased cost of commodities and services. Annually recurring deficits, in some cases exceeding $1,000,000, proved too great a strain for the resources of the Reid Newfoundland Co., which was operating the entire system under a 50-year contract of which about 20 years had expired, and in 1923 the Government bought out the Reid interests for a payment of £2,000,000 and took over the railroad and the steamers. Since then, these public utilities have been operated under direct Government control. The telegraph system, which is being gradually extended all over the seaboard, is similarly operated, and the wireless service has also been extended. The ocean steamship services have been gradually improving, and in 1925 the Government constructed a new steamer for the service which connects the Newfoundland railway system at Port-aux-Basques with the Canadian National Railway system at North Sydney. In the same year the Government decided on a policy of constructing modern highways, suitable for motor traffic, to link up the best scenic and sporting areas in the Island, and also secured the construction of a new modern hotel in St. John's.

(P. T. M.)

NEW GUINEA: *see* PAPUA.

NEW HAMPSHIRE (*see* 19.490); a State of the United States of America. The population in 1920 was 443,083, a gain of 12,511 since 1910, or 2·9%, as against 4·6% in the preceding decade. The urban population was in 1920, 279,761, or 63·1% of the whole, as against 59·2% in 1910. The estimated population in 1925 was 450,175. The population of the eight cities having more than 10,000 inhabitants was:—

	1910	1920		1910	1920
Manchester	70,063	78,384	Portsmouth	11,269	13,569
Nashua	26,005	28,379	Dover	13,247	13,029
Concord	21,497	22,167	Keene	10,068	11,210
Berlin	11,780	16,014	Laconia	10,183	10,897

Agriculture.—The statistics for farm property, showing the changes from 1910 to 1920, are as follows:—

	1910	1920
Number of farms	27,053	20,523
Value of farm property	$103,704,196	$118,656,115
Average acreage, all land	120·1	126·9
Average acreage, improved land	34·3	34·2
Av. value per ac. (farm property)	$31.91	$45.57

Farms of from 100 to 499 ac. constituted 42·9% of the whole: farms of 20 ac. or less had the greatest proportion of land improved, 67·4%, and farms of over 1,000 ac. had the least—13·5%. Of all farms 90·6% were operated by owners, 2·7% by managers, and 6·7% by tenants, these percentages being without substantial change from 1910. Native farmers decreased from 24,347 in 1910 to 20,509 in 1920. The table at top of next column shows the increase in agricultural production between 1909 and 1919. In 1925 livestock included 32,000 horses, 121,000 milch cows, 32,000 other cattle, 18,000 sheep and 28,000 swine.

Forestry, Highways and Motors.—The biennial report of the forestry commission for the period ending June 30 1924 shows

	1909	1919
Dairy products sold	$5,130,057	$9,627,286
All crops	12,112,260	23,509,665
Cereals	879,631	1,456,628
Hay and forage	7,847,148	13,616,378
Vegetables	2,276,176	5,228,489
Potatoes	1,204,620	2,952,351
Miscellaneous crops	200,845	480,804
Orchard fruits and grapes	730,703	2,420,837
Maple sugar and syrup	182,341	440,250

a total of 47 state reservations containing 20,538 acres. The estimate of forest-bearing land in the State is 4,434,793 ac., of which the Federal Govt. owns 9·42% and the state 46%. The total acreage of tree-bearing land is valued at about $95,000,000. The legislature of 1925 provided for the purchase of Franconia Notch, and its dedication "as a memorial to the men and women of New Hampshire who have served the nation in times of war." The policy of establishing and maintaining state highways has been continued with increased scope. During the year ending Dec. 31 1924 the number of motor registrations was 71,929. In 1923 there were 1,239 m. of steam railway in the State: electric railways totalled 261 m. in length in 1924.

Manufactures.—According to the census of 1919 the nine leading industries, according to value of products, were: cotton goods, boots and shoes, paper and pulp, woollen goods, boot and shoe stock, lumber and timber products, worsted goods, foundry and machine shop products, and leather (tanned), ranging in value from $85,986,000, for the products of the first of these industries, to $7,309,000 for the last. The number of wage-earners increased, 1914–9, from 78,993 to 83,074; female employees from 23,115 to 83,074; workers under 16 from 485 to 859; wage-earners in the group "48 hours and under" from 5·7% to 65·6%. Manchester has the most wage-earners in the State, 25,512, Hillsborough county, containing Manchester and Nashua, has 44·6% of the total and manufactures 45·1% of the products. The tendency noticed in 1914 toward the diminution of the number of small establishments and of the number of wage-earners in them continues. The following table shows the development from 1909 to 1919:—

	1909	1914	1919
Establishments	1,961	1,736	1,499
Employees	84,191	85,013	90,332
Salaries and wages	$ 40,391,440	$ 46,523,733	$ 92,538,743
Value of products	164,581,019	182,843,863	407,204,934

Legislation.—Important Acts were those establishing a state Board of Conciliation and Arbitration; providing employers' liability and workmen's compensation; regulating child labour and hours of labour; providing for medical and surgical devices in factories; for safety and health of employees; and for reporting of occupational diseases. The legislature of 1917 enacted a law prohibiting the manufacture and sale of spirituous liquors. The law took effect May 1 1918, superseding local option.

Finances and Taxation.—The following figures show the increase in expenditures:—

	1910	1920	1924
Revenue	$1,694,636.54	$4,344,322.20	$5,176,948.75
Payments	1,662,694.07	5,198,534.62	4,296,724.69
Debt	1,293,209.33	3,040,524.17	181,966.65
Bonded Debt	1,071,070.00	2,589,500.00	1,619,500.00

The increase in expenditures was on account of increased cost of maintaining public institutions and for highways. The increase in the bonded debt was nearly all due to the World War. In 1918 the State issued $500,000 of bonds to assist the Federal Govt. in the War; and in 1919 it issued $1,489,000 in order to increase the war service recognition from $30 to $100 for those who served. The total valuation of property for purposes of taxation in 1924 was $585,422,877; amount of taxes assessed was $14,599,100. The average rate was $2.49 per $100. Poll taxes assessed were 235,765 in number. The total valuation

of all public utility companies was $51,252,200. The tax on the income of intangibles for two-thirds of the year was about $220,000.

Education.—Important work was done in 1918 by the state committee on Americanisation. In the parochial elementary schools the principle was established that instruction in designated branches and in administration should be exclusively in English. In the large industrial plants the plan was largely carried out by evening schools for adults. The system of public instruction was reorganised by the legislature of 1919. In the bill "the work of Americanisation is hereby declared to be an essential part of public-school education." The legislature of 1923 changed the name of the New Hampshire College of Agriculture and the Mechanic Arts to the University of New Hampshire, and the legislature of 1925 provided for it a stable annual revenue of one mill on every dollar of assessed valuation.

History.—The Ninth Constitutional Convention, held in 1912, submitted to the voters 12 amendments, of which four received the necessary two-thirds vote, namely, defranchisement for treason, bribery and deliberate violation of the election laws; the substitution of plurality for majority vote in the election of governor, councillors and senators; extension of the jurisdiction of police courts; the substitution of a basis of population for that of property in the election of councillors. In 1915 the office of assistant attorney-general was created, and the number of bank commissioners was reduced to three, and in 1925 to one, and their term of office was made six years. The Railroad Commission became the Public Service Commission in 1911, its powers were enlarged, and the term of office of the three members was made six years. In 1913 the Fish and Game Commission was reorganised, and the number of commissioners reduced from three to one. The Department of Public Instruction was reorganised in 1913, so that the superintendent holds office indefinitely; it was again reorganised in 1919.

In 1913 the Department of Agriculture was reorganised with a commissioner instead of a board, and in 1915 it was further reorganised. In 1911 the name Board of Equalisation was changed to Tax Commission; the members were reduced from five to three, and the tenure of office was extended from two to five years. The Bureau of Labour was reorganised in 1911, and in 1913 a Board of Arbitration and Conciliation was organised to work with it. In 1913 the License Commission was reorganised, in 1915 it was again reorganised and its name was changed to Excise Commission. The Highway Department was reorganised in 1915 with a highway commissioner at its head appointed by the governor for five years. A Department of Institutions was created in 1913 and reorganised in 1919. The State institutions were managed by seven trustees, consisting of the governor and one member of the council, *ex officio*, and five appointed trustees. The institutions governed by the department were the prison, the hospital, the sanatorium, the industrial school, and the school for feeble-minded children. The legislature of 1925 vetoed bills to abolish the direct primary, and to limit the working hours of women and children to 48 per week, and permitted absentees to vote for President of the United States, made examination of the finances of the state institutions, and revised the salaries of state officers.

The governors after 1910 were: Robert R. Bass (Rep.), 1911–2; Samuel D. Felker (Dem.), 1913–4; Rolland H. Spaulding (Rep.), 1915–6; Henry W. Keyes (Rep.), 1917–8; John H. Bartlett (Rep.), 1919–20; Albert O. Brown (Rep.), 1921–2; Fred H. Brown (Dem.), 1923–4; John G. Winant (Rep.), 1925– .

(E. J. B.)

NEW HAVEN, Conn., U.S.A. (*see* 19.499), enlarged its boundaries to include 22·4 sq. m. by 1925. Its population grew to 162,537 in 1920 (of whom 4,573 were negroes and 45,686 foreign-born), and was estimated by the Census Bureau at 178,927 in 1925. The varied output of its factories was valued at $50,870,000 in 1909; $125,455,000 in 1919; $113,924,862 in 1923, when there were 483 establishments, employing 26,108 wage-earners. The Cedar Hill classification yard of the New York, New Haven and Hartford Railroad Co., covering 1,160 ac., had a capacity of 11,000 cars in 1925. Additions to the park system, including a large acreage with a bathing beach at Lighthouse Point, brought the total area to 1,549 acres. There were 59 public grade schools, a manual training school, two high schools (one for commercial training) and two junior high schools, with a total enrolment of 34,315 pupils. New construction included hotels, industrial and commercial buildings, a railway station, and buildings for Yale University (*q.v.*).

NEW HEBRIDES: *see* OCEANIA.

NEW JERSEY (*see* 19.501), a State of the United States of America. In 1920 the population was 3,155,900, as against 2,537,167 in 1910, an increase of 618,733, or 24·4%. The population in July 1925 was estimated at 3,506,428. The density of the population, exceeded in the United States only by that of Rhode Island and Massachusetts, averaged 426 to the sq. m. in 1925. The proportion of people living in places of 2,500 or more inhabitants increased from 75·2% in 1910 to 78·7% in 1920—the urban population in 1920 being 2,482,289; the rural, 673,611. The 10 largest cities, with populations in 1925 as estimated by the census bureau, are as follows: Newark, 445,606; Jersey City, 312,157; Paterson, 140,637; Trenton, 129,705; Camden, 126,399; Elizabeth, 106,251; Bayonne, 86,582; Hoboken, 68,166; Passaic, 68,045; and East Orange, 58,284.

Agriculture.—The State is steadily developing its industries, and is tending towards specialisation in agricultural production, particularly the production of fruits and vegetables. Between 1910 and 1925 the number of farms decreased at the rate of about 1·5% per annum. Vocational training in agriculture in the public schools was made possible by Acts of 1914 and 1917. County farm demonstrators have been established since 1913 in 18 of the 21 counties in the State. The years 1920–5 witnessed a rapid extension of the highway systems, and the motor-truck has developed into the chief transportation unit for agricultural products. In 1925 there were 39 farmers' co-operative organisations in the State. The dairy industry is confined mainly to the production of milk for consumption in New York, Philadelphia, and other large cities. The variation in the number of the chief farm animals from 1920–5 was as follows:—

Livestock	1925		1920	
	No.	Value	No.	Value
Swine	113,000	$ 1,978,000	139,000	$ 3,503,000
Dairy Cows	153,000	11,475,000	148,000	18,944,000
Horses and Mules	73,000	8,035,000	79,000	12,201,000

Livestock products were worth about $20,000,000 in 1920, and approximately $15,000,000 in 1925. There are about 2,750,000 chickens on farms, and considerable numbers in urban districts, producing nearly 15,000,000 dozens of eggs each year, worth about $6,000,000. Poultry products other than eggs bring the total value up to about $10,000,000.

The State ranks among the leaders in the commercial production of many crops, viz.: peaches, sweet corn for market, sweet potatoes, asparagus, string beans, lima beans, tomatoes, early Irish potatoes, peppers and egg-plants. The most important single crop is hay, although it is not raised for sale to any extent, being largely used for feeding livestock on the farms. The total value of the tame hay crop in 1925 was $8,584,000. The corn crop of 1925 was worth over $7,820,000 and was produced on about 206,000 acres. The value of the wheat crop in 1924 exceeded $2,100,000. The oat crop is gradually declining in importance, the climate being too warm for the highest yields; in 1924 the crop occupied approximately 67,000 ac., and the product was worth about $1,372,000. Rye, grown on 65,000 ac., was valued at $1,286,000, and buckwheat at about $250,000. The total net value of New Jersey's agricultural production each year is nearly $100,000,000, as compared with manufactured and mineral products worth over one and three-quarter billion dollars.

Mining.—The output of zinc ore in 1923 was 584,891 tons. The iron-mining industry, which from about 100 mines attained a maximum output of nearly 1,000,000 tons in 1882 and then

declined, has revived, and the post-War annual production was about 400,000 tons. Eight iron mines were actively operated in 1923. Raw clay production in 1923 was 375,854 tons: the total value of clay and clay products in 1923 was $47,618,171, of which $23,836,455 was for pottery. The State possesses in the green sand (marl) deposits vast stores of potash, 10,656 tons of which, valued at $131,123, were mined in 1923 and used chiefly for softening water.

Manufacturing.—About 17% of the population is actively engaged in manufacturing. It ranks first in the list of States in the smelting and refining of copper, in the refining of oil, in shipbuilding, in dyeing and finishing textiles, and in the manufacture of paving materials, phonographs and upholstering materials; second in the manufacture of linoleum and silk goods; third in the manufacture of iron and steel, pottery and electric fixtures; and fourth in the manufacture of electrical machinery and paper goods. In 1923 the value of the products of the State's 8,766 manufacturing establishments was $3,321,301,524; wages paid to 447,948 employees amounted to $578,999,234.

Education.—The Russell Sage Foundation, after an exhaustive examination of the public-school systems of the various States, ranked New Jersey in 1920 first among the States east of the Mississippi river, and fourth in the whole country, and added that it was "the only State in the eastern division that has gained in relative rank during a period of 28 years, 1890–1918." The State Board of Education, which had consisted of eight members, was enlarged in 1921 to 10, of whom at least two must be women. In 1923–4 the total enrolment of pupils was 715,877, an increase of 136,946 over 1916. The number of teachers was 22,693; of school buildings, 2,210. Nearly 310,000 pupils received manual or industrial training of some sort, and 16,000 some form of vocational training. The current expense for operating the schools during the year 1923–4 was $63,528,320, an increase over that of 1918–9 of $38,077,241. Of this total more than $38,500,000 was for salaries of teachers, superintendents and principals, the average salary being $1,757. The Catholic parochial schools numbered 201 in 1924, with about 91,000 pupils. A legislative Act of 1917 designated the State college (Rutgers) which in 1923–4 had 2,663 students, as the "State University of New Jersey." A college for women affiliated with it was opened in Sept. 1918. Stevens Institute of Technology in 1924 had an attendance of 529; Princeton, of 2,446 (*see* PRINCETON UNIVERSITY).

Legislation.—For more than two generations New Jersey had sedulously fostered the aggregation of capital in corporate form, but this policy was reversed by the passage in 1913 of the series of Acts widely known as the "Seven Sisters," the purpose of which was the elimination of the power of trusts to create monopoly, limitation of production, price-fixing and restraint of trade. In 1920 the legislature proposed and the people ratified an issue of bonds to the amount of $28,000,000 for the construction of a bridge across the Delaware and a tunnel under the Hudson river. Bonds subsequently authorised for the highway system and water-supply conservation brought this total, in 1925, to $76,000,000.

The laws governing elections were radically changed in 1911 and subsequently, by provisions extending the application of the direct primary law and providing the blanket ballot and safeguards against frauds. In 1911 also, the commission form of municipal government was introduced. The Practice Act of 1912 is noteworthy as simplifying procedure in the courts. The legislation of this period further embraced the following subjects: the regulation and control of public utilities; jury reform; employers' liability; workmen's compensation; conditions and hours of labour; labour of women and children; juvenile courts; sanitary and safety conditions; motor vehicle control; a State system of highways; inheritance and bank stock taxation; regulation of insurance; water supply; food laws and storage of food; civil service in state and municipalities; state administration of municipal sinking funds; and the establishment of a police force.

Political History.—Woodrow Wilson was elected governor in 1910 as candidate of the Democratic party, receiving a plurality of 49,056; in 1912 Wilson secured a plurality of 24,873. He lost the State to Hughes in 1916 by 57,964 plurality. In 1924 Coolidge (Rep.) received 675,162 votes; Davis (Dem.) 309,743. In the elections for the State executive the Democratic party was successful from 1910–25 with the exception of the election in 1916. From 1914 the Republicans controlled both branches of the Legislature. In 1925, of the 21 Senators, 18 were Republicans, 3 Democrats; in the Assembly there were 13 Democrats; the other 47 were Republicans. Despite the predominantly Republican complexion of recent New Jersey politics, no Republican governor was elected later than 1916, a fact largely due to the anti-prohibition stand of the Democratic party in the state.

New Jersey's governors were: Woodrow Wilson, 1911–3; James P. Fielder (acting), 1913; Leon R. Taylor (acting), 1914; James P. Fielder, 1914–7; Walter E. Edge, 1917–9; William N. Runyon (acting), 1919–20; Edward I. Edwards, 1920–3; George S. Silzer, 1923–6; A. Harry Moore, 1926– . (W. N. R.)

NEW MEXICO (*see* 19.520), a State of the United States of America. The estimated population in 1925 was 379,074. The population in 1920 was 360,350, as against 327,301 in 1910, an increase of 33,049, or 10·1%. The urban population (in places of 2,500 inhabitants or more) in 1920 was 18% of the total. The average number of inhabitants per sq. m. in 1920 was 2·9. The following table shows the growth of the principal cities for the period 1910–20:—

City	1920	1910	Increase %
Albuquerque	15,157	11,020	37·5
Santa Fé	7,236	5,072	42·7
Roswell	7,033	6,172	13·9
Raton	5,544	4,539	22·1
Clovis	4,904	3,255	50·7

Agriculture.—During the period 1910–25 the number of farms decreased from 35,676 to 31,687. Farm-land increased from 11,270,021 ac. in 1910 to 24,409,653 ac. in 1920, or 116·6%; improved land from 1,467,191 ac. to 1,717,224 ac. or 17%. The value of farm property rose from $159,447,000 in 1910 to $325,185,999 in 1920. The average acreage per farm in 1920 was 817·9; in 1910 it was 315·0. The average value of land per acre decreased from $8.77 in 1910 to $8.04 in 1920. Of the 29,844 farmers in 1920, 25,756 were owners, 433 managers and 3,655 tenants. The figures in respect to the chief agricultural products in the years 1909 and 1924 are shown in the following table:—

Crop	Year	Area	Production	Value in $
Corn	1924	210,000 ac.	4,200,000 bu.	4,620,000
	1909	85,999	1,164,970	984,052
Wheat	1924	163,000	2,551,000	3,188,000
	1909	32,341	499,799	508,726
Beans	1924	110,000	559,000	2,090,000
	1909	20,766	85,795	232,023
Hay and forage	1924	175,000	309,000 tons	4,759,000
	1909	370,596	433,504	4,493,918

Of livestock on farms Jan. 1 1925 it was estimated that there were 167,000 horses, valued at $6,179,000; 21,000 mules, valued at $1,218,000; 1,009,000 beef cattle, valued at $21,694,000; 47,000 dairy cattle, valued at $2,115,000; 60,000 swine, valued at $660,000; and 2,360,000 sheep, valued at $18,172,000. The production of wool in 1924 was estimated at 12,408,000 lb., as against 15,076,000 lb. in 1919. In 1920 the number of farms irrigated was 11,390; the area irrigated was 538,377 ac., or 31·4% of the improved land in farms. The capital invested in irrigation enterprises was $18,210,412 in 1920, as against $9,154,897 in 1910.

Manufactures.—Between 1914 and 1919 the capital invested increased from $8,984,000 to $15,226,000, or 69·5%; and the value of products of manufacturing establishments increased

from $9,320,000 in 1914 to $20,422,126 in 1923, or 119%. The operation of steam-railway repair shops is the leading industry, as measured either by the number of wage-earners or by the value of the products.

Transportation.—In 1923 the railway mileage of New Mexico was 2,959, excluding switches and sidings. The Atchison, Topeka and Santa Fé railway owned almost half of the total.

Mineral Products.—The total value for 1922 was $18,038,022, as compared with $40,631,024 in 1918. The chief products in 1922 were: coal, 3,100,000 (in 1924, 2,550,000) short tons; copper, 31,037,207 (in 1924, 78,145,629) lb.; silver, 752,240 (in 1924, 783,338) oz.; gold, 19,964 (in 1924, 24,207) oz.; also zinc and lead. In addition, granite, marble, limestone and sandstone are quarried.

Education.—On June 30 1924 the total school enrolment was 80,368. The number of school houses was 1,551, made up as follows: 1,358 public elementary schools, 164 public high schools, 26 Indian schools and three public normal schools. The University of New Mexico, at Albuquerque, founded in 1889, had in 1923 457 students and 23 professors. The Museum of New Mexico, established at Santa Fé in 1909 in the historic palace, built about 1630, of the governors of the old Spanish province, contains a notable library of works on general linguistics and a remarkable collection illustrating American archaeology. The Archaeological Institute of America maintains there a special school of American research.

Finance.—For the first seven years of statehood—Dec. 1 1911 to Nov. 30 1918—the aggregate State expenditure was $15,573,817, and county expenditure $34,227,143, making a total of $49,800,960. State receipts amounted to $16,520,448, and county receipts $34,235,224, making a total of $50,755,672. At the end of that period the bonded State debt was $3,385,500; county, $2,972,335; city, town and village, $3,250,000; school, $1,800,000, making a total of $11,407,835. The total assessed valuation of property was $360,961,891. In 1923 this total valuation had fallen to $313,065,248, upon which taxes were levied amounting to $1,493,625, being $7.03 *per capita* of the population. At the close of 1923 the funded debt amounted to $4,035,500, the net debt being $3,947,875, or $10.61 *per capita.*

Legislation.—In 1917 a workmen's compensation law was enacted. In 1919 legislative acts included the establishment of State mounted police; a child's welfare bureau; an annual franchise tax on corporation; state inheritance and income taxes; provisions, on petition, for the teaching of Spanish in high schools; and the establishment of night schools for illiterates. In 1918 an amendment to the constitution prohibited the manufacture and sale of intoxicating liquors after Oct. 1 1918 (28,732 for, 12,147 against). In 1919 the State Legislature ratified the prohibition amendment to the Federal Constitution, and in 1920 the amendment extending the right of suffrage to women.

History.—The most important historical fact concerning New Mexico during the period 1910–25 was its admission into the Union, Jan. 6 1912, as the 47th state. Following the Enabling Act, passed by Congress June 20 1910, the territorial governor ordered an election of delegates to frame a constitution. The election was held Sept. 6 1910; the convention, consisting of 71 Republicans and 29 Democrats, assembled Oct. 3; and the adopted constitution was approved by the people Jan. 31 1911. The vote was 31,742 for and 13,300 against. The chief opposition came from the voters who favoured the inclusion of state prohibition. In 1916 the Elephant Butte Dam, under active construction since 1910, was completed by the United States Reclamation Service at a cost of about $5,000,000. It is situated 12 m. west of Engle, Sierra county, and, built across canyons of the Rio Grande, governs the entire flow of the river and is one of the largest storage irrigation reservoirs in the world. The average width of the reservoir is 1¼ m.; maximum length 45 m.; area of water surface when full, 40,080 ac.; shore line, 200 m.; average depth, 66 ft.; and maximum depth near the dam, 193 feet. When full it holds 115,498 million cu. ft., or 862,200 million gallons. It irrigates 185,000 ac. of land lying in New Mexico, Texas and Mexico.

The last territorial governor was W. J. Mills (Rep.), 1910–2. State governors were: W. C. McDonald (Dem.), 1912–7; Ezequiel de Baca (Dem.), Jan. 1–Feb. 18 1917; W. E. Lindsey (Rep.), 1917–9; A. Larrazolo (Rep.), 1919–21; M. C. Mechem (Rep.), 1921–3; James F. Hinkle (Dem.), 1923–5; A. T. Hannett (Dem.), 1925– .

NEW ORLEANS, La., U.S.A. (*see* 19.526), increased in population 14·2% in the decade after 1910, reaching 387,219 in 1920 (of whom 100,930 were negroes and 25,992 foreign-born), and 414,493 in 1925 according to the Census Bureau estimate. Foreign commerce grew from 3,754,705 net tons in 1911 to 9,239,546 in 1923; coastwise commerce from 733,021 net tons to 4,385,166; and the Mississippi-Warrior river Federal Barge Line, established in 1918, handled 849,503 tons of cargo in 1924. Harbour facilities and equipment were much improved. The state commission which administers the port had by 1925 built wharves, steel sheds, public cotton warehouses, a grain elevator, a coal and ore tipple and a bulk commodity handling plant, along six miles of the 41 m. frontage on the Mississippi river. Railway terminals, U.S. Govt. wharves and the private wharves and warehouses of over 30 industries, brought the total improved frontage to about nine miles, with berthing space for 90 vessels 500 ft. long.

The board of port commissioners constructed (1918–23), at a cost of about $20,000,000, the Inner Harbour Navigation canal, commonly called the Industrial canal, 5½ m. long, which crosses the city from the Mississippi to Lake Pontchartrain, serving as an inner harbour with still water, a navigation artery with advantageous industrial sites on its banks and on the banks of its proposed laterals, and which will eventually, after the construction of the necessary channels, provide a shorter route to the sea. The output of the manufacturing establishments within the city limits was valued at $135,184,088 in 1923, as compared with $78,794,000 in 1909. For the entire industrial area, with some 1,200 factories instead of 648, the value would be perhaps double that amount.

By 1925 about $39,000,000 had been expended on the water drainage and sewerage system begun in 1903; there were 661 m. of water mains and 547 m. of sewers. The death-rate, though still high (17·7 per 1,000 in 1923), had decreased appreciably. Enrolment in the public schools (1924) was 59,954; in Tulane University, 2,605; in Loyola University, established in 1911, 870. Public improvements and important new buildings under construction in Oct. 1925, or planned for the immediate future, represented a valuation of about $200,000,000. The cost of living is relatively low (93·2% of the average for 31 American cities, Dec. 1924). The commission form of government was adopted in 1912. The governing body is the commission council, consisting of the mayor and four other commissioners, elected for four years.

NEWPORT, Monmouthshire, England (*see* 19.533), with an area of 5,020 ac. and a population of 92,369 in 1921 has developed into one of the chief ports of Great Britain. Over 7,000,000 tons of goods were dealt with in 1913, and trade is now again expected to increase. A number of large factories have been erected in recent years on and near the Usk, and the national cartridge and box repairing factory was established here during the World War. Shipbuilding has increased in importance. A sea lock, with a length of 1,000 ft. which gives direct access to the Bristol Channel and brings the port 1½ m. nearer to the sea, was opened in 1913, and has resulted in the calling of an increased number of large ships. The town has grown rapidly under a town-planning scheme, and extensive building has been carried out at Somerleyton and St. Julian's. The electricity and water services are being extended. The diocese of Monmouthshire formed in 1921, has the church of St. Woolos, Stow Hill, as its pro-cathedral. The parishes of St. Matthew, St. Julian and St. Andrew have been formed, largely out of that of Maindee. In 1924 it was decided to remodel the town market. The ruins of a castle on the Usk were given to the corporation in 1924, on condition that they should be restored and preserved.

NEW SOUTH WALES (*see* 19.537), a state of the Australian Commonwealth. Its area of 309,432 sq. m. had in 1925 a popula-

tion of 2,271,944, 67·8% of which was urban, an increase of 625,210 since 1911.

Political History.—In 1910 the first Labour Government of the State was returned, with Mr. J. S. T. McGowen as Premier, followed by another Labour Government in 1913–14, with Mr. W. A. Holman as Premier. In the latter year the Liberals and Moderate Labour formed a coalition Government which held office until 1920. Between 1920 and 1925 power alternated between Labour and the Nationalists supported by the Progressive party. Industrial legislation passed after 1918 included provision for a basic wage and a 44-hour week. The Lang Labour Government in 1925 was the first Government in Australia to carry a measure providing pensions for widows. An attempt in 1926 to abolish the Legislative Council was defeated by the Council. A movement for the formation of new States within New South Wales gained much prominence during the post-War period. The movement aims at decentralisation from Sydney by the opening up of deep-sea ports north of Sydney served direct by railways from the producing centres.

Production.—New South Wales produces nearly one-half of the wool, one-fourth of the agricultural products, two-thirds of the minerals and some 45% of the manufacturing output of the Commonwealth. Whilst wool was still the principal product in 1925, agriculture had made great progress. A vigorous State-aided migration policy between 1910 and 1914 brought large numbers of settlers from Great Britain for work on the land. The area under wheat increased from 2,128,000 ac. in 1911 to 3,543,000 ac. in 1925 and the yield from 27,913,000 bu. to 59,785,000 bushels. Bulk handling of wheat was introduced in 1920. Dairy production also steadily increased, and in 1921 the output was more than 100,000,000 pounds. The industry is highly organised, the butter factories being run on a co-operative basis under the strict supervision of Government experts.

Irrigation.—Irrigation schemes carried out by the New South Wales Govt. are playing a big part in the development of the State. The Murrumbidgee Irrigation Scheme, the main feature of which is a storage dam across the Murrumbidgee river at Burrinjuck to retain the flood waters, will ultimately serve water to an area over 200,000 ac. in extent devoted to fruit and vegetable growing, dairying and stock-raising: the district is one of the greatest fruit-producing centres of the State and has a large output of fresh, canned and dried fruits. A fruit-canning factory has been erected and is operated by the Government, which processes fruit grown by the settlers. The Government is also co-operating with the Commonwealth, Victorian and South Australian Governments in the scheme to lock the waters of the River Murray.

Minerals and Manufactures.—Broken Hill is the great centre of silver production in Australia. In 1913 the output of ore from its mines amounted to the record figure of 1,744,000 tons. In 1923 the production of ore was 878,537 tons, from which 7,233,236 oz. of silver, 124,570 tons of lead and 41,153 tons of zinc were produced. New South Wales is the principal coal-producing State, the output in 1923 exceeding 10,000,000 tons, and is the centre of the iron and steel trade. In 1923 the Lithgow Iron Works produced from local ores 94,350 tons of pig iron. The Newcastle Iron and Steel Works, established by the Broken Hill Proprietary Co. in 1915, produced in 1924 327,809 tons of pig iron and 302,384 tons of steel ingots. The works are capable of producing from 8,000 to 10,000 tons of ingot steel weekly. The total value of the manufacturing output of New South Wales in 1924 was £146,359,260 of which metal works and machinery accounted for £38,121,000, food and drink, etc., £40,789,000 and clothing and textile fabrics £13,684,000. In 1924 there were 11 woollen and tweed mills in the State, besides a large number of hosiery and knitting mills. In 1923 the first up-to-date mill for the manufacture of cotton goods was erected in Sydney for the treatment of Australian-grown cotton. In 1924 the value of the output was £361,773.

Besides undertakings of a national character, such as the Murrumbidgee Irrigation Works and the Walsh Island Dockyards, the State has engaged in various industrial enterprises since 1911, when the brick works at Homebush and metal quarries were established. In 1913 the State took over the Monier Pipe Industry. All three enterprises were operating profitably in 1925. Other enterprises, such as the state bakery, state timber yards and state trawlers, were established but ultimately abandoned as unprofitable.

Sydney, the capital and principal port, had at Dec. 31 1924 a population of 1,012,000, 45% of the total for the State. Other towns of importance are Newcastle, the coal-mining centre; Broken Hill, silver Zinc and lead mining; and Tamworth, Bathurst, Goulburn, Wagga and Albury, pastoral and agricultural centres. (*See* AUSTRALIA.)

NEWSPAPERS (*see* 19.544).—The outstanding feature of the newspaper world during the years 1910–25 is the remarkable change that has come over the Press in Great Britain during that period by the formation of great newspaper trusts and amalgamations, the elimination of the financially weaker journals and the enormous expansion of the popular illustrated newspapers.

I. PRESS ENTERPRISE IN GREAT BRITAIN

At the beginning of 1910 there were 2,331 newspapers in the United Kingdom, distributed as follows: London, with the postal area, 414, of which 23 were morning dailies and 7 evening dailies; the English provinces, including localised issues, 1,342, of which 46 were morning and 76 evening dailies; Wales, 118, including 4 morning and 4 evening dailies; Scotland, 258, including 8 morning and 10 evening dailies; Ireland, 183, including 10 morning and 7 evening dailies; the British Isles, 16, of which 5 are dailies.

After 26 years the newspapers, in spite of the addition to the population, had decreased owing to amalgamations and cessations, to 2,149 in Great Britain and Ireland, distributed as follows: London, 406, of which 23 were morning, including specialist papers (*Jewish Express*, in Hebrew, *Jewish Times*, *Lloyd's List, and Lloyd's Daily Index*), and three evening dailies (and the *Jewish Evening News*, published in Whitechapel). The newspapers in the English provinces and Wales, including localised issues, numbered 1,330, of which 37 were morning and 79 evening dailies; Scotland, 235, including 7 morning and 9 evening dailies; Ireland, 166, including 8 morning and 6 evening dailies; the British Isles, 16, of which 5 were dailies.

While the number of newspapers has decreased, the sales in the period have more than doubled. Up to the year of the World War the halfpenny newspaper gained in popularity and prestige. Following upon the unprecedented success of *The Daily Mail*, which had become a national newspaper, with simultaneous publication in London and Manchester begun during the Boer War, other newspapers had come down to a halfpenny, including the old established *Daily News* and *Daily Chronicle*. These papers appealed to a new and wider public and were made interesting to the masses.

The new class of readers included women and young people, who had hitherto been only occasional patrons of the daily Press. Space was devoted to social news, personal gossip, magazine features and serial stories, which had a stabilising effect on sales. The late Lord Northcliffe was the first journalist to see the significance of women readers. Not only did the attraction of women readers mean a wider public, but it stimulated advertising. The remarkable success of *The Daily Mail* was due primarily to the influx of advertisements which appealed specially to women.

The introduction of the half-tone pictures to illustrate the news of the day was another new element in extending the sphere of the daily Press and in popularising it. The continued journalistic and commercial success of the halfpenny newspaper had created a revolution in the newspaper world and made it increasingly difficult for the old-fashioned provincial newspapers to prosper.

The World War brought other changes. At first, like all other industries, except those concerned with the production of munitions or in some way associated with catering for the

forces, the Press was disorganised. The Government recognised that the Press was an essential element in national effort, and facilities were granted to newspapers, both in regard to obtaining materials and in retaining man power. For the first time also, war correspondents became more than camp followers, were granted uniforms and became officially attached to armies. Many papers suffered losses in the earlier years of the World War, but adapted themselves to the emergency, and made up in profits on sales for what they lost in advertisements. In the boom period after the War their prosperity increased amazingly. The post-War period brought more amalgamations and organisation of syndicates.

Picture Papers.—Encouraged by the support which he received from women readers of *The Daily Mail* and of his many weekly variety papers, Lord Northcliffe issued a newspaper which was to be edited by women for women. He produced *The Daily Mirror*, intended to be a higher type of paper than *The Daily Mail*, and to appeal more to the interests of serious-minded women. It was stillborn. It was Lord Northcliffe's greatest failure. It was a lucky failure. The paper which was intended to be the women's *Times* was transformed into the first illustrated daily newspaper, and became, with its offshoot, *The Sunday Pictorial*, as great a financial success as *The Daily Mail*.

A new type of paper was thereby added to daily journalism. Other picture papers were started, and every newspaper was by-and-by led to introduce half-tone illustrations. *The Times*, *The Daily Telegraph* and *The Morning Post* were the last to adopt the new feature. Press photographers became as indispensable as reporters; photo-engraving was a new big industry associated with the Press.

The first phase in the popularisation of the Press was the growth of the halfpenny paper which began with *The Morning Leader* in 1892, followed by *The Daily Mail* in 1896. Next came the establishment of the illustrated paper beginning with *The Daily Mirror* in 1903. Another development has been the introduction of features specially for children, which, in the case of the illustrated dailies, has become a big factor in circulation. There has been a general adoption of a system of insurance, the object of which is to keep up sales, and, for the same reason, cross-word and other puzzles and competitions are introduced, including competitions in connection with sport.

The Evening Press.—One of the more remarkable developments of the post-War period has been the great progress of the evening Press in its earning capacity and its circulation. In these respects it has gone ahead in the provinces. The average man in provincial cities has little time to read the morning paper, but devotes his leisure to the evening sheet when his day's work is finished. Thus it comes about that the conditions of modern life favour the evening Press, which is accordingly in a state of increasing prosperity. The local evening paper is not subject to the competition from national newspapers from which the provincial morning papers suffer. Some of the latter have gone under, others are kept alive by evening papers issued under the same ownership. The trend of events indicates that before many years there will not be in England more than a dozen provincial morning newspapers run on a commercial basis. The demand for net sales forced by Lord Northcliffe, and taken up by the Association of British Advertising Agents, has had a prejudicial effect on country morning newspapers with small sales, although the value of publicity cannot always be measured by numbers. Much depends on the class of paper and the nature of the goods advertised.

London has fewer evening papers per head of the population than any city in the world. There were once nine evening papers in the metropolis. In 1919 there were six. In 1926 there were three. The old-established *Globe* was absorbed by *The Pall Mall Gazette* which in 1924 was taken over by *The Evening Standard* when the latter was acquired by Lord Beaverbrook, while *The Westminster Gazette* retired from the evening field, in which it occupied a distinctive and influential position, and joined the morning newspaper journals among which competition was intensely keen. The three existing evening papers, which have a monopoly of circulation in a population of over 10,000,000 living within 10 m. of Fleet street, are *The Evening News*, belonging to the Rothermere Press, *The Evening Standard*, controlled by Lord Beaverbrook, but in which Lord Rothermere has a 49% interest, and *The Star*, issued by *The Daily News*. Glasgow, with a population of a little over 1,000,000 publishes three evening newspapers—two belonging to *The Glasgow Herald*—which contain far more news than the London evening Press. Indeed, the provincial evening newspapers, as a rule, contain more reading matter than their London contemporaries.

The Sunday Press.—The colossal growth in the sale and prosperity of Sunday newspapers since the World War is of particular significance in the light which it throws on the changed outlook of the nation towards its duties, moral and ethical. A few of these journals show continual improvement in make-up and matter; but the big circulations are practically monopolised by those which pander to the more sordid tastes of the masses. The Sunday newspaper is a national paper. By special trains it is circulated all over the country. In order to reach the uttermost parts early editions are printed on Friday night. Sunday newspapers represent almost the best, and certainly the worst, of English journalism. If we exclude the Sunday illustrated papers, which are of a special type, the less creditable productions have the largest sales. *The Observer* and *The Sunday Times* are in a category by themselves and consist chiefly of Saturday's news home and foreign and special features. Following upon these, but of a more popular type, come *The Sunday Express*, *The Weekly Dispatch* and *The Sunday News*, while the large sellers give more space to the news of the week, or of the world, selecting the most sensational stories of crimes, and serving up the reports of unsavoury law cases, although several days old. The majority of the Sunday papers give such full accounts of Saturday's news and sport that they make inroads into the former news province of the Monday paper. On April 16 1926 a bill was introduced by Sir Evelyn Cecil and supported by the Government for restricting the publication of the reports of judicial proceedings "in such a manner as to prevent injury to public morals." The second reading was carried by a majority of 222 to 3.

The General Strike and the Press.—A development of the coal dispute in England, which came to a head at the end of April 1926 was a general strike organised by the General Council of the Trades Union Congress. It began on May 3, being precipitated by the action of members of the National Society of Operative Printers and Assistants in the office of the London *Daily Mail*, who objected to the opinions expressed in an editorial article. As the editor refused to accept their dictation, the men left work, although other sections of trade unionists, including the compositors, process engravers and telegraphists employed in the office did not then join the strike. Stoppages of other newspapers, before the general strike was formerly declared, followed, and for the same reasons, viz.: that the National Society of Operative Printers and Assistants objected either to opinions expressed or to certain items of news.

The strike developed quickly and paralysed newspaper production. It was the direct cause of the break off in negotiations by the Government for the settlement of the coal dispute. Interference with the freedom of the Press was considered by the Government to be an overt act and they called upon the Trades Union Council to withdraw the strike notices, as a condition precedent to the resumption of the negotiations. The trade union leaders did not accept this suggestion and the strike became general. The policy adopted was not consistent in regard to newspapers, nor was the suppression of the Press complete. While *The Daily Mail* of Monday, May 3, was suppressed in London it was permitted to appear in Manchester and was circulated throughout the country. In some towns the employees of newspapers were not in agreement with the general strike policy and resumed work.

Newspapers began to appear in the first instance mostly by photographic processes, but in two or four diminutive pages

which were gradually increased in size as voluntary labour was obtained. *The Times* appeared as a four-page paper two days after the strike took place. The Government issued an official paper, *The British Gazette*, containing all news relating to the strike, describing the action of the Government to meet the national emergency, and appeals to all classes to help in maintaining the supremacy of Parliament and constitutional action. The Trades Union Council, which was placed in charge of the strike, produced an official organ entitled *The British Worker* by trade union labour. The newspaper and periodical business probably suffered more by the strike than any other industry, as a considerable proportion of the staff had to be retained and heavy general expenses incurred. The general strike was called off under the Government's original conditions, on Thursday, May 13, and after negotiations the newspapers resumed normal publication on Tuesday the 18th. One condition of the settlement was that " there shall be no interference with the contents of newspapers owned by members of this association " (*i.e.*, the association of newspaper proprietors), and other conditions were agreed to by both parties which considerably reduced the powers hitherto exercised by trade unions without, however, modifying the policy of collective bargaining.

The Era of Amalgamations

The great change in the British Press was begun by Lord Northcliffe in promoting limited liability companies to take over Harmsworth Bros., and afterwards *The Evening News*. Amalgamations and groupings of papers followed. Referring to this phase of newspaper development Sir Robert Donald, in an address at York, as president of the Institute of Journalists in 1913, said: " combination has been the chief characteristic of industry all over the world, and the Press could not remain outside this tendency. One company sometimes owns or controls a series of newspapers. There have been absorptions, amalgamations and alliances, with the result that vast aggregations of capital have been built up in which thousands of shareholders are interested. These agglomerations, piling up power and wealth, are controlled by the same forces which operate in other fields of industrial activity." He also predicted that the future would see combinations increase; there would be fewer newspapers and " colossal circulations would continue to grow." The newspaper run as a luxury and for a mission, and not as a business enterprise, would be squeezed out of existence. There would, therefore, be fewer newspapers, but the total circulations would be greater.

These predictions, made a year before the World War, have been fulfilled; but no one foresaw that the Press combinations would reach such gigantic proportions, or become so immensely profitable. The War expedited and facilitated the rise of the Press syndicates. The movement for consolidation received its chief impetus since the War, and more especially since the death of Lord Northcliffe. The *Daily Mail* Trust, Ltd., was incorporated on Sept. 27 1922 to purchase the 400,000 deferred (controlling) shares in Associated Newspapers, Ltd. sanctioned by the court. The price paid was £1,600,000, which was met by an issue of 7% first mortgage debentures. Early in 1923 the Trust purchased 49% in the *London Express* Newspaper, Ltd. A little later it purchased the large newspaper business of E. Hulton and Company, Ltd., and paid for it by a second issue of £8,000,000 7% debentures, liquidating out of the proceeds the former issue of £1,600,000 debentures. At the same time the Trust acquired 49% interest in *The Evening Standard*. In the same year the Trust sold the greater portion of the Hulton Press to the Berry brothers for more than the original purchase price, while retaining possession of *The Daily Sketch*, *The Sunday Herald* and new printing works; these three assets being subsequently promoted and sold for £1,600,000 under control of Lord Rothermere. The Trust paid £4 for the deferred shares in Associated Newspapers, Ltd. They appreciated almost as much again. The Trust in two years discharged a debenture obligation of £9,000,000. Its financial success enabled it to benefit by premiums and to issue bonuses. The marketing price of one share (2/- paid in 1925) was £2 10·0. A bonus of 5/6 per share was allotted out of reserves to the ordinary shareholder in Nov. 1925. The capital was £810,450 and £1,158,779 debentures but these were being redeemed.

The Rothermere Group.—*The Daily Mail* Trust is controlled by Lord Rothermere through *The Daily Mirror* and *The Sunday Pictorial*, which in turn control Associated Newspapers, Ltd. In 1925 Lord Rothermere sold the Glasgow *Daily Record* and *The Sunday Mail* to the Berry group. The chief combinations at the end of 1925 were Associated Newspapers, Ltd. (capital of £3,000,000 increased by the gift of bonus shares and capitalisation of reserves), proprietors of *The Daily Mail*, *The Evening News* and *The Weekly Dispatch; Daily Mirror* Newspapers, Ltd. (capital £1,110,000); proprietors of *The Daily Mirror*, associated with which is *The Sunday Pictorial*, Ltd. (capital £1,370,000); and *The Daily Sketch* and *Sunday Herald*, Ltd. (capital £1,710,000). The above newspapers form the Rothermere group. Debentures are included in the capital. The combined sale of the daily papers in the group in 1925 was about 3,500,000 and of the weeklies nearly 3,000,000. In addition to these newspapers the Rothermere group, through the *Daily Mail* Trust, owns 49% of the ordinary capital in *The Daily Express*, *The Sunday Express* and *The Evening Standard*. Lord Rothermere's companies also own very large paper-making works in England and Newfoundland. He is also proprietor of *The Continental Daily Mail*.

The Berry Group.—Then there is Allied Newspapers, Ltd., capital £8,157,015, and Allied Northern Newspapers, Ltd., capital £4,000,000, including £3,000,000 debentures. These companies form the Berry group, so called because Sir William Berry and Mr. Gomer Berry are the controlling shareholders, and consist of a large number of properties including the following daily and evening newspapers: *The Financial Times*, *The Daily Graphic*, *The Daily Despatch*, Manchester, *The Evening Chronicle*, Manchester, *The North Mail*, Newcastle, *The Glasgow Daily Record*, *The Newcastle Evening Journal*, *The Glasgow Evening News*. They also own *The Sunday Times*, *The Sunday Chronicle*, *The Empire News* (*Manchester*), *The Sunday Sun* (*Newcastle*), *The Sunday Mail* (*Glasgow*). The Berry group have also acquired a large interest in *The Sheffield Daily Telegraph*, *The Sheffield Evening Telegraph*, and *Star*, *Weekly Telegraph* and associated publications. Among the other properties of the Berry group may be mentioned Kelly's Directories, a group of technical and trade papers, fashion journals, the old publishing business of Cassell, the weekly *Graphic*, *The Bystander* and large printing works.

The Beaverbrook Group.—The Beaverbrook group, in which Lord Rothermere has a minority interest, consists of *The Daily Express*, *The Sunday Express*, owned by London *Express* Newspapers, Ltd. (capital £539,439), and *The Evening Standard*. The policy of Lord Beaverbrook has not been to distribute dividends on the ordinary shares, but to extend plant and building, reduce capital and organise a future impregnable position.

United Newspapers (1918), Ltd.—This company (capital £2,000,000) owns *The Daily Chronicle*, the northern edition of which is printed in Leeds, *The Sunday News* and *The Edinburgh Evening News*. It also controls *The Yorkshire Evening News*, and *The Doncaster Gazette*.

The Cowdray Group.—A widespread association of newspapers is described as the Lord Cowdray, Sir Charles Starmer, and Rowntree group. Its nucleus was the *Northern Echo* of Darlington. It expanded rapidly and includes the following morning and evening newspapers: *The Birmingham Gazette* and *The Evening Dispatch*, *The Nottingham Journal* and *The Evening News*, *The Sheffield Independent* and *The Sheffield Mail*, *The Northern Echo* and *The Northern Evening Dispatch* (*Darlington*), *The Swindon Evening Advertiser* and *The Islington Daily Gazette*. Lord Cowdray, who had for some years been supporting the group, added *The Westminster Gazette* as a morning newspaper to the combination. At least 12 weekly papers throughout the country are under the same control, and also a Sunday paper, *The Sunday Mercury and News* (Birmingham).

The foregoing represent the national owning syndicates. There are a number of other combinations among newspapers. *The Glasgow Herald* owns two evening papers and one morning paper in Glasgow. *The Liverpool Daily Post* and *The Echo* have acquired interests in *The Liverpool Daily Courier* and *The Liverpool Evening Express*. There have been a number of local concentrations as in Aberdeen, Dundee, Plymouth and other cities, where, in each case, all the morning and evening newspapers are under one proprietory.

The increased prosperity of newspapers is due partly to improved organisation, but chiefly to the fact that the selling price has been doubled and the rates for advertisement trebled, which more than covers the extra cost of production.

The weekly literary and political reviews have lost ground, and so have the monthlies. On the other hand, the illustrated weekly press shows a remarkable vitality. The six chief illustrated newspapers, *The Illustrated London News*, *The Sphere*,

The Sketch, The Tatler, The Illustrated Sporting and Dramatic News and *Eve*, all belong to Sir John Ellerman, the shipping magnate.

Organisations.—A net-work of organisations exists for employers and workers. In the newspaper business collective bargaining is the rule. On the employers' side, there is the Newspaper Proprietors Association, which represents the London Press, the Newspaper Society for the provincial Press, the Scottish Newspaper Proprietors' Association, and the Irish Newspaper Society. There is also the British Trade and Technical Trade Journals Organisation.

Since 1913 the position of the working journalist has been vastly improved by the continued activities of the Institute of Journalists, and more especially by the influence exercised by the National Union of Journalists, which is organised on trade union principles and was the means of raising the standard in the lower ranks of newspaper workers and of establishing the principle of the minimum weekly salary to all ranks of journalists.

On the side of the manual workers there is also a complete net-work of organisations. The chief federated societies are the Typographical Association, representing compositors throughout the country; the London Society of Compositors; the National Society of Operative Printers and Assistants and Printing Machine Managers. Press telegraphists; correctors of the press; electrotypers and stereotypers; pressmen; paper-makers and others engaged in connection with newspapers, all have their unions. Beyond the federated Societies is a large number of affiliated federations covering Great Britain.

Advertisers have organisations also, including advertising managers, circulation managers, and, indeed, every one associated with the production and distribution side of the press. Newsagents combine chiefly in the Federation of Wholesale Newsagents and the National Federation of Retail Newsagents.

Another organisation which represents not only the Press of Great Britain but of the Dominions, is the Empire Press Union, which was the outcome of the first Imperial Press Conference held in 1909. It represents newspapers, either by proprietors or responsible members of the staff. It has branch sections in the overseas Dominions and keeps a permanent supervision over such questions affecting cable services and charges, and matters of common interest to the Press as a whole. The second Imperial Press Conference was held in Canada in 1920, and the third in Australia in 1925. The first president of the Empire Press Union was the first Lord Burnham, and he was succeeded by his son, the present Lord Burnham, who is also president of the Newspaper Proprietors Association. The Chairman of the Council from 1915–26 was Sir Robert Donald, who was succeeded by Mr. J. L. Garvin. The Empire Press Union has insisted continuously on better and cheaper communications with the overseas Dominions and has devoted particular attention to the promotion of Empire wireless. After many years delay the first Empire wireless station began to operate in Jan. 1926 in the super-station at Rugby. A series of stations was erected, which began to operate in the same year for communication to and from the Dominions.

Cheaper Communications.—Cheaper and quicker means of communication and distribution of news is always in process of evolution. What are known as "loaded cables" have been laid down, increasing enormously the capacity and speed by which messages can be transmitted by cable, the advantages of which newspapers will share. In the address to the Institute of Journalists in 1913, to which reference has already been made, Sir Robert Donald visualised a time when news would be collected by wireless telephone and the reporter would always have a portable telephone with him, with which to communicate with his paper without the trouble of going to the telephone office, or writing out a message. The competitor, he said, to the national newspaper would not be another national newspaper, but a method of circulating news by means of some scientific mechanism for transmitting the spoken word. He predicted that all the news of the day would be laid on to houses and offices, just like gas and water. During the years 1924 and 1925 the development of broadcasting brought this vision within the region of realisation. Newspapers look on this development with a watchful eye, lest it should, in addition to supplementing their functions, arrest their progress.

Subordination of the Editor.—Compared with 50 years ago, the most marked change in the personal side of British journalism has been the ascendancy of the proprietor and the subordination of the editor. This is reflected in the now prevailing habit of referring to the Northcliffe Press, the Rothermere Press, the Beaverbrook Press and the Berry Press. There are now only a few well-known editors whose personalities are impressed on the public mind. First, there is Mr. C. P. Scott, the veteran editor of *The Manchester Guardian*, who is also controlling proprietor of his paper. Mr. Scott represents the finest type of editor-proprietor in England, while his journal, distinguished for its honesty and consistency, stands for the highest ideals of journalism and has acquired a great international reputation and influence. It has been under the control of Mr. Scott for over half a century. On the occasion of the centenary of *The Manchester Guardian* in May 1921, King George congratulated Mr. Scott on his 50 years' association with the paper which, "under your courageous and high-minded guidance, has secured for itself a position of such eminence and esteem in the world of journalism."

The other great personality in English journalism is Mr. J. L. Garvin, editor of *The Observer*, who is pre-eminent as a writing editor, brilliant and independent. He is a recognised authority on foreign affairs, who has exercised an influence on world politics for many years. In 1926 Mr. Garvin took on new responsibilities, becoming editor of *The Encyclopædia Britannica* and chairman of the Empire Press Union. Four editors of London papers who were controlling policies before and during the World War lost their posts, partly through proprietorial changes. Mr. H. W. Massingham, who had been editor of two daily newspapers and, afterwards, of *The Nation*, died in 1924, soon after he was displaced from the editorship of that journal; Mr. A. G. Gardiner, of *The Daily News*, Mr. J. A. Spender, of *The Westminster Gazette*, and Sir Robert Donald, of *The Daily Chronicle*, who had all for many years been controlling editors, left their positions during these years.

The proprietor who pushes himself before the public occasionally prints signed articles in his papers. He uses them as vehicles for expressing his personal views. One effect of the change, accentuated by the syndication of newspapers, is that consistency is not so well maintained and editorial responsibility is very much weakened. The old conception of an anonymous entity, who regarded a newspaper as a public trust and took responsibility seriously, has been dispelled. One individual may be in financial control of several or many newspapers; but as organs of opinion they either become a "gramophone Press," or different interpretations are given to the same policy in papers under the same ownership. The mass production of public opinion does not carry weight.

The changed system of ownership has unseated most of the old newspaper dynasties. The Press families no longer in power include the Lloyds (*Daily Chronicle*, etc.); Hulton (*Daily Dispatch*, etc.); Ingram (*Illustrated London News*); and Borthwick (*Morning Post*). The Walter association with *The Times* is maintained, but the family control has gone. There remains, however, *The Daily Telegraph*, in control of the second Lord Burnham, representing the third generation of the Lawson family. *The Times* has reverted to its traditional policy, as the first newspaper in the world, occupying its place with easy dignity. Its scholarly editor, Mr. Geoffrey Dawson, maintains anonymity, while the controlling proprietor, Hon. J. J. Astor, M.P., maintains the reserved tradition of the Walters. The change has, however, assured *The Times* the position of independence as a national newspaper. When *The Times* Holding Company, Ltd., acquired Lord Northcliffe's controlling interest in the newspaper, special restrictions and conditions were introduced, which provided that none of the shares may be transferred

to any person other than Major Astor or Mr. John Walter, unless or until such person shall have been approved as a proper person to hold ordinary shares in the company by a resolution of the committee which the articles of association appointed. The same restriction applies to a corporation. The committee consists of the persons who for the time being are Lord Chief Justice of England, Warden of All Souls College, President of the Royal Society, President of the Institute of Chartered Accountants and Governor of the Bank of England. The decisions of this committee must be by a majority of votes, the chairman to have a casting vote. In exercising their decision in regard to the transfer of shares the committee must have regard to the importance of maintaining the best traditions of *The Times* newspaper, and national rather than personal interests, and eliminating as far as reasonably possible questions of personal ambition and commercial profit.

Sir William Berry and Mr. Gomer Berry carry on their vast and varied interests in a business spirit without bringing their personalities before their many millions of readers. An arresting personality in the British Press is Lord Beaverbrook—controlling proprietor of *The Daily Express*, *The Sunday Express* and *The Evening Standard*. He went into the newspaper business during the World War and it was not long before he showed striking gifts for the particular kind of journalism which he took up. He has the news and the political sense highly developed and if he frequently annoys he always interests.

Popular Weeklies.—The popular periodicals during the last 30 years attained great sales, pushed up artificially by means of prizes, competitions and the insurance system. The period, which may be described as the era of popular journalism, was begun by the late Sir George Newnes over 40 years ago with *Tit Bits*. Two men who had been contributors to his paper followed his example. Alfred Harmsworth started *Answers*, and C. Arthur Pearson, *Pearson's Weekly*. These three little weekly papers were the foundations upon which arose three great publishing and newspaper businesses. The George Newnes publishing business expanded in several directions. Sir George Newnes himself made excursions into newspaper journalism. He founded as a political organ *The Westminster Gazette* and other papers which did not survive. C. Arthur Pearson (afterwards Sir Arthur Pearson), besides building up a big periodical business, also entered the newspaper world, but was not commercially successful. The Newnes business is now amalgamated with Pearson's, and publishes a large number of popular information and entertaining weekly papers.

The one man who attained unprecedented success, both in the periodical and newspaper field, was Alfred Harmsworth (*see* NORTHCLIFFE, VISCOUNT). His creation, Amalgamated Press Ltd., is to-day the biggest business of its kind in the world. Its publications appeal to all classes, and in recent years it has been expanding and appealing to a higher class of reader, publishing a number of very useful encyclopaedias, histories and reference works of various kinds, issued in very attractive form.

II. THE BRITISH DOMINIONS

Irish Free State.—Newspapers in the Irish Free State are settling down to Dominion conditions, but it cannot be said that the new political freedom has stimulated newspaper enterprises. The Dublin morning papers are now *The Irish Times* and *The Irish Independent*, and the evening papers, *The Herald* and *The Dublin Evening Mail*. In 1910 there were four morning papers and three evening papers in the Irish capital. The historic *Freeman's Journal* passed through many vicissitudes, and finally disappeared in 1923, after 160 years of existence. There are two morning papers and one evening paper in Cork. British newspapers, daily and weekly, have a considerable sale in the Irish Free State.

Canada.—There are no more independent newspapers than those published in the British Overseas Dominions. They are comparatively free from Government influences, and are not subject to the domination of syndicates or trusts. The Press of each Dominion has its own characteristics. Canadian newspapers not unnaturally reflect the style and appearance of American newspapers, while retaining some of the more sedate qualities of English journalism. There are no Sunday newspapers in Canada, although American Sunday newspapers are sold at railway stations and at hotels throughout the Dominion. The evening Press is more important than the morning Press. Such evening papers as the *Montreal Star* and the *Toronto Globe* have very large sales and are second to none in enterprise. The Canadian Press publishes a great deal of British news and carries American magazine features.

There are no national newspapers in Canada, as the Dominion is too vast for papers to circulate beyond the area of one province, but there are several newspapers of national reputation and wide political influence, such as *The Manitoba Free Press*, *The Montreal Gazette*, *The Toronto Globe*, *The Vancouver Daily Province*, and *The Halifax Chronicle*. In merit, such newspapers stand high, and Canadian journalists are continually being tempted to cross the border to fill important posts on the American Press, and in recent years have been drawn in greater numbers to London. In some towns, such as Ottawa, the same papers have morning and evening issues. There is a healthy French Press in the Quebec province. *La Presse* of Montreal claims to have the largest sale of any newspaper in Canada, French or English. Every town in Canada, even if its population does not exceed 5,000, has a daily newspaper, as is the case in most communities in other British dominions. The trade and technical Press of Canada compares well with similar papers in other countries. Monthly publications are at a disadvantage because of competition from the excellent cheap magazines and Sunday supplements from the United States, which regard the Dominion as a dependency for periodical literature. The small town of St. John's, population 38,645, in the large island Dominion of Newfoundland, prides itself in having one morning and three evening newspapers.

Australia and New Zealand.—In Australia, two-thirds of the population are concentrated in cities. The evolution of the Press in Australia has led to the building up of very prosperous newspaper properties. There are not many newspapers per 1,000,000 population. Competing newspapers and cable agencies send a very full service of news from Great Britain, and the place occupied by an Australian newspaper is determined chiefly by the volume of British news which it contains and by the literary quality of its editorial articles. The Australian daily Press combines the dignified appearance and solid qualities of British papers like *The Times*, *The Daily Telegraph*, *The Manchester Guardian* and *The Glasgow Herald*. Without exception, they are prosperous and are efficiently equipped mechanically. In Melbourne, which with its suburbs has a population of nearly 1,000,000, there are only two morning newspapers—*The Age* and *The Argus*—a pictorial paper, founded in 1922; and one evening paper, *The Herald*. The selling price of each is 1½d. In Sydney, the parent city of Australia, with 1,000,000 inhabitants, there are four morning newspapers and two evening newspapers. Sydney has the cheapest newspapers in the world. *The Morning Herald* and the Sydney *Daily Telegraph* are larger than *The Times* or the London *Daily Telegraph*, and are sold at 1d. Brisbane has two morning and three evening papers, all 2d. each. Adelaide has two well-known morning newspapers, *The Advertiser*—"from 96 to 252 columns daily,"—and *The Register*, selling price 1½d. There is one evening newspaper.

Australia possesses a healthy weekly Press which devotes special attention to the farming industries and several national journals, notably *The Sydney Bulletin*, which is read throughout the island-continent, and *Truth*, described as "the most virile organ of democracy." There are Labour daily and weekly papers in Australia. An Act has been in operation for some time in Australia, which provides that during a Federal electoral campaign all articles on reports or news dealing with political matters must be signed by the writer. A similar law has been adopted in South Africa.

Wealth is well distributed in New Zealand among its population of 1,000,000 and the trade statistics per head is excep-

tionally high. This state of things is reflected in the prosperity of the New Zealand Press. The daily Press is even more characteristically English than are the Australian newspapers. The capital, Wellington, with a population of less than 100,000, has three daily newspapers.

South Africa.—With a white population of 1,350,000 divided racially between the British and the Dutch, the Union of South Africa makes a good showing in the matter of the Press. All branches of the newspaper business are well organised. The leading English papers are well known outside the Union, such as *The Cape Times*, *The Cape Argus*, *The Rand Daily Mail* and *The Star* of Johannesburg. There are four well-conducted daily papers in Natal. *The Friend* of Bloemfontein and *The Diamond Field Advertiser* of Kimberley are also influential organs. The leading Dutch papers are *Die Burger* and *Ons Land* of Cape Town and *Volkstem* of Pretoria. It is customary for many newspapers in South Africa to be sold by subscription. There are newspapers in the smaller towns throughout the Union and in every British settlement of a few thousand people in all African colonies.

India.—The part played by English newspapers in India cannot be measured by the copies which they sell. In Calcutta, with a population of nearly 1,500,000, is published the oldest newspaper in India, *The Englishman*, and also the most popular, *The Statesman*. *The Times of India* (Bombay), *The Madras Weekly Mail*, *The Pioneer* of Allahabad, *The Civil and Military Gazette* of Lahore, are the best-known papers and organs of opinion. There are quite a number of official journals in India. The vernacular papers are growing in number and in influence, and some of the Nationalist organs are published in English—as, for instance, the *Amrita Bazar Patrika* of Calcutta. Some papers are published in two languages, in English and vernacular.

III. THE UNITED STATES AND S. AMERICA

The newspapers in the United States tend with the passing years to become more and more economic products. They offer two things for sale: to the reader they sell news, editorials and other interesting reading matter, and to the advertiser they offer white space at so much per inch. Economic complications are numerous because these two joint products must be marketed in the same container—the white paper on which the news is printed and on which the advertising is displayed.

The Economic Side.—In other economic products the cost of the container is relatively small in comparison with the cost of the product itself; the paper which wraps a cake of soap may well serve as an illustration. In the newspaper business the cost of paper is the largest bill the publisher must pay. The increase in the cost of newsprint paper, especially during the World War, forced an increase in subscription price. During certain war years this high cost necessitated a curtailment of the privilege of returning unsold copies, compelled some newspapers to limit the number of their pages, required editors to present news in condensed form and reduced in many instances the size of headlines. Those publishers who, having during this period a liberal supply of white paper from their own mills, were able to maintain pre-War sizes, often printed issues nearly as valuable for waste paper as for news media—from the financial point of view. Since the War the increased subscription price has for the most part been maintained.

After the outbreak of the War economies in newspaper production were secured through pools and combinations. Pools in cable tolls came with the advance in rates for trans-Atlantic messages. London newspapers resold their news to American newspapers, and obviously, after the declaration of hostilities, news from London was wanted more in detail. Consequently when the New York *World*, the New York *Times*, and the New York *Tribune* pooled their interests and let one cable dispatch serve all, each saved two-thirds in tolls.

The War Period.—When the United States, after entering the War, made preparations to send troops overseas newspapers combined to save expense in war correspondence. Such combinations are seen in the accredited correspondents who were permitted to accompany the first Expeditionary Force to France and who represented the following: The Associated Press, The United Press, The International News Service, The Associated Papers, The Newspaper Enterprise Assn., the Philadelphia *Ledger* syndicate, the Munsey group of newspapers, the New York *Times* and group of newspapers, the New York *Herald* syndicate, the Chicago *Tribune* and group of newspapers, the New York *World* and group of newspapers, the New York *Tribune*, the Philadelphia *North American* and group of newspapers, the Denver *Post* and *Collier's Weekly*. The Hearst string of newspapers was represented by The International News Service. It will be noticed that most of these newspaper combinations were headed by either a New York or a Philadelphia newspaper. American troops overseas soon had their own newspaper, *The Stars and Stripes:* its publisher was Richard H. Waldo, formerly business manager of the New York *Tribune*. *The Stars and Stripes* was run as a commercial proposition, was entirely self-supporting, and, *mirabile dictu*, had, when it ceased publication, a large surplus.

Press censorship in the United States during the War may be dismissed with few words. A Committee on Public Information, appointed by President Wilson, consisted of the Secretary of State, the Secretary of War, the Secretary of the Navy and one civilian, George Creel. Its two principal purposes were first, to be a clearing-house for the news of the various departments at Washington; second, to act as censors for war intelligence received from overseas. In practice it limited its activities principally to the dissemination of information. But it did publish a pamphlet, similar to that issued by the Press Censor of Canada, to aid American newspapers in voluntary censorship. (*See* CENSORSHIP.)

The War favoured the evening papers in the presentation of the news and the reason may be found in the difference in time between Europe and America. If correspondents filed their cable dispatches promptly and if they wrote their accounts so that little, if any, work was required by the official censors there was time enough to record the hostilities of the day before the late editions of the evening newspapers went to press. Previous to the War there was a marked tendency on the part of the evening papers to present the day's news more or less in bulletin form and to devote most of the contents to special features, to regular household departments and to comic strips. There were notable exceptions to this tendency, but they were the exceptions which prove the rule. War, for the time being at least, put the news back in the evening papers.

The editorial page, which had been steadily declining in influence since the days of Greeley of the New York *Tribune*, Dana of the New York *Sun*, Godkin of the New York *Post*, Medill of the Chicago *Tribune*, Waterson of the Louisville *Courier Journal*—to mention only a few—came to be a necessity for thoughtful readers. To them the news from overseas needed not only presentation, but also interpretation. This interpretation, plus the tremendous increase in the amount of foreign news, gave an international character to the American newspaper never found before.

Facts and Figures.—Census figures collected by the U.S. Govt. about newspapers, while technically accurate, are somewhat misleading. Among daily newspapers, for example, they include the dailies published by undergraduates at various universities, such as *The Daily Californian*, the Yale *Daily News*, the New York *University Daily News*, *The Harvard Crimson*, *The Columbian Spectator*, the Wisconsin *Daily Cardinal*, etc.—to say nothing of the daily trade bulletins issued in the interests of various industries. The statistics compiled for *The Interna-*

tional Year Book by *The Editor and Publisher* are more reliable. Its figures for 1925 show that there were in the United States 427 morning newspapers with a daily circulation of 12,440,387; 1,581 evening newspapers with a daily circulation of 21,208,982; and 548 Sunday newspapers with a weekly circulation of 23,354,622. These figures mean that there was one and one-third (1⅓) newspapers for every family in the United States and one Sunday paper for nearly every home. The number of weekly newspapers has declined almost steadily every year from 1910 to 1925. At the close of the latter year the United States had 13,176 community weeklies. Of these a little over 11,000 might be considered as small town newspapers. The number of weekly newspapers serving special sections of cities has increased and doubtless will continue to do so as cities expand. Since the War country newspapers have shown a decrease of something like 3,000. But what rural newspapers have lost in quantity they have made up in quality.

The Associated Press, the great co-operative news-gathering organization, in 1910 was furnishing its service to 826 papers; at the close of 1925 it had on its list 1,211. During this period its annual cable tolls increased from $87,187.46 to $147,912.18. Facts and figures about *The New York Times* illustrate from the business side the making of a leading metropolitan newspaper. The paper consumption increased from 24,421,082 lbs. in 1910 to 160,230,367 lbs. in 1925. Advertising, measured by lines, grew from 7,550,650 to 28,200,444. The average number of pages for a daily issue in 1910 was 18·6 and in 1925 was 40·5. For the Sunday edition the average number of pages was 74·6 (1910) and 173·0 (1925). The 646 employees in 1910 were distributed as follows: business, 158; editorial, 159; mechanical 329; the 2828 in 1925 were thus divided among the various departments: business, 757; editorial, 418; mechanical, 1,653. To visualize these figures it may be said that if all the printed matter, including advertisements and illustrations, of an entire Sunday edition of *The Times* could be pasted on a ribbon a column wide this ribbon would circle the globe twelve times.

Amalgamations.—The movement in the American Fourth Estate is unquestionably toward consolidation. Space does not permit mention of the amalgamations of smaller papers, but important changes in metropolitan fields may be noted. Frank A. Munsey before his death in 1925 had in New York City merged *The Press* with *The Sun* in 1916, later in 1920 he purchased the New York *Herald* and *The Evening Telegram*. Discontinuing *The Morning Sun* he transferred that title to *The Evening Sun* with which in 1923 he merged *The Globe*. At about the same time he purchased *The Evening Mail* which he consolidated with *The Evening Telegram*. He then sold (1924) *The Herald* to the New York *Tribune*, now published under a joint title. In Boston *The Herald* (morning) took over (1912) *The Traveler* (evening) and continued it as its evening edition. Later (1917) *The Herald* absorbed *The Journal* (morning). In Kansas City W. S. Dickey bought (1921) *The Journal* (morning) and (1922) *The Post* (evening). He continued *The Journal* as a morning paper and *The Post* as an afternoon, with joint publication on Sunday, with a flat subscription price for both papers. In this he followed the example of *The Star* which since 1901 has been printing *The Times* as its morning issue, with both papers going to the same subscribers.

In Philadelphia Cyrus H. K. Curtis became on Jan. 1 1913 the publisher of *The Public Ledger* which he purchased from Adolph S. Ochs. On Sept. 14 1914 he started *The Evening Public Ledger* with which he united (1918) *The Evening Telegraph*. In 1920 he purchased *The Press* to unite with *The Public Ledger* and in 1925 he did the same with the Philadelphia *North American*. In Chicago *The Record-Herald* purchased (1913) *The Inter-Ocean* and appeared as *The Herald* which later was purchased by W. R. Hearst and united with his Chicago *Examiner*. In Cleveland *The Plain Dealer* absorbed *The Leader* and in St. Louis *The Globe-Democrat* purchased *The Republic*, one of the oldest daily papers in Missouri.

New Developments.—Newspapers showed in 1925 a most marked improvement over those of 1910 in mechanical make-up. Especially has the change for the better been noted in the arrangement of material on the first page, where attempts have been made to give that page something like an artistic balance. A few papers have conducted expensive experiments to determine the kind of type that is easiest for the reader. Headlines, even during the World War, were kept within legitimate bounds and did not, even in the case of accounts of big battles, approach the streamer monstrosities printed in the days of the Spanish-American War. Illustrations, especially for Sunday supplements and for special Saturday issues, were by the more influential newspapers grouped together and printed on a finer grade of paper by the rotogravure process. Seventy-seven papers have (1925) rotogravure photographic supplements as a part of their Sunday or other editions. Improvement in speed of production may be seen in the modern Unit-Type press of 12 units which can print 180 m. of paper in an hour.

Radio has, at least up to 1926, supplemented rather than supplanted the newspaper. In almost every daily newspaper it has created a special department to list the attractions of broadcasting stations. In some it has created a special section—occasionally printed in tabloid form as a supplement. People hearing over the radio, like the people in the audience, have wanted to see what the press printed about the address. News broadcast in condensed form has awakened an interest for details to be found in the paper of the morrow. Pictures by radio, still in their infancy, promise much by way of making newspapers more timely in illustrations. In 1925 the United States had 68 newspapers owning or operating a radio station or studio.

Tabloid Newspapers.—The introduction of tabloids may be explained, in part, by the passing remark of Lord Northcliffe, "If some American does not start one I shall have to come over to do it." The first in the field was *The Illustrated Daily News*, established in New York City June 26 1919 by the Chicago *Tribune*. At the close of 1925 it had the largest circulation of any American newspaper, over a million copies daily. Its success doubtless led W. R. Hearst, publisher of the New York *American* and the New York *Evening Journal*, to establish (1924) *The Mirror* and make over his Boston *Advertiser* (est. 1813) into a tabloid. The third tabloid in New York is *The Graphic* (1924). Philadelphia has two tabloids. The first, the Philadelphia *Daily News*, was started March 31 1925 and is as sensational as any in New York. The second, the Philadelphia *Sun*, came two months later and, under the ownership of Cyrus H. K. Curtis, has followed more after the London tabloids. Others are *The News* of Washington, D.C.; *The Post* of Baltimore, Maryland; *The Daily News* of Los Angeles, California; *The Ledger* of Newark, N.J.; *The Daily Tab* of Miami, Florida; and *The News* of St. Petersburg, Florida. Pictures, features and contests constitute the stock in trade for tabloids which, together with motion pictures, doubtless put picture pages into conservative newspapers of standard size.

Adless Newspapers.—Los Angeles, California, attracted some attention in 1912 when it made an attempt to publish a weekly municipal newspaper. *The News*, a copy of which was left without cost at every home regardless of the wishes of the tenant, was controlled by three municipal newspaper commissioners appointed by the mayor. Any political party polling 3% of the vote of the city was entitled to a column in each issue. A space of half a column was available for the mayor, or any member of the city council in all issues. After the appropriation set aside by the city had been expended the paper was discontinued. A publicly owned daily newspaper, however, may be one of the papers of to-morrow.

Two advertisement-less daily newspapers have appeared. Chicago, on Sept. 28 1911, saw the first appearance of *The Day Book* which printed no advertisements. Its circulation increased until in 1916 it was averaging over 20,000 daily. The latter year witnessed its suspension because of the increased cost of white paper. *The News-Post* (1912–4), an adless newspaper in Philadelphia, was edited by Marlen E. Pew. Adless newspapers, lacking the bargain sales of department stores, will never be

popular with women. Adolph S. Ochs, publisher of the New York *Times*, once remarked that a full page advertisement of a department store was more extensively read than an address by the President of the United States, when both appeared in the same paper.

The foreign language press has shown the largest decrease in number of papers, especially those printed in German. The stricter immigration laws have doubtless reduced most materially the audience to which such a newspaper addresses itself. Consequently numerous papers have begun to insert departments printed in English and possibly have in mind the time when still more space, if not the entire paper, must be given over to material in English. The decrease in foreign language papers has been most marked in New York and Chicago.

Legal Enactments.—Two government regulations, both of Aug. 24 1912, need passing mention. The first provided that all periodicals should "file with the Postmaster-General and the postmaster at the office at which said publication is entered, not later than the first day of April and the first day of Oct. of each year a sworn statement setting forth the names and post-office addresses of the editor and managing editor, publisher, business managers and owners, and, in addition, the stockholders, if the publication be owned by a corporation; and also the names of known bondholders, mortgagees, or other security holders; and also, in the case of daily newspapers, there shall be included in such statement the average of the number of copies of each issue of such publication sold or distributed to paid subscribers during the preceding six months."

The other Act provided that "all editorial or other reading matter published in any such newspaper, magazine or periodical for the publication of which money or other valuable consideration is paid, accepted or promised shall be plainly marked 'advertisement.'" These two regulations have made circulation statements more truthful and have made American newspapers more ethical from the advertising point of view. Incidentally, it may be said that the most remarkable change in American journalism from 1910 to 1925 may be found in the advertising columns where truth in advertising has been promoted both by state statutes and by support of the Associated Advertising Clubs of the World. The Association of National Advertisers has gone definitely on record as being opposed to black squares, circles, sweeping curves and the follow-the-arrow lines—all of which smudge the typographical appearance of newspapers.

Advertising, the economic background of the newspaper, has with slight fluctuations steadily increased in volume since 1910. A remarkable fact is that newspaper advertising in 1925 was double that of 1914 and 5% more than that of 1924. Advertising rates for newspapers in metropolitan cities have advanced with increases in circulation. But carefully collected statistics indicate that in smaller cities and towns the increase in advertising rates have been in proportion to increased operating expenses. Mention has already been made of the ethical advance in advertising copy. An unusually high standard has been set by the New York *Times* in order to prevent the printing of fraudulent and misleading advertisements. Where advertising offered has exceeded the space available, *The Times* and other newspapers have favoured advertisements that had news value.

Overseas Newspapers.—A postscript paragraph may be inserted about American journalism overseas, the Paris edition of the Chicago *Tribune* and the European edition of the New York *Herald*. The latter, the first in the field, was started in Paris in 1887 merely to gratify a whim of the late James Gordon Bennett. It was the only newspaper in English and one of the few in any language to publish in Paris when the Germans were practically battling at the gates. In the latter half of 1918 and the first half of 1919 this *Herald* reached its largest circulation (400,000). The sale of the New York *Herald* to Mr. Munsey included its Parisian namesake; he put in charge of it as managing director Laurence Hills, who remained in control when the paper in 1924 was again sold to the New York *Tribune*. The Paris edition of the Chicago *Tribune* was something of a war enterprise and was started on July 4 1917 with Joseph Pierson as editor. As the number of American troops increased the circulation grew and at Armistice time it numbered around 100,000. The managing editor (1926) is Bernhard Ragner.

Magazines.—New York City has, if anything, strengthened its claim of being the publishing centre of the periodical press, except possibly for agricultural publications and religious journals. To be more exact, the editorial offices are in New York City, but the periodicals themselves are being printed in plants often outside even of the State of New York. While technical journals have not experienced consolidations to the extent found in the newspaper field, they have tended to drift to the larger publishing corporations to save overhead charges and permit economy in composition and in the purchase of paper. In technical and trade magazines the improvement in the literary quality of material and in the mechanical make-up of pages has been especially noticeable since 1910. Industrial journalism is yielding greater profit than ever before in its history—profits that have come for the most part from increased advertising.

Popular magazines have seen a much more radical change than newspapers. Dime novels have taken on a new dress and now appear nicely printed as magazines with three-colour covers. Clean and wholesome for the most part, these magazines of adventure have done little harm compared with the sex-story magazines of which the United States has had enough and to spare. The epidemic of questionable magazine fiction must be left for explanation to the pathological expert. Fortunately, the decline in questionable fiction seemed at the close of 1925 to be in sight. Three magazines now published consist almost entirely of reprints of short story classics; they are *The Golden Book*, *The Famous Story Magazine* and *Ainslee's Magazine*. The first two are new publications and the last was formerly a short story magazine which had done much to develop new writers. It introduced O. Henry, for example, to America. Feeling the competition, some of the popular magazines changed their editorial policy and limited their contents exclusively to fiction. *Everybody's Magazine* and *Munsey's Magazine*, at the close of 1925, illustrate this change. Of the literary trio, *Harper's*, *The Century* and *Scribner's*, the last only has remained unchanged. *Harper's* and *The Century* now appear without illustrations for their special articles and have materially changed the character of the fiction which they print. It must be frankly admitted that news stands do not offer purchasers the same quality of goods in 1926 as they did in 1910.

The brighter side of the picture for 1926 may be found in that *The National Geographic Magazine* of Washington has a circulation of nearly 1,000,000 and that *The Atlantic Monthly* has the largest circulation in its history. *The North American Review* has become a quarterly and now competes with *The Yale Review* which was started in 1911. *Current History Magazine*, started by the New York *Times* in 1914, presents each month an intelligent discussion of public affairs. *The World's Work*, though a trifle more popular in its mode of treatment of articles, has not departed from its high standards. The sophisticated reader is having his needs met by *The American Mercury*. *The Nation* has changed from a conservative to a somewhat radical organ and *The Independent* after several ups and downs—chiefly the latter—has moved from New York to Boston where it seems to be regaining its old popularity. *The Weekly Review* and *The Freeman* are no longer published. They disappeared about the same time as *The Unpopular Review*.

The periodical having the largest circulation in the United States (2,436,734) is *The Saturday Evening Post* of Philadelphia which, both in its fiction and special articles, is addressed to men. Publications designed to appeal primarily to women have since 1910 witnessed a remarkable growth in circulation. *The Ladies' Home Journal* of Philadelphia, *The Pictorial Review* of New York and *McCall's Magazine* of New York have each a circulation exceeding 2,000,000, while *The Woman's Home Companion* of New York has one nearly reaching that figure and *The Delineator* of New York has a circulation of over

1,000,000. Mr. Hearst has purchased *The Cosmopolitan*, *Good Housekeeping* and *Harper's Bazar*. With the first mentioned he combined in 1925 *Hearst's International Magazine*.

Radio and motion pictures have added to the periodical press numerous technical and popular journals. The introduction of the magazine section into the Sunday newspaper explains to some extent the disappearance of articles from popular magazines. The pictorial and rotogravure sections of the Sunday newspaper account, in part, for the disappearance of *Harper's Weekly* and *Leslie's Weekly* and the changing in contents of *Collier's Weekly*. The suspension of *The Bellman* of Minneapolis was deeply regretted by its readers. Among the new periodicals the success of *Liberty*, edited in New York and published in Chicago, is somewhat startling. Established in 1924 it had at the end of 1925 a circulation of over 1,000,000. In conclusion, it must be frankly said that the average American reader is seeking entertainment and amusement rather than education and enlightenment in his periodical literature.

South America

The two leading newspapers, not only in Argentina but also in South America, are *La Prensa*, founded Oct. 18 1869 by Dr. José C. Paz, and *La Nación*, founded Jan. 4 1870 by Gen. Bartolomé Mitre, of Buenos Aires. For 56 years (1926) both papers have remained in the families of their founders. Each compares favourably with any other newspaper in any country. Both specialise in printing foreign news; possibly *La Nación* pays more for cable tolls than any other newspaper in the world. Classified advertisements are usually a safe index as to character of newspapers because they represent local opinion. Judged by such a yardstick, *La Nación* resembles the New York *Times* and *La Prensa* the New York *World*. The editorial page of *La Nación* is always dignified in subject-matter and serious in mode of treatment. Its Sunday supplement contains contributions from the best writers, not only of Argentina but also of Spain. Much material later appears in book form. *La Nación* had (1910) a circulation of 80,000: its sworn statement of daily average for Aug. 1925 was 192,007: its average Sunday circulation for the same month was 238,000. At the first Pan-American Congress of Journalists held in Washington in April 1926 Dr. Jorge A. Mitre had the honour of responding to the address of welcome by the President of the United States. He is a grandson of the founder of *La Nación* who was the first constitutional president of the Argentine Republic.

To campaign for civic righteousness seems to be the editorial policy of *La Prensa*. Its evening competitor, *La Razón*, established in 1905, once spoke of it as being a safe and serene guide in the difficult task of creating a public conscience. *La Prensa* widens its influence through syndicating to some 175 provincial papers a weekly feature supplement for Saturday or Sunday editions. *La Prensa* operates a free clinic, offers free legal advice to the poor, pays for a free industrial and agricultural bureau, opens its library to the public and awards 1,000 pesos annually to the person teaching the largest number of illiterates to read. The oldest evening paper in Buenos Aires is *El Diario* (est. 1881). The oldest of all is the English paper, *The Standard* (est. 1861) which competes with *The Herald* (est. 1876). In 1925 Argentina had about 1,000 newspapers and other periodicals.

Crossing the Andes, one finds the newspapers of Chile next in influence. First comes *El Mercurio* (est. 1827) of Valparaiso with separate publication in Santiago and Antofagasta. Its chief competitor is *La Union*, which also publishes a paper of the same name in Santiago. In the city last mentioned are the rather influential *La Nación* and *El Diario Ilustrado*. The total number of newspapers and periodicals published in Chile (1925) is about 500. In Peru the three leading papers are *La Cronica*, *La Prensa* and *El Comércio* of Lima.

In Brazil the most influential paper is probably *O Estado* of São Paulo. *Fanfulla*, the Italian daily of that city, wields considerable power through the State of São Paulo. The oldest and best known daily in Rio de Janeiro is the *Jornal do Commercio* (est. 1827), an extremely conservative paper of limited circulation. Two other influential morning papers are *O Paiz* and *Correio da Manha*. Newspapers in Brazil are often the personal organs of owners to whom they are useful for political purposes. At the fall of the Empire Brazilian journals numbered about 600. In 1910 the total exceeded 1,000, since when the increase has been about 100 to a decade. The more influential papers in Mexico are limited to the capital city and frequently contain features obtained from American syndicates. They include *El Universal*, *El Nacional* and *El Democrata*.

References.—James Melvin Lee, *Historia de la Prensa Periodística de la América del Sur;* Affonso Celso, *Historia da Imprensa do Brazil;* Ricardo Rojas, *La Literatura Argentina.*

To South America, rather than to its sister continent to the north, belongs the honour of printing the first sheets of news in the Western Hemisphere. Not only in contents but also in mechanical make-up they followed the pattern set by the sheets of Southern Europe. This relationship was further emphasised by a similarity in titles for these precursors of printed newspapers: *Gazeta Diario*, *Mercurio*, *Relación*, etc. But these stray sheets lacked regularity of publication and continuity in presenting news. The first newspapers, in the technical sense of that term, for the countries of South America may be listed as follows:—

Mexico. *Gazeta de México* (1679).
Guatemala. *Gazeta de Goatemala* (1729).
Peru. *Gazeta de Lima* (1744).
Cuba. *La Gaceta de la Habana* (1764).
Colombia. *La Gaceta de Santa Fé* (1785).
Ecuador. *La Gaceta* (1785).
Argentina. *El Telégrafa Mercantil* (1801).
Haiti. *La Gaceta del Cabo* (1804).
Uruguay. *La Estrella del Sur* (1807).
Brasil. *Gazeta do Rio de Janeiro* (1808).
Venezuela. *La Gaceta de Caracas* (1808).
Chile. *La Aurora de Chile* (1812).
Panama. *Miscelanea del Istmo* (1822).
Bolivia. *El Condor de Bolivia* (1825).
Paraguay. *El Paraguay Independiente* (1845).

Bibliography.—Before 1910 the literature relating to journalism was most scant and jejune, but since then books have rapidly increased in number. Histories of individual newspapers include: *History of the New York Times 1851–1921*, Elmer Davis (1921); *The Story of a Page* (N.Y. World), John L. Heaton (1913); *The Story of the New York Sun 1833–1918*, Frank M. O'Brien (1918); *The Evening Post* (New York), Allan Nevins (1922); *The New York Globe*, James Melvin Lee; and *The Story of an Independent Newspaper* (Springfield Republican), Richard Hooker (1924). Among the books on newspaper editing and making are: George C. Bastian, *Editing the Day's News;* Willard G. Bleyer, *Newspaper Writing and Editing* (1923); Jason Rogers, *Newspaper Building* (1918); Norman J. Radder, *Newspaper Make-up and Headlines* (1924); M. Lyle Spencer, *News Writing* (1917); Oswald Garrison Villard, *Some Newspapers and Newspaper Men*, offers a critical survey of some of the leading American newspapers; L. N. Flint, *The Conscience of the Newspaper* (1925), and N. A. Crawford, *Ethics of Journalism*, make notable contributions to the field of ethics. *The New York Times* publishes in book form a quarterly index for that newspaper in particular and others in general. Carl L. Canon, *Journalism—A List of References in English*, lists both books and magazine articles relating to journalism. James Melvin Lee, *Instruction in Journalism in Institutions of Higher Education* (U.S. Dept. of Education, 1918), traces the development of such instruction since the first school of journalism was established at the University of Missouri in 1909. (J. M. L.*)

IV. NEWSPAPERS IN OTHER COUNTRIES

Freedom of the Press did not accompany the introduction of democratic institutions and universal suffrage. The Press laws in the new countries of continental Europe usually begin with the declaration that the Press is free and then follow with provisions which can be used to muzzle or suppress the newspapers. Nevertheless there has been a significant growth of newspapers representing Social Democrats, Socialists and Communists, and so long as they do not openly advocate revolution and direct action for upsetting the social order they are tolerated. In Germany, the Social Democratic Press has gained in strength as the parties are well organised and associated with the trade union movement. It is the same in Czechoslovakia and Austria. In France, where the trade unionists are loosely organised and

undisciplined, there has been no notable increase in journals representing the extreme Left in politics. In all the new countries there are papers representing agrarian interests as well as democratic. All parties have their newspapers and governments have organs which are more or less official.

Germany.—Under the old German Empire, especially when Bismarck was the power behind the throne, the Press was not respected, but it was exploited by the Government for its own purposes. There was liberty of the Press within reason and a few independent voices were raised; but, as a rule, most papers were obliged, for one reason or another, to accept inspiration from the Foreign Office. In domestic affairs they reflected the opinion of political parties. Journalists did not enjoy a high standing, but before 1914 they had begun to conquer positions in the political world. To-day the Press has complete freedom and is independent of the Government. The German Press is the most serious in Europe. There are few sensational newspapers. Newspapers do not sell because of sport and "stunts." Journals which cater to the working classes discuss economic problems. Literature, the drama, art, music and economics occupy a greater proportion of space in German newspapers than in the Press of any other country.

The journalistic characteristics of the German Press—apart from the greater freedom which it now enjoys—have not changed since the War. The former national organs occupy relatively the same positions, but there has been a shifting of ownership, not due to the political revolution but to the effects of inflation. During this period of inflation many of the old family newspaper owners, particularly in the provinces, were unable to survive and sold to industrialists. Hugo Stinnes, the industrial magnate, was able to create a great newspaper trust, which was, however, broken up after his death, when his mushroom millions were dispersed. There are few afternoon papers in Germany. A new syndicate, financed by industrialists, is the Hugenberg Press, which owns a string of country newspapers. It has its own news agency. It is a new political force representing Nationalist feelings. While the Nationalist newspapers are controlled largely by industrialists, the organs of the Centre or Roman Catholic party are under strict party control and owned by party men. The Centre represents about a third of the population of Germany, but its Press, although vigorous, consists of papers which have not big circulations. The most influential are the *Germania* of Berlin, and the *Volkszeitung* of Cologne. Another group of papers which has increased in prestige since the War is the Democratic and Social Democratic Press, powerful factors in political life.

The German Government has no longer an interest in newspapers as in the days of the Kaiser, when the Foreign Office directed or swayed the policy of several political journals. Its connection with the Press is now confined to its participation in Wolff's Agency, which is parallel to the Havas Agency in France.

Among the most independent and influential papers in Germany are the provincial organs, *Frankfurter Zeitung* and the *Kölnische Zeitung*, known throughout the political world as the *Frankfurter* and the *Kölnische*. The chief papers in Berlin are the *Börsen Zeitung* (non-party), the *Lokal Anzeiger* (Popular), *Der Tag* (Nationalist), the *Berliner Tageblatt* and *Vossische Zeitung* (Democratic), *Allgemeine Zeitung* (Nationalist), the *Tägliche Rundschau* (Patriotic), *Deutsche Tageszeitung* (National and Agrarian), the *Morgenpost* (Democratic) and the *Vorwärts* (Social Democratic) and a Communist paper, *Die Rote Fahne* or *Red Flag* (sale, 65,000). The more popular papers in Berlin have sales exceeding 250,000. Among the most widely circulated papers outside Berlin are the *Erzgebirgischer Volksfreund* (Democratic), which has a daily circulation of over 100,000. The *Düsseldorfer Nachrichten* (Independent-National), which reaches the same figure, the *Frankfurter General-Anzeiger*, 115,000, the *Hamburger Anzeiger*, 110,000, the *Leipziger Neueste Nachrichten* (Patriotic), 175,000, the *Münchner Neueste Nachrichten* (National), 145,000, the Dortmund *General Anzeiger* (non-party), 122,000, and the *Dresdener Neueste Nachrichten* (Liberal Democratic), over 100,000. There are a number of Communist journals, including, besides the Berlin *Rote Fahne*, papers in the following cities: Breslau, the *Arbeiterzeitung*, sale 15,000; Chemnitz, *Der Kampfer*, 75,000; Bochum, the *Westfälischer Arbeiter Zeitung*, 22,000; Essen, the *Ruhr Echo*, 47,000; Hamburg, the *Volkszeitung*, 25,000; Leipzig, the *Sächsische Arbeiterzeitung*, 30,000.

There are several newspapers which occupy a status and exercise an influence in German journalism and public life which cannot be measured by sales. The *Frankfurter Zeitung*, already mentioned, is perhaps the most powerful. It has 19 issues a week—morning and afternoon. Of a similar type is the *Kölnische Zeitung* and the *Hamburger Nachrichten*, founded in 1792. The *Jenaische Zeitung* has been in the same family since it was founded in 1674. A still older paper, the *Königsberger Hartungsche Zeitung*, dating from 1640, keeps its flag flying in the Eastern outpost on the Baltic. Papers published in districts which are inhabited by Germans, although not now under the German flag, are intensely Nationalist, such as the *Saarbrücker Zeitung*, papers in Polish Upper Silesia, Danzig and other territories formerly included in the Empire.

In Germany, no general newspapers are published on Monday, except two or three in Berlin. Sunday is a day of rest to newspaper workers. The provincial morning papers in Germany issue three editions during the day, the contents varying more or less. In Berlin, two editions are issued.

According to the *Politischer Almanach* there are over 100 important newspapers in Germany, and 38 serious political journals, representing all shades of political opinion. There are 24 large news agencies in Berlin, with branches in the chief cities. All the political parties have their Press agencies. Among the best-known German Reviews are the *Preussische Jahrbücher*, *Deutsche Rundschau*, *Neue Rundschau*, *Süddeutsche Monatshefte* and the *Neue Zeit*.

France.—In no other country is the political influence of the Press so great, or its literary merits so high, as in France. In France, journalism is literature and literature is journalism. Journalism and politics are also inextricably mixed. Presidents of the Republic, Prime Ministers, Colonial Governors, Academicians and others who attain high positions in national life, graduate through the Press. When they retire, they return to their muttons. The most famous journalistic statesman was Georges Clemenceau, the great War Premier. He retired a year after the Treaty of Peace was signed, and at the age of eighty was an unsuccessful candidate for the Presidency. He did not profess disappointment at his failure but consoled himself with the observation: "What matters; with good pen and paper one could be king of the world." While the literary reputation of the French Press stands high, its commercial and political morality is not on the whole quite so commendable. Many newspapers are run for, or by, ambitious politicians, or in some interest, and nearly all of them accept inspiration from the Foreign Office. Ministers change frequently but the system remains. It is like part of the constitution. The smaller papers—and there are many of them—farm out their financial and advertising columns to agencies.

The French Press has been little changed by the World War. During the War many newspapers temporarily disappeared, owing to the lack of staff, or of means, or shortage of paper. All papers were under a severe censorship and, more than ever, were the servants of the Government.

In 1926 there were 227 political journals published in Paris, of which 48 were political dailies. This total does not include papers dealing with technical subjects or sport. There were 127 sporting newspapers, of which five were dailies. The number of newspapers published in the provinces was 3,076, including publications of all descriptions. Morning and evening dailies numbered 256.

France was the first country to have national newspapers with sales of over 1,000,000. The sale was stimulated more by two serial stories run by each paper than by news, but since the War news has become conspicuous in such widely circulated papers as *Le Petit Parisien* (1,200,000), *Le Petit Journal* (1,000,000),

Le Matin (900,000) and the *Petit Journal* (800,000), which may be described as the "Big Four of the Paris Press." Following upon these in point of sales comes the *Echo de Paris* (800,000). The better-known political papers are *Le Temps*, the venerable *Journal des Débats*, *La Liberté*, *L'Oeuvre*, *L'Humanité* and the *Ere Nouvelle*. The *Figaro* maintains its unique position. Characteristics of all the popular Press are signed articles and serial stories. There is a popular daily illustrated paper, *Excelsior*, established 1910, and numerous dailies devoted to sport, finance, the drama, motoring, etc. Four daily papers are published in Paris in English; *The Daily Mail*, *The New York Herald*, *The Chicago Tribune* and *The Evening Times*. Every phase of politics is represented in the Paris Press, from Legitimist to Communist, and every trade and interest has its organ. The provincial Press is more independent politically than the Paris papers and several journals, such as the *Dépêche* of Toulouse, the *Progrès*, of Lyons, the *Petit Marseillais*, *La Petite Gironde* of Bordeaux, have national reputations. The small local Press exercises an independent influence during elections.

Improvements have taken place in the mechanical equipment of the French Press in recent years, and there has been a marked increase in illustrated weeklies and monthlies. The best known weeklies are the dignified *Illustration* and the gay *Vie Parisienne*, which flourished during the War, the literary *Annales Politiques et Littéraires*, and a light variety paper *Nos Loisirs*. The *Revue des Deux Mondes*, the *Mercure de France* and the *Revue Hebdomadaire* are the best known monthlies. The sale of the French Press is pushed all over Europe. The chief news agency, Havas, has official support. There is also a universal wireless service which broadcasts news and propaganda. It is a subsidiary of the wireless company, which holds a concession from the State.

Italy.—Until the fascist régime of Mussolini, the Italian Press laws were based on a Royal decree of 1848. In July 1924 a decree was issued which made newspapers liable to suppression and editors to punishment if they published "tendencious news" which might embarrass the Government in foreign or domestic affairs; and an elastic interpretation of these powers has enabled the Government to suppress all newspapers which ventured to offer any independent criticism to such an extent that in the early part of 1926 the freedom of the Press no longer existed. The most famous newspapers in Italy suffered punishment, and were only tolerated on condition that they refrained from hostile criticism. Where the Press was not muzzled there was a forced change of proprietorship in harmony with Fascist policy. This was the case with the well-known *Corriere della Sera* of Milan, for some years the most powerful organ in Italy. The *Stampa* of Turin, although never strongly anti-Fascist, was tamed; the same fate overtook the influential journal in the south, the *Mattino* of Naples. The complexion of the best-known papers in Rome has been changed. The only journals which enjoy a certain restrained independence are the semi-official organs of the Vatican. A number of newspapers have ceased to exist, and the journalists' associations have been placed under the control of Government Commissioners. There were only 68 daily newspapers in Italy in 1926.

The Press in New Countries.—The rebirth of nations after the World War was followed by a revival in journalism. Every new State had its crop of new journals. Although freedom was not complete, the influence of political parties led to the maintenance of rival organs. Under the three Empires out of which it was carved, Poland's Press existed on sufferance. Now, there are nine daily papers in Warsaw—two of them official, one in Polish and one in French. There are four dailies in Cracow and several in other cities. Besides exponents of the various national political policies there are Zionist, Ukrainian and German papers in Poland, but the authorities sometimes suppress non-Polish journals.

In Czechoslovakia there is a greater measure of freedom and there are far more newspapers. The Press of Yugoslavia has not yet developed a full sense of responsibility. It represents all races, policies and languages. New Turkey now possesses a democratic Press which can speak its mind within limits. The new Baltic States have a Press which is creditable for the small populations for which it caters. In these states and in other territories, where under old conditions there were German interests, newspapers in German are still published. The Press of new Rumania is largely concentrated in the capital, Bucharest, with 24 dailies, of which one is in French and three are in German. In Hungary the popular papers are in the Magyar language—*Az Est* and *Az Ujsag*—and the most influential in German—the *Pester Lloyd* and the *Neues Pester Journal*. The Austrian Press—still headed by the *Neue Freie Presse* of Vienna—is free, but not flourishing under the narrowed limits of the country. Under the new Austrian Press laws power is given to the educational authorities to prohibit the sales of newspapers which "by exploiting youthful impulses may endanger the normal health of young persons."

Russia.—Freedom of the Press has been completely suppressed in Soviet Russia. In Tsarist Russia censorship was severe, but a measure of toleration existed. In Soviet Russia censorship is applied before the matter is printed, which has to be submitted to an official editorial Board known as the Gosizdat. There is a further check on the publication of news and expression of opinion, as newspapers are only published under the auspices of the governing authorities and are thus practically all official organs.

In 1914 there were 17 dailies in the capital, some of them of international reputation, such as the *Novoe Vrèmja*, and the *Retch*, and five in Moscow. In 1910 there were 52 daily newspapers in Russia, of which 13 were in St. Petersburg (Leningrad), and four in Moscow, exclusive of papers in Finland and Polish Russia. In 1926 almost all the Press was concentrated in Moscow. There were 11 morning and evening papers in Moscow, but only two of any importance, the *Izvestia* and the *Pravda*. In Leningrad there were only two morning papers, the *Pravda* and the *Krasnaya Gazeta*. The number of daily newspapers in Russia was, in 1926, eighteen.

Belgium.—Belgium possesses a vigorous Press, published in French and in Flemish. Although the chief Paris papers circulate all over Belgium, the Belgian Press nevertheless enjoys a large sale, and the popular journals are highly prosperous. There are 17 daily papers published in Brussels and nine in Antwerp. There are a number of Socialist journals, the chief organ of the party being *Le Peuple*. The success of the Socialist Press is due largely to its association with the co-operative movement. *La Libre Belgique*, which appeared regularly during the War in occupied Belgium in spite of the vigilance of the Germans, now exists as a daily newspaper. In Belgium, the Press laws have not been changed for many years and the Press enjoys almost unlimited freedom.

The Netherlands.—The Netherlands, with a population of over 7,000,000, possesses a healthy Press, including journals which enjoy a high reputation for their literary merits and as organs of opinion. The chief among these are the *Nieuwe Rotterdamsche Courant*, *De Telgraaf* and the *Algemeen Handelsblad*, of Amsterdam. There are eight daily papers in Amsterdam, seven in The Hague and five in Rotterdam, and these circulate throughout the country.

Scandinavia.—The newspapers in the Scandinavian countries appeal to a highly intelligent reading public and are among the best written and the best produced on the Continent. The three kindred races can understand each others' newspapers.

Spain and Portugal.—There is little progress to record in the Spanish Press, and circulations are small. The illustrated *A.B.C.* is the most popular paper. The *Imparcial* is an important political organ. The *Heraldo* and the *Liberal* are other leading Madrid journals. *El Sol* was founded in 1917 by the Spanish Paper Trust. There are 20 daily papers in Madrid and 17 in Barcelona, and about 200 dailies of sorts in Spain. The principal Portuguese papers are the *Diaris Noticia* (founded 1820) and the *Jornaldo Commercio*, both published in Lisbon.

Switzerland.—Switzerland, owing perhaps to its small population, has few papers known outside the country. In 1926 there were 38 daily newspapers published in German, 19 in French

and two in Italian. The best known are the *Journal de Genève*, read in France, the *Neue Zuercher Zeitung* and the *Zuericher Post*, which have a considerable circulation in Germany.

China.—By no means the least result of the Chinese revolution of 1911 was the amazing expansion of the vernacular press. Actually the movement had begun some years earlier, but after the revolution it developed into a portent. Native newspapers sprang up in all parts of the Empire in a night, as it were, and it is not surprising that the Chinese Press exhibits most of the undesirable attributes of a mushroom growth. The general quality is poor. Most of the papers are run for political or personal ends, the news supplied by them is untrustworthy and their standard of journalistic ethics low. This is the more to be regretted as their multitude testifies to the interest which awakened China takes in affairs and their influence on public opinion is beyond doubt enormous; but little improvement is to be expected until political conditions become more settled. As things are it is only fair to say that, with all its irresponsibility and corruption, the Chinese Press is on the whole liberal and patriotic in intention if not always in fact. It may be noted that Chinese periodical publications are on a much higher level than the newspaper press.

Between twenty and thirty European and American newspapers are published in China, more than half of them at Shanghai. The majority are British, including the *North China Daily News* of Shanghai which, founded in 1864, is the oldest foreign daily in China. Other British morning newspapers are *The Shanghai Times, The Central China Post* (Hankow), *The Peking and Tientsin Times, The Hongkong Daily Press* and *The South China Morning Post* (Hongkong), The principal British evening papers are *The Shanghai Mercury, The North China Daily Mail* (Tientsin), *The Hongkong Telegraph* and *The China Mail* (Hongkong). There are three American morning dailies, *The China Press* (Shanghai); *The Peking Leader* and *The North China Star* (Tientsin)—and three French, *L'Echo de Chine* (Shanghai), *Le Journal de Pékin* and *L'Echo de Tientsin*. In addition there are a number of Chinese and Japanese-owned journals published in English.

Japan.—The restraint of the Press which was common to all belligerent countries during the World War was maintained much longer in Japan than elsewhere, and it was not until 1922 that the War-time regulations were repealed. Nevertheless the period 1911–25 was marked by steady progress and a great expansion of the circulation of the more important newspapers, and while there is no Japanese journal that can be said to belong to the first class in the world's Press, there are several that rank high in the second class. The most widely read newspapers are the *Osaka Asahi Shimbun* and the *Osaka Mainichi Shimbun*, each of which has a circulation of 700,000 daily. The leading Tokyo papers, such as the *Jiji Shimpo* and the *Tokyo Nichi Nichi Shimbun*, are influential but have a far smaller circulation. The most notable feature of Japanese newspaper enterprise during the period under review was the growth of the evening Press. Formerly there was but one evening paper, the *Maiyu Shimbun* of Tokyo, and even now there are, strictly speaking, only two, the *Tokyo Mainichi Shimbun* having been converted into an evening paper in 1918, but practically all the principal morning dailies publish evening editions.

NEW TESTAMENT: *see* BIBLICAL CRITICISM.

NEW YORK CITY (*see* 19.610).—The population of New York City in 1925, according to the State census, was 5,873,356, as against 4,766,883 in 1910, an increase of 1,106,473 or 23·2%. The population of the separate boroughs was: Manhattan, 1,945,029 (in 1910, 2,331,542); Bronx, 872,168 (in 1910, 430,980); Brooklyn, 2,203,235 (in 1910, 1,634,351); Richmond, 138,277 (in 1910, 85,069); Queens, 714,647 (in 1910, 284,041). The average number of inhabitants per acre was: Manhattan, 139·0; Brooklyn, 48·5; Bronx, 32·9; Queens, 10·3; Richmond, 3·8; whole city, 30·6. In 1924 the average death-rate for the city was 11·8 per 1,000, as compared with 15·98 per 1,000 in 1910. The reduction of the general death-rate has been due mainly to special activities in the prevention and control of communicable diseases, especially those of childhood.

I. PUBLIC SERVICES

Finance.—The city's budget grew from $163,130,270 in 1910 to $399,618,885 in 1925. Important items were $95,099,162 for education and recreation; $59,068,521 for protection of life and property; $60,255,956 for health, sanitation and care of dependents; $106,487,232 for debt service and tax deficiencies. The assessed values on which taxes for 1925 were levied were $11,901,348,553 real estate and $239,507,540 personal property, or a total of $12,140,856,093. In 1910 the total assessed value of taxable property, real and personal, was $7,416,837,499. The net funded debt of the city as of March 1925 was $1,262,736,066, the gross funded debt being $1,969,515,440.

Water Supply.—The most notable extensions to public services made since 1909 include the development of additional water supply from the Esopus and Schoharie watersheds in the Catskill Mts., and extending rapid transit facilities throughout the city. The two watersheds have an area of 571 sq. m. and a safe minimum yield estimated at 515,000,000 gal. daily. The flow of the Schoharie creek is intercepted by a temporary diversion dam through the Shandaken tunnel, 18 m. long, to join the water of Esopus creek, which discharges into the Ashokan reservoir. The Gilboa dam, under construction in 1925, was designed to form the Schoharie reservoir with a storage of 20 thousand million gallons. The main reservoir of the system, the Ashokan, is located about 92 m. from the northern boundary of New York City. Its estimated available storage capacity amounts to 130,400 million gallons. Other features of the Catskill system are the Kensico dam, the Catskill aqueduct and city tunnel and the Hudson river crossing. The Kensico dam is one of the great masonry structures of the world, containing nearly 1,000,000 cubic yards of masonry and at its highest point rising 307 ft. above the rock fonndations on which it rests. The Catskill aqueduct includes 69 m. of plain concrete grade aqueduct and tunnel, 17 m. of reinforced concrete pressure tunnel and 6 m. riveted steel inverted siphons. The Hudson river crossing comprises a 14-ft. tunnel driven in granite rock 1,114 ft. below the sea-level. The total cost of the completed Catskill supply will be about $180,000,000. Other supplies, together with the Catskill, provide a safe yield estimated at approximately 1,000 million gal. per day. Water consumption during 1925 reached 865 million gal. per day, thus indicating the need for developing additional supply in the near future.

Rapid Transit Development.—As a means of meeting the demand for additional rapid transit facilities, the city, in March 1913, entered into separate contracts with the Interborough Rapid Transit Co. and the New York Municipal Railway Corporation, for the construction, equipment and operation of a system of rapid transit lines known as the dual system. At that time the Interborough Rapid Transit Co. operated the subway lines in Manhattan, the Bronx and Brooklyn and under lease the elevated lines owned by the Manhattan Railway Company. The New York Municipal Railway Corporation was formed in the interests of the Brooklyn Rapid Transit Co. for the operation of various lines constructed or to be constructed as outlined in the dual plan. The New York Railway Co. and Third Avenue Railway Co., which operated most of the surface lines in Manhattan and the Bronx and the surface lines of the Brooklyn Rapid Transit Co. were the only large traction systems in the city not included in the dual system. The operating contracts made with each company run for a period of 49 years (dating from Jan. 1 1919 in the case of the Interborough; and from Aug. 1 1920 for the Brooklyn Co.), at the end of which time all leases and agreements will terminate and the city will have complete ownership and control over the construction included in the dual plan. Provision is made for the sharing of profits with the city after the

operating company has paid all necessary expenses and taken out an amount designated as a preferential. The contracts also specify that the fare for a continuous ride shall be five cents.

The dual plan provided for the construction of about 325 m. of new tracks, making the total mileage of the completed system 618·4. While the plan as outlined approximately doubled the existing mileage, it tripled the facilities then available, as the third tracking and extension of existing elevated railways materially increased the carrying capacity. For the Interborough these extensions comprised subway construction north and south of 42nd street, Manhattan. North of 42nd street, the new subway extended up Lexington avenue and connected with the existing Fourth avenue subway. New subway construction south of Times Square extended the west side subway down Seventh avenue to lower Manhattan and by tunnel under the East river and to South Brooklyn. This construction provided independent through north and south rapid transit lines for the east and west sides of Manhattan Island. The addition of third tracks and extension of existing elevated lines have brought the route mileage to 115·4, and the total track mileage for the Interborough system to 333·3.

The main feature of the extension of the lines of the New York Municipal Railway Corporation was the subway beginning at the Queensboro Bridge and extending west by 59th and 60th streets to Seventh avenue, thence south by Seventh avenue, Broadway, Vesey street, Church street and Trinity place to a connection with a tunnel under the East river at Whitehall street. This construction and other extensions make a total of 99·4 route m. and a total track mileage for the New York municipal railway system of 274·3 m. now in operation. A continuous ride of 26·63 m. for five cents is available on the Interborough system and one of 18·5 for the same fare on the Brooklyn lines. Up to June 30 1925, expenditure by the city and the operating companies for rapid transit construction and equipment, exclusive of the cost of the privately owned lines of the old Manhattan elevated structures, amounted to approximately $537,000,000. Of this amount the city's part was about $327,000,000 and the operating companies' $210,000,000.

Communications.—Two important enterprises in providing additional direct lines of communication with New York City are the New York connecting railway across the East river and the vehicular tunnel under the North river. The New York connecting railroad provides direct rail connection with the New York, New Haven and Hartford line for the boroughs of Queens and Brooklyn. The main features include a reinforced concrete arch viaduct extending from the connection with the New York, New Haven and Hartford railroad in the Bronx to a point on Ward's Island, in the East river, a steel arch spanning that section of the East river known as Hell Gate, and connecting with a similar reinforced concrete viaduct in the Astoria section of Queensborough. Surface construction provides direct passenger rail connection with the Sunnyside Yard of the Long Island railroad and thence access to the Pennsylvania railroad terminal in Manhattan, while another branch for freight only extends to the Bay Ridge section on the water-front of South Brooklyn. The entire length of the connecting railway is 12 miles. The total amount expended was approximately $30,000,000. The bridge itself (Hell Gate), having the largest steel arch in the world, cost $18,500,000. Its massive granite piers rise to a height of 240 ft. and are 1,017 ft. apart. The steel arches which support the deck of the bridge rise 300 ft. above the water, and the clearance for vessels at mean highwater is 135 feet. The bridge carries four tracks, two of them for both passenger and freight service.

The Holland vehicular tunnel beneath the North river connecting Manhattan Island and Jersey City was to be open for traffic during 1926. Its construction is under the joint jurisdiction of the New York Interstate Bridge and Tunnel Commission and the New Jersey Interstate Bridge Commission, and the cost was to be shared equally by the two States. The estimated traffic capacity of the tunnel is 15,000,000 vehicles per annum. The tunnel section, the construction of which was completed Oct. 1 1925, comprises two tubes each 29 ft. 6 in. outside diameter and approximately 9,500 ft. in length. The tubes are constructed of cast-iron segments and reinforced concrete and were built by the Shield method of construction. Each tube includes a 20-ft. roadway to accommodate two lines of traffic moving in the same direction and a 3-ft. sidewalk for pedestrians. The greatest single engineering difficulty involved was that of providing an adequate system of ventilation. That adopted was the so-called transverse system, under which fresh air is forced into the tunnel structure through air ducts under the roadway and ejected into the tunnel section through apertures along the roadway curb at each side The foul air is discharged through air ports in the tunnel roof section, and thence forced through air ducts to the ventilation shafts and the outer air.

Other Public Improvements.—Growth of the city and the great development in the use of motor vehicles have produced serious traffic congestion which has necessitated extensive street widening and the construction of new thoroughfares. Notable examples of new construction are the Varick street extension of Seventh avenue, Manhattan, the extension of Flatbush avenue, Brooklyn, and the construction of the Jamaica Bay boulevard in Queens. The removal of elevated railway structures from 42nd street and Upper Sixth avenue and the construction of a viaduct carrying Park avenue over 42nd street at Grand Central Station have aided in relieving traffic congestion at those points. Progress has been made in relieving the waters of New York Harbour from sewage pollution by the construction of sewage screening plants along the North and East rivers and at other points.

There have been marked changes in the use of property, particularly in Manhattan, since 1909. The principal shopping district has shifted northwards, until in 1926 its boundaries, broadly speaking, were 34th street, Broadway, 59th street and Madison avenue. In the vicinity of 42nd street there has been an extensive development of office buildings. The buildings formerly housing the Knickerbocker, Holland House and Manhattan hotels and two famous restaurants—Sherry's and Delmonico's—have been replaced by office buildings. Notable building construction from 1909–25 includes the Woolworth building (792 ft.), the highest structure in the world excepting the Eiffel Tower, Bankers' Trust (539 ft.), City Investing (487 ft.), Equitable (485 ft.), Adams Express (424 ft.), Whitehall (424 ft.), Bush Terminal (419 ft.), American Express (415 ft.), American Telephone and Telegraph (403 ft.), and the new Telephone building (400 ft.). Height restrictions and set-back provisions in the city zoning ordinance have offered the opportunity for considerable variation in the architectural treatment of high buildings constructed during recent years, which have resulted in securing more artistic effects than were formerly possible. Among the newer hotels are the Pennsylvania, with 2,200 rooms, the largest hotel in the world; the Commodore; the Ambassador; and the Roosevelt. Madison Square Garden, an historic structure used for amusement purposes and as a place of public assembly, was demolished in 1925, a 28-storey office building being erected on its site.

II. COMMERCE AND INDUSTRY

Port of New York.—During 1924 the tonnage of vessels entering the Port of New York direct amounted to 18,280,975, while ships clearing from the port carried 18,858,693 tons. The value of the imports received during 1924 aggregated $2,047,759,136, representing an increase of 130% over 1909. Exports for 1924 amounted to $1,685,562,079, an increase of 169% over 1909, but a decrease of 52% from those made during 1920. Improvements in port facilities made since 1909 include the completion of the Ambrose Channel work and deepening of the East river channel by the Federal Govt. and the reconstruction and extension of the Erie canal by the State. Eight canal terminals have been built at various points along the North and East rivers together with a modern grain elevator with a capacity of 2,000,000 bu. located at the Gowanus Bay terminal. Expenditures on the canals up to 1925 aggregated $167,123,774. The most noteworthy port development works carried out by the city since 1909 include the North river, Staten Island and Jamaica Bay

projects. Along the North river two 1,000-ft. piers were built between 44th and 50th streets, and by 1925 two others had been planned. The completed construction, which cost approximately $5,500,000, including real estate, provides 285,000 sq. ft. additional dock space. The construction of a steamship pier 1,000 ft. long and 174 ft. wide above the Holland vehicular tunnel, involving an estimated expenditure of $2,500,000, was planned. A railroad pier costing about $900,000 and providing 92,000 sq. ft. additional dock space, was completed during 1925 at Pier 2, North river. Three piers providing 568,500 sq. ft. dock space were built along the East river during 1916 at the foot of 29th, 30th and 35th streets respectively, South Brooklyn, and subsequently there was extensive bulkhead improvement of both the Manhattan and Brooklyn waterfronts along the East river. Remodelling High Bridge over the Harlem river and straightening of the alignment of that waterway was also accomplished. In 1919 the city initiated the Staten Island improvement project involving the construction of 12 modern steamship piers with terminal warehouse facilities. This improvement, built at a cost of about $30,000,000, includes over six miles of wharfage and 1,800,000 sq. ft. dock space. Through its connection with the Baltimore and Ohio railroad, opportunity was provided for track railhead connections between these piers and all but two of the railways entering the Port of New York. The facilities afforded by this improvement exceeded, in 1926, those available for similar purposes on the island of Manhattan.

The Jamaica Bay project constitutes the most important development undertaken by the city in recent years. Jamaica Bay has an area of about 26 sq. miles. In 1909 the State of New York ceded to the city all of the State's ownership in the Bay, amounting to about 16,000 acres. The Federal Govt. adopted a project to dredge a channel through Rockaway Inlet and from Barren Island to Cornell Basin, to an ultimate depth of 30 ft. and to a width of 1,000 feet.

In 1923 the Department of Docks laid out in the middle of Jamaica Bay a scheme for the construction of two islands, to be made by dredging a channel 2,500 ft. wide and 30 ft. deep around the bay. The islands will contain 6,500 ac., and will have a quay wharfage of about 28 miles. At an expenditure of about $1,250,000 the department has completed an embankment 550 ft. wide and more than two miles long. This embankment provides a roadway of 150 ft., which is the Cross Bay boulevard, over the island and in addition gives the city about 2,000 building lots. The two islands, will provide homes for about 400,000 people.

Port Authority.—In 1921, on recommendation by a joint commission appointed in 1917 by the governors of New York and New Jersey to investigate conditions at the Port of New York, a treaty was entered into between these two States providing for the creation of the Port of New York District and the establishment of the Port of New York Authority. This treaty was subsequently ratified by Congress; and the Port Authority was appointed, consisting of six commissioners, three from each State, serving for overlapping terms. In Dec. 1921 the Port Authority presented to the legislatures of New York and New Jersey a comprehensive plan for the development of the port, which was adopted by the legislatures and ratified by Congress. The principal features of the plan are a series of belt lines and marginal railways, a freight tunnel from Greenville, N.J., to Bay Ridge, Brooklyn and an automatic electric system of freight transportation for serving Manhattan and union inland terminal stations on Manhattan Island.

In 1924 the states of New York and New Jersey made appropriations for and granted authority to the Port Authority to make surveys and borings for two bridges across the Arthur Hill from Staten Island to New Jersey. In 1925 the legislatures provided for the building of these bridges by the Port Authority, the States contributing a total of $4,000,000 toward the cost, to be eventually repaid from the collection of tolls, and the balance of the cost is to be financed by the issuance of bonds, to be amortised from the tolls collected. In 1925 the legislatures also provided for studies for a bridge across the Hudson river from Manhattan, in the neighbourhood of 178th street, to Fort Lee, New Jersey.

Manufactures.—The New York City Metropolitan District (a district of 616,928 ac., including in addition to New York City the neighbouring cities and towns both in New York State and New Jersey) is by far the largest industrial district in the United States. In 1919 there were 32,590 manufacturing establishments in New York City with a total number of 825,056 persons engaged in the industries. Of these 638,775 were wage-earners; 35,101 were proprietors and firm members; 36,894 were salaried officers, superintendents and managers; and 114,286 were clerks. The sum of $326,171,741 was expended for salaries and $805,822,451 for wages. The total value of the products manufactured was $5,260,707,577, and the amount of capital invested in industries in the whole city was $3,038,557,492. The clothing industry ranked first in importance, the total value of men's and women's clothing manufactured being $1,346,839,946 or 57% of the value of clothing produced throughout the entire country. Printing and publishing ranked second, with products valued at $206,585,376.

Art.—The additions to the Metropolitan Museum of Art during the years 1910–25 have made it rank with the large museums of the world. Among the notable bequests have been those of Francis L. Leland, $1,000,000; Joseph Pulitzer, $900,000; Benjamin Altman, collection of paintings, sculpture, Chinese porcelains, etc., with a fund for their care; William Henry Riggs, collection of arms and armour; Harris B. Dick, collections and funds over $1,000,000; Isaac D. Fletcher, collection of paintings and objects of art and fund over $3,400,000; John Hoge, over $1,000,000; and Frank A. Munsey, the bulk of an estate estimated at $40,000,000.

III. LOCAL POLITICS

Mayor Mitchel's Administration.—During the administration of Mayor Gaynor, which began in 1910, there arose an increased interest in city affairs. The mayor who in consequence of an attempt to assassinate him had gained a hold on popular sympathy, died on Sept 10 1913 while on a voyage to Europe. Adolph L. Kline (b. 1858), president of the Board of Aldermen, succeeded to the office for the remaining few months of the term. A fusion ticket, led by John Purroy Mitchel (1879–1918), who had made an enviable record in public office as Commissioner of Accounts, Collector of the Port and president of the Board of Aldermen, easily defeated the Tammany ticket. Mitchel, but 35 years of age, undertook a complete reorganisation of administration and obtained remarkable results, making his mayoralty a period of unprecedented efficiency in the city's government. Of special note were the improvements in police, street cleaning, charities and corrections and the establishment of high standards and expert service in taxation, purchasing and the selection of personnel.

The Tammany Reaction.—Though admittedly efficient, economical and honest, this administration saw itself at the end of four years buried under the greatest majority for Tammany on record. John F. Hylan (b. 1868), a candidate from Brooklyn, led a complete Tammany ticket into office, with a platform of outspoken opposition to almost everything the Mitchel administration had done. Subsequently, however, upon the election of the president of the Board of Aldermen, Alfred E. Smith, to the governorship of the State and the death in office of the president of the borough of Manhattan, Republicans were elected to the vacancies.

In 1921, largely as a result of the enactment of legislation sponsored by Gov. Miller which seriously curtailed New York City's powers over local rapid transit matters, Mayor Hylan was renominated and again elected by a substantial majority, together with a complete Tammany ticket. During both terms of Mayor Hylan's administration there was practically continual wrangling among the members of the Board of Estimate and complete lack of co-operation with other public agencies. These conditions, together with the general character of appointments made by the mayor, resulted in a distinct lowering of the morale of city employees and a disturbance of administrative machinery that interfered seriously with the public service. Particularly in

providing for much-needed rapid transit facilities the demagogic attitude of Mayor Hylan and to a less degree that of the other members of the Board of Estimate in refusing to work with the transit commissioners, brought about a virtual *impasse* that for seven years prevented action necessary to afford public relief. Finally, in 1924, the Board of Estimate filed charges against the transit commissioners with Gov. Alfred E. Smith, and the latter appointed the Hon. John V. McAvoy, Supreme Court Justice, Appellate Division of the State of New York, a commissioner to investigate the charges. Commissioner McAvoy's report, presented early in 1925, placed responsibility for the transit situation directly on Mayor Hylan. The administrative incompetence of Mayor Hylan and his subservience to Mr. William Randolph Hearst, publisher, were factors in causing many influential Tammany leaders to withdraw their support and in Sept. 1925 he was soundly defeated in the primaries as a candidate for mayor by James J. Walker. The Republican nominee was Frank D. Waterman, a prominent manufacturer. Walker was easily elected in the Nov. elections.

Home Rule.—Important legislation affecting New York City since 1910 included the Home Rule Act of 1924 and the Home Rule Transit law. Under the provisions of the Home Rule Act the power to enact local laws in New York City is conferred on a bicameral body known as the " municipal assembly " consisting of the Board of Estimate and Apportionment and the Board of Aldermen. The Home Rule Transit law provided for the establishment of a Board of Transportation to have jurisdiction over the regulation of existing rapid transit lines and gave the board broad powers for providing additional transit facilities together with the right to undertake municipal operation of such lines.

(R. B. F.)

NEW YORK STATE (*see* 19.594), a State of the United States. The population in 1920 was 10,385,227 as compared with 9,113,614 in 1910, a gain of 14%. The average population per sq. m. in 1920 was 217·9 as compared with 191·2 in 1910. The urban population (in cities with 2,500 or more inhabitants) was 8,589,844, or 82·7%. The native white population was 7,385,915, of whom 3,668,266 were of native parentage; 2,844,083 of foreign parentage; and 873,566 of mixed parentage. The foreign-born white population was 2,786,112.

In 1920 there were 28 cities with populations of over 20,000, of which the chief were:—

Albany	113,344	Rochester	295,750
Binghamton	66,800	Schenectady	88,723
Buffalo	506,775	Syracuse	171,717
New York	5,620,048	Utica	94,156
Niagara Falls	50,760	Yonkers	100,176

Government and Political History.—The constitution of 1894 was frequently amended during the period 1910–25, but the amendments did not alter fundamentally the system of government. Among the most important constitutional changes were the adoption of woman suffrage in 1917, the establishment of a literacy test for new voters in 1921 and the granting of home rule to cities in 1923. An important constitutional amendment providing for the consolidation of numerous state administrative establishments (187 in 1919) into 20 departments was approved in Nov. 1925.

On Oct. 6 1910 Gov. Hughes resigned to accept a position on the U.S. Supreme Court, and was succeeded by Horace White, the lieutenant-governor. In the election of Nov. 1910 the Democrats carried not only the State but also the Legislature, and John A. Dix was elected governor. The 1911 Legislature adopted a compromise direct primary law, which retained the party convention for the selection of candidates for state-wide offices. The Wagner-Levy election law limited independent nominations to registered and enrolled voters, made registration days uniform and provided for personal registration in rural districts for voters who had not voted in the previous election. It also prevented a candidate's name from appearing more than once on the ballot, and thus made fusion tickets and independent voting difficult. In the fall elections the Republicans regained control of the Assembly. The Legislature of 1912 allowed party organisations to substitute the assembly district for the election district as the unit of representation. This caused absurdly long ballots and tended to discredit the direct primary system. The hours of labour for minors in factories were restricted.

The Democrats again carried the State and the Legislature in Nov. 1912, and Sulzer became governor. The Legislature of 1913 passed laws insuring greater safety in factories, providing for an eight-hour day for employees on public works, and a 54-hour week for women and children under 16 in certain industries. In April 1913 Gov. Sulzer sent a special message to the Legislature urging a direct primary law that would abolish party conventions. The Legislature refused to enact the primary bill, and the governor vetoed the legislative substitute. When the Legislature recessed on July 23 the governor declared the special session adjourned, but the Legislature reassembled on Aug. 11. Two days later the assembly voted to impeach the governor; on Oct. 17 he was removed from office and Martin H. Glynn, lieutenant-governor, succeeded. In the elections of Nov. 1913 Sulzer was elected to the Assembly. A constitutional amendment authorising a workmen's compensation law was adopted by a large majority. The special session of the Legislature which had impeached Gov. Sulzer reassembled on Dec. 18 and adopted a direct primary law abolishing conventions; a modified office group ballot law; measures to carry out the 17th amendment providing for the popular election of U.S. senators; a resolution submitting to the voters the question of calling a constitutional convention; and the adoption of a workmen's compensation law for certain hazardous employments.

The Republicans were successful in the elections of Nov. 1914, and Whitman became governor. The new Legislature passed a widowed mothers' pension law; reorganised the inferior criminal courts of New York City by creating a board of city magistrates, the judges of which were given the right to sit in special sessions and to dispose summarily of minor misdemeanours; and authorised parole commissions in cities of the first class. In Nov. 1916 Gov. Whitman was re-elected, the Assembly continuing Republican; in the presidential contest, also, the Republicans carried the State. State legislation of 1917 was strongly influenced by the entrance of the United States into the World War. The woman-suffrage amendment was ratified by a large majority.

In the Nov. election, 1918, Alfred E. Smith (Dem.) was elected governor. Most of the other state officers and the Legislature, however, remained Republican. One of the most important laws of the year was the one providing for an income tax of from 1% to 3%. The Federal prohibition amendment was ratified. Shortly after his inauguration Gov. Smith appointed a non-partisan reconstruction commission to investigate the problem of reorganising the state government. This commission in its report of Oct. 10 1919 recommended an executive budget and the consolidation of the numerous administrative agencies. The most constructive work of the session was the passage of several laws for the relief of the housing situation.

In the elections of 1920 the Republicans carried the state by large majorities, and their candidate for governor, Judge Nathan Miller, was elected. The Legislature passed a law placing all public utilities, except transit in New York City, under the jurisdiction of one state commission. A state prohibition enforcement law was adopted. The direct primary was abandoned and the convention system restored for the nomination of state and judicial officers. The state industrial commission and the state tax commission were reorganised, and a board of estimate and control created.

The 1922 Legislature authorised life-insurance companies to invest 10% of their assets in new buildings for dwelling purposes; extended the emergency rent laws to 1924 and fixed assessments as the basis for determining the reasonableness of rents. Women were given representation on county party committees. A home rule amendment was adopted. Under the law passed the previous year the candidates for state office were nominated by party conventions in 1922. The election resulted in the election of Alfred Smith as governor. The 1923 Legislature provided for a commission to study the problem of bringing the state laws into

conformity with the home rule amendment, which the Legislature again approved. Some progress was also made in carrying out the governor's consolidation programme for a constitutional amendment providing for consolidation of the numerous administrative agencies into 20 departments. The Mullan-Gage prohibition enforcement Act was repealed, and Congress was memorialised in favour of liberalising the Volstead law.

In the fall elections the voters approved by large majorities two constitutional amendments. One authorised a bond issue of $45,000,000 to pay a bonus to World War veterans. The second amendment extended to cities a large measure of home rule. The referendum on a bond issue for $50,000,000 for new hospitals was likewise approved. The Republicans increased their majority in the assembly. The Legislature of 1924 passed a bonus law awarding $10 for each month of service to all active participants in the World War who were residents of the state; the maximum payment was fixed at $150. The emergency rent laws of 1920 and the following years were extended to 1926. An important measure of the session was the Home Rule Enabling Act, designed to carry out the amendment adopted the previous year. This law, drafted by the state home rule commission, was adopted unanimously by both Houses of the Legislature. The New York amendment differs from constitutional provisions in some other states in that it grants powers in general terms. In the presidential election of 1924, the Republicans were successful. Gov. Smith was re-elected, but the Republican candidates for the other six elective state offices were successful, and the Legislature became more strongly Republican.

Agriculture and Stock-Raising.—In 1924 New York, with crops valued at $303,812,600, ranked eighth among the states in the value of all crops and first in the production of hay and potatoes. In 1923 the number of farms in the state was 190,000 and the total acreage 20,300,000. The U.S. Census of 1920 placed the value of all farm property at $1,908,483,201. In 1924 7,327,000 tons of hay; 24,519,000 bu. of corn; 6,840,000 bu. of wheat; 34,056,000 bu. of oats; 6,900,000 bu. of barley; 935,000 bu. of rye; 5,363,000 bu. of buckwheat; 46,620,000 bu. of potatoes; 1,820,000 bu. of beans; 23,800,000 bu. of apples; 2,178,000 bu. of peaches; 2,100,000 bu. of pears; 80,000 tons of grapes; and 2,350,000 lb. of tobacco were produced. In 1923 there were 532,000 sheep in the state, and the wool production was 2,968,000 pounds. The dairy business was one of the most important.

Minerals.—In 1923 mineral products valued at $89,975,134 were produced. The average value for the years 1919–23 was $62,243,270. In 1923 clay products were valued at $25,226,187; cement, $12,834,471; gypsum, $10,344,745; stone $9,610,324; salt, $7,431,155; sand and gravel, $7,291,076; petroleum, $4,140,000; natural gas, $3,739,000; and iron ore, $3,320,004.

Manufactures.—According to the United States report on manufactures for the year 1923, the value of the products of manufacturing establishments in the state was $8,960,693,000, as compared with $6,973,506,000 for 1921, a gain of 28.5%. The number of establishments in 1923 was 38,187; in 1921, 38,107; in 1919, 49,330; and in 1914, 48,203. The decrease in number is partly accounted for by the fact that the last two reports did not include establishments which reported products under $5,000 in value. The wage-earners in 1923 numbered 1,150,901 as compared with 1,000,414 in 1921, an increase of 15%. The wage payments in 1923 amounted to $1,582,006,000. The industries whose products were valued at more than $100,000,000 in 1923 were:—

Clothing	$1,636,529,625	Paper and wood pulp	$140,468,586
Printing and publishing	503,411,143	Furniture	137,328,234
Foundry and machine shop	273,933,262	Cigars and cigarettes	129,659,423
Bread and bakery products	236,546,477	Chemicals	128,376,073
Knit goods	230,525,505	Steel works and rolling mills	122,964,813
Millinery, lace	197,627,982	Silk	105,018,097
Boots and shoes	195,082,384	Confectionery and ice cream	103,215,335
Electrical machinery	192,224,937		

The chief manufacturing centres and the values of their products in 1921 were: New York City, $4,328,187,499; Buffalo, $431,383,131; Rochester, $291,117,230; Syracuse, $109,061,617; Yonkers, $107,182,668; and Albany, $41,171,786.

Transportation and Commerce.—In 1925 the operated railway mileage in New York was 8,401. In 1925 there were 4,792 m. of electric railways. There were 81,878 m. of highways in the state, 18,566 m. of which were surfaced. Of the $75,000,000 appropriated by Congress to the states for highway building in the year 1924–5 under the Federal aid system, New York received $3,663,105. The Erie Barge Canal was opened from Troy to Buffalo in 1918. The Champlain and the Oswego Barge canals have also been completed. In addition to the canalised rivers and lakes (382 m.) the state has a canal mileage of 525.

Education.—The University of the State of New York, a supervising and examining institution, is the State Department of Education, and controls the educational system of the state. It is governed by 12 regents, one elected each year for a 12-year term at a joint session of the two Houses of the Legislature. The board of regents elects the president of the university, who is the commissioner of education. The regents apportion the state educational funds. In 1924 there were 62,401 teachers, and 1,610,076 enrolled pupils. The cost of school maintenance in that year was $250,553,776.

Finance.—On June 30 1925 the total debt of the State was $318,456,000. The sinking funds, however, amounted to $87,123,821. Approximately one-half of the total debt was incurred for canals. Highway bonds amounted to $98,800,000, and World War bonus bonds to $45,000,000. The general revenue receipts for the year ending June 30 1924 amounted to $146,587,656, and the disbursements to $146,456,708. (E. D. G.)

NEW ZEALAND (*see* 19.624), a Dominion of the British Empire and a member of the League of Nations. The area of the Dominion proper is 103,285 sq. m., but if outlying islands are included the total area is 103,862 square miles. In addition New Zealand is responsible under the mandate of the League of Nations for the administration of the Western Samoan group, and shares with Great Britain and Australia the administration of the former German island of Nauru. Also, since 1923, the Governor-General of New Zealand is responsible for the administration of the Ross Sea area in the Antarctic. In Feb. 1926, at the invitation of the British Govt., New Zealand took over the administration of the Tokelau or Union group of islands in the Pacific. The population of the Dominion proper, according to the census of 1921, was 1,271,664. By letters patent dated May 11 1917 the designation of the representative of the British Crown in New Zealand was altered from Governor and commander-in-chief to governor-general and commander-in-chief.

I. POLITICAL HISTORY

The year 1910 saw the Dominion recovering from the financial crisis of 1908. Political control was in the hands of the Ward Ministry, which, with incidental cabinet changes, had carried on the Liberal-Labour Govt. and régime of the late Mr. Seddon, who himself had been Prime Minister without intermission for 13 years. Political interest had centred largely around the system of Crown Land tenure; amendments to industrial legislation; the passing in 1910 of the National Provident Fund Act; and questions of military and naval defence. The government was being assailed by Mr. Massey's already growing party with the proposal to relinquish the remaining remnants of leasehold principles, and to permit the sale outright, under certain safeguards against monopolistic holdings, of Crown lands. A Defence Act, embodying the principle of universal service within certain ages, had been passed in 1909, though it had not been put into operation; and in 1910 Lord Kitchener, at the invitation of the New Zealand Govt., visited the country, and, after slight alterations had been carried out at his suggestion, the system was introduced in Jan. 1911. In the naval sphere an arrangement had been made in 1909 with the Home Govt. under which it was understood that the Domin-

ion's "gift" battle-cruiser, the "New Zealand," should be the flagship of a new China unit, and that seven vessels of the unit should be stationed in peace time in New Zealand waters, the ships to be manned as far as possible with New Zealand officers and men.

The general election of 1911 was disastrous to the Ward government. The Liberal-Labour combination, which had held together for 21 years, had for some time been showing signs of disruption, while the Conservative opposition, now known as the Reform party, had improved its organisation. The polls gave the latter an apparently slight advantage, though the issue was still in doubt. In the recess the Ward Ministry resigned because of internal discord, and a new Liberal Cabinet was formed under Sir Thomas Mackenzie. The latter was defeated on a no-confidence motion two weeks after the new Parliament met; and on July 10 1912 Mr. W. F. Massey became Prime Minister.

The Reform Régime.—The new government in its first session passed the necessary legislation to enable holders of Crown leases in perpetuity to acquire the freehold. Another important measure passed placed the control of the public services largely under commissioners. No important changes in general policy were made. Nevertheless, there was ample work for the government. For some time, aided by agitators from abroad, sections of labour had shown considerable restlessness and dissatisfaction with the Arbitration Act, and this culminated in 1913 in a strike of all transport workers, seamen, and miners, who, cancelling their registration under the Arbitration Act and thus being able to strike without incurring penalties, ranged themselves under a federation of Labour. The strike, one of the most extensive in the history of New Zealand, was a grave menace to the country, for at the time it took place produce from every part of the Dominion was in store at the ports awaiting shipment to Great Britain. The government took firm measures to deal with the situation. A new Waterside Workers' Union was established under the Arbitration Act, and all temporary workers, chiefly farmers' sons and employees, joining it were given security by the police and special constables from interference; ultimately the ships, manned by volunteer crews, were dispatched with their cargoes. The strike ended after a protracted struggle. As one result of it the Labour Disputes Investigation Act was passed in the same year; it applied to workers or societies and to employers not bound by the Conciliation and Arbitration Act.

The remainder of the parliamentary session was devoted chiefly to amending legislation, and in this connection useful, if not outstanding, work was done. To the amended land laws of the previous session was added a further provision giving the same privilege of purchase to those possessing similar leases of Settlement Lands, *i.e.*, lands which had been purchased by the State and leased. Acts were also passed to provide funds to assist irrigation and also the fruit industry. A board of agriculture was established to act in a consultative and advisory capacity to the Lands Department. In this session also the second Ballot Act was repealed.

In 1913 the Minister for Defence, Finance and Education, Mr. (Sir) J. Allen, visited England, at the wish of the government, to confer with the British Admiralty and War Office in regard to New Zealand's military and naval defence, and also to attend to certain matters of general finance. Arrangements were completed with the War Office in regard to the strength and composition of the voluntary expeditionary force authorised under the Defence Act of 1909; but the negotiations with the Admiralty were not very satisfactory. It had been found necessary by the Admiralty to depart from the previous arrangement, and station the ships designed for the China Seas in English waters; and the only offer to New Zealand was of two obsolete vessels of the old Australian and New Zealand squadron. New Zealand then asked that the vessels to be sent should be of the "Bristol" type, but this could not be done. In the same year, 1913, the Naval Defence Act was passed: it provided for the establishment of a New Zealand naval force by voluntary enlistment. A New Zealand division was inaugurated in 1914, but the outbreak of war stopped the scheme of training.

During his return trip to New Zealand via Canada, the Minister, who had been instructed to purchase in Britain a stock of small arms for the Dominion's newly constituted territorial army, but had only been able, owing to a shortage, to obtain a small quantity, bought a large number of ·303 Lee-Enfield rifles—discarded by Canada for the Ross rifle—which were destined not only to serve for the training of New Zealand's expeditionary forces for the first two years of the War, but to become, many of them, the weapon of the New Zealanders in Gallipoli.

The War Period.—A considerable programme of important legislation had been arranged for 1914, but Parliament had not been in session very long before war broke out. It was, however, possible to pass, amongst other measures, an Education Amendment Act, under which there was a complete reorganisation of the educational department and the system of education control. At the declaration of hostilities neither government nor people displayed any hesitation as to the course New Zealand would pursue. Secret preparations had been made for the mobilisation of an Expeditionary Force of approximately 8,000 officers and men, and these preparations were immediately put into operation. But first, at the request of the British Govt., a force of 55 officers and 1,358 men was mobilised, and on Aug. 15 dispatched to capture German Samoa, a feat accomplished without fighting. The first expeditionary force for the actual scene of war, consisting of 360 officers and 8,139 other ranks, sailed on Dec. 14 1914. The preparation of reinforcements was meanwhile proceeded with, and also the necessary organisation for a sustained war effort.

New Zealand maintained her war effort on a scale considerably greater than that involved in her first arrangement with the War Office; her infantry division in France and mounted force in Palestine were kept at full strength with necessary reserves to the day of the Armistice, and by the close of hostilities she had sent overseas (out of a population of 1,089,825) 100,444 trained troops. In addition, 12,000 were mobilised and preparing for service when hostilities terminated. The financial cost of an undertaking on such a scale was extremely heavy. The budget of 1914 was already in print when the declaration of war was received, and authority was therefore given by Parliament to raise £2,000,000 by Treasury bills to meet immediate expenses. Afterwards loans were arranged according to requirements. Meanwhile, in Dec. 1914, the Parliamentary elections were held and Mr. Massey was returned with a small majority. Subsequently, in Aug. 1915, a National Govt. composed of the two chief parties, Reform and Liberal (the small Labour section declining representation), was formed; Mr. Massey remained Prime Minister, with Mr. (Sir) J. Allen as Minister of Defence and Sir Joseph Ward as Minister of Finance. A complete party truce was declared.

New Zealand shipped to Britain during the War produce and other supplies to a value of £160,000,000, which were sold to the Imperial Govt. at prices fixed by mutual arrangements. On three occasions during the War the Prime Minister and the Finance Minister attended Imperial Conferences in London, and on such occasions the Defence Minister, as Acting Prime Minister, combined their duties with his own. Though the country was wholeheartedly behind the war effort, problems naturally followed in the wake of the compulsory enlistment enactment, for which in 1916 the majority of the people had themselves agitated. One serious coal-miners' dispute at the West Coast mines also required settling. But whatever sectional and temporary difficulties arose, the nation as a whole supported the policy of the government.

The ability of the Dominion to ship its produce at satisfactory prices overcame the difficulties of financial provision. The output increased considerably, and extra taxation was met without inconvenience. Up to 1917, comparatively small portions only of loans authorised were raised in London, and the rest in New Zealand, an innovation so far as the Dominion was

concerned. After 1917, New Zealand provided her own financial requirements. The actual fighting costs of the troops in the field were advanced to New Zealand by the Imperial Govt. on a *per capita* basis (which fluctuated according to the engagements in which the New Zealand units participated). The total cost of the War to the Dominion was assessed in 1921 at £81,538,570, and of this amount £55,198,325 had been raised in New Zealand.

Post-War Years.—The National Govt. came to an end in 1919 by the withdrawal of the Liberal Party from the Ministry. At the general elections which ensued late in the same year the Reform party was returned with a heavy majority. Labour also showed a considerable accession of strength, and, for the first time for many years, became a distinct party in the House. The government turned its attention with concentrated effort to the repatriation of the returned soldiers, seeking particularly, under special legislation that had been passed, to place satisfactorily on the land all those who so desired. Financial assistance was also given, chiefly by loans on easy terms, to men who desired houses of their own, or wished to start in business, etc. Each case was carefully investigated by special repatriation organisations, and in every possible respect the government sought to provide for the future of each individual soldier who presented himself. In the case of those seeking land occupations, suitable areas were purchased by the government, sub-divided, and resold or leased to the men under special legislative provision at easy terms of interest; or the money was advanced as a first mortgage, with essential safeguards, if a man desired any particular farm.

An abnormal demand for land was created, and naturally, assisted by the enhanced values of produce, land values became inflated. House properties also went up greatly in value, and the shortage, since but few had been built during the War, became very acute. Altogether 9,388 men were assisted to obtain rural homes and properties, and 10,890 in securing homes in towns; 61,254 were placed in employment, trained in some future livelihood or financially assisted to re-establish themselves—a total altogether of 81,532 men. The cost to the country by July 1922 was £28,718,578. The problems of repatriation and others following in the wake of the War were in the forefront of the new government's duties. Fortunately during the later War years there had been heavy surpluses of revenue over expenditure, and these were available for partial application to repatriation needs.

The immediate post-War years were years of high prices and prosperity, but in 1921 the prices of produce, especially of wool and meat, on the British market rapidly fell. Land values in New Zealand were too high and there had been extremely heavy over-importation, largely due to merchants and manufacturers abroad being able to fulfil long-standing orders. The country was faced with an immediate crisis. Taxes were already at a high level, and there were cries for easement to meet the strain of financial calls. The country's ordinary current expenditure had grown tremendously, and it was impossible to afford much relief. The Prime Minister decided at once on a policy of the most rigid economy. Departmental expenditure was closely examined by a specially appointed commission; war bonuses were attacked, and, since a fall was shown in the cost of living, deductions were made accordingly.

As a result of its measures for economy, the popularity of the government was seriously affected. There was much unemployment, but it was possible, by pushing forward the public works programme, to offer manual labour to those able to undertake it. Meanwhile, the overseas marketing problems were tackled, reductions were obtained in freights, insurance, storage, etc., and by the middle of 1922 a recovery in market returns abroad was in evidence. The meat producers of the Dominion had tackled their own marketing problems, and had set up an organisation under which the whole industry was able to seek reasonable terms in all matters of costs from the farm to the overseas markets; the dairy producers had taken the preliminary steps for a like movement. The government was in close touch with these developments and, in the case of the meat producers, passed the necessary legislation.

The vexed question of heavy taxation was seriously disturbing the community, the commercial interests especially desiring a change in the incidence of taxation. The government then set up a commission to investigate the whole matter. By the middle of 1922, however, the general situation had considerably improved. Towards the end of the year, while the government was still unpopular owing to its drastic economies, a general election became due. The result was not unexpected. Mr. Massey could not muster a sufficient number to provide an absolute majority over the Liberal and Labour parties, the latter of whom had increased their strength to 17, the largest representation they had ever had. But when the new Parliament met in 1923, three Liberal Independent members, who had given pledges to vote against Labour, ranged themselves on the side of the government, and saved a defeat.

The year 1923 was remarkable for the recovery of the New Zealand produce markets in Britain, for the State revenue revival, and for various taxation burden remissions the government was able to institute. Income tax was greatly reduced, penny postage was reinstituted, reductions were made in telegraph rates, the income tax on revenue from farm products was removed, and a sum of approximately £2,000,000 was provided for the aid of soldier settlers who were unable to carry on under the burden of the high value at which their land had been purchased, and for further pension assistance. The incidence of taxation was also altered in some particulars, and a policy of progressive reduction of income tax was instituted, the maximum rate falling from 7s. 4d. to 4s. 6d. in the £, and the minimum from 1s. to 7d. Substantial reductions were also made in the rates of land tax. Exemptions in respect of children were increased.

An energetic policy of development was also undertaken. Legislative provision was made for the State Advances Department to extend its security for advances to 75% in the case of farming land, and to 95% for workers' houses, and legislation was passed to authorise the necessary borrowing to provide the money. For a number of years the payments from borrowers under the scheme had provided sufficient revenue to meet all applications for advances. The customs tariff was also revised, the chief features being the increase of British preference, and a separate reciprocal tariff with Australia. In 1924 the Old Age Pensions Act was improved, further beneficial amendments were made in the education legislation, the Companies Act was altered to enable the issue of "labour shares," and Acts were passed to permit the dairy, honey, fruit and poultry farmers to exercise control over their industries similar to that enjoyed by the meat producers, though differing in some essential details. Legislation was also passed making registration of electors for general election purposes compulsory.

On May 10 1925 the Prime Minister, the Right Hon. W. F. Massey, died at Wellington. Sir F. H. D. Bell, the first New Zealander born in the Dominion to occupy the office, was appointed Prime Minister on May 14, and was succeeded on May 30, following a reorganisation of the Executive Council, by Mr. J. G. Coates, previously Minister for Public Works and Railways and Postmaster-General. The session closed without any legislation of outstanding importance. In Nov. a general election was held, and resulted in an overwhelming victory for the Reform party under Mr. Coates, which secured 57 seats as against 11 held by the National (Liberal) party, and 12 by Labour.

Defence.—New Zealand's attention since the War has been directed chiefly to additional naval security. In 1919 Admiral Jellicoe of the British Navy visited New Zealand, and presented a report making recommendations and suggestions for the naval defence of the Dominion. In 1926 the Dominion maintained a training ship and two modern light cruisers. The cruisers were loaned free of charge by the Imperial Govt., the Dominion being responsible for all payments for the ships and their personnel, a considerable number of which consisted

of New Zealanders. A naval oil-tank vessel is also maintained, and at the naval base at Devonport, Auckland, one oil-tank had been erected while another was under construction in 1925. The amount provided in the Estimates for 1925-6 as the Dominion's contribution to naval defence was £538,325. All matters relating to the naval forces of the Dominion are administered by a Naval Board, constituted in 1921.

The military forces consist of the Permanent Forces, the Territorial Force and the Senior Cadets. The Permanent Forces, excluding the Air Force, contain 101 professional officers who are charged with the training of the forces and the administration of all matters connected therewith. The strength of the Territorial Force in 1925 was 699 officers and 15,481 other ranks. The strength of the Senior Cadets was 427 officers and 26,515 other ranks. Rifle clubs exist throughout the Dominion. All male inhabitants of New Zealand who have resided therein for six months and are British subjects are liable to be trained in the Senior Cadets from 14 years of age, or the date of leaving school, to 18 years of age, or, in the case of those who at the age of 18 are attending a secondary school, to the date of their leaving school; or in the Territorial Force to the age of 25. The New Zealand Permanent Air Force, with an establishment of five officers and 19 other ranks, is a unit of the military forces.

Public Finance.—The gross national debt, which at March 31 1910 stood at £74,890,645 (£72 6s. 10d. per head of population), had increased to £201,170,755 (£162 12s. 9d. per head) at March 31 1920; at March 31 1925 it amounted to £227,814,647 (£165 2s. 11d. per head). This is the gross amount, and against it are accumulated sinking funds amounting to £13,462,839, leaving the net indebtedness of £214,287,128. With the exception of that portion incurred for war purposes, the greater portion of the borrowings has been for productive and developmental purposes, resulting in revenue-producing assets such as railways, hydroelectrical installations, telegraphs and telephones. The war debt to the Imperial Govt. had been funded and repayment was already well advanced by 1925.

The following table shows the revenue and expenditure for each financial year from 1910 to 1925:—

Year ending Mar. 31	Revenue	Expenditure	Excess of Revenue over Expenditure
	£	£	£
1910	9,238,917	8,990,922	247,995
1911	10,297,273	9,343,106	954,167
1912	11,061,161	10,340,368	720,793
1913	11,734,271	11,082,038	652,233
1914	12,229,661	11,825,864	403,797
1915	12,451,945	12,379,803	72,142
1916	14,507,530	12,493,107	2,014,423
1917	18,355,194	14,058,770	4,296,424
1918	20,206,222	15,120,288	5,085,934
1919	22,352,372	18,673,599	3,678,773
1920	26,081,340	23,781,524	2,299,816
1921	34,260,961	28,068,730	6,192,231
1922	28,127,007	28,466,838	− 339,831
1923	27,579,443	26,263,760	1,315,683
1924	27,960,370	26,148,005	1,812,365
1925	28,643,000	27,399,200	1,243,800

These tables show that revenue from taxation increased very considerably from 1914 to 1921, but fell heavily from 1921 to 1925. The public services (chiefly railways and post and telegraphs) increased their revenue after 1921, while the costs of their administration were reduced, showing the excellent results of the severe and continued economies instituted in the services' administration during the post-War period.

The movement of direct and indirect taxation from 1914 to 1925 is shown in the following table:—

Year ending Mar. 31	Customs and Excise	Land tax	Income tax	Death duties
	£	£	£	£
1914	3,553,785	767,451	554,271	613,751
1917	4,037,628	713,118	4,262,126	570,040
1921	8,769,251	1,688,979	8,248,945	1,106,925
1922	5,554,334	1,637,816	6,002,987	1,512,754
1925	8,339,576	1,335,251	3,386,052	1,520,749

Education.—In 1914 the whole of the law relating not only to public, but to secondary, technical, and special schools was recast. The principal changes involved the reorganisation of the Department of Education and the inspector-general of Schools became the director of education. Provision was also made for the constitution of fewer education districts, and by an Act of 1915 nine were created from the existing 13. A council of education was also constituted, with statutory duty to report to the Minister and advise upon any matters in connection with education referred to it, or which it may consider advisable to introduce into New Zealand. By the Education Amendment Act 1921-2 the registration of all private schools was made compulsory, and teachers in all schools were required to take the oath of allegiance. The Education Amendment Act 1924 included provisions for the establishment of junior high schools, for the amalgamation of the governing bodies of secondary and technical schools and for the creation of a teachers' register.

The number of scholars receiving instruction in all educational institutions in 1911 was 194,325, and in 1924 289,033. The following table shows the advance in the state primary schools (including district high schools):—

Year	No. of schools	Pupils at end of year	Average attendances
			%
1913	2,255	172,168	89·2
1918	2,365	194,934	88·7
1924	2,574	216,190	90·7

The number of teachers in the public schools in 1913 was 4,262; in 1924, 5,822. In 1915 there were 11,958 children receiving secondary and technical instruction at all classes of schools; in 1924 there were 23,276. Free places at secondary schools are granted to suitably qualified pupils. There are also liberal national scholarships. Control of higher education is vested in the New Zealand University, which by Royal charter is entitled to grant degrees. In 1921 the degrees of bachelor of science in forestry and doctor of philosophy were instituted. There is a liberal scholarship system in connection with the universities.

The following table shows the increased expenditure on education:—

	Expenditure from public funds	Expenditure per head of mean population
	£	s. d.
1909	980,000	19 7
1915	1,378,000	24 1
1921	3,224,000	51 6
1924	3,247,000	48 8
1925	3,643,000	53 7

Chief Sources of Revenue and Expenditure

Year ending Mar. 31	Taxation	Railways	Post and Telegraphs	Crown Lands	Other Sources	Total
1914	£5,918,034	£4,028,739	£1,269,922	£262,846	£750,120	£12,229,661
1921	22,184,414	6,918,492	2,478,532	319,641	2,359,882	34,260,961
1925	16,172,306	7,105,106	2,706,882	211,749	2,446,957	28,643,000

The details of expenditure for the same years were:—

Year ending Mar. 31	Working Railways	Post and Telegraphs	Education	Interest, etc., on Public Debt	Other Expenses	Total
1914	£3,004,181	£1,170,883	£1,206,678	£2,887,981	£3,556,141	£11,825,864
1921	6,211,011	2,588,360	2,633,977	7,831,593	8,803,789	28,068,730
1925	5,636,583	2,413,436	2,777,271	8,862,644	7,709,266	27,399,200

II. POPULATION AND SETTLEMENT

Population.—The census figures for 1911, 1916 and 1921, and the estimated population on Dec. 31 1925 were as follows:—

	1911	1916	1921	1925
Europeans . .	1,008,468	1,099,449	1,218,913	1,335,719
Maoris . .	49,844	49,776	52,751	54,768
	1,058,312	1,149,225	1,271,664	1,390,487

The actual gain in population in the decade 1911–21 (excluding Maoris) was 210,445, or 20·87%. Taking the two census periods, the gain from 1911–6 was 90,981, or 9·02%, and from 1916–21, 119,464, or 10·87%. Three factors influenced the comparatively small increase:—

1. Immigration during the War years was severely restricted;
2. Emigration figures were swelled by the inclusion of over 100,000 members of the Expeditionary Force, thousands of whom did not return;
3. The rate of natural increase was reduced owing to the absence of so many thousands of men.

In 1911 the birth-rate per 1,000 was 25·97, and in 1924, 21·57. In the same periods the death-rates per 1,000 were 9·39, and 8·29 respectively. The proportion of females to males, excluding the War years, is steadily increasing. The number of females to 1,000 males in 1911 were 896; in 1916, 993; in 1921, 956; and in 1925, 959. The population is chiefly centred in the North Island, and the " drift " that way, largely due to the development of the dairy industry, is growing. In 1911, 55·90% of the people resided there; in 1916, 59·22%, and in 1921, 60·81%. The Maoris, who are not included in these percentages, chiefly reside in the North Island. The census statistics of 1921 classed 56% of the population as urban.

In 1921, 98·43% of the inhabitants, exclusive of Maoris, had been born in the British Empire, an increase of ·51% as compared with 1911. Of the total in 1921, 74·39% were born in New Zealand, 19·54% in the United Kingdom and 3·94% in Australia. A certain number of those born in foreign countries were of British parentage or nationality, and including these the proportion of the population owning British nationality in 1921 was 99·35%. The number of aliens steadily diminished—from 12,050 in 1911 to 7,901 in 1921. Of the 7,901, 2,712 were Chinese, 1,013 Americans and 857 Yugoslavs. Certain restrictions are placed upon the entry into the Dominion of race aliens, a classification implying persons of other than European race. Of the total population in 1925 43·66% were members of the Church of England, 25·42% Presbyterian, 13·93% Catholics and 9·53% Methodists.

The Maori race increased in numbers from 49,844 in 1911 to 54,768 in 1925, and continued to preserve their individuality and strength. The above 1925 figure includes 7,352 half-castes, the majority of whom live as Europeans. There are 125 native schools, with an average daily attendance of 5,610 scholars.

Immigration.—The immigration policy of the New Zealand Government is to provide assistance, by free or reduced passage rates, to desirable immigrants from Great Britain. Assistance is restricted to persons who are nominated by permanent residents of the Dominion, or by bona fide New Zealanders visiting Great Britain, provided such persons are healthy and under 50 years of age. In the case of a married person, nomination must include the wife and family, except where a judicial separation exists, or desertion is proved. The nominator must undertake to make provision for the maintenance and employment of the nominee, and guarantee that residence will extend to at least five years. The quota of such assisted new arrivals is fixed from period to period. From shortly after the War until 1925 the quota was 10,000 per annum, but early in 1926 it was extended to 13,500. Exceptions to the nomination rule are single domestic servants and farm workers, for both of which classes there exists an unsatisfied demand.

Very complete arrangements, under the direction of the Immigration Department, which in turn is responsible to the Minister for Immigration, exist for the care and comfort of immigrants both at their departure and arrival. Assisted immigrants are required to pass severe medical tests, and to present certificates of good character. These, and all allied matters, are administered by the High Commissioner for New Zealand in London. The reduced rates of passage from Great Britain to New Zealand in 1926 were as follows:—

	£
Married or widowed adults	11
Single adults (males)	13 15s. od.
Single adults (females)	11
Farm labourers	11
Domestic servants	Free, with a £2 bonus
Boys, over 17 and under 19 years of age, not travelling with their parents	5 10s. od.
Children under 19 years travelling with parents	Free

In addition to the general immigration scheme, there exist special arrangements for British public schoolboys between the ages of 17 and 19 years. If satisfactory they are provided with passages at a cost of £7 10s. od.; they travel in groups under a prefect, and on arrival are placed with specially selected farmers at fixed rates of wages and taught farming. In 1924, 208 boys went to New Zealand under the scheme, and about an equal number in 1925. A large section of the sheepowners of the Dominion also have a fund of over £200,000, allocated out of wool profits of the War period, for training sons and daughters of sailors of the navy and mercantile marine who were killed or incapacitated during the War, the lads in farming at a special institution in New Zealand, and the girls in domestic and light farming work at another. Free passages are provided by the Government of New Zealand, and the children are provided with suitable employment after training. Both schemes are under the scrutiny of the Minister for Immigration and both have operated with entire success and satisfaction. The British Govt. co-operates with the Dominion in its assisted migration and provides a share of the passage money.

The following table shows the number of assisted immigrants entering New Zealand for each year from 1911 to 1924:—

Year	Number	Year	Number
1911	3,070	1918	421
1912	3,535	1919	3,569
1913	5,151	1920	7,615
1914	3,716	1921	8,085
1915	1,300	1922	7,773
1916	695	1923	6,181
1917	231	1924	8,091
		1925	8,236

Land Settlement.—The total area of the Dominion is 66,390,262 ac., and the following is the condition of the land in 1925:—

	Acres
Held on freehold	21,068,660
Reserved for public purposes	14,425,181
Crown lands leased	18,226,492
Crown lands yet available for disposal	2,925,410
Lands held by the native race	5,881,571
Unfit for settlement (including rivers, lakes, roads, etc.)	3,862,948
	66,390,262

It is impossible, in the absence of available statistics, to give a comparative table for the year 1910, but other statistics show that individual holdings increased from 73,876 in 1911 to 85,977 in 1925, and areas held from 40,238,126 ac. to 43,632,372 acres. These figures disclose the extent of new lands taken into occupa-

tion, and also the sub-division that has taken place. Of the 43,632,372 ac. of occupied land in 1925, 18,510,558 ac. were in cultivation as follows:—

Grain and pulse	699,844
Grasses and clover (for hay and seed), and green and root crops	1,068,459
Fallow	124,459
Grasses and clover (permanent pasture)	16,450,625
Vineyards and orchards	27,749
Market goods, etc.	4,998
Private gardens and grounds	63,206
Plantations	71,218
	18,510,558
Unimproved land	25,121,814
	43,632,372

The unimproved land was divided up into 54,814 ac. under flax; 14,470,990 ac. of tussock and native grasses; 4,054,760 ac. of fern, scrub, etc.; 4,331,333 ac. of standing virgin bush; and 2,209,917 ac. of barren land. The Wellington and Auckland provinces possess the greatest flax areas, and Canterbury and Otago the tussock land (used for sheep grazing); the fern and scrub areas are well distributed; Westland and the Auckland provinces contain the chief forest lands; the barren lands mainly consist of the mountain areas of South Island. The remaining Crown lands are being thrown open as rapidly as possible. In the 1924–5 financial year 168,748 ac. were offered for selection under the various tenures provided by the Land Act 1924, Land for Settlements Act 1908, and Education Reserves Amendment Act 1910. There is provision in the legislation for compulsory prevention of aggregation in large areas and for sub-division if such is desirable.

The Advances to Settlers Act 1894, was embodied in the State Advances Act 1913 under which money is lent to settlers on first mortgage of lands and improvements held under certain specified classes of tenure. The Government has authority under the Act to borrow money for these advances. The scheme has proved very successful and from 1917–21 repayments exceeded advances. In 1923 its application was widened to enable larger amounts to be borrowed and increased advances to be made; as a result the loans authorised in the two succeeding years were greatly increased. In 1924–5, 3,321 loans amounting to a total of £4,289,875 were authorised, £3,516,130 advanced, and £846,771 repaid.

III. ECONOMIC HISTORY

Agriculture.—New Zealand is primarily a grazing country, largely because better financial returns are obtained from the pastoral industries. Of the total area of 18,510,558 ac. under cultivation in 1924–5, 699,844 ac. were in grain and pulse crops; the area under crops intended for threshing was only 371,944 acres. Grain crops, principally oats and wheat, are chiefly grown in the eastern and southern districts of the South Island; barley is also grown, but to a very much smaller extent. Before the 1915–6 season agricultural statistics were rarely correct, owing to the unsatisfactory methods of collecting returns.

The table below clearly shows the decline in the area under grain crops, particularly wheat. The decrease in production necessitates grain imports in some years and in 1924–5, 4,181,422 bu. of wheat were imported from Australia. About 14,000 persons were engaged in agriculture in 1925. Linseed is grown mainly in Canterbury, South Island. Its cultivation increased rapidly after 1916–7, when only 1,431 ac. were sown until 1923–4, when 12,119 ac. were sown; the acreage fell, however, to 6,679 in 1924–5. The area under potatoes in 1924–5 was 23,092 ac., yielding a return of 122,184 tons. Other root crops are grown on a large scale for winter feed and for stock fattening purposes. Turnips are a most important crop in a sheep breeding country such as New Zealand; in 1924–5 the area under the crop was 452,894 acres. The cultivation of mangolds is increasing, with 15,111 ac. under the crop in 1924–5, and the value of lucerne cultivation is being realised.

The Department of Agriculture, under a director-general with divisional heads controlling chemistry, livestock, dairy fields and horticulture sections, is concerned mainly in advancing the interests of primary production. The sum allocated to this department in 1925–6 was £368,297. While the service is mainly educational, it also is responsible for the inspection and grading of all produce exported from the country. Experimental farms and horticultural stations are maintained in various localities, and farmers are assisted by visits and letters of advice. A Board of Agriculture was established in 1913 to advise the Minister for Agriculture upon matters relating to the development of agricultural and other rural industries.

Pastoral Industry.—The number of dairy cows in the Dominion in 1910 was 804,078, while in 1925 it had risen to 1,323,432. The dairy industry is largely conducted upon a co-operation basis, and the most up-to-date mechanical aids are used. In 1925, 15,561 milking plants were in operation, milking 705,000 cows each day, and 44,656 cream separators were in use on the farms. There were 156 butter, 267 cheese, and 69 dual (butter and cheese) factories. Over 76,000 persons were employed in the industry. Pastoral products comprised over 90% of total exports in 1925. The great advance made in the dairy industry is shown by the following table of comparative percentage increases in export quantities and values for the decade 1914–24.

	Value	Quantity
	%	%
Butter	398	192
Cheese	174	85
Frozen meat	62	−1
Wool	64	−6

During the post-War period two very important branches of the dairy industry were developed: the manufacture of casein, and of dried (or powdered) milk. In 1925, 43,908 cwt. of casein were exported, valued at £110,171, and 12,598,321 lb. of dried milk, valued at £390,045. Preserved milk was also exported to a value of £35,693. The decrease in the dairy output in 1925 (as shown in the export trade table) is attributable chiefly to an extremely unfavourable season and a shipping strike.

The number of sheep and lambs in the Dominion in 1925 was only some 500,000 more than in 1910. There was a normal increase in the flocks until 1918, when a total of 26,538,302 was

Acreage and Yield of Principal Crops, 1915–25

Season	Wheat		Oats		Barley		Maize		Peas and Beans	
	Area Thous. Ac.	Quantity Thous. Bu.	Area Thous. Ac.	Quantity Thous. Bu.	Area Thous. Ac.	Quantity Thous. Bu.	Area Thous. Ac.	Quantity Thous. Bu.	Area Thous. Ac.	Quantity Thous. Bu.
1915–6	329	7,108	213	7,653	30	820	8	340	9	163
1916–7	218	5,051	178	5,371	30	738	6	274	12	243

1923–4	174	4,175	64	1,964	21	597	8	406	19	363
1924–5	167	5,448	147	5,707	25	798	9	427	14	411

reached, but heavy exports followed in the next three years, and in 1922 the number had fallen to 22,222,259. In 1925 a recovery had been made to 24,547,955. Only a comparatively small proportion of the frozen meat exported from New Zealand is beef, for the price of frozen beef on the British market is very low owing to competition with the chilled article from South America. As a result of this competition markets other than Britain are being sought. Shipments of frozen pork are rapidly increasing. In 1924 there were 46 meat freezing and preserving works in the Dominion, employing 7,361 hands.

Co-operation.—One of the greatest aids to the development of the primary industries has been the application of the principle of co-operation, particularly in the case of the dairy industry. The farmers have their co-operative companies, arrange their own finance, and receive monthly cheques—based on a percentage of the prices current on the British market, any surplus over the amounts paid out being subsequently distributed proportionately as a bonus. This system largely obviates the necessity for extensive capital.

After 1922 co-operative marketing was put into operation by the meat producers. Under the Meat Export Control Act 1921–2 the meat industry obtained powers to set up a board, elected by all the sheep and cattle farmers in the Dominion, to supervise the industry, shipment and marketing of the produce. The board consists of eight members, five representing the producers and one the stock and station agents, while two are appointed by the government. Since its inception much useful work has been done, chiefly in regard to the marking of parcels, grading of meat, loading and discharging, regulation of shipments and in arranging satisfactory rail and sea freights and freezing charges. The dairy producers obtained power under the Dairy Produce Export Control Act 1923, to set up a similar board, but the Act was not in full operation by the end of 1925. Both bodies have representation in London, the former by a manager, and the latter by a board consisting of three members and a manager. The fruit and honey producers also have similar organisations governing their export affairs.

Afforestation.—A very active and progressive policy is pursued in reafforestation. The first organised attempt with imported trees, chiefly European larch, Austrian pine, Corsican and western yellow pine and a variety of eucalypti, was made in 1896, when an afforestation section of the lands department was formed. This work continued with more or less progress until 1919, when a separate forestry department was set up, and was reorganised in 1920 as the State Forest Service. Then in 1921–2 the Forests Act was passed defining the forest authority as the Minister of Forestry, the Director of Forestry, with a secretary, five conservators, a milling expert, an engineer in forest products, a grazing specialist and various sub-officials. The total personnel in 1925 was 95. At March 31 1925 the area dedicated to forestry and conservation was 7,485,590 acres. Over 100,000 ac. were acquired by purchase between 1920–5. In 1923 a national forest inventory and stock-taking took place and a great deal of valuable research work in regard to the New Zealand timbers was accomplished. The total expenditure on State afforestation up to March 31 1925 was £701,675, the area of state plantations being 62,945 acres. In the year 1924–5 local bodies, owners of private lands, tree and planting companies, etc., developed great afforestation activities, and to these the state has supplied some 13,670,000 trees. The area of private and company plantations and shelter beds was about 9,000 ac. in 1925.

Fisheries.—Although New Zealand possesses a most valuable asset in the great quantities of edible fish in the seas around her coasts, very little had been done up to 1925 in the systematic exploitation of the industry. In the year ending March 31 1925 some 330,000 cwt. of fish, valued at over £400,000, were brought in from the fishing grounds. In addition, the produce of the oyster fisheries was valued at £23,268, and of the whale fisheries at £15,000. Exports in 1924 totalled £67,896 in value, including fish, £58,417; whale oil, £6,515; and ambergris, £2,000. The whale fisheries declined considerably from 1920–4. In 1924, 2,921 persons were employed in the fishing industry.

Minerals and Mining.—The gold-mining industry has declined in importance: up to 1924 the total value of gold exported was £91,414,828, the value for 1924 being £551,788. Work on a scheme for obtaining gold from the bed of the Kawarau river, running from Lake Wakatipu (in Otago), by damming the exit of the waters from the lake, was well advanced in 1925. Silver is obtained in small quantities: up to 1924 total exports were valued at £2,904,651. The exploitation of iron ore and iron sand, of which there are plentiful deposits of the best quality, has not greatly progressed, though in 1924–5 enterprise revived. During the World War, tungsten ore mining became very active, but the fall in prices during the post-War period caused a collapse in the industry: the output of sheelite (tungsten ore) fell from 266 tons in 1916 to 15 tons in 1924. Copper, manganese ores platinum cinnabar, tin and sulphur are also found. Coal is mined for local consumption. The deposits are very extensive, the proved resources amounting to 610,000,000 tons: in 1910 2,197,362 tons were produced, and in 1924, 2,083,207 tons. Kauri gum, the fossilised resin of the Kauri tree, is classed as a mineral, and during 1924 5,261 tons of gum valued at £443,576 were exported. The total quantity of gum exported to the end of 1924 was 389,052 tons, valued at £21,108,085.

Secondary Industries.—Manufacturing industry had been but little developed up to 1925. The principal branches of industry, however, advanced considerably after 1910, with a tendency to greater diversity in production as the population increased. Owing to changes in system of collecting industrial data, and in the classification of industries made in various periods, together with the fact that the statistical data available include the dairy produce and meat handling establishments, it is not possible to give accurate tables to indicate the progress made. Including small-scale establishments, the Dominion had about 100 distinct manufacturing industries in 1925. Woollen factories supplied a large proportion of the internal requirements: much ready-made clothing is manufactured locally, and also furniture and footwear as well as other commodities.

Engineering and the manufacture of metal products are increasing in importance. Motor and cycle engineering, motor body building and the manufacture of chemicals, brushware and glassware are comparatively new industries which are making rapid headway. The government, through an Industries and Commerce Department, encourages and assists secondary manufacture, and the Customs tariff is scientifically arranged to foster such industries as are capable of development. The total number of employees engaged in factories in 1923–4 was 77,661. The value of the products of manufacturing industries in 1924 was £77,000,000. This sum includes semi-primary industries engaged in the preparation of agricultural and pastoral produce for export with products valued at £32,000,000.

Water Power.—The Public Works Act 1908 vested in the Crown the sole right to use the water power of the Dominion, subject to any existing rights, and gave the government the right to develop such power. The Aid to Water Power Works Act 1910 empowered the state to establish hydroelectric supply installations. The Lake Coleridge scheme to supply Christchurch was the first undertaken and was completed in 1915; in 1925 it was being extended to supply 27,000 kilowatts. At the close of the War a policy of concentration on works to supply the whole Dominion was adopted. The Mangahao system to supply Wellington and the Wellington province came into operation in 1925. Under legislation passed in 1918, and later amendments, 39 Boards were set up to administer and finance the supply of power in created districts. The full development of the schemes in progress in 1926 will give the following results, though each scheme is capable of greater development:—

North Island	H.P.
Mangahao (Wellington province)	24,000
Waikaremoana (East Coast)	40,000
Arapuni (Auckland)	96,000

South Island	H.P.
Coleridge (Canterbury)	36,000
Waipori (Otago)	25,000
Monowai (Southland)	16,000

The progress of development (in H.P.) was as follows:—

1910	1915	1921	1925
18,353	43,016	51,114	70,143

The total cost to March 31 1925, including capital outlay, stocks, and debit balances on trading accounts, was £4,010,666; statutory authorisations existed for £10,830,000. In 1925 there were 56 power distributing stations and a net profit was shown of 1·31%. The total water power resources are estimated at 4,109,950 horsepower.

Trade.—The external trade of New Zealand rapidly developed after 1910, particularly in the post-War period, as is shown in the following table:—

Year	Exports	Imports	Total trade
1910	£22,180,209	£17,051,583	£39,231,792
1914	26,261,447	21,856,096	48,117,543
1918	28,516,188	24,234,007	52,750,195
1922	42,726,249	35,012,561	77,738,810
1923	45,967,165	43,378,493	89,345,658
1924	52,612,711	48,527,603	101,140,314
1925	55,262,272	52,456,407	107,718,679

The *per capita* value of exports in 1910 was over £21, and in 1925 £39. The imports *per capita* in the same years were £16 and £38 respectively. (Imports are valued at the current domestic value in the country of export plus 10% to cover "charges, freight and insurance"; exports are valued f.o.b.)

The following tables show the values in thousands of pounds and quantities in thousands of hundredweight or pounds, of the principal exports for certain years:—

Exports: Values and Quantities (000's omitted)

Year	Wool		Frozen Meat		Butter		Cheese		Skins, Hides and Pelts
	Value £	Quantity lb.	Value £	Quantity cwt.	Value £	Quantity cwt.	Value £	Quantity cwt.	Value £
1910	8,308	204,369	3,851	2,654	1,812	357	1,195	452	1,129
1914	9,318	220,473	5,863	3,230	2,339	434	2,564	864	1,318
1922	11,882	321,533	8,387	3,518	9,042	1,120	4,687	1,161	2,054
1923	10,905	217,566	9,013	3,044	10,689	1,250	6,870	1,441	2,380
1924	15,268	206,190	9,490	3,159	11,642	1,269	7,023	1,594	3,144
1925	17,739	..[1]	11,215	3,349	10,240	1,245	5,801	1,377	..[1]

[1] Not available.

The successful application of refrigeration to the sea-carriage of apples and eggs opened up great possibilities, and the volume of exports is rapidly increasing. In the 1926 season some 600,000 cases of apples were shipped to Britain; in 1925 the quantity was only 200,000 cases, the value of which was £116,101. Honey exported in 1925 totalled 1,822,043 lb. valued at £53,156. Increasing markets for these small lines are of very great importance to New Zealand, because as industries, either allied or run separately, they provide local people and immigrants with limited capital and opportunity to start in land occupations. It is impossible for the Dominion to consume the whole output, and success is dependent upon markets overseas, the chief of which is Great Britain. There are many localities in New Zealand eminently suitable for apple growing, and the industry is capable of very great development.

Other exports of minor importance and their values in 1925 were: hemp, £516,466; sawn timber (chiefly to Australia), £573,879; kauri gum, £414,901; gold, £472,364; grass seed, £113,046; and silver, £60,773. The following table shows the value of goods exported to each of the chief markets in 1925:—

	Value	Per cent of total
To Great Britain	£44,073,717	80
To United States of America	4,531,153	8
To Australia	2,502,113	5
To Germany	1,614,090	3

The principal import groups are: clothing and textiles, metals and machinery, sugar, tea, alcoholic liquors, tobacco, paper and stationery, oils, motor vehicles and accessories, chemicals, drugs and timber. Imports of motor-vehicles and oils (including motor spirits) have increased very rapidly: before 1911 their value was less than £300,000 annually, but in 1924 the amount was £4,567,496. The following table shows the imports for 1910 and 1925 from Great Britain, other British countries and foreign states:—

Year	Great Britain	Other British countries	Foreign countries
	£	£	£
1910	10,498,771 (61·57%)	3,967,053 (23·27%)	2,585,759 (15·16%)
1925	25,535,332 (48·68%)	12,726,269 (24·26%)	14,194,806 (27·06%)

In 1910 the figures represent the countries of shipment, whereas those for the second period are of the countries of origin. In 1910 imports from Australia were valued at £1,520,000, and in 1925 £5,238,773; imports from the United States were £1,399,737 and £8,977,840 respectively.

Customs Duties.—In 1915 changes were made in the rates of duty levied on certain articles to meet the extraordinary expenses of the year, and in 1917 additional War impositions were made, these rates remaining in force until the coming into operation of the 1921 revised tariff. The revenue from customs duties in 1910 was £2,954,989, and in 1924, £7,480,947. The Dominion's system of Imperial preference extends to all British countries. The principle was greatly extended in 1921, when 425 items in the 644 subject to duty were made subject to the preference. At the same time, the average preference was raised from 10 to 15%. Australia has a special reciprocal tariff agreement with New Zealand, arranged in 1922, and does not come under the general British preferential provision. In 1924 about one-half the total imports from the British Empire were admitted free of duty.

Communications and Transport.—Considerable progress was made in state railway communication after 1910, as is shown by the following table:—

	Length open (miles)	Revenue (gross)	Expenditure
		£	£
1910	2,717	3,249,790	2,169,474
1920	2,996	5,752,487	4,105,067
1925	3,085	7,112,524	5,545,416

The net receipts in 1925 represented £3 11s. 0d. on capital costs. The capital value of the railways (including unopened lines and assets) was £50,833,500. The state builds its own rolling stock and locomotives, and in 1925 was providing extensive new railway workshops. In 1924 the whole control of managerial organisation was changed, the affairs being placed under the control of a board responsible to the Minister.

Important railway works were carried out during the post-War period. The North Main Trunk was extended from Auckland to beyond Whangarei; sections were constructed on the east coast of North Island, and a tunnel (5¼ m.) through the Southern Alps at Arthur's Pass, to link up the railheads in the

Westland and Canterbury provinces, was completed and electrified in 1923. Railway extension work has been slow and costly, as the sections of country requiring linking-up are of a mountainous character. Duplications have been made in city suburban areas, and works are in progress to obviate the heavy grades running out of Wellington City.

In 1925 there were 64,625 m. of roads in the Dominion, 28,553 m. of which were metalled. By the Main Highways Act (1922) main highways are under the administration of a Highways Board which is responsible for their upkeep. This step has been rendered necessary by the heavy increase that has taken place in motor traffic.

Banking.—There are six banks of issue operating in the Dominion, two of them, the Bank of New Zealand and the National Bank of New Zealand, being incorporated by special Acts of the general assembly of the Dominion. In 1925 the Bank of New Zealand had branches and agencies within the Dominion numbering 219, and the other five between them 259, making a total of 478.

Development of Banking 1910–24

	Deposits	Advances	Assets	Liabilities
	£	£	£	£
1910 .	24,968,761	18,439,999	26,398,927	26,742,081
1920 .	59,405,341	38,241,932	56,111,433	67,818,469
1921 .	49,397,411	50,607,541	68,701,282	58,808,439
1922 .	45,913,394	44,768,178	61,779,570	53,868,834
1923 .	49,039,482	43,322,242	59,641,235	56,204,292
1924 .	49,502,499	44,559,661	61,325,865	57,131,235

The number of open accounts in the Post Office Savings Bank at the end of 1910 was 380,585; at the end of 1915, 509,085; and at March 31 1925, 735,148. In 1910 (calendar year) the proportion of open accounts to the total population was 1 in every 2·76; in 1925 (March 31) the proportion was 1 in every 1·88. The deposits and withdrawals in the calendar year 1910 were £10,708,939 and £9,695,515 respectively; and in 1925 (March 31) £29,582,897 and £30,413,609 respectively. The amount standing to credit of all accounts in 1910 (Dec. 31) was £14,104,990, and in 1925 (March 31) £46,948,628.

NICARAGUA (*see* 19.642) has an area of 49,200 square miles. Nicaragua declared war on Germany, May 7 1918, and acquired membership in the League of Nations 1920. The western half of Nicaragua contains three-quarters of the population, mostly of mixed Spanish and Indian blood. There are many Nicaraguans of pure Spanish descent. In the east the inhabitants are mostly Zambos and Caribbean Indians and negroes. There are also a few Americans. Estimated population in 1923 was 700,000: Managua, the capital, 60,342; Leon, 47,234; Matagalpa, 32,271; Granada, 21,925.

I. POLITICAL HISTORY

On the flight from Nicaragua of President Zelaya on Dec. 24 1909 Dr. José Madriz, one of his supporters, succeeded him as provisional President. The United States refused to acknowledge the succession, and Madriz was superseded in 1910 by Juan M. Estrada, a member of the artisan class, who was supported by the Conservatives and a few Liberals. He was recognised by the United States and relations were resumed; but a fresh outbreak of factional quarrels amongst the political parties obliged Estrada to resign. The United States intervened, and Adolfo Diaz was elected provisional President in 1910, being elected to a second term of office in 1913. During the first term of office of President Diaz a private loan was negotiated in 1912, the currency reformed, and the customs collections placed under American control. A claims commission, sitting from 1911 to 1914, scaled down and adjusted claims. A revolt of the old Zelaya party, led by Gen. Mana, was unsuccessful in its effort to seize power in opposition to American reform of finances. After Dec. 1914 the Government was supported by American marines stationed at the legation. In Feb. 1913 a treaty was signed whereby Nicaragua gave to the United States for $3,000,000 exclusive inter-ocean canal rights through her territory together with accessory control over the entrances on the Corn Is. and in the Gulf of Fonseca. Protests by Costa Rica and Salvador on the ground that this treaty infringed their sovereignty were sustained by the Central American Court of Justice, but the decision was ignored by both parties to the treaty.

The maintenance of the Chamorro family in the presidency (Emiliano 1917–20, Diego M. 1921–3), while securing peace, caused continuous dissatisfaction. Nicaragua rejected the Central American Union of 1921, fearing that its operation would affect her status with reference to the Canal Treaty, though American official opinion denied this possibility. Crimes by U.S. marines in 1921 and 1922, arising from feuds with Nicaraguans, resulted in several courts-martial and the policy of frequent changes of personnel in the legation guard.

There were border revolts in 1921. The movement of rebel troops upon Managua in 1922 led to a conference on Aug. 22 on board the U.S.S. "Tacoma," in the Gulf of Fonseca, attended by the presidents of Nicaragua, Honduras and Salvador, for the purpose of securing united action in stopping revolutions fomented by political immigrants. This conference renewed the acknowledgment of the Treaty of Amity of 1907, and invited Costa Rica and Guatemala to reiterate their adhesion also; they declined on the ground that the pact was still in force. The Washington Conference of 1922-3 was called at the solicitation of the republics which were parties to the "Tacoma" conference. Nicaragua had before mid-Aug. 1925 approved the first 13 of the Washington agreements.

Diego M. Chamorro died in 1923, and was succeeded provisionally by Dr. Bartolo Martinez. In Jan. 1925 Carlos Solorzano took office as President The United States, Nov. 14 1924, expressed a desire to withdraw its marines in Jan. 1925, but Nicaragua asked that they be retained until the new Government should be installed after an election to be held under a new electoral law framed by Dr. H. W. Dodds. They were ultimately withdrawn on Aug. 3 1925 and replaced by native constabulary under an American officer. In 1924 claims of Mosquito Indians for land title adjustments under the British cession of 1906 were adjudicated by the British and American consuls sitting with the Minister of Foreign Relations.

Defence.—Military service is obligatory between the ages of 17 and 55 years. Active service is for one year. Under the convention for the limitation of armaments signed at Washington on Feb. 7 1923 Nicaragua agreed to limit its standing army to 2,500 of all ranks. In war time the army may be increased to 7,000. Beyond a single small boat, stationed on the Pacific coast, Nicaragua possesses no navy, and by the 1923 convention is pledged to acquire no more than 10 serviceable aeroplanes.

Education.—Primary education is compulsory and free. Secondary education, which is conducted under private auspices, is neither free nor compulsory. Fifty per cent of the population is estimated to be illiterate. In 1923 there were 344 state elementary schools with 730 teachers and 21,651 pupils. There were three secondary schools, five provincial schools, two normal schools and 160 private and municipal schools. The total school population was 29,864. There are universities at Managua, Leon and Granada and a national industrial, commercial and scientific museum at Managua.

II. FINANCIAL AND ECONOMIC HISTORY

Finance.—The revenues and expenditures of the Government were, in cordobas:—

	1925	1924	1920
Revenues . . .	2,772,640	2,211,706	3,147,752
Expenditures . .	2,772,640	1,580,000	1,528,077

The surplus was used each year until July 1924 for public works and on treasury bills; the treasury bills being then paid, the surplus was thereafter used for Government purposes. Customs collections for the five years 1920-4 were, in cordobas: 1920, 2,055,989; 1921,

990,168; 1922, 972,024; 1923, 1,591,131; 1924, 1,988,865. The report of the Collector-General of Customs for 1924 showed a sound financial condition for the republic; the public debt of 32,236,223 cordobas in 1911 was reduced to 7,390,590, March 31 1925.

Production and Commerce.—Agriculture continued to expand throughout 1924, though retarded by labour shortage. Bananas on the east coast constitute an important crop, and coconuts, oranges, pineapples and yucca are raised. Rice, wheat and tobacco also are grown on the east coast. Coffee, the most important crop of Nicaragua, showed export values in cordobas (1 cordoba = 1 U.S. gold dollar), as follows: 1920, 2,874,141; 1921, 2,352,487; 1922, 2,300,572; 1923, 3,937,833; 1924, 7,321,784. The total commerce for 1924 was over 20,000,000 cordobas, twice the average of 10 years previous. The increase was due to the excellent coffee crop, which was the largest in the history of the republic, and its high price. The other principal products exported—gold, mahogany, bananas and sugar—showed a slight decrease. In the west, beans, corn, cheese, lard and sugar are exported. Important lumber exports go from both coasts, as well as dye woods, gums and medicinal plants. The gold export in 1921 was 989,973 cordobas; in 1922, 1,065,733; in 1923, 823,554; in 1924, 771,375 cordobas. Operations were curtailed in 1924 and several mines closed.

Leading exports for recent years were (in cordobas):—

	1924	1923	1920
Cotton goods . .	2,504,670	2,276,781	5,242,189
Iron and steel mfr. .	676,727	471,638	754,075
Leather and mfr. .	244,973	242,321	370,804
Flour	439,294	383,852	665,660

Since 1916 the United States has supplied from 73 to 84% of Nicaraguan imports. For the same period the United States has taken from 62 to 85% of the exports, save in 1924 when it took 57%. Proposals to reduce import duties on manufactures used in development were pending in March 1925. A convention between Nicaragua and Guatemala, Sept. 10 1924, provided for free trade for five years in natural products or those manufactured with native raw materials.

The trade movement for the four years 1921–4 was:—

	1924	1923	1922	1921
All Countries				
Imports . . .	$8,806,896	$7,268,432	$5,123,505	$5,309,903
Exports . . .	12,990,025	11,028,309	7,903,446	8,070,949
United Kingdom				
Imports . . .	£ 349,223	£ 235,773	£ 114,425	£ 150,549
Exports . . .	112,324	82,728	75,119	97,707
United States				
Imports . . .	$5,453,167	$5,509,254	$4,127,205	$3,857,202
Exports . . .	6,250,499	7,896,177	5,617,507	6,264,531

Communications.—Most of the roads in the country are nearly impassable in the winter season, but construction has been carried on as follows: from Managua through Matagalpa to Jinotega, 104 m.; Managua to Dirianba 35 m.; Leon to Matagalpa, 80 m.; Puerto Diaz through Juigalpa to La Libertad, 50 miles. Construction on these roads is intermittent. The Pacific railway of Nicaragua has a total length of 146 miles. It runs from Corinto *via* Leon, Managua and Granada to Diriamba. The total railway mileage is 172. The government has contracted for the installation of wireless stations at Managua, Cabo, Gracias a Dios and Bluefields. The station at Managua was under construction in 1925.

Banking.—A new monetary unit was introduced in 1912, the *cordoba*, equivalent to the United States dollar and containing 1·672 gr. of gold $\frac{9}{10}$ fine. Provision was made by law for a gold coinage of 10·5 and 2½ cordobas, but no gold coins have been minted. Cordobas in circulation amounted to 2,379,254 in Nov. 1923. In 1912 the National Bank of Nicaragua was established in Managua, the nominal capital being $300,000.

NICHOLAS (1841–1921), King of Montenegro (*see* 19.651), was the last member of his house to reign over a separate Montenegrin realm. The story of the last 20 years of his life is very largely the contemporary history of Montenegro. His grant of a constitution in 1905 was followed by a period of violent internal conflict between him and his opponents, whose position had been strengthened by the elections to the Skupshtina, whom he sought to discredit by the Cetinje bomb plot mystification. His assumption of the kingly title in 1910 marked a further stage in the evolution of his plans, of which it constituted a public notification, and aroused hostile comment among his own people as well as in Serbia. The Balkan wars resulted in a marked *diminutio capitis* for Nicholas, who failed to play a conspicuous part in them and was forced to call in Serbian aid before Scutari. At this time already the survival of a Montenegrin throne appeared a doubtful problem. In the World War the breach between him and his people was complete, and even before the final act the old monarch was apostrophised derisively as Nicholas the first and Petrovich the last. He died at Antibes March 1 1921, and was buried at San Remo.

NICHOLAS (1856–), Russian Grand Duke and soldier. Nikolai Nikolaievich was born Nov. 6 1856, the grandson of the Emperor Nicholas I. and first cousin of the Emperor Alexander III. Educated at the school of military engineers, he received his commission in 1872, and in the following year, at the early age of 16, entered the military academy. In the war of 1877–8, as a general staff officer for special service, he joined the staff of his father, the very popular Grand Duke Nikolai Nikolaievich (Senr.), who had been appointed commander-in-chief of the Russian forces. At the crossing of the Danube at Zimnicea on April 15 1877 he was awarded, for his courage, the Cross of St. George, 4th Class. In the attack on the Shipka he acted as chief of staff to one of the columns, and received the distinction of the Golden Sword.

After the war the Grand Duke joined the Guard Hussar Regiment, in which the Emperor Nicholas afterwards served, and passed through every stage as officer till appointed commander in 1884—a position he occupied for 6½ years. He then commanded in succession a brigade and a division, and in 1895 was appointed inspector-general of cavalry. He held this post for 10 years, a period which is regarded as a bright epoch in the history of the Russian cavalry, for he carried through fundamental reforms in training and in the organisation of the cavalry schools, of the cavalry reserves and of the remount service.

In 1905 Nicholas was appointed commander-in-chief of the St. Petersburg military district, a post he held till the outbreak of the World War in Aug. 1914. Here, as elsewhere, he gave proof of his zeal for efficiency. Setting himself the task of instilling the lessons of the Japanese war, he encouraged musketry and work in extended order, but at the same time allowed no slackness in ceremonial. To help him in his work he called from the Far East men like Generals Ivanov, Lesh and Lechitski, who were of comparatively humble origin but had made their reputation in the field. The appointment of such men to high command in the Imperial Guard was characterised in his diary at the time by another Grand Duke as "revolutionary," but the men selected justified their choice in the World War.

In the same year (1905) as he was appointed commander-in-chief of the St. Petersburg military district, Nikolai Nikolaievich became the first president of the newly created council of national defence, and he held this position till 1908, when the council was abolished. During this time the Emperor seems to have hesitated between the final adoption of a military system analogous to that of Germany, under which the chief of the general staff, as well as the minister of war, should have the right of access and of direct report to the Sovereign, and of the system in vogue in countries with a constitutional government, under which that right was confined to the minister of war. On the council the Grand Duke worked in close co-operation with General Palitsin, who, in 1908, on the Emperor's decision in favour of the latter system, gave way to General Sukhomlinov as chief of the general staff, the latter, in the following year, replacing General Rediger as minister of war.

From 1908 to 1914 Nicholas took no part in the strategical

preparation for the War, the work being delegated by the Emperor to General Sukhomlinov and his nominees on the general staff. At the outbreak of war the Emperor first intended to take command himself, and actually appointed the Grand Duke Commander-in-chief of the 6th (Reserve) Army at St. Petersburg (Leningrad). It was only on the evening of Aug. 1, the day of Germany's declaration of war, that he yielded to the entreaties of his ministers and decided to hand over the supreme command to the Grand Duke.

Services During the War.—The position the commander-in-chief was called upon to fill was a peculiarly difficult one. He was responsible for carrying out a plan which he had no hand in drawing up, a plan which was dependent on promises previously made, without his cognisance, to the French general staff. He had to work in accordance with the "Regulations for the Direction of the Army in the Field," a new edition of which had been issued on the very eve of the War, handing over much power to the two group commanders. Finally, he was compelled, by the Emperor's directly expressed personal wish, to take as his chief of staff and general quartermaster, Generals Yanushchkkevich and Danilov in preference to Generals Palitsin and Alexeyev, whom he would have preferred.

The plan of the Russian general staff consisted of the invasion of East Prussia by a right group (I. and II. Armies), while a left group (IV., V., III. and VIII. Armies) operated against the Austrians in Galicia, and a centre group (IX. and X. Armies) assembled at Warsaw to advance on Posen. It was owing to the decision of the Grand Duke that this centre group was broken up, the X. Army being sent north to fill the gap left by the failure in East Prussia, and the IX. Army sent south to overwhelm the Austrians in southern Poland.

When the Germans came to the rescue of their discomfited ally by advancing in Oct. 1914 to the outskirts of Warsaw, the transfer of the Russian Armies from left to right in rear of the Vistula, and the concentration of superior forces on the enemy's left or northern flank which compelled his retreat, were masterly movements. If the next German advance, culminating in the operation of Łódź owing to mistakes by Russian army commanders, definitely removed all possibility of an invasion of Posen, the Russians held on through the winter of 1914–5 to the line of the Narev-Vistula-San-Carpathians, and were only compelled by lack of munitions in the spring and summer of 1915 to retreat to a line that they held substantially throughout 1916–7. With the cause of this retreat from Poland and the lack of munitions the Grand Duke had nothing to do, but to him must belong the credit for the harmonious carrying out, without incurring a Sedan, of this movement with such skill that the Russian Armies, when they reached the line on which they were to rest for the winter, were still a fighting force with confidence in their commander.

There was no demand from the fighting men at the front for the change at G.H.Q. which occurred on Aug. 21 1915, when the Emperor announced that he would assume the supreme command. It is said that Rasputin had prophesied that the Russian armies would continue to be defeated till the Emperor placed himself at their head. Certainly the impostor had no reason to love the Grand Duke Nicholas. A story repeated among the soldiers relates that he had applied to the commander-in-chief for permission to come to the front "to bless the troops," and the latter had telegraphed in reply two Russian words which being translated run—"Come, I shall hang you."

The Grand Duke was appointed viceroy and commander-in-chief in the Caucasus. Up to that time the brunt of the fighting against Turkey had been borne by the British in Gallipoli, the Sinai Peninsula and Mesopotamia. The advent of the new commander put new life into the Russian forces. He pushed forward an expeditionary force under General Baratov through Enzeli and Hamadan to screen Persia from further German penetration, and to establish touch with the British troops in Mesopotamia. He collected guns and stores, and raised and trained efficient troops, and, in spite of immense difficulties in supply, ably assisted by Generals Yudenich and Prjvalski, occupied in three successful offensives all Armenia, including the fortress of Erzerum, the port of Trebizond and the town of Erzinjan.

The revolution of March 12 1917 found the Grand Duke still in the Caucasus. The Emperor's last official act was to nominate him to be once more supreme commander-in-chief. His journey from the Caucasian headquarters at Tiflis to the headquarters at Mogilev was in the nature of a triumphal procession, patriotic demonstrations and crowds of people greeting him at every station on the way. Twenty-four hours after his arrival at Mogilev he received a telegram from Prince Lvov, the chief of the provisional government, cancelling his appointment. The next two years the Grand Duke spent in the Crimea, taking no part in politics. At last, in March 1919, he left Russian soil on the British Cruiser "Marlborough," and went to live quietly near Paris.

Nikolai Nikolaievich was, before everything, a patriot with a strong sense of duty. Though destined by birth to great wealth and high position, he devoted himself to the scientific study of his chosen profession of arms. His active career showed that he possessed the qualities of a real leader of men. Of commanding stature, and extraordinarily handsome, he was gifted with boundless energy, a strong will and the power of rapid decision. Every form of intrigue was absolutely foreign to his nature. That he had the broad mind of the true statesman was proved by his conciliatory proclamation to the Poles at the commencement of the World War. He possessed to an extraordinary degree the power of inspiring love and trust. His sense of justice made him treat general and soldier exactly alike, and the many stories of his doings told by the peasant soldiers of the Russian Army showed that he was regarded as a sort of legendary champion of Holy Russia in the struggle against Germanism and court corruption. They felt that, though he was a strict disciplinarian and very exacting in his demands on their strength, he would ask from the private soldier no greater effort than he did from his general or imposed upon himself. (*See* EASTERN FRONT CAMPAIGNS). (A. W. F. K.)

NICHOLAS II. (1868–1918), Tsar of Russia (*see* 19.655).–In view of the tragic end of the Tsar Nicholas II. and his family in the Russian revolution, it may be noted that, even in the lifetime of his father, Alexander III., his mind had been deeply imbued by mystic belief in divine rights and providential guidance, and he was prepared to suffer and to endure, if necessary, in carrying out the duties of his office. His intellectual preparation as heir to the throne was very insufficient. As the second son he had been left in the background for some time, and even when it became clear that his elder brother, George, was doomed to untimely death by consumption, no special efforts were made to prepare him for his task by any elaborate teaching. An English tutor, Mr. Heath, taught him excellent English, and inspired a love of sports and healthy exercise, while a Russian general, Danilovich, supervised his military training, but there was no attempt to provide him with the comprehensive knowledge required from one whom fate had destined to rule an immense empire. The only occasion which was offered to the young Tsarevich to acquaint himself with the problems of the world was his journey to the Far East, so abruptly cut short in Kyoto by the sabre cut of a Japanese fanatic.

It is not strange that Nicholas II.'s range of ideas was not very wide or profound, although he was by no means unintelligent, and possessed in high degree the royal habit to move with ease and tact in complicated personal surroundings. His disposition towards fatalistic mysticism made him particularly amenable to the promptings of superstitious and irrational suggestion. He told Stolypin on one occasion, when he had to take an important decision, that he was loath to do so, because he was sure that his interference would be accompanied by bad luck; he saw a warning in the fact that he had been born on May 6, the day when the Church honoured the memory of Job; he was predestinated to say with Job: "As soon as I apprehend a danger, it occurs, and all the misfortunes dreaded by me come over me." He wedded Princess Alix of Hesse at the deathbed of his father; at the festival of his Coronation more than 3,000

people were crushed to death through the negligence of the officials who had to arrange a distribution of bounties; and during the Coronation itself the imperial chain on his breast fell to the ground. Such impressions contributed strongly to inspire him with a mystic resignation, especially unsuitable for a monarch who had to lead the nation through times of great crisis at home and in foreign affairs.

Nicholas II.'s political outlook was dominated by a kind of theocratic or hieratic spirit; he was looking back for inspirations to the ideas and customs of the Moscovite period; he was induced to impersonate the figure of Alexis Mikhailovich, the father of the western reformer Peter the Great; in 1913 the tercentenary of Michail Feodorovich's accession to the throne after the "Great Troubles" was celebrated with much splendour and emphasis. Pilgrimages were performed with great devotion and circumstance.

The courtiers and bureaucrats in the immediate surroundings of the Tsar, men like Sipiaguin, Nicolas Maklakov and Sabler, took advantage of these prepossessions in order to keep up a constant hostility against progressive reformers and western adaptations. But the most dangerous representative of mystic reaction was the Tsar's consort, the Empress Alexandra Feodorovna. Of German descent on her father's side and of English descent on the side of her mother (Princess Alice, the daughter of Queen Victoria), she had received her education in England, but, on coming to Russia, she surrendered completely to the most extreme form of theocratic exaltation.

While her sister, the widow of the Grand Duke Sergius, killed by a terrorist, had devoted herself to a simple life at the head of a community of hospital nurses, Alexandra Feodorovna, highly strung and hysterical, sought providential guidance in the midst of unbalanced women and false prophets like the French medium Philippe and the famous Rasputin. The latter obtained a hold on her through the hypnotising influence he exercised over her son, the Tsarevich Alexis, a boy affected by the rare disease of hereditary haemophilia. But the crafty peasant had contrived to obtain gradually a psychical domination over the Empress and her friends which made it possible for him to distribute political favours and to have his say in the most important affairs of State. The Empress considered him as the God-sent representative of the Russian nation, of that mass of peasants which, as she was convinced, was the firm mainstay of autocracy in Russia. And in the later years of Nicholas II.'s reign, the years of great trial and danger, Alexandra Feodorovna stepped in more and more often to direct the Tsar's choice of his ministers and to prevent him from making concessions to the spirit of the time.

The suspicion that Alexandra Feodorovna was secretly favouring the cause of Germany and revealing military secrets to the Kaiser—a suspicion often expressed abroad and popularly accepted in Russia—is, according to most competent witnesses, devoid of any basis in fact. The Empress was intensely patriotic in her own way, opposed to the aggressive policy of the Hohenzollerns, and never advocated a treacherous compromise with the Central Powers. A former lady-in-waiting, Princess Vassiltchikov, who towards the close of 1916 brought the project of such a compromise from Germany was promptly ordered out of St. Petersburg (Leningrad). Nevertheless, Alexandra Feodorovna proved to be the evil genius of the Russian dynasty, by her blind and obstinate support of reactionary tendencies and of worthless adventurers, at a time when a wise and firm policy of reform was more needed than ever. All the better representatives of the dynasty—the Dowager Empress Maria Feodorovna, the Grand Duke Nicholas Mikhailovich, the Grand Duchess Victoria, warned the Empress Alexandra Feodorovna of the imminent danger of that régime of fleeting ministerial shadows which set in after the catastrophe of the War Office in 1915.

The Emperor remained passive as commander-in-chief at headquarters while the Empress Alexandra spurned all advice with contempt and continued to pull the strings by dismissing men like Sazonov and Palivanov, and appointing timeservers like Sturmer, Protopopov or Galitzin. The assassination of Rasputin did not frighten but enraged her; she erected a kind of shrine over the body of the prophet and sent the Grand Duke Dmitry Pavlovich, who had taken part in the murder, into exile. Her power was broken only by the revolution.

The thread of the Romanov dynasty was cut without much resistance. When in March 1917 the Emperor received at headquarters a telegram from the president of the Duma informing him of the events of St. Petersburg and demanding his abdication, and MM. Gutchkov and Shulgin arrived with the act of abdication itself, he submitted with fatalistic composure. He refused to give up his crown to his son with Grand Duke Michael as regent, because he did not wish to trust the boy to the danger of a political storm; and his abdication was made in favour of the Grand Duke Michael, who in his turn refused to accept the crown unless it was tendered to him by the will of the people. The last chance of a régime of constitutional monarchy was cut short. Proposals were made on behalf of the British Govt. to allow Nicholas II. and his family to take up their abode in England; but the Provisional Govt. in St. Petersburg did not accede to that plan. Kerensky and Milyukov declared that the imperial family were in safety in Russia. Later on the Emperor submitted meekly to be transferred from Pskov to Tsarskoe Selo and thence to Tobolsk, where he was interned with his family—his wife, his son and his four daughters—for months.

The life in Tobolsk has been described by a French tutor, M. Gillard, who followed the imperial family into exile. All the qualities of the unfortunate prisoners of state came to the fore in these sad times. The Tsar taught his son history and Russian literature, the family circle assembled in the evening to read and converse, they prayed and attended the church services with touching devotion. In Ekaterinburg, where they were transferred by the Bolsheviks in 1918, their captivity assumed an oppressive form. They were huddled together in an apartment consisting of two bedrooms and one sitting-room. Their guard consisted mainly of Lettish soldiers, while Russians were kept on the outskirts of the house; they had to listen to the uproar and the ribald songs of their watchmen; the walls of the sitting-room were covered with obscene drawings and inscriptions; the head gaoler, Yourkovsky, was a fanatical communist, a Jew, who harboured feelings of fierce hatred against the potentates of Holy Russia.

The end came in connection with Kolchak's advance on the Ural in 1918. The Soviet of Commissaries in Moscow enjoined the greatest vigilance to the Ekaterinburg commissar, Yourkovsky, and the commander of the guard, Medvediev, without indicating any means for removing the prisoners from the threatened zone. The communists of Ekaterinburg held a secret meeting in which they decided to put the Tsar and his family to death, and sent an order in this sense to Yourkovsky. The latter demanded that it should be duly signed, and 16 signatures were affixed to it. On the night of July 16 Yourkosvky roused the prisoners and conducted them into a cellar of the house. Medvediev, with the Lettish guards, entered the room while some Russian soldiers were looking in from the staircase. Yourkovsky placed the seven doomed persons at one end of the room and read the sentence hurriedly by torchlight. The Tsar stepped forward and said something indistinctly, when Yourkovsky drew his revolver and shot him in the head. A general fusillade followed, and, not content with this, the executioners pierced the bodies with their bayonets and struck them with the butt-end of their rifles. The Grand Duchess Tatiana is said to have recovered consciousness for a while, but she was struck down once more and forever. Besides the seven members of the imperial family four of their attendants were probably slaughtered the same night. In the course of the next few days the corpses were removed to an isolated spot in the neighbourhood of Ekaterinburg and destroyed by fire, after having been soaked with petroleum. A few objects of apparel were later picked up on the spot. (*See* RUSSIA.) (P. VI.)

NICHOLSON, WILLIAM GUSTAVUS NICHOLSON, 1ST BARON (1845–1918), British soldier, was born March 2 1845, and joined the Royal Engineers in 1865. He served in the Afghan War, 1878–80, and in the Egyptian campaign of 1882. He next served as chief of the staff in the Tirah campaign, and as adjutant-general in India. In 1899 he went out to South Africa as military secretary to Lord Roberts, but on arrival he was placed at the head of the transport service. Early in 1904 he went to the Far East as chief military attaché with the Japanese forces. At the end of 1905 he was appointed quartermaster-general; in 1908 he was transferred to the post of Chief of the Imperial General Staff, which he held during the important period of the Haldane reforms. He was promoted field-marshal in 1911 and, on vacating his appointment at the War Office in the following year, was raised to the peerage as Baron Nicholson of Roundhay. In 1913 he was chairman of a commission on Indian military expenditure, and in 1916–7 he was a member of the Dardanelles commission; this was his last public service. He died in London on Sept. 13 1918. Lord Nicholson was a man of high intellectual attainments and, although somewhat given to controversy, a successful military administrator.

NICHOLSON, MEREDITH (1866–), American writer, was born at Crawfordsville, Ind., Dec. 9 1866. He was educated in the public schools of Indianapolis, and engaged in journalism from 1885 to 1907, being reporter and later editor on the Indianapolis *News*. His works include the following novels: *The Main Chance* (1903); *The House of a Thousand Candles* (1905); *The Port of Missing Men* (1907); *The Little Brown Jug at Kildare* (1908); *The Lords of High Decision* (1909); *A Hoosier Chronicle* (1912); *The Madness of May* (1917); *Broken Barriers* (1922); *The Hope of Happiness* (1923); *And They Lived Happily Ever After* (1925); also a volume of *Poems* (1906); and four volumes of historical and critical essays, including *The Valley of Democracy* (1918) and *The Man in the Street* (1921).

NICKEL (*see* 19.658).—The world's chief source of nickel is Canada: in 1913 she contributed 69% of the world's production. The great need of nickel for armaments during the World War caused the Canadian output to increase, and by 1918 it had risen from 20,000 tons in 1914 to 41,000 tons in 1918, which latter figure represented 87% of the world's production for that year. The highest percentage was reached in 1920, when Canada produced 88% of the world's supply. As a result of the market being congested with large stocks and accumulated scraps at the end of the War, Canadian production declined, reaching its lowest ebb in 1922, when less than 8,000 tons of Canadian nickel were mined. When the congested supplies had been absorbed, the industry quickly revived; demand soon exceeded production, and a steadily increasing output has since been maintained. The world's output in 1923 was estimated at about 30,000 tons, of which approximately 27,000 tons was produced from the nickel mines in Canada, including a relatively small quantity of nickel recovered as a by-product from the cobalt-silver ores in that Dominion.

With regard to foreign producers of nickel, the most important is the island of New Caledonia, a French possession about 1,250 m. northeast of Australia. This island's output, in spite of the increased demand for the metal between 1914 and 1918, has since then gradually fallen, being in 1921 only about 14% of the world's output.

Norway, which in the earliest days of the industry held a monopoly of the world's supply, closed down her mines in 1921 for economic reasons. In the United States the nickel deposits are nowhere being worked for the metal, though a small quantity is incidentally recovered there each year in the process of electrolytic refining of blister copper. Under the exigencies of war Germany produced from her own low-grade mines a small tonnage of nickel ore, but since the close of hostilities she has reverted to the practice of importing refined metal. Besides the above, there have been obtained from time to time small supplies of ore from Greece, Tasmania, Sweden, etc.

Practically the whole of the Canadian output is obtained from the Sudbury district in the Province of Ontario, relatively small quantities being obtained from the deposits 150 m. due north of Sudbury in the Temiscaming district, and from the cobalt-silver area in the same province. Other occurrences are known in the townships of MaCart, Munro, Strathy and near Lake Shebendowan in the district of Thunder Bay, Ontario, and nickeliferous pyrrhotite associated with copper occurs in the Gabbro copper mines, Vancouver Island, British Columbia.

World's Production of Nickel Ore
Long Tons

	1913	1918	1923[4]
Canada	22,177	41,298	27,881
Germany	267	1,841	3[3]
Greece	943	658	..
Norway	492	238	61
Sweden	..	24	..
New Caledonia[1]	8,098	2,666	2,624
U. S. A.[2]	214	394	89

[1] Exports. [2] Produced as by-product in electrolytic refining of copper. [3] Ore, nickel content not stated. [4] Italy produced 44 tons in this year.

NICOLL, SIR WILLIAM ROBERTSON (1851–1923), Scottish Nonconformist divine and man of letters (*see* 19.663), died at Hampstead, London, May 4 1923. After 1910 he published *The Problem of Edwin Drood* (1912); *Dickens' Own Story* (1923); *Memories of Mark Rutherford* (1924); as well as a devotional work, *Reunion in Eternity* (1918).

NIEDERLE, LUBOR (1865–), Czechoslovak archaeologist and anthropologist, studied at Prague, Munich and Paris. In 1891 he became a lecturer and in 1904 a professor of archaeology and ethnology at the Charles University in Prague. In 1905 he organised the collections in the Czechoslovak ethnographical museum. By his work *Slavonic Antiquities* (Prague, 1904) Niederle became the recognised leader of Czech research on the history of the ancient Slavs. Among his other works are *Mankind in the Prehistoric Period* (Prague, 1893–4), and *On the Origin of the Slavs* (Prague, 1896). In 1898 he founded and directed the *Bulletin of Slavonic Antiquities*, and, from 1901 onwards, the *Bulletin of Slavonic Anthropology and Antiquities*. Professor Niederle became a member of many Slavonic learned societies, and received numerous foreign distinctions.

NIGERIA (*see* 19.677).—This British colony and protectorate has three main divisions: (1) the Colony, up to 1906 called Lagos colony, (2) the Southern Provinces and (3) the Northern Provinces. The provinces form the protectorate, but for descriptive purposes the Colony may be regarded as part of the Southern Provinces. The total area is about 335,000 sq. miles. The native population, based on the 1921 census returns and partly estimated is slightly over 18,000,000; and the European population about 4,000. The capital is Lagos (*q.v.*). There are over 20 other large towns.

I. POLITICAL HISTORY

In 1911 Nigeria consisted of two very different, and for political purposes distinct dependencies of the Crown. Southern Nigeria (that is, the Colony and Protectorate of Southern Nigeria), with an area of about 76,000 sq. m., stretched inland from the Guinea coast through a tropical belt of generally dense forest

land to a line irregularly corresponding with the latitude of 7′10″ N. Northern Nigeria, with an area of 255,700 sq. m., composed largely of open prairie, hill country and dry desert plains, extended from the latitude of 7′ 10″ to the frontiers of the French and Zinder territory on the north, to French Dahomey on the west and to the German Cameroons on the east. The population of Southern Nigeria was about 8,000,000 and the population of Northern Nigeria, with more than three times the area, was about 9,000,000. In both divisions primitive and very backward races had been overrun and influenced by civilisations of a higher type. In the south the new civilisation had been European and Christian; in the north, Arab and Mahommedan.

The interdependence of these two regions was obvious, and their amalgamation had long been urged upon the Imperial Government. It was not, however, until 1911 that the Secretary for the Colonies, Mr. L. V. Harcourt, determined to adopt the policy. Sir Frederick Lugard, who had been the first high commissioner for Northern Nigeria, was asked to initiate and carry out a scheme of amalgamation, being in 1912 appointed governor at the same time of both Southern and Northern Nigeria. The preliminary work was completed in about 18 months, and on Jan. 1 1914 the governments of Southern and Northern Nigeria were formally amalgamated, Sir Frederick Lugard receiving the personal title of governor-general. The geographical divisions of north and south were maintained. Two lieutenant-governors were appointed, one for the northern and one for the southern province, an administrator was appointed to the Colony, the jurisdiction of the legislative council was now confined to the narrow limits of the Colony's 1,400 sq. m. and the governor-general retained, in his central secretariat, services necessarily general to the whole. These were intentionally limited, and as much responsibility as possible was delegated to the two lieutenant-governors.

At the time of amalgamation Northern Nigeria was divided into 12 provinces, the native communities being for the most part each under its native ruler, the five principal native States being known as first-class emirates, while each independent chieftainship, however small, retained its treasured liberty, and this system of government was maintained. The southern provinces at that period, consisted of three divisions under provincial commissioners. They were the territories east of the Niger, west of the Niger and the hinterland of Lagos. The native races in the hinterland of Lagos and to the east of the Niger were in a much less advanced state of tribal organisation than were the tribes in the north and scarcely fitted for any form of enlightened self-rule. Fetish worship, cannibalism and barbarous practices were rife. On the west of the Niger, however, three native states, Yoruba, Egbe and Benin, were strongly organised. They were induced to renounce the exceptional position they enjoyed, under treaties made with Great Britain, and to accept conditions similar to those of the first-class emirates of the north. The introduction of the new system was accompanied by some difficulty, and in 1918 an easily suppressed rising in Egbeland gave momentary uneasiness. Indirect rule has now been fully accepted in both Egbeland and Yorubaland and the report of 1924 especially mentions that it is working admirably in Benin. The way for the extension of such indirect rule as might be found possible, was prepared by the division of Southern Nigeria into nine provinces (later increased to ten), each under a British Resident, as in the North.

The World War.—The outbreak of the World War within seven months of amalgamation postponed the consolidation of the new system. Patriotic sentiment in the Protectorate ran high. Every department was depleted by volunteers for active service, and it was with difficulty that the administrative machine was held together with the remnant of overworked staff retained. For four years, the first thought of every Englishman in Nigeria was given to the War. And not of the Englishmen only. The War served at once to test and to exemplify the solid results of British rule. Throughout the War period the great native chiefs of the North were constant and unflagging in their loyalty. They contributed liberally to Red Cross and other war funds. They prayed for British victory in their mosques. They joined in public thanksgiving when victory was won, and they rendered the great service, when the country was practically denuded of troops, of maintaining absolute tranquillity in their dominions.

The native troops of the West African Frontier Force did gallant service, both in the arduous campaign carried out under the leadership of Generals Dobell and Cunliffe in the Cameroons, and in what was to them foreign service in East Africa. The Cameroons campaign which opened in Aug. and Sept. 1914, with reverses all along the British line, at Mora (Aug. 25) and Garua (Aug. 29) in the north, and at Nsanakang (Sept. 6) in the south, lasted until Feb. 1916. It was a severe test for the troops engaged. The fighting was heavy, but they stood it well. Early in 1915 the campaign, in which French troops took an active part, was reorganised. British Forces in the north were placed under the command of General Cunliffe, and the final taking of Garua and the storming of Banyo Hill under his leadership on Nov. 6 1915, in face of a hail of dynamite bombs, was a feat of which any regiment might be proud. The conquered territory was divided between France and Great Britain, to be administered under mandate according to the provisions of the Treaty of Versailles. The portion taken by Great Britain was 31,000 sq. m., with an estimated population of 600,000 (*see* CAMEROONS).

Reforms.—While the War, by arresting material development also delayed the application of schemes for the moral welfare of the native population, some progress was made. The judicial and legal systems of the two Protectorates were, on amalgamation, combined. One Chief Justice for the whole of Nigeria, with four puisne judges, were appointed, and each lieutenant-governor was provided with a legal adviser. The reorganisation of the two systems and the revision of the laws of the two Protectorates, was a long and heavy job. The first reforms were initiated in 1914. After 10 years of working, the system introduced had been found to be generally beneficial and acceptable. Notwithstanding the difficulties of the moment, an education ordinance was promulgated in 1916, having for its object the reform and co-ordination of the systems of the North and South. It set a definite standard, of which the principal aim was to substitute self-discipline and the formation of character, for set examinations in literary subjects, and generally to fit local education to local needs. A forestry ordinance of the same year (1916) dealt with the rapid destruction which was taking place of the forests that constitute the principal wealth of the Southern Provinces, and its provisions have safeguarded this asset of the country for future development.

Not the least achievement of the War period was the elimination of the traffic in foreign " trade spirits " on which the revenue of the southern provinces had largely depended. It was the declared policy of the amalgamated Government to kill this trade by gradually raising the duty. Conditions of war hastened the process. Before the War the revenue from this traffic formed 34.26% of the revenue of Southern Nigeria. By the end of the War it had fallen to a proportion of 1·23. It was held that this result established two important conclusions. First, that the Government of Nigeria could dispense with revenue derived from spirits, secondly, that the produce trade could be conducted successfully without them. As from Feb. 1 1919 the importation of trade spirits was formally prohibited in all the West African Colonies and Protectorates.

Constitutional Changes.—Sir Frederick Lugard retired at the end of the War, and Sir Hugh Clifford succeeded him as governor of Nigeria in July 1919. It was an era of material prosperity, and at the close of his five years of governorship, Sir Hugh Clifford had the satisfaction of leaving behind him a country in which great economic progress had been made under his rule. In other respects Sir Hugh's tenure of office was notable for two modifications in the system of administration. The first was the extension and reorganisation of the central secretariat, a step which in practice tended to curtail the responsibility and initiative of the lieutenant-governors and residents of provinces. The second was the abolition of the advisory Nigerian Council

established under the amalgamation scheme, and the restoration of the jurisdiction of the legislative council for the Colony over the whole of the southern provinces. In the new and enlarged council the elective principle was introduced. The introduction of this elective principle, of which experience in the West Indies has not been altogether encouraging, was new to West Africa, though it is now also applied to Sierra Leone and the Gold Coast. The new council still has an official majority, but includes three elected unofficial members representing the municipal area of Lagos, and one elected unofficial member representing the municipal area of Calabar. The first elections for this council were held in Sept. 1923, and the council was inaugurated by the Governor on Oct. 1 1923. The governor retains the power to legislate for the northern provinces, but the council may discuss affairs of interest to any part of Nigeria.

The last year of Sir Hugh Clifford's period of office was marked by an incident which gave profound pleasure alike to the native population and the Europeans. This was the visit of the Prince of Wales, the first heir to the Throne who had ever visited the tropical regions of West Africa. He landed at Lagos in April 1925, and visited the principal native towns, where he was everywhere received with demonstrations of enthusiastic loyalty. In Sept. 1925 Sir Hugh Clifford was succeeded as governor by Sir Graeme Thomson.

II. ECONOMIC CONDITIONS

Railways and Mines.—Trade development has depended largely on the increase of communications. The Western Railway from Lagos to Kano, save for the bridging of the Niger at Jebba, was completed in 1911. (The river was bridged in 1914.) Meanwhile the Udi coalfields, on the left bank of the lower Niger, had been made known and working was begun in 1912. A suitable site for a new port had been found on the Bonny river, and from this place, named Port Harcourt, it was determined to build a railway to the coalfields. This development may be viewed as the inauguration of a recognised railway policy. A new capital of the Northern Provinces had been established at Kaduna, in the province of Zaria, where the railways from Lagos and Port Harcourt reach, and thus constitute it the centre of the system. The total railway mileage of Nigeria at the end of the War was 1,110 miles. The principal development since the War has been the continuation of the Udi line towards Kaduna, of which a section of 141 m. to the Benue was opened for traffic on Aug. 1 1924. By Feb. 1926 railhead had reached Jaginde, over 100 m. further north. In 1925 the building of a line from Zaria, northwest to Gusau (120 m.), tapping a rich cotton and ground nut area was sanctioned.

The development of the Udi coalfields was satisfactory. The railway reached Udi in May 1916 and the first truck of coal was delivered at Port Harcourt in the last week of that month. The discovery of this supply of fuel was of first importance to the development of local transport. By the end of the War the output of the field was already substantial. In the *1924 Report* it is given as 201,923 tons for the year. The coal is of excellent quality, equivalent for steam-raising purposes to 80% of best Welsh. The tin mining industry in the Bauchi Highlands, well established before the War, increased its output from 4,140 tons in 1913 to 9,000 tons (valued at £1,425,000) in 1924.

Agriculture, etc.—The chief wealth of Nigeria is, however, sylvan, agricultural and pastoral. The figures of the ground nut trade illustrate the value of the railway in creating trade. Before the Lagos-Kano line was built there were no exports of these nuts. In 1913 19,000 tons were exported. In 1918 the bulk had increased to 57,500 tons. In the railway report 1924–5 the nuts carried are given as 100,724 tons, of which the value was £434,445.

But the most important export of Nigeria continued to be palm kernels and palm oil; the oil palm being abundant in the Southern Provinces. The administration, however, sought to broaden the basis of production and gave encouragement to the cultivation of cocoa and cotton, supplementing with regard to cotton the efforts which the British Cotton Growing Association began in 1903. The introduction of a long stapled American variety of cotton in the Northern Provinces gave excellent results. By 1919–20 the industry was well established, the season's export being 3,500 bales; for the 1924–5 season it was 21,000 bales. The cocoa industry also proved successful, the shipments in 1924 being 4,375 tons.

Trade.—The external trade suffered as a result of the War, but towards its close a general recovery was noticeable. An interesting change took place in the direction of some of this trade. Trade with Germany, which had ceased with the outbreak of the War, was to a great extent absorbed by the United States. In 1913 trade with Germany was valued at £3,885,000 and American trade was practically nil. In 1917 the position was reversed. German trade was nil, and American trade was valued at £1,812,000. After the War, however, German competition revived. In 1924 Germany took 13% of the total trade and the United States but 5%. In the year named Great Britain supplied 71% of the imports and took 60% of the exports. Besides the products indicated—palm kernels, palm oil, ground nuts, cocoa, cotton lint and tin—hides and skins and timber are important exports. The principal imports are cotton goods, hardware, cutlery, iron, steel and machinery, coopers' stores, bags and sacks, tobacco, grain, flour, kola, nuts and salt. Spirits have become a negligible quantity. The following statistics show the progress made and the influence of the War on trade:—

Year	Value of Imports	Value of Exports	Total Value of Trade
	£	£	£
1913 .	6,331,751	7,197,646	13,529,397
1914 .	6,276,957	6,420,461	12,697,418
1915 .	4,983,728	4,946,228	9,929,956
1916 .	5,174,474	6,029,546	11,204,020
1917 .	5,808,592	8,602,486	14,411,078
1918 .	7,423,158	9,511,971	16,935,129
1919 .	10,798,671	14,675,789	25,474,460
1920 .	25,216,000	16,987,000	42,203,000
1921 .	10,550,287	9,655,915	20,206,202
1922 .	10,689,000	10,421,000	21,110,000
1923 .	11,457,000	11,672,000	23,129,000
1924 .	12,635,866	15,004,874	27,640,740

The mid years of the War show the lowest figures touched. In the two years succeeding the War a great boom carried the total of trade to the unprecedented figure of £42,203,000. The boom was followed by a slump of some severity. Nevertheless, it will be observed that under the more normal conditions reached the total trade of Nigeria in 1924 was slightly more than double the total trade of 1913. The increase in the price level of commodities must be taken into account, but even so the advance is considerable.

Revenue.—Revenue moved largely in correspondence with trade. Taking 1913 and 1923–4 (in 1921 the accounts were altered to make the financial year end by March 31) the figures of revenue and expenditure were: 1913, revenue £3,362,000, expenditure £2,916,000; 1923–4, revenue £6,260,000, expenditure £5,501,000. There was at the end of the year 1920 an excess of assets over liabilities of £3,296,789, a surplus which fully justified the issue in Oct. 1921 of a loan of £3,000,000 for the continuation of the Eastern Railway and the carrying out of public works.

NIKISCH, ARTHUR (1855–1922), Hungarian conductor (*see* 19.690), died in Leipzig Jan. 23 1922.

NILE (*see* 19.692).—Although the geographical problems connected with the origin of the river have been solved, the Nile continues to offer problems of extraordinary interest in connection with the conservation and distribution of its waters. The

energy formerly directed to exploration has only been diverted to a closer and more scientific study of the hydrography of the river, with a view to determining how the available flow of water in its various tributaries can be most advantageously and economically protected from dissipation and wastage in the swamps of the upper river, and stored in reservoirs for utilisation as required. These studies have mostly been directed by the Egyptian Govt. towards increasing the flow of the river in the early summer months, when its natural flow falls short of requirements for irrigation in Egypt; it has come to be realised that the control of the Nile waters is not wholly an Egyptian question but concerns the rapidly developing countries higher up the river.

The Aswan, Gebel Aulia and Makwar Dams.—The original Aswan dam, which was opened in 1902, was raised in height by seven metres in 1912 and the storage capacity of the reservoir increased from 1,000 million cu. metres to 2,250 million cu. metres of water. Following on Sir William Garstin's famous report on the basin of the Upper Nile (British Blue Book, *Egypt, No. 2 1904*), schemes for constructing a large reservoir on the lower White Nile by means of a dam at Gebel Aulia some 20 m. south of Khartum, and for a canal to irrigate the great Gezira plain between the Blue and White Niles, began to take definite form about 1913. Progress with these schemes was necessarily suspended during the World War, and in the meanwhile the increasing tendency towards the development of an independent existence by the Sudan caused all schemes for the control of the river beyond the limits of Egypt proper to be viewed with some apprehension and mistrust in Egypt. The general position was summed up to date by the then adviser to the Egyptian Ministry of Public Works, Sir Murdoch MacDonald, in *Nile Control* (published by the Egyptian Govt. in 1920), and an international commission was appointed by the Egyptian Govt. to report on the proposed works.

The commission reported favourably on the general scheme outlined in *Nile Control*, and pointed out that under a carefully considered scheme of control there was sufficient water to meet any possible developments in both Egypt and the Sudan for many years to come. Financial considerations, complicated by the political position, again led to the temporary suspension of the works and to the preparation of further reports on the irrigation programme by Mr. C. E. Dupuis, formerly adviser to the Egyptian Ministry of Public Works (published by the Egyptian Govt. in 1925). The construction of the Gezira canal was then actively resumed by the Sudan Govt., and the canal, with its great dam and reservoir, with a capacity of nearly 500,000 million cu. metres of water, at Makwar, near Senaar, on the Blue Nile, was completed to the extent necessary for the irrigation of 300,000 ac. in 1925, and formally opened in 1926. The Egyptian Govt. also actively pressed on the construction of the Gebel Aulia dam and reservoir on the White Nile, with a storage capacity of about 2,500 million cu. metres of water, and is taking up again the scheme for the canalisation of the river through the swamps, on which some preliminary work was done between 1904 and 1913. (*See* DAMS; IRRIGATION.)

Lake Albert.—It is further recognised that to be fully effective this canalisation of the river must be supplemented by further storage works higher up the river, presumably by the conversion of Lake Albert into a reservoir, but this scheme has not yet emerged from the stage of preliminary consideration. The most recent information concerning the physical conditions and régime of the great lakes forming the basin of the upper White Nile, essential to the consideration of this project, has been collected in a report on *The Lake Plateau Basin of the Nile* by Mr. H. E. Hurst (published by the Egyptian Govt. in 1925.)

Lake Tsana.—The study of the possibilities of Lake Tsana as a reservoir for the Blue Nile, originally reported on by Mr. C. E. Dupuis in 1903, has been continued by expeditions visiting the lake under Mr. A. B. Buckley in 1916–7, and under Mr. G. W. Grabham in 1920–1. The results of all these studies have been published by the Egyptian Govt. and the *Report of the Mission to Lake Tsana in 1920–1* by Messrs. G. W. Grabham and R. P. Black is particularly full and interesting. All reports agree in emphasising the extreme suitability of Lake Tsana for conversion into a reservoir of a capacity of between 3,000 and 4,000 million cu. metres. The political questions arising from the gradual conversion of the Nile from a natural river into an artificially regulated stream, whose flow is controlled by reservoirs at various points on its course in several different countries, are only just beginning to make themselves felt, and a comprehensive solution of the resulting difficulties has yet to be found.[1]

Navigation and Water Power.—From the point of view of navigation and trade no new developments have taken place on the Nile in recent years. The river remains a most useful highway for local traffic in the various sections into which its length of 4,000 m. is divided by the occurrence of falls and rapids; but the nature of these breaks is such that the development of through traffic on any scale is never likely to be economically possible. There are considerable possibilities for the development of water-power on the Nile, especially at the Ripon and Murchison falls in Uganda; and the utilisation of the large amount of power running to waste at the Aswan dam has been repeatedly considered and discussed; but the localities in which these opportunities occur are remote, and no useful application of them to practical purposes has yet been devised; in the case of Aswan the intermittent character of the power obtainable, which though very large when the reservoir is full in the early part of the year is practically nil during the flood season, has hitherto proved an insurmountable objection to economic utilisation. (C. E. D.)

NILSSON, CHRISTINE (1843–1921), Swedish singer (*see* 19.701), died at Copenhagen, Denmark, Nov. 22 1921.

NITROGEN, FIXATION OF (*see* 19.714).—Extensive developments in the fixation of atmospheric nitrogen have taken place in the period under review, the War serving as a primary cause and fertiliser requirements continuing the need of production. The older process of heating air to temperatures over 2,000° in order to obtain oxides of nitrogen has been definitely overhauled by the synthetic production of ammonia by direct union of nitrogen and hydrogen in presence of a catalyst, many technical difficulties in dealing with gases at fairly high temperatures and decidedly high pressures having been overcome. The energy required in effecting combination of nitrogen and oxygen at the temperature of the electric arc is very high and as the yield is always below that theoretically obtainable, it is unlikely that the process can be exploited economically except where water-power can be obtained at a very low cost.

Direct Synthesis of Ammonia. (*q.v.*).—In these processes, a mixture of 1 volume of nitrogen and 3 volumes of hydrogen is compressed and the reaction, $N_2+3H_2 \rightleftarrows 2NH_3$, brought about by sending the gas over a heated catalyst. The reaction is driven from left to right by increase of pressure, whilst increase of temperature sends it from right to left. The ammonia produced (5 to over 20%) is subsequently condensed as anhydrous liquid or absorbed in water.

Haber-Bosch Process.—The Haber-Bosch process, worked by the Badische Anilin-und Soda-Fabrik, is carried out at about 200 atmospheres and a catalysis temperature of about 500°. According to Waeser (*Luftstickstoffindustrie*, 1922, p. 364), a three-stage compressor is used and the reaction is carried out in tubular vessels (the autoclave shape having been abandoned)

[1] Under the Anglo-Abyssinian Treaty of May 15 1902 the Emperor Menelik undertook not to construct or allow to be constructed any work across the Blue Nile, Lake Tsana or the Sobat which would arrest the flow of their waters into the Nile except in agreement with the British and Sudan governments. An agreement between Great Britain, France and Italy, signed on Dec. 13 1906, provided for the co-operation of the three powers in maintaining the political and territorial status quo in Abyssinia as determined by the series of previous agreements, including the Anglo-Abyssinian Treaty referred to above. The recently concluded exchange of notes between the British and Italian governments provides for mutual support in connection with British rights and interests in the Nile waters, and Italian rights and interests in railway construction as defined in the Tripartite Agreement of 1906.

constructed of special steel. The heating of the incoming mixture is effected, once the operation is started, by the heat of the outgoing gases, the reaction proceeding exothermically. The gases leave the catalyst with an average ammonia content of 10%, and after thorough cooling are brought in contact with water under pressure. A 20-25% ammonia solution is thus produced whilst the issuing mixture of nitrogen and hydrogen is mixed with the fresh supply and returned to the catalyst plant. The other processes for effecting the synthesis of ammonia also depend on heating a stoichiometric mixture of the reacting elements with a catalyst under pressure.

American Process.—The American process of the General Chemical Co. works at approximately 100 atmospheres, the lower pressure being possible owing to the use of a very active catalyst. The removal of the ammonia is effected by liquefaction at −40°, this low temperature being necessitated by the small concentration of ammonia resulting at the low pressure of 100 atmospheres.

Claude Process.—On the other hand, Claude uses pressures of 600 to 1,000 atmospheres. This displaces the equilibrium so far in the direction of ammonia formation that it is possible to use higher temperatures at which catalysts are more active and less sensitive to poisoning. Thus, with a comparatively poor catalyst, concentrations of over 20% can be attained and on cooling the issuing gases, the ammonia is for the greater part liquefied and may be removed in the anhydrous condition. No special refrigeration is required as in the American process.

With the large concentration of ammonia obtained, converters can be used in series, the ammonia being liquefied and removed after each passage and the residual gas rejected. A combination of series and circulating systems has been used, the gases from the high stage compressors being passed through two converters in series and ammonia removed after each exit. The residual gas from the second condensation is then returned to an intermediate compressing stage where it is mixed with fresh gas.

Casale Process.—In the process of Casale, pressures of 300 to 600 atmospheres are employed and a circulating system is adopted. Again, the ammonia is removed by cooling and consequent liquefaction. The process adopted in England appears to be an adaptation of that of Haber. The mixture of 1 volume of nitrogen and 3 volumes of hydrogen is obtained in one of two different ways. In the first of these, the initial materials are coke, water and air; in the second, nitrogen, isolated from the air, is mixed with electrolytic hydrogen. When the cost of electrical energy is sufficiently low, the latter process is preferable as the hydrogen is practically free from impurities.

Heater Gas.—The first process (Bosch) utilises a mixture of water-gas and producer-gas. Water-gas is made in the usual manner. Air is blown through a generator containing a coke fire, the air is shut off and steam blown through, the reaction $C+H_2O=CO+H_2$ then taking place. The mixture obtained in practice contains about 50% of hydrogen and 42 to 45% of carbon monoxide, the small balance being chiefly carbon dioxide and nitrogen.

Producer-gas.—Producer-gas, obtained from air and coke, contains H_2, 5–15; N_2, 65–50; CO, 20–30; CO_2, CH_4, etc., 5–10 per cent. By mixing these gases in suitable proportions one may obtain a gas with 22–23% nitrogen and a combined percentage of hydrogen and carbon monoxide rather over three times this amount. By passing this mixture with an excess of steam through a heated converter containing a catalyst, most of the carbon monoxide is oxidised to dioxide and an equivalent of hydrogen liberated. $CO+H_2O=CO_2+H_2$. The reaction is not complete; the resulting mixture contains about 17% of nitrogen, 52% of hydrogen, 27 to 29% of carbon dioxide and 2 to 4% of carbon monoxide, together with small amounts of argon, methane, etc. The carbon dioxide may be reduced to 0.1 to 1% by water scrubbing under pressure, and the remainder by washing with cold alkali solution. Removal of carbon monoxide and residual sulphur compounds is essential since they are catalyst poisons; for the former, a solution of cuprous ammonium carbonate (or formate) can be used.

Treatment of the gases with ammonia is also employed (*e.g.*, Synthetic Ammonia and Nitrates Ltd., Slade and Parkes, *Brit. Pat.* 240350; Casale, *Brit. Pat.* 231417) whilst de Jahn states that scrubbing with liquid ammonia usually renders further purification unnecessary (*Brit. Pat.* 251789). Finally moisture must be removed, the greater amount by refrigeration, the remainder by a drying agent. In the alternative process of mixing nitrogen with electrolytic hydrogen, the former can be obtained by liquefaction of air and fractional distillation. The Claude plant at Muscle Shoals is stated to give nitrogen of 99.995% purity. Electrolytic hydrogen is obtained by electrolytic processes described in the article ELECTRO-CHEMISTRY.

Catalysts, etc.—Catalysts (*q.v.*) for the reaction between nitrogen and hydrogen are usually of iron with a basic oxide as promoter, the latter being introduced on fusion. A suitable electric furnace is described by Larson (*J. Ind. and Eng. Chem.*, 17, 1925, 971). Apparently a ferrite is formed during fusion and Synthetic Ammonia and Nitrates, Ltd. (Brit. Pat. 237394) claim the preparation of calcium ferrite from iron oxide and lime in the electric furnace which gives a more active catalyst on subsequent reduction. A low temperature method of catalyst production is suggested by Technical Research Works (Ltd.) and Lush, pure iron being anodically oxidised in an alkaline carbonate solution (Brit. Pat. 241278).

AMMONIA FROM NITRIDES, CYANIDES AND CYANAMIDE

In the Serpek process, ammonia is obtained by the reaction between aluminium nitride, AlN, and caustic soda. Peacock proposes to heat aluminium hydride with nitrogen above 400°, so obtaining aluminium nitride and ammonia (*U.S.P.* 1,521,-708). The Bücher process, employing synthetic sodium cyanide, has been operated by the du Pont Company. A description of their plant, which utilises soda-pulp mill "black liquor" as the source of the necessary soda and carbon, is given by Chickering (*Chem. and Met. Eng.*, 1924).

Nitrates and Nitrites.—The production of oxides of nitrogen from air ($N_2+O_2 \rightleftharpoons 2NO$) at the temperature of the electric arc is only economical with cheap and plentiful electric energy. Where water-power is not available, it is cheaper to prepare oxides of nitrogen by the combustion of ammonia, a process in which great improvements have been effected. The reaction, $4NH_3+5O_2 \rightleftharpoons 4NO+6H_2O$, can be brought about on platinum gauze; other catalysts, *e.g.*, activated iron oxide, may also be used. The subsequent oxidation of the nitric oxide to nitric acid, nitrates and nitrites follows the lines adopted in the case of arc processes. (*See* 19.714.) The collection of nitrogen peroxide as a liquid and absorption of oxides of nitrogen by silica gel are notable developments. (See Perley, *J. Ind. and Eng. Chem.*, 17, 1925, 258.)

(J. T. H.)

NITTI, FRANCESCO SAVERIO (1868–), Italian statesman, was born at Melfi (Potenza). He had already become known as a barrister and as professor of financial science at the university of Naples when he entered Parliament in 1904. He made his reputation as an authority on economic and financial questions, and was minister of agriculture, industry and trade in the Giolitti Cabinet of 1911–4. When the United States entered the World War in 1917, he was entrusted with an economic mission to that country, and certain of his utterances and acts in this connection were severely criticised. He became minister of the treasury in the Orlando Cabinet from Oct. 1917 to Jan. 1919. On the fall of the Orlando Ministry, which he helped to bring about, he succeeded as Premier, but his administration was exaggeratedly timid, and he allowed the Socialists and Communists practically a free hand in their acts of criminal violence. In his reaction against what he regarded as the war spirit he was closely associated with the policy of *svalutamento* of Italy's victory and of renouncing the fruits of it. He was determined to secure the support of the Socialists and the Popolari at all costs, and dared not resist the wave of Bolshevik madness with which a part of the population was affected, and which he believed stronger than it actually was. He enacted a series of demagogic financial measures and refused to suppress

the costly bread subsidy, thereby increasing the budget deficit by several milliards.

Nitti's adoption of the system of proportional representation resulted in an important increase in the Socialist and Popolari deputies at the elections of Nov. 1919, but he failed to conciliate either group. The indignation aroused by his weakness in dealing with the epidemic of revolutionary strikes and disorders, his contemptuous treatment of the army, his decree amnestying deserters and his failure to effect a settlement of the Adriatic problem, seriously weakened his position, and he felt forced to resign on March 12 1920. But no other statesman being willing to assume the succession, he reconstructed his Cabinet; defeated in the Chamber after the San Remo meeting of the Supreme Council presided over by him, to prepare the peace with Turkey, he resigned a second time but reconstructed his Cabinet. The arrest ordered by him of the Dalmatians and Fiumani in Rome provoked further irritation, and while he at first reduced the bread subsidy for financial reasons, he revoked the decree immediately afterward from fear of the Socialist menaces, and resigned for the last time on June 9 1920, leaving the door open for Giolitti's return.

On retiring from office he returned to journalism and business. In Parliament he opposed Giolitti, but was still more hostile to the Fascists. He was re-elected in 1921, but did not stand in the 1924 elections held under Mussolini's auspices. He was particularly hated by the Fascists for his anti-patriotic and demagogic policy, and his house in Rome was broken into by a band of Fascist hotheads and some of the furniture wrecked. He subsequently went abroad to lecture and write in the foreign Press on political affairs, attacking both the Fascist Govt. of Italy and the peace treaties.

Nitti wrote several books on economic questions, including one entitled *Nord e Sud* (1900), dealing with what he regards as the unfair treatment of South Italy by the wealthier North, and *L'Italia all' alba del secolo XX.* (1901). Among his other works, the following have been translated into English: *L'Europa senza pace* (Eng. tr. 1922); *La Decadenza dell' Europa* (Eng. tr., 1923); *La Tragedia dell' Europa* (Eng. tr., *They Make a Desert*, 1924). In 1925 his son Vincenzo Nitti published a vindication of his father's policy, *L'opera di Nitti*. (L. V.*)

NIVELLE, ROBERT GEORGE (1856–1924), French soldier, was born Oct. 15 1856 at Tulle, Corrèze. He entered the Polytechnic in 1876 and left two years later to join the artillery. He became a lieutenant on Oct. 1 1880 and a captain on July 12 1887; with this rank he took part in the Chinese expedition of 1900. The greater part of his later career was spent in Algiers, where he was appointed commander of a battalion on July 12 1901 and lieutenant-colonel on Sept. 24 1908. When the World War broke out he had been a colonel since 1911, was an officer of the Legion of Honour and commanded the 5th Artillery at Besançon. With the VII. Corps he took part in the Alsace engagements and the battle of the Ourcq.

Appointed a general of brigade on Oct. 24 1914, he fought successfully on the Aisne, and in Jan. 1915 took a prominent part in the attack on Quesnevières. On Dec. 23 1915 he was placed at the head of the III. Corps, and in March 1916 was sent to Verdun, where after some remarkable fighting he succeeded in checking the Crown Prince's first attack. On May 2 he succeeded General Pétain in the command of the II. Army, and definitely held the enemy before that glorious citadel. It was he who, in orders which have become famous, made the unforgettable declaration: "Ils ne passeront pas." On March 12 1916 he succeeded General Joffre as commander-in-chief of the armies of the north and north-east. In conjunction with the British armies he prepared the great offensive of April 16 between Soissons and Auberive, which, however, was not entirely successful. After this semi-defeat he was replaced by General Pétain in the command of the French armies. On May 15 1917 he was appointed commander of the armies "chargé de mission," and on Dec. 23 1917 took over the French troops in North Africa.

On Oct. 14 1918 General Nivelle was confirmed in his command despite the rules of superannuation, and on Jan. 30 1920 was nominated a member of the Supreme War Council. On March 5 1920 he gave up the command of the XIX. Corps, and in Nov. 1920 he was ordered to represent France in the United States at the tercentenary of the arrival of the "Mayflower" which had in 1620 carried the Pilgrim Fathers to New England. He afterwards visited the southern and western cities of the United States. He was placed on the retired list on Oct. 11 1921; he held the Grand Cross of the Legion of Honour and had received the Médaille Militaire and died suddenly of double pneumonia on March 23 1924. (M. Gc.)

NOBLE, SIR ANDREW, (1852–1915), British physicist (*see* 19.730), died at Ardkinglas, Argyllshire, Oct. 22 1915.

NOGI, MARESUKE, COUNT (1849–1912), Japanese general (*see* 19.733). As a sign of their devotion he and Countess Nogi committed suicide on Sept. 13 1912 when the state funeral of the Emperor Mutsuhito was taking place. Their memory is deified in the Nogi Shrine in Kyoto.

NOGUCHI, HIDEYO (1876–), Japanese bacteriologist, was born in Inawashiro, Yama, Fukushima, Japan, Nov. 24 1876. He received the degree of M.D. in 1897 from the Tokyo Medical College and subsequently did post-graduate work in the United States and Europe, becoming connected with the Rockefeller Institute for Medical Research in New York in 1904. He was the first to obtain pure cultures of the spirochete of syphilis and to establish the syphilitic nature of general paralysis and *tabes dorsalis* by demonstrating the organism in the cells of the central nervous system of persons dying of these diseases. He has done considerable work on the analysis of the Wassermann reaction for the diagnosis of syphilis and has devised a skin test for syphilis and a method for the detection of syphilitic and other pathological conditions in the spinal fluid. One of the first to recognize the germicidal properties of certain compounds of unsaturated fatty acids for acid-fast micro-organisms, *e.g.*, the tubercle bacillus, he discovered the parasite of yellow fever in 1918 and prepared a prophylactic vaccine and a curative serum for combating this disease. He has isolated the parasite of Oroya fever and Verruga peruviana. His published works include *Snake Venoms* (1909) *Serum Diagnosis of Syphilis and Luetin Reaction* (1910) and *Laboratory Diagnosis of Syphilis* (1923).

NORDAU, MAX SIMON (1849–1923), German author and philosopher (*see* 19.739), published *Biologie der Ethik* in 1921. He died in Paris Jan. 22 1923.

NORDICA, LILIAN (1859–1914), American operatic singer (*see* 19.741), died in Batavia, Java, May 10 1914.

NORFOLK, HENRY FITZALAN HOWARD, 15TH DUKE OF (1847–1917), British statesman (*see* 19.744), died in London Feb. 11 1917. He was succeeded by the son of his second marriage, Bernard Marmaduke Fitzalan Howard (b. 1908).

NORFOLK, Virginia (*see* 19.747), had a period of intoxicating prosperity during the World War, due at first to heavy shipments of orders for the Allies, and after 1917 to the establishment by the Federal Govt. of the army supply base (at a cost of $25,000,000) and the Hampton Roads naval operating base. After the War, with the closing down of the army base, the transfer of the fleet to the Pacific coast, and the reduction of the naval training station to a skeleton organisation, the deflation was severe, but the following years saw foundations laid for a healthy commercial and industrial development. On Jan. 1 1919, the charter of 1918, which established the commission manager form of government, came into effect.

Within the next five years the city invested $6,000,000 in a water supply system which is expected to meet all needs for 50 years; leased the army base piers from the Federal Govt. and created a port commission; built a municipal grain elevator and a city market; protected the milk supply; reorganised the police force and the fire department; established a juvenile and domestic relations court and a detention home; enlarged the system of parks and playgrounds; improved the public school system in many respects, connected the city thoroughfares with county highways; established the budget system in the city's business; annexed territory with a population of 30,000 and taxable values of $30,000,000; established a city-planning commission (1919), and set out to develop a city plan.

The population grew 71·6% between 1910 and 1920, to 115,777 (107·6 males to 100 females), of whom 43,392 were negroes and 6,998 foreign-born; and was estimated at 166,000 in 1925. The area increased from 5·5 sq. m. (1910) to 7·5 in 1920 and 27 in 1923. Manufactures within the changing city limits were valued at $10,341,000 in 1909; $29,231,739 in 1923. An assembly plant of the Ford Motor Co. and a large plant of the Virginia Portland Cement Co. were opened in 1925. Exports moving through the port of Hampton Roads (Norfolk and Newport News) increased from $15,162,855 in 1914 to $168,664,547 in 1925, reaching the peak ($325,023,090) in 1921; imports, from $7,105,822 to $16,551,835, with the peak ($22,402,477) in 1918. Exports of tobacco increased from 10,444,485 lb. in 1918 (only 1·6% of the total for the United States) to 203,743,817 lb. in 1924, which was 51% of the total. Hampton Roads is the tidewater terminus of three of the principal coal-carrying railways. An average of over 1,000,000 tons is dumped each month, and the total handled in the record year 1920 was 21,644,328 tons. It is also an important oil-bunkering port, having a storage capacity of 2,432,500 barrels. Truck farming around the Roads brought returns estimated at $10,000,000 in 1924, chiefly from shipments to New York.

NORMAN, MONTAGU COLLET (1871–), British financier, was educated at Eton and King's College, Cambridge. He served in the South African War 1900–1 and was awarded the D.S.O. He afterwards became connected with the financial side of business, and his active association with the Bank of England began during the World War. In 1918 he was appointed deputy-governor and in 1920 governor of the Bank of England. He was re-elected for the seventh time in 1926, having held the post for longer than any previous governor. In 1922 he accompanied Mr. Baldwin, then Chancellor of the Exchequer, to the United States to arrange for the funding of the British war debt. The outstanding event of Mr. Norman's governorship was the restoration of the gold standard. In 1923 he was made a privy councillor.

NORRIS, WILLIAM EDWARD (1847–1925), British novelist (*see* 19.757), died at Torquay Nov. 19 1925. His later works were *Not Guilty* (1910); *The Rt. Hon. Gentleman* (1913); *Barbara and Company* (1914); *Proud Peter* (1916); *The Fond Fugitives* (1917); *The Obstinate Lady* (1919); *The Triumphs of Sarah* (1920); *Tony the Exceptional* (1921); *Sabine and Sabina* (1922); *Next of Kin* (1923); *The Conscience of Gavin Blane* (1924); and *Trevalion* (1925).

NORTHAMPTON, England (*see* 19.767), had a population of 90,895 in 1921 and an area of 3,469 ac. in the borough, which has included since 1914 the parishes of Abington, Dallington, Duston and Kingsthorpe. Northampton has returned only one member to parliament since 1918, instead of two. A town plan, which includes large schemes for by-pass roads and road widening, was brought forward in 1925. A new public library building was opened in Abington street in 1910, and a post office in St. Giles street in 1917. A large girls' secondary school was opened in September 1915. It stands on St. George's avenue, and has playing fields attached. In 1924 Weston Favell House was given to the Northampton Crippled Children's Fund for use as an orthopaedic hospital.

NORTH CAROLINA (*see* 19.771), a state of the United States of America. The estimated population in 1925 was 2,759,014 as compared with 2,559,123 in 1920, a gain of 199,891, or 7·2%. About one-third were negroes; the foreign-born whites had not increased notably from the 7,099 present in 1920, North Carolina still having less foreign admixture than any other state. In 1920, 490,370 persons were living in cities of 25,000 or more, 240,753 in villages and 1,828,000 in the open country. The state was thus predominantly rural, 71% of the population living outside of incorporated towns as against 76% in 1910. The chief towns in 1925 and their populations were Winston-Salem, 65,806; Charlotte, 52,049; Wilmington, 36,390; Asheville, 30,934; Greensboro, 45,000; and Durham, 40,000. The death rate steadily decreased after 1914, and in 1924 was only 11·9 per 1,000; the birth rate in the same year was 31·6 per 1,000.

Agriculture.—The period from 1920 to 1925 saw considerable shrinkage in agricultural values, and, in some crops, in the yield. The tendency noted in 1910 and 1920 toward smaller holdings continued; in 1920 the number of farms was 269,763 as against 253,725 in 1910. The following table presents the more striking figures for 1924 as estimated by the United States Department of Agriculture:—

Crop	Acres	Yield (bu.)	Value
Corn	2,473,000	44,514,000	$55,197,000
Wheat	462,000	5,544,000	8,870,000
Oats	258,000	4,644,000	3,901,000
Rye	71,000	852,000	1,269,000
Potatoes (Sweet)	101,000	2,292,000	9,664,000
Potatoes	59,000	6,195,000	6,938,000
Tobacco	497,000	278,320,000[1]	71,807,000
Hay	738,000	728,000[2]	15,288,000
Cotton	1,901,000	765,000[3]	86,000,445
Peanuts	181,000	7,400,000	10,706,000

[1] Pounds. [2] Tons. [3] Bales.

The value of all crops in 1924 was estimated to be $320,485,000, as against $412,374,000 in 1920. Trucking and fruit growing continued to show marked increase, especially peaches and strawberries. The following table shows the numbers and values of livestock in 1920 and 1924:—

Farm Animals	1924		1920	
	Numbers	Value	Numbers	Value
Mules	260,000	$30,680,000	236,000	$44,840,000
Horses	158,000	15,484,000	183,000	27,999,000
Milch cows	383,000	15,320,000	328,000	25,584,000
Other Cattle	253,000	4,123,900	394,000	13,908,000
Swine	1,000,000	12,000,000	1,575,000	31,500,000
Sheep	82,000	508,400	144,000	1,368,000

Manufactures.—In 1914 the industrial capital of the state was $253,842,000 and the value of manufactured products was $289,412,000; in 1920 the industrial capital was $669,144,000 and in 1923 the value of manufactured products rose to $951,911,000. Textiles led with a value of $363,000,000, followed by tobacco with $295,000,000, and furniture with $40,000,000. In 1920 there were about 550 cotton mills in operation with 5,321,450 producing spindles, which increased to 5,773,244 in 1924. The volume of the tobacco industry can best be estimated from the fact that for the year 1923–4 the Federal stamp tax yielded $136,892,475. The syndicating of cotton mills was a pronounced movement during the years 1916–24 following upon the the syndicating of tobacco factories, fertiliser plants and cotton-oil mills. Steam power was generally employed in the decade 1910–20, but there was an ever-increasing use of hydroelectric power. In 1924, 431,500 H.P. had been developed, with 816,000 H.P. estimated as available for development.

Forest and Mines.—The total value of lumber and timber products in 1914 was $39,631,573. It increased largely in the years which followed, and, in spite of the ruthless lumbering operations of past years, it was estimated in 1920 that there was timber standing ready for the saw to the value of $167,450,000, with young growth valued at $192,500,000. Mining products, valued in 1917 at $5,246,391, had increased by 1923 to $10,020,559, the more important being stone, clay products, sand and gravel and feldspar.

Transportation.—Railway development in the state was checked in 1914 and stopped completely in 1917 by the World War. Only 357 m. of new line and 217 m. of sidings were built, making a total mileage in 1920 of 4,997, which had increased by 1924 to 5,222 miles. In 1917 there were 172 m. of electric road in operation, which decreased to 155 m. in 1924. The legislature of 1921 undertook the creation of a great state system of highways and authorised for the purpose bonds amounting to $50,000,000, and the legislatures of 1923 and 1925 increased it by $15,000,000 and $20,000,000 respectively. By 1925, 2,776 m. of improved highways had been built and nearly a thousand miles more was under construction.

Finance.—The revenue for the year ending June 30 1925, exclusive of the proceeds from bonds, was $6,215,656, while county, city and school taxes in 1922 yielded $44,147,000, and have since increased. The bonded indebtedness of the state in 1924 was $108,847,600, of the counties $87,062,352, and of the cities $97,563,114, making a total of $293,473,066. In addition to bonds totalling $85,000,000 authorised for highways, mentioned above, the legislatures of 1921, 1923 and 1925 authorised $5,000,000 for a state-aid loan fund for consolidated schools, and $20,242,000 for permanent improvements in the state's hospitals and institutions of higher learning.

The legislature of 1919, in order to reform the ineffective and inequitable system of taxation, passed a law providing for assessment of all real and personal property at its actual value. A constitutional amendment authorised a general income tax, limited the rate of combined state and county taxes on property to $0.15 per $100 of valuation, permitted a segregation of taxes for state purposes, and abolished the existing equality between the tax rate on property and the poll tax. The requirement of payment of poll tax as a prerequisite for voting was abolished. Revaluation was accomplished in 1920 and the property of the state was assessed at $3,530,000,000. More than a million acres of land not hitherto on the tax books were included. The *per capita* wealth was increased 183%. Marked reaction came in 1921, and many of the good results of revaluation were lost. The assessed valuation of all property in 1924 was $2,604,508,000

Education.—The State made educational progress between 1910 and 1925. The public schools funds increased from approximately $3,000,000 in 1910 to $15,066,487 in 1920 and to $35,000,000 in 1925. Teachers' salaries continued to rise, and teachers were better trained. The most notable educational achievement was the rapid growth of a state high-school system. The state institutions of higher learning received more substantial support and their growth was steady. Wake Forest College came into possession of a large bequest. Trinity College, receiving from James B. Duke the sum of $6,000,000 for building and an annual income of more than half a million dollars from a trust fund, established by him, became in 1925 Duke University.

History.—The state Government throughout the period 1910–25 was under the undisputed control of the Democratic party. In 1913 Locke Craig succeeded William Walton Kitchin as governor. Thomas Walter Bickett became governor in 1917, and Cameron Morrison in 1921. The latter was succeeded in 1925 by Angus Wilton McLean. The legislature at every session had large Democratic majorities. One Republican member of Congress was elected in 1914. So confirmed was the Democratic faith of the people of the State that alone of all the States it increased the party majority in the election of 1920. The party majority was again increased in 1924. (J. G. DE R. H.)

NORTHCLIFFE, ALFRED CHARLES WILLIAM HARMSWORTH, VISCOUNT (1865–1922), British newspaper proprietor was born July 15 1865 at Chapelizod, Dublin, the eldest of a family of fourteen. His father, Alfred Harmsworth (1837–1889), descended from an old Hampshire family, was a barrister-at-law of the Middle Temple. His mother, Geraldine Mary, who died Aug. 29 1925, a woman of remarkable intellect and strong character, was a daughter of William Maffett.

Of the seven sons, the two eldest, Alfred and Harold, became members of the House of Lords as Lord Northcliffe and Lord Rothermere respectively; the third, Cecil Bisshopp (b. 1869), became in 1915 under-secretary for home affairs and in 1919 under-secretary for foreign affairs, having entered the House of Commons as Liberal M.P. for Droitwich (1906–10) and subsequently sitting for S. Beds; while the fourth, Robert Leicester (b. 1870), who was created a baronet in 1918, entered the House of Commons in 1900 as Liberal M.P. for Caithness, a seat which he retained till 1922. The other three sons were Hildebrand Aubrey (b. 1872), from 1901 to 1904 editor of *The New Liberal Review*; St. John (b. 1876), the creator of the Perrier mineral water business; and Vyvyan George (b. 1881).

Early Journalism.—It was in 1867 that the Harmsworths moved to London, and the family means were then small. Alfred was exceptionally energetic and thoughtful. At 11 he went to Stamford grammar school and at 13 to Henley House school, West Hampstead, where in 1878 he started the first of his journalistic adventures, a school magazine. This was originally issued in MS. but was afterwards printed and sometimes set up by himself in his spare time. At 15 he did some work for Mr. Jealous, then editor of *The Hampstead and Highgate Express*. In 1881 he began to work under a tutor for Cambridge, while contributing to *The Bicycling News*, *Globe* and the publications issued by James Henderson for boys and girls. As secretary and companion to one of the third Lord Lilford's sons, he travelled extensively in Europe. On his return to London Sir William Ingram (of the *Illustrated London News*) made him assistant editor of his paper *Youth* and he continued "free-lance" work for the Press, contributing leading articles to various newspapers, among which was *The Morning Post*, and articles to the *St. James's Gazette*, where his work attracted the attention and praise of Frederick Greenwood.

But his health temporarily broke down in 1884. Ordered to live out of London, he went to Coventry in 1885 and worked for the firm of Iliffe and Sons, owners of many publications. With them he remained till 1886, and he then went back to London and joined a general publishing business. Among other ventures he started on June 16 1888 *Answers to Correspondents*, a weekly periodical intended to be a more popular form of *Notes and Queries*. As *Answers* it laid the foundation of what eventually became the largest periodical publishing business in the world, the Amalgamated Press. Alfred Harmsworth had already been joined by his second brother, Harold (*see* ROTHERMERE, VISCOUNT), to whom he ascribed a great share of the success of the undertaking, particularly on the business side. He himself wrote much, outlined serials, trained young editors, discovered new writers and artists and revolutionised the current methods of periodical journalism. The profits of the accumulated publications soon soared to £50,000 a year. In the next few years Alfred Harmsworth travelled much in Europe, India, Africa, Canada and the United States; he was a good athlete, excelling in lawn tennis, and in the days before the motor car, which as far back as 1894 became one of his chief interests, was a great lover of horses, fond of cycling and devoted to fishing. On April 11 1888 he had married Mary Elizabeth, daughter of Robert Milner, a West Indian merchant, and to her sure judgment and quick brain he attributed much of his success.

On Aug. 31 1894 he and his brother Harold acquired the London *Evening News*, in which the Conservative party had sunk some £300,000. It was then losing money heavily, but it was at once reorganised with such effect that the first working week yielded a profit of £7, and the first year one of £14,000. In the same year he fitted out an Arctic expedition under Mr. F. G. Jackson, which explored Franz Josef Land. In the general election of 1895 he stood unsuccessfully as a Conservative candidate for Parliament at Portsmouth.

The Daily Mail.—On May 4 1896 a new halfpenny morning paper, *The Daily Mail*, was launched, "the busy man's newspaper," as he called it. It embodied many innovations, a very full service of cables, the employment of numerous famous writers, condensation of unimportant topics, and costly and daring enterprises of various kinds. A comparison of past files of the London Press shows how it revolutionised daily journalism. The most rapid machinery was used; a system of arrangement was introduced which enabled the reader to know where to find the news he wanted. It was characteristic of his foresight that one of the three leading articles in the first number dealt with the then almost unknown motor-car, in the future of which Alfred Harmsworth had a firm belief, being himself already a qualified driver. *The Daily Mail* attained a sale of 600,000 copies a day in the Boer War, and this gave him great influence on policy at home and abroad.

In 1903 he founded *The Daily Mirror;* it was at first a complete failure, losing £1,500 a week but after being transformed from a penny paper for women into a halfpenny illustrated morning journal, became as signal a success. In 1905 a

Continental edition of *The Daily Mail* was established, with headquarters in France. In 1904 Alfred Harmsworth was created a baronet, and in 1905 he was raised to the peerage as Baron Northcliffe. In 1906 he and his brothers acquired for their companies about 3,000 sq. m. of forest land in Newfoundland, with lakes, rivers and water transport, for the manufacture of paper and wood pulp, the result being the formation of the Anglo-Newfoundland Development Co., a gigantic enterprise with its works at Grand Falls, and two lines of railway, a port and Atlantic and other steamers.

In 1908 Lord Northcliffe obtained control of *The Times*, to own which had always been one of the aims of his life. New machinery was installed, and the size of the paper greatly increased; in March 1914 he reduced the price to one penny, with the result of a large increase in circulation, though the enormous rise of 600% in the cost of paper during the World War forced a subsequent increase in price. Meanwhile Lord Northcliffe had acquired *The Weekly Dispatch;* disposed of the Sunday *Observer*, which he for some time owned; and sold *The Daily Mirror* to his brother, Lord Rothermere. Among the reforms which Lord Northcliffe introduced into newspaper management were the five-day week for editors, subeditors and reporters, a more generous payment of journalists and a system of profit-sharing by the chief members of his staffs.

From 1900 onwards, through his newspapers, he had exercised an ever-increasing influence on politics. He had at one time been anxious, like Edward VII. and Cecil Rhodes, to obtain a friendly understanding between England and Germany, but the Boer War caused him to abandon that idea as impracticable. His newspapers consistently pleaded the cause of a strong navy, and as consistently warned the nation for 20 years of the peril from Germany. From 1902 he sought to effect an entente with France, and also to promote agreements with Russia and the United States, whose sentiments and prejudices he had learnt in many visits. He opposed in 1911 the Declaration of London—a code of sea law which most naval officers condemned as "made in Germany"—and finally assisted in securing its rejection. Through *The Daily Mail* he gave large prizes for airmanship, in which, from 1906 onwards, he took the warmest interest; the offer of a prize of £10,000 in 1906 for the first aeroplane flight from London to Manchester was received in some quarters with a good deal of derision, which vanished, however, when in 1910 the prize was won. His maiden speech in the House of Lords was devoted to the pressing claims of aircraft. He was a strong believer in the future of flying and a daily advocate of the value of aircraft in war. He was also interested from the first in submarines, in one of which craft he made an early and hazardous descent.

The World War.—In the World War he took the lead in advocating almost every measure of reform that was carried through in Great Britain, usually weeks or months before it was introduced. He was indeed described by Mr. L. J. Maxse as "the great driving force in our country during the War" (*National Review*, July 1917). He aimed at the most vigorous possible conduct of the struggle, and was from the first of opinion that the War would be long and desperately contested. The chief newspaper campaigns which he carried out, always with the aims of victory and close union between the Allies, were: (1) for the organisation of the munition supply and provision of high-explosive shells in April and May 1915, when he did not hesitate to lay the responsibility for the shortage of ammunition on Lord Kitchener in leading articles written by himself in *The Daily Mail* of May 19 and 21, the second of which was publicly burned on the London and other stock exchanges; (2) this campaign was one of the causes of the formation of the Coalition Ministry by Mr. Asquith; (3) throughout 1915 and early 1916, in the teeth of storms of abuse, he urged the necessity of introducing compulsory service; (4) he protested continuously against the excessive optimism of Mr. Asquith's Govt. and of its Press supporters, and against the whole system of official secretiveness by which grave failure was concealed; (5) he called for the strict enforcement of the blockade and the stoppage of the supplies which were reaching Germany through neutral countries; (6) so far as the censorship would allow, he resisted the "side-shows," such as the Dardanelles and Salonika campaigns, which absorbed so large a part of the national forces; (7) he continued his pre-War demand for the construction of aircraft—and "the right kind of aircraft"—on the largest possible scale, and he called for effective measures against zeppelins and for warnings in the case of imminent air-attacks; (8) he urged the necessity of creating a strong naval war staff and taking offensive measures against the enemy submarines; (9) he insisted on the need for a system of compulsory food rationing.

While always active with his pen and through his Press, he went repeatedly to the various battle-fronts, British, French, Belgian, Italian and American, and kept in close touch with the various staffs. Thus in 1916, at the crisis of the battle of Verdun, he visited Verdun (March 4), conferred with Gen. Pétain, watched the struggle, and the same night motored back to Paris and wrote a long dispatch which was reproduced in whole or part by 3,000 Allied or neutral newspapers. He paid other visits—to Spain, whence he sent warning of the activity of the German propaganda, and to Switzerland, where he investigated the condition of the British interned prisoners. With his daily assistance, Sir R. Hudson raised through *The Times* fund a sum of approximately £21,000,000 for the British Red Cross, while Lady Northcliffe (who in 1918 was created G.B.E.) maintained a private hospital and took a prominent part in the control of Red Cross finance and operations. So wide was Lord Northcliffe's influence and so greatly feared by the Germans that they published a special periodical, the *Anti-Northcliffe Mail*, devoted entirely to attacks upon him as the chief Allied stimulus in the War. In Dec. 1916 he gave his support to Mr. Lloyd George in the political crisis which led to the fall of Mr. Asquith's Government, and dealt the final thrust which brought that Government down, though after the Armistice, by reason of his objection to the long-drawn-out after-war negotiations with the Germans, he became Mr. Lloyd George's most persistent critic. He was offered office but declined, believing that it was his duty to keep his hands free and hold the Government up to the mark.

Work in New York.—Before the United States entered the War he was offered and declined the post of British ambassador at Washington. He received, however, an urgent call to go the United States on May 30 1917. The War Cabinet had greatly desired him, after conference with leading Americans, to go to the United States as chairman of the much-needed British War Mission. He accepted this appointment, though with some reluctance. After an audience with the King, he left England on June 2, arriving in New York on June 11, with the understanding that he should not remain more than three months. During the next few months he co-ordinated the work of the numerous British departmental missions; controlled an expenditure of £10,000,000 to £15,000,000 a week, and maintained the closest and most friendly relations with President Wilson and the American Govt. He returned to London on Nov. 12 1917, when he was created a viscount, as Viscount Northcliffe of St. Peter-in-Thanet, for his services.

In a letter dated Nov. 15 1917 he declined Mr. Lloyd George's offer of the post of Air Minister, but on Feb. 13 1918, on the distinct understanding that he was to remain free to criticise and suggest, he accepted the office of Director of Propaganda in Enemy Countries. To pave the way for operations among the nationalities subject to the Habsburgs, he secured an agreement between the Yugoslavs and the Italian Govt., which played an important part in the defeat of the Austrian Army and was subsequently embodied, in substance, in the peace terms. The evidence of numerous German generals, statesmen and writers is that the skilful direction of his propaganda against Germany helped greatly to destroy confidence in the German people and weaken the German Army on the eve of its last offensive (July 15 1918), when it seemed on the verge of decisive success. Gen. Ludendorff himself says: "Lloyd George knew what he was doing when, after the close of the War, he gave

Lord Northcliffe the thanks of England for the propaganda which he had carried out. Lord Northcliffe was a master of mass-suggestion." The deadliness of his propaganda lay in its veracity. An account of his work was given in Sir Campbell Stuart's *Secrets of Crewe House* (1920), Crewe House being the London headquarters of the organization.

Last Days.—At the Armistice Lord Northcliffe was ill, suffering from an adenoma of the thyroid gland, for which, in June 1919, he underwent a serious operation, and it was only after some months that he recovered. During the Peace Conference his Press and the *Continental Daily Mail* in particular exerted a powerful influence on the British Govt., extracting from Mr. Lloyd George a promise to fulfil his election pledges and striving to maintain the closest and most cordial relations with France. In July 1921 he went for a prolonged tour of the world, as he was medically advised to take a rest cure. Unfortunately his journey tried him to the utmost. He visited the United States, Canada, Honolulu, Australia, New Zealand, China, Japan, Indo-China, India, Egypt and Palestine, but when he returned in early 1922 his friends were deeply anxious for his health. He looked worn and tired. A complete breakdown followed, and after a long illness he died on Aug. 14 1922 of ulcerative endocarditis. It may be said with confidence that he never recovered from the severe strain which the War and his activities during it imposed on his delicate constitution.

In golf and motoring Lord Northcliffe found his main relaxations in later life, and he remained a keen and skilful fly fisherman and salmon angler. He was the author of volumes in the Badminton series on *Motors and Motor-Driving* (1902) and *Tarpon Fishing* (1895), and he also published a collection of letters, telegrams and accounts of his visits to the various fronts (*At the War*, 1916), of which 60,000 copies were sold. A selection from his letters to his family during his last tour was edited in 1922 by his brothers Cecil and St. John and published under the title *My Journey Round the World*. Simple and direct in style, his own writing was always marked by pugnacity and humour. Throughout his newspaper organisations he was accustomed to insist on economy of words and the employment of straightforward Anglo-Saxon diction. (H. W. W.)

NORTH DAKOTA (*see* 19.779), a state of the United States of America. The population in 1910 was 577,056, and in 1920, 646,872, the increase in the decade being 69,816, or 12·1%; in the decade 1900–10, the increase was 257,910 or 80·8 per cent. The United States' census bureau estimate of the population in 1925 was 686,424. The state remains essentially rural, as is indicated by the population of the chief cities in 1920: Fargo, 21,961; Grand Forks, 14,010; Minot, 10,476; Bismarck, 7,122; Jamestown, 6,627; Devils Lake, 5,140. The percentage of urban population (in places having 2,500 inhabitants or more) was 13·6 in 1920, 11·0 in 1910 and 7·3 in 1900. In 1920 the foreign-born white population numbered 131,503; its sources were chiefly Norway (38,190), Russia (29,617), Germany (11,960) and Sweden (10,543).

Agriculture.—There were 75,969 farms in 1925 (U.S. Census Bureau estimate), as compared with 77,690 in 1920 and 74,360 in 1910. The average farm in 1920 comprised 466·1 ac., with 316·2 ac. improved; the value of all property of the average farm was $22,651; the value of land and buildings, $19,160. The average mortgage debt on farms owned wholly by the operators was 28·5% of the value of the land and buildings in 1920, and 22·4% in 1910. The total acreage in chief crops (000's omitted) was as follows:—

	1924	Average 1914–8	Average 1909–13
Wheat	8,685	7,511	8,108
Oats	2,746	2,484	2,208
Barley	1,350	1,638	1,162
Rye	1,129	760	50
Maize	1,137	557	278
Flax	1,129		
Potatoes	130	81	50
Tame hay	1,924	1,028	692

The acreage in flax in 1923 was 1,349,000; the average acreage in 1916–20 was 793,000. The value of all livestock on farms for the years 1919–23 averaged $121,000,000; on Jan. 1 1924 it was $88,000,000.

Education.—A state normal school was opened in Minot in 1913 and another at Dickinson in 1918. The number of children of school age in 1924 was 212,872; the number enrolled in public schools, 174,797; the average daily attendance, 144,263.

Finance.—The state bonded debt July 1 1925 was $27,859,000. The receipts for the biennium ending June 30 1925, were $20,646,922.75, and the expenditures, $16,566,560.21. For the year ending June 30 1925, the income tax yielded $402,530.43. New sources of revenue created after 1911 were: inheritance tax, capital stock tax, oil tax, motor-vehicle licence tax and gasoline tax.

Government.—The state Supreme Court was by constitutional amendment increased to five members in 1908, and by a further amendment adopted in 1918 the power of the court to declare legislation unconstitutional was limited to cases in which four of the five judges concurred. In 1914 by constitutional amendment the initiative and referendum were made applicable to all legislation, and provision was made that a constitutional amendment could be initiated by popular vote. Other amendments gave the legislature power to exempt from taxation all personal property and to levy an acreage tax on farm land to provide funds for a state system of hail insurance.

History.—Serious abuses in grain grading and marketing had been pointed out by the state Bankers' Assn. as far back as 1906. An amendment to the constitution, ratified by popular vote in 1912, made it legal to provide a state-owned terminal grain elevator. A second amendment for a terminal elevator within the state became effective in 1914. In the spring of 1915 a movement was begun to organise the farmers politically (in the Non-partisan League) upon the following platform: (1) state ownership of terminal elevators, flour-mills, packing houses and cold-storage plants; (2) state inspection of grain and grain dockage; (3) exemption of farm improvements from taxation; (4) state hail insurance on an acreage basis; (5) rural credit banks operated at cost.

The movement was so successful that by Nov. the membership of the league was 26,000. The first state convention of the league was held at Fargo, March 28 1916, and a full state ticket was nominated. At the primary election in June all the nominees supporting the league were elected, with the exception of the state treasurer. The legislature (1917) was divided; the House was controlled by the supporters of the league, the Senate by its opponents. The legislature provided for: (1) state grain grading; (2) Torrens land title registration; (3) state guarantee of deposits in state banks; (4) reduction of assessments on farm improvements to 5%; (5) a state highway commission; (6) a tripling of the former appropriation for rural schools.

In 1918 the Non-partisan League elected the governor and a majority of both branches of the legislature. The measures passed at the legislative session of 1919 were in accordance with the pledges made by the party leaders. There was created in 1919 an Industrial Commission, (1) to manage, operate and control all state-owned utilities, industries and business projects created by law; (2) to purchase or lease sites for these industries; (3) to sell all such property and to fix prices of all products of these industries; and (4) to provide funds by the sale of bonds for the carrying on of the state-owned industries and other business undertakings. The State Bank of North Dakota began business on July 28 1919 as an institution founded, owned and controlled by the state, which therefore guarantees all deposits in this bank and also all bonds that are handled by the state.

The recall election of Oct. 28 1921 resulted in the recall of the three Non-partisan League Officials who composed the Industrial Commission; the governor, the attorney-general, and the commissioner of agriculture and labour. At this election, however, the constitutional amendments and initiated laws which were proposed for the purpose of changing or overturning

the programme of the Non-partisan League were all defeated by substantial majorities. The recalled governor, Lynn J. Frazier, was elected U. S. Senator in 1922.

The state governors from 1907–25 were: John Burke (Dem.), 1907–13; L. B. Hanna (Rep.), 1913–7, Lynn J. Frazier (Rep.), 1917–21; R. A. Nestos (Rep.), 1921–5; A. G. Sorlie (Rep.), 1925– . (O. G. L.)

NORTHERN TERRITORY (*see* South Australia, 25.492), a territory of the Australian Commonwealth. Its area is 523,620 sq. miles. The total population in 1925, exclusive of aborigines, was 3,597, of whom 2,250 were whites and the remainder Asiatics, mainly Chinese. The white population reached its maximum in 1919 with 3,767 persons; after that date it declined, mainly owing to the closing of the meat works at Darwin. The total number of aboriginals in the territory was estimated at 20,700 in 1924.

History.—The Northern Territory Acceptance Act, 1910, transferred this territory from the jurisdiction of the State Government of South Australia to that of the Commonwealth Government, as from Jan. 1 1911. The territory is governed by a resident administrator who is responsible to the Federal Minister for Home and Territories. The seat of administration is at Darwin. The administrator is vested with supreme authority in internal affairs, with the exception of railways, posts and telegraphs, customs, taxation, public works, which are controlled by the appropriate Commonwealth authority. The Northern Territory Representation Act, passed in 1922, provided for the election of one member to represent the territory in the House of Representatives. The member is entitled to take part in any debate in the House, but not to vote. In March 1926 the Commonwealth Parliament passed the Northern Australia Bill providing for the division of the territory at the 20th parallel, the northern part to be known as North Australia, and the southern as Central Australia. The seat of administration of the former will be temporarily at Darwin and ultimately at Newcastle Waters. The seat of administration of Central Australia will be at Alice Springs. Under the Act a commission of three members is to be appointed, with full control over the railways, roads, etc., to prepare and carry out schemes for the development of North Australia. A resident and advisory council will also be appointed.

Production.—Agriculture had made little progress in the territory by 1925, although it had been found that rice, tobacco, coconuts, mangoes, cotton, various fodder plants and peanuts thrive well. The cattle industry made considerable progress, and in 1924 there were over 843,000 head in the territory. Great impetus was given to the industry in 1917 by the opening of extensive meat works at Darwin. Chiefly owing to labour troubles the works closed down in 1920 and the practice was resumed of overlanding surplus stock to neighbouring states. For various reasons sheep raising has not been successful, but horses thrive well, and in 1924 there were about 44,600 horses in the territory. Minerals to the value of £18,856 were produced in 1924, tin ore accounting for £12,855, gold £2,988 and mica £2,718. Production fluctuates considerably: in 1922 it was at its lowest ebb, amounting only to £9,959; in 1920, it was £80,101 which included wolfram to the value of £45,648, tin ore £27,610 and gold £5,282.

The problem of developing the territory depends largely on the development of means of transport and communication. The only railway line in the territory in 1925 was from Darwin south to Emungalan—198½ miles. The line to connect up with Oodnadatta, South Australia, 1,012 m., had been surveyed, and the construction of the section southwards to Daly Waters, 160 m., authorised; the section running northwards from Oodnadatta to Alice Springs, 297 m., was agreed upon early in 1926 (*see* Australia).

NORTHUMBERLAND, ALAN IAN PERCY, 8th Duke of (1880–), was born April 17 1880, a son of the 7th Duke. He succeeded to the title in 1918 as the eldest surviving son of his father, his elder brother Henry Algernon George, Earl Percy (*see* 19.788) having died prematurely in Paris Dec. 30 1909. As one of the largest coal-owners in the north of England, he was summoned to appear as a witness before the Sankey Coal Commission (1919) and came much into public notice owing to his prolonged controversy with Mr. Robert Smillie, the leader of the miners, and subsequently to his anti-Communist campaign. In 1924 the Duke acquired an interest in *The Morning Post* newspaper when Countess Bathurst sold that journal to a company of which he became chairman. He married in 1911 Lady Helen Magdalen Gordon-Lennox, youngest daughter of the Duke of Richmond and Gordon.

His father, Henry George Percy, the 7th Duke (1846–1918), was born May 29 1846 and succeeded to the title in 1899. He sat in the House of Commons as Conservative member for Northern Northumberland from 1868 to 1885 and died at Alnwick May 14 1918.

NORTHWEST TERRITORIES (*see* Canada, 5.142), territories of the Dominion of Canada. In 1912 that part of northwest Canada known as Ungava was incorporated in the province of Quebec, and the area of Kewatin south of 60° N. latitude was divided between Manitoba and Ontario. The Northwest Territories in 1926 consisted of the provisional districts of Kewatin, Franklin and Mackenzie, and included that part of Canada north of the 60th parallel, N. lat., between Hudson Bay on the E. and the Yukon on the W., including the islands in James Bay, Hudson Bay, Hudson Straits and other northern waters. The extent of these territories is estimated at 1,242,224 square miles. Of this area 34,298 sq. m. are covered with water. Many of these northern regions are uninhabited; parts are even unexplored. In 1921 the population amounted to 7,988. Of this number 3,873 were Indians, 3,242 Eskimos, 473 of British stock and 258 French.

The territories are administered by the Northwest Territories' branch of the Department of the Interior. The government is carried on under the direction of a commissioner and five councillors. Law and order are enforced by members of the Royal Canadian Mounted Police.

Fur is an important product: for the season 1922–3, the number of pelts purchased by traders amounted to 287,698 valued at $2,171,424. The territories have been widely searched for oil and other minerals, and oil in paying quantities has been discovered in the Fort Norman area. Agricultural possibilities are limited to the Mackenzie district, where cereals and vegetables have been successfully grown.

Two routes lead into the Mackenzie district, the one from McMurray, to which a railway has been constructed, via the Athabasca, Slave and Mackenzie rivers, the other *via* the Peace, Slave and Mackenzie rivers. Boats ply on these rivers during the summer, and in winter travel is confined to dog trains. Radio communications now keep the trading posts in touch with the outside world. (*See* Canada.) (D. A. MacG.)

NORWAY, or Norge (*see* 19.799), a kingdom of northern Europe and a member of the League of Nations. Its estimated area is 124,495 sq. m. and the population (1920) 2,649,775, including 19,328 Laps, 7,309 Finns and 2,814 Lap-Finns.

I. POLITICAL HISTORY

1910–1914.—The dissolution of the union between Norway and Sweden in 1905 was followed by new elections in the following year; these, for the first time, being direct elections by constituencies. There were no great political issues; the programme of the Coalition Govt. was a proclamation of trust in the Michelsen Cabinet and its willingness to "safeguard and consolidate the results of 1905." The Labour party had, however, now entered the field. The elections gave it 10 seats, the Conservatives 36, the Liberals and Left parties 77. Party dissension began to appear and weaken the coalition. After Michelsen resigned (Oct. 1907) he was succeeded as Premier by his Minister of Foreign Affairs, R. Jörgen Läland. Most of the Left then reorganised as the Consolidated Left under Gunnar Knudsen, who became Premier in March 1908. Knudsen's administration carried through the "concession laws," making it impossible to buy waterfalls of more than 1,000 H.P., forests, mines and other

real property, without a concession from the government.

The Conservative parties sharply opposed these laws, as too severe an encroachment on private property; especially the proviso that concessions should not be granted for more than 60 years, and that on their expiration all waterfalls, power stations, etc., should become national property without compensation to the owners. In March 1909 a group of the old Liberals reorganised as the Liberal Left. In the general elections of Oct. 1909 the Conservatives and Liberals secured 63 seats, as against 47 Radicals, 11 Socialists and two Independents, and on Feb. 1 1910 formed a Coalition government under the old Liberal leader Wollert Konow. In 1911 the government passed a new taxation law introducing compulsory declaration of income and limiting rights of municipal taxation. Owing to persistent friction on the *landsmål* question (*see* NORWEGIAN LITERATURE), Konow resigned (Feb. 1912), and was succeeded by the Conservative leader Bratlie. But this friction had weakened the coalition; the elections of 1912 returned 76 Radicals against 24 Conservatives and Liberals and 23 Socialists. Knudsen again became Premier, with Castberg the leading member of his Cabinet. Controversy centred round the so-called "Castberg laws," giving illegitimate children equal rights of inheritance with legitimate, except in the case of peasants' farms, and imposing on the fathers increased obligations to protect their illegitimate children and the mothers of them. The laws were passed in 1915 by the radical majority, after Castberg had left the Cabinet. In 1914 the centenary of the Norwegian constitution was celebrated.

1914–1918.—A controversy with Sweden concerning the suzerainty over a group of submarine skerries, Grisebaaerne, was decided by The Hague Tribunal in 1908. The World War brought the three Scandinavian countries closer together. On Aug. 1 1914 they proclaimed strict neutrality in the conflict between Austria-Hungary and Serbia; on Aug. 4 this declaration was repeated and extended to form a general rule of conduct during the War. On Aug. 8 a separate Norwegian-Swedish agreement was signed to remove any possibility of either country preparing hostile actions against the other. On Dec. 18–19 the three Scandinavian kings with their premiers and foreign ministers met in Malmö to discuss joint action regarding the diplomatic and international questions raised by the War. Similar conferences of the Scandinavian premiers and foreign ministers were held in Copenhagen (March 1916), in Oslo (Sept. 1916), in Stockholm (May 1917), Copenhagen (June 1918), Stockholm (May 1919), Oslo (Feb. 1920) and in Copenhagen (Aug. 1920).

After the first panic at the outbreak of war, both public and private enterprises made vast profits and incurred extravagant expenditure. Wages and salaries rose rapidly; the shipping companies paid huge dividends; all sorts of new financial and industrial enterprises were started; imports reached an enormous height. The War elections of 1915 returned the previous government with an increased majority; 80 Radicals were elected, 20 Conservatives, 19 Socialists and 4 Independents. The government received extraordinary powers. A victualling commission controlled prices and imports, and a price directorate controlled retail prices. In 1916 grains and cereals, meat, sugar, coffee and tea were rationed. Temporary prohibition was enforced in Dec. 1916, making all trade in liquors and brandies a penal offence. In June 1917 all trade in wines of an alcoholic strength of over 12% was prohibited. In July 1916, as the result of a violent struggle in the labour market, an emergency measure was passed—under protests from both Labour and Conservatives—prohibiting strikes and lock-outs and enforcing public arbitration in industrial conflicts. In spite of extraordinary revenues, however, the national debt, thanks to the needs of defence and bonuses to officials, rose from 362,300,000 kroner in 1914 to 736,600,000 kroner in 1917 and 1,008 million at the end of 1918.

The new elections in the autumn of 1918 brought a strong reaction. The Radicals lost 26 seats, the Socialists lost one, the Conservative-Liberals gained 30. These elections threw into relief the unfair electoral system, which had hitherto secured the Left a number of seats out of all proportion to the votes cast for them. The Conservatives, assisted by Labour—where the moderates were losing power in consequence of the impossibility of achieving results by Parliamentary methods—were now able to introduce and pass proportional representation. The Knudsen cabinet tendered its resignation in Jan. 1919, but as the Conservatives had no working majority it continued to sit till June 1920, when Otto Halvorsen, the Conservative leader, succeeded Knudsen as Premier.

1920–1925.—Halvorsen's Cabinet was immediately faced with the most formidable labour troubles. The Norwegian Labour party had been organised in 1882 but remained unimportant until after 1905. The first Socialist members of the Storting represented, not the industrial workmen, but the fishing population of the north against the big fish merchants and exporters. After 1906 more Socialists entered the Storting and gained rapidly in influence. They collaborated closely with the trade unions. The first of these had been organised in 1872; in 1889 existing trade unions were merged into the National Federation of Trades Unions under a central committee, elected partly by the trade unions, partly by the Labour party. The trade unions were similarly represented in the executive committee of the Labour party. From 1912 on a Radical minority became prominent; under the influence of the Russian revolution of 1917 it gained the upper hand at the party congress and in the executive committee in 1918; in 1919 the Norwegian Labour party joined the Third International, and sent a member to the executive committee in Moscow. The moderate leaders then left the Labour party and founded the Social Democrat party.

A wave of revolutionary feeling spread over Norway, the fruits of which were the "revolutionary" railway strike of Dec. 1920 and the national strike of May 1921. The Cabinet met both strikes successfully; the railwaymen (who were State employees) capitulated unconditionally after 17 days, and the national strike proved a fiasco and caused much bitterness against the radical leaders and Moscow. The Conservative position was strengthened; yet in June 1921 the Government was defeated on the prohibition question and resigned.

In Oct. 1919 a referendum had sanctioned the temporary prohibitions of 1916 and 1917 by 489,660 votes cast for prohibition to 305,241 against, over 410,000 votes not being cast. The Norwegian constitution does not provide for a referendum; but all parties felt the force of this expression of popular opinion. Yet the Conservatives were unwilling to legalise prohibition before reaching an arrangement with the wine-exporting and fish-importing countries of Southern Europe. The result of the prohibition policy was a trade war with Spain and Portugal, which cost Norwegian shipowners and the whole fishing population heavy losses. Moreover, the moral results of prohibition were very disappointing. Before it, Norway had been a very sober country; local prohibition was widespread and the liquor trade under control; the consumption the lowest in Europe, except Finland, and smuggling unknown. Now smuggling increased enormously, as did secret home distilling. The prohibitionists, supported officially by the Left, Labour and Socialists, were passing through severer laws and stricter control.

The elections of 1921, on the revised basis, gave 57 seats to the Conservative-Liberal coalition, 39 to the Left, 29 to the Labour party, 8 to the Socialist, 17 to the new Farmers' party. The Government, although it had lost seats and votes, remained in power, the Left holding the balance between Conservatives and Labour. Otto Blehr, who had succeeded Halvorsen, was unable to come to terms with Spain and Portugal while maintaining prohibition. The cabinet was voted down on March 2 1923. The second Halvorsen Govt. came in, and on the 17th the prohibition laws were revised and the importation of port and sherry allowed. A few days later a new treaty was concluded with Portugal, and the commercial war with Spain came to an end. The importation and sale of wines and brandies is now a monopoly under government control. The shareholders get 6%, the surplus (in 1925 5,000,000 kroner) goes to public funds. The temporary measure enforcing public arbitration in industrial disputes expired in April 1923 and was not renewed.

Halvorsen died suddenly May 23 1923. He was succeeded as Premier by his Minister of Finance, Berge. Berge had an insecure majority, but the public desired stability in the financial crisis which was overtaking banks and municipalities. But in July 1924 Berge wanted prohibition replaced by a well-controlled sale of highly taxed brandies, pointing out that smuggling had increased enormously, while drunkenness had but little diminished since prohibition. The Left, Labour and some of the Farmers' party, however, desired another referendum before abolishing prohibition. Berge resigned, and was succeeded by J. L. Mowinckel.

In Oct. 1924 there were new elections, the Left losing three seats. The Labour party had split again in the preceding autumn; the Norwegian party had withdrawn from the Third International; whereupon their left wing organised the Communist party, which remained affiliated with Moscow. The elections gave the Social Democrats 8 seats, the Labour party 24 and the Communists 6. The Left came in with 36, the Conservative coalition with 54 and the Farmer's party with 22. The Conservative parties thus had a majority of two in the new Storting; but as the Farmers' party refused to form an active coalition the Mowinckel Govt. retained office till March 1926, when they were defeated on the budget and succeeded by a Conservative Cabinet under Lykke. The municipal elections of Nov. 1925 also brought victories to the "bourgeois" parties at the expense of the Labour party, and even more the Communists.

The Spitsbergen archipelago had from time immemorial been under the suzerainty of Norway, but when the discovery of coal on them gave them a new value certain complications arose, resulting in various international conferences in Oslo; the Versailles Treaty gave this group of islands and Beeren Island to Norway, who solemnly took them over in the summer of 1925. On March 4 1920 the Storting resolved that Norway should join the League of Nations. In the following years there was some friction between Norway and Denmark concerning Greenland, which had belonged to Norway until the union with Denmark was severed in 1814. Norway had always resented the loss of Greenland, and its east coast had been regarded as the fishing and hunting ground of the Norwegian west coast population. Denmark's request in 1919 for recognition by the Powers of Danish suzerainty over the whole of Greenland renewed the question and led to a separate agreement between the two countries, neither giving up its principal contention, but both agreeing to regard the east of Greenland as no-man's-land *vis-à-vis* the other. Treaties of unconditional arbitration were concluded with various Powers (Germany, Uruguay, etc.) from 1924 and onwards.

Defence.—The army is a national militia with universal and compulsory service from the ages of 18 to 55; men are called up at the age of 20 and belong to the line for 12 years, but the period of service is short: from 48 to 102 days according to the branch of the service, with four subsequent periods of 24 days each. The strength of the permanent establishment, which includes the General Staff, the Guards battalion, army schools and garrison troops, in 1924 was 5,801 all ranks; the numbers trained in that year were 19,280. In event of mobilisation, a further 300,000 men would be available. The navy is designed only for coast defence duties, and comprises four small battleships, three destroyers, 29 torpedo boats and six submarines. Its permanent establishment is about 1,200 all ranks. All seafaring men between the ages of 20 and 44 are enrolled on the lists of the active fleet, and are liable to service.

II. FINANCIAL AND ECONOMIC HISTORY

The confidence engendered by the new political situation in Norway led to a remarkable expansion in all fields from 1905 on. Many large new industrial undertakings were founded with foreign capital, and smaller concerns for the home market. During the three years 1911–4 the export trade became important, and a substantial rise in international freight prices brought an influx of capital which completely changed the Norwegian money market. Both prices and wages rose substantially; indeed, in 1913, the contrast with the general tendency elsewhere grew disquieting. During the first half of 1914 there was a heavy contraction of the markets on which Norwegian exports chiefly depended; but conditions in the home market were not impaired. In July 1914 the resident population was approximately 2,471,000 an increase of about 88,000 since the census of 1901 in spite of an emigration, mainly to the United States, which aggregated 31,500 in 1911–3. The chief increase of population was in the industrially developing regions of the north, south, east and Trondbjem; in the inland peasant districts and on the south and west coast the population was stationary or declining.

Agriculture and Forestry.—In 1907 the cultivated area was officially estimated at 2,200,000 ac.; since then about 150,000 ac., chiefly in west and north Norway, had come under plough. Small holdings, occupied with root crops and cattle raising on modern methods were on the increase. The average annual value (1904–14) of the products of forestry (exports only) exceeded £400,000. Forestry made important progress, thanks to the efforts of the State and the Norwegian Afforestation Association (founded 1898) which up to 1913 had planted 104,000,000 new trees; nevertheless, the annual lumbering exceeded the growth.

Fishing Industry.—The fisheries were changing character from coastal to modern deep-sea concerns. In 1914 the Norwegian fishing fleet consisted of about 550 registered vessels (above 25 gross tons for steamers and 50 for sailing boats, most of which were now provided with motors). The Antarctic whaling industry initiated in 1906 was growing rapidly; in 1913 there were 54 whaling companies with 160 vessels, 36 floating factories and 30 permanent stations. The capital invested in whaling exceeded £2,220,000. In 1914 the output of Norwegian mines was 1,200,000 tons, over three-quarters being iron ore and sulphuric pyrites. The production of iron ore was increasing, and in 1915 reached the record figure of 715,000 tons; but sank later owing to extraordinary difficulties.

Commerce.—Between 1897 and 1914 the number of industrial workmen rose by 100%, wages by 225%. The mercantile marine evolved rapidly from sail to steam; in 1914 Norway possessed a fleet of 1,973 steamers and 1,106 sailing vessels with gross tonnages of 1,793,227 and 687,968 respectively with a total value of £19,000,000. From 1911–3 inclusive the value of imports rose from £26,000,000 to £30,680,000, and of exports from £16,600,000. to £21,800,000. Great Britain supplied most of the imports, Germany took most of the exports; but there were signs that this position would be reversed.

Effect of the World War.—The outbreak of war brought a sudden check and temporary panic, followed by great prosperity up to the entry of the United States into the War in 1917. After this event the restrictions on neutral trade became very oppressive and seriously curtailed Norwegian business profits. Meanwhile the general expansion continued. The arable area was extended, and the corn crop rose from 290,000 tons in 1917 to 4,400,000 in 1918. In these two years official investigations were conducted to determine the limit to which cultivation could be extended; and this limit had been reached by 1925. The area covered with forest was approximately 28,422 sq. m. in 1917, or 22·9·7% of the total area of Norway. Between 1916 and 1920 the average annual export value of pulp and paper products was about 321,900,000 kroner.

The revenues that are derived by the state from the fisheries were very satisfactory up to 1916; in that year the revenue from the large cod fisheries was 70,800,000 kr., which decreased to 41,000,000 kr. in 1917 and 30,000,000 kr. in 1918; the value of the herring fisheries dropped from 71,500,000 kr. in 1916 to 60,600,000 in 1917, 51,700,000 in 1918; trade restrictions, shortage of petrol, and floating mines were serious difficulties. In 1919 the Storting adopted the Government Bill on the establishment

of a Fishing bank for safeguarding the interests of the fishing population. The whaling industry declined throughout the War, many vessels being diverted to the general freights. Norwegian whale oil had been 78% of the world's output in 1913; in 1918 it was only 43·5 %.

Shipping.—The chief fluctuations were in the shipping trade. The heavy demand for tonnage by the belligerent powers brought an early and very rapid rise in freights which continued throughout the War and gave rise to unparalleled speculation. The annual profits of Norwegian shipping 1914–8 were about 500,000,000 kroner. But the gross freightage profit did not rise proportionately with freights on the open market, partly owing to the depreciation of sterling, partly to hampering restrictions, rising expenses and heavy taxation. Eight hundred and twenty-nine vessels with an aggregate gross tonnage of 1,250,000, and 1,162 lives were lost during the War. Norway escaped the first decline in the international market after the War, owing partly to the depreciation of the kroner, partly to the sustained demand for products of the wood-refining industry. In 1920 conditions grew gloomy, especially in shipping, the bottom having been knocked out of freights. The State and the municipalities were borrowing heavily, and bank loans rose by 300,000,000 kr. in the year to over 4,000,000,000 kr., while deposits rose only by 100,000,000 kr. to 3,400,000,000, and foreign credits of Norwegian banks were reduced from 152,000,000 to 17,000,000 kroner.

Foreign Exchange.—In 1921 the kroner dropped heavily, weakening the position of Norwegian exporters, especially in the pulp and paper industry. Many works closed down or worked short time. By midsummer 1,400,000 tons of the mercantile fleet were lying idle. The trade balance, however, improved as regards exports. From 1922–5 conditions improved gradually in spite of the banking crisis of 1922-3. Thirty-four joint stock banks were put under public administration; 10 will definitely be wound up; the fate of the rest will be settled in 1926. The chief problems of to-day are the exchange owing to the over-rapid rise of the kroner in 1925, and the public debt which has been swollen by recent passive budgets.

NORWEGIAN LITERATURE (*see* 19.815).—The first decade of the 20th century marks the passing away of the four great classics of the preceding age: Ibsen, Björnson, Lie and Kielland. Thereby the field of fiction was thrown open to a new generation of authors, who found themselves confronted with problems essentially different from those which had taxed the attention of the former generation.

Norway was no longer the country of consuls, shipowners, vicars, rectors, chamberlains and estate owners, representing official views and opinions against which persons not "made of that self metal" occasionally revolted, and always with deplorable result to their own social interests; nor was Norway the country of women suffering in silence under slow torture of an apparently correct marriage, or a country of workers imbued by a patriarchal respect to their employers, based on personal connections from generation to generation. On the contrary, thanks primarily to the claim of the right of personality which had been raised so energetically and consistently by the authors of the preceding age, Norway had gradually developed into a community in which democracy had established itself on a broad basis, and in which, generally speaking, a remarkably tolerant spirit prevailed. At the same time, a number of social and economic questions had come to the forefront in consequence of the extraordinary industrial development which had taken place, especially since the beginning of the 'nineties. It might have been expected that all these facts and features, which should be taken into consideration for a fair judgment on the position of Norwegian literature on the eve of the new epoch, would have contributed to bring about a new departure in literature, but nothing of the kind happened.

Drama.—As far as the drama is concerned, its flourishing age came to an end with the age of Ibsen and Björnson. Their younger contemporary, Gunnar Heiberg (1857–) who after their death was considered the greatest dramatic author in Norway, did not, however, develop any further in this line, and as a whole the Norwegian drama since Ibsen and Björnson has followed more fortuitous lines. This applies, by way of example, to *The Happy Election*[1] (1914) by Niels Kjaer (1870–), in which this author, who is considered one of the most accomplished writers of modern Norwegian prose, deals with certain contemporary phenomena of Norwegian politics, among them the language question, in a very clever and realistic way. Another example is Oskar Braaten (1881–) who has scored great success on the stage with his comedies *The Kird* (1911) and *The Wholesale Christening* (1925), written in the characteristic language of the industrial population in the vicinity of Oslo and dealing with its life and manners. A dramatist of an entirely different type is Hans E. Kinck (1865–), whose remarkable drama *The Cattle Dealer* (1908), in the opinion of many critics, is unrivalled in Norwegian literature since Ibsen's *Peer Gynt*. This drama, which is too unwieldy for the stage notwithstanding its intrinsic merits as a work of fiction, has never been performed, contrary to his Italian drama *Agilulf the Wise*, which was acted at the National Theatre in the spring of 1910, when it gave rise to a lively discussion engendered primarily by the sovereign way in which the author disregarded the conventional rules of rhythm and stanzas.

Fiction.—An examination of the history of the Norwegian novel during the same period leaves a more satisfactory impression for the very simple reason that this special form of art had not reached the same state of perfection as the drama at the end of the preceding period and, accordingly, contained possibilities of a further development. By that time some 20 years had passed since Hamsun had made his appearance in literature. Within this period he had produced a number of works, generally written in an exquisite style and filled with an exuberant vitality, of which *Pan* (English translation) 1895, ranks particularly high. Compared with this work, the *Growth of the Soil* (1917; English translation 1920), by which Hamsun has become famous all over the English-speaking world, does not approach it in range of passion and in mystic grandeur. The former is a consummate work of fiction and art. The latter is an exceedingly fine novel, inspired by the cooler views of the more mature years as well as of a more prosaic age. In the struggle between the ideas of agriculture and the ideals of industrialism, Hamsun, like the rest of his contemporaries, sides with the representatives of the "mother trade of the country" notwithstanding the marvellous industrial transformation of Norway during the last generation, or perhaps we should rather say because of it. This even applies to Kinck, who is anything but prepossessed in favour of the peasants.

Kinck, who is by all critics admitted to be an author of rare gifts, has not yet received general recognition either at home or abroad. Yet by his daring metaphors, his exuberant passions, his deep psychology supported by extensive historical studies, he is one of the most intimate guides to the depths of the Norwegian mind. His Hardanger novel, *The Avalanche* (1919–20), is considered his greatest work, but generally speaking he is at his best in the short story. Another classic writer is Trygve Andersen (1867–1920), a self-controlled author with a limited production but whose work is stamped by a keen psychological insight and imaginative inspiration and moulded in an exquisite and transparent style.

Besides these three poet-artists and classics should be mentioned Johan Bojer (1872–) whose novels notwithstanding their fame in the English-speaking world and elsewhere are not considered by Norwegian critics as revealing any particular feature typical of the Norwegian mind. A more intimate author is Peter Egge (1869–), a conscientious writer with an artistic style which adds to his original gifts as a narrator and psychologist.

[1] In this article the titles of books are translated into English for the convenience of the reader, although unless otherwise stated the books themselves have not been so translated. (Ed. E. B.)

One of the chief characteristics of Norwegian literature during the last generation is the ever-increasing number of local authors who, substituting particular districts for the country as a whole, have given rise to local literature, partly written in the literary tongue of the country known as the *Riksmaal*, partly in the *landsmaal* (*see* 19.818) or in a *riksmaal* coloured to a marked degree by some local dialect. The most conspicuous of these authors are Oskar Braaten, Hans Aanrud (1863–) who scored success as a playwright of broad humour in the 'nineties, and Johan Falkberget (1879–)—all typical East Norway novelists. Braaten's literary domain, not only as a playwright but as a novelist, is the industrial quarters in the immediate neighbourhood of Oslo. Aanrud is a keen observer of life and manners in the midland countries round Lake Mjösen. Falkberget is intimately acquainted with the miners of the mountain districts of the valley of Österdalen, whom he has depicted vividly in surroundings of an overwhelming nature.

Gabriel Scott has, in an idyllic novel *The Source* (1918), found an exquisite expression of the typical Sörland (literally Southerland) nature and Sörland temper as they reveal themselves all through the charming coastland. West Norway country life has been ably sketched by Jens Tvedt (1857–), who writes in the *landsmaal*. The particular district of the North Trondhjem country, known as the valley of Namdalen, has in Olav Duun (1876–), whose works all deal with life and manners in his native valley, produced the most gifted author of modern times writing in the *landsmaal*. Another significant author in the same language is Kristofer Uppdal (1878–), originally a navvy whose works in prose and poetry are imbued by the ideals of the labour movement. This tendency in the direction of developing a special county or district literature, as it were, is intimately connected with the national current which in 1905 brought about the dissolution of the Union with Sweden and which since then has given rise to a rather voluminous literature dealing with the local history, of which Madame Sigrid Undset may be considered the chief exponent.

Poetry.—In the noble art of poetry Nils Collett Vogt (1864–), who already in the 'nineties was known as a highly gifted lyric poet, continued to proclaim his emotions in stanzas of vigorous and beautiful metaphors. Olaf Bull (1882–) combines to a rare degree a refined versification with silent resignation and lofty enthusiasm. Herman Wildenvey (1885–) a genial troubadour talent, sings out his joys, his cares and his whims in easy verses and metaphors, striking by the felicity of phrase. Simultaneously with this lyric flourishing in the *riksmaal*, no adequate revival has taken place in the *landsmaal*. The gem of lyric poetry in that tongue is Haugtussa (1895), a lasting tribute to the genius of Arne Garborg (1851–1925), by whose death the *landsmaal* literature was left temporarily without any first rate lyric poet. (S. C. H.)

NORWICH, England (*see* 19.819), is extending and enlarging its industries. Its banking interests are less localised than formerly, owing to amalgamations, but it is the headquarters of the Norwich Union Life Office and the Norwich Union Fire Office, which societies have been under one control since 1925. The area of the borough is 7,923 ac., and the population was 120,661 in 1921. The chief magistrate was created lord mayor in 1910. The church of St. Luke's, New Catton, was consecrated and given a parish in 1915.

The house in which George Borrow resided with his parents when in Norwich is now a Borrow Museum, presented by Mr. A. M. Samuel, M.P., in 1913. Stuart Gardens, bequeathed to the city by the late Mrs. James Stuart as a memorial to her husband, was formally presented in 1922, in which year the Strangers' Hall, a 15th-century house on Charing Cross, was given as an English folk museum by Mr. L. G. Bolingbroke. In 1921 Sir Eustace Gurney presented to the city the Lazar House, a fine Norman relic contemporary with the cathedral, for the purpose of a branch public library, and as such it was opened in 1923. The City Bridewell, a fine old, flint-faced building, was presented by Mr. H. N. Holmes in 1923, and after restoration was opened in 1925 as a museum of local industries, past and present. In 1925 Miss Ethel M. Colman, the first lady in the country to hold the office of lord mayor (1923–4), and her sister, Miss Helen Colman, restored and presented to the city Suckling House (14th century), together with the adjoining Stuart Hall, which was erected by them as a memorial to their sister, Mrs. James Stuart, to be used for educational purposes. In the same year the famous Samson and Hercules House on Tombland, and the adjoining Augustine Steward House, were opened as a Y.W.C.A. centre, and the ancient and almost unique bishop's throne in the cathedral was restored by the bishop, (the Rt. Rev. Bertram Pollock).

In Jan. 1925, Prince Henry laid the foundation stone of a new children's block at the Norfolk and Norwich Hospital, and this was opened in Jan. 1926. The Maddermarket Theatre, an exact model of an Elizabethan theatre, in a building once a Roman Catholic chapel, was opened in 1921 for performances by the Norwich Players, an amateur dramatic company. Considerable developments in town planning have taken place, and several new arterial roads have been made. In 1923 the new Carrow Bridge over the river Wensum was formally opened by the Prince of Wales, and in 1925 Wensum Park was opened on the site of a refuse ground.

See Ian Hannah, *Heart of East Anglia* (1914); G. A. Stephen, *Guide to the Study of Norwich: a Bibliography*, 2nd. ed. (1919).

NOSE: *see* EAR, NOSE AND THROAT, DISEASES OF.

NOSKE, GUSTAV (1868–), German politician, was born in Brandenburg July 9 1868. He became a writer for Social Democratic papers and from 1897–1902 worked on the staff of the *Königsberger Volkszeitung* and later the *Volksstimme*, at Chemnitz. Returning to Brandenburg in 1902, he was elected to the municipal council, and in 1906 entered the Reichstag. Throughout the World War Noske belonged to the majority Socialists. In Nov. 1918 he accompanied the secretary of state to Kiel and arranged a suspension of the mutiny then prevailing. He remained in Kiel as governor till Feb. 11 1919, when he returned to Berlin as minister of national defence. In his book *Von Kiel bis Kapp* (1920) he gives an account of his difficulties in organising an army for home defence. On the occasion of the Kapp coup of March 1920 Noske was unable to prevent the occupation of the capital by Gen. von Luttwitz and fled with Ebert and Bauer to Dresden and later to Stuttgart; but after the suppression of the Kapp troubles it was impossible for him to resume office, owing to his lenient treatment of the military reactionaries, coupled with his ruthless suppression of Communist rioters.

NOTTINGHAM, England (*see* 19.826), with an area of 10,935 ac. and a population in 1921 of 262,624, has several flourishing industries, although the lace trade is less prosperous than formerly. Cycles, drugs and hosiery are made here in large quantities. The leather trade expanded greatly during the World War. Since 1918 the city has returned four members to Parliament.

In 1921 Wollaton Hall, a magnificent example of Elizabethan architecture, with the park of 750 ac. that surrounds it, was bought by the corporation from Lord Middleton. A portion of the land is to be used for building purposes, but the greater part of the park will remain an open space. Municipal schemes have provided a number of new houses since 1918. The new churches and parishes include St. Cyprian (1910), St. Christopher, Sneinton (1910), St. Faith, NorthWilford (1914) and St. Michael and All Angels (1914). The William Woodsend Memorial Homes were opened in 1913 and the William Booth Memorial Hall in 1915; the Natural History Museum was transferred from University College to Carlton road in 1920. New buildings contemplated include one for municipal purposes overlooking the market place, a large power station and a public library. A railway line to Mansfield, leaving the London & North Eastern a few miles north of the town, was opened in 1917 and gives access to the docks at Immingham.

The most important development is the erection, at the cost of Sir Jesse Boot, of new buildings for University College. These are on the western side of the town, on a site of 220 ac. called

Highfields, part of which has been devoted to recreation grounds for the public and the students. A large open-air swimming bath was opened near the estate in 1924 and a new road connecting it with the city has been made. In 1926 the work of doubling the width of Trent Bridge was completed, a slum area of 400 houses being demolished to make a new road to the bridge. Sir Jesse Boot has given 16 ac. to complete the Victoria Embankment.

NOVÁK, VÍTĚZSLAV (1870–), Czech composer, was born at Kamenice in Bohemia. He completed his studies at the Prague conservatoire of music, of which he became director in 1919. Early in his career he came under the influence of Dvořák, Brahms, Schumann and others, but he soon revealed his own individual method of expression, which was marked by powerful phantasy and boldness in musical resources. His early piano compositions, consisting of overtures and songs, are lyrical, phantastic and passionate by turns, but romanticism forms the basis throughout. Later he turned his attention to the popular music of Moravia and Slovakia, by which his subsequent compositions were strongly influenced. These include many of his best works, such as the symphonic picture *In the Tatra*, Slovak Suite, two Valach dances, the symphonic poem *Legend of Yearning*, Moravian songs, Czech suite, gypsy melodies, as well as a number of compositions based upon national ballads. Among his earlier works may be mentioned the overtures *The Corsair* and *Manfred*, *Memories*, serenades, eclogues and barcaroles. Of his orchestral works the most noteworthy are *Toman and The Wood Nymph* and *The Storm*. Novák also composed some operatic works, the best of which is *The Lantern*, based upon a play by A. Jirásek and exhibiting his art in its maturest form.

NOVA SCOTIA (*see* 19.830), a province of the Dominion of Canada. The population, which includes the island of Cape Breton, was 523,837 in 1921. This showed an increase of 6·4% since 1911; of the total 56·98% was classed as rural. About 80% of the inhabitants are of British descent. Halifax, the capital (pop. 58,372) and Sydney (pop. 22,545) are the chief commercial and shipping centres. The Government consists of a Lieut.-Governor, a legislative council of 21 members appointed for life, a legislative assembly of 43 members elected on general suffrage; an executive council of Ministers is appointed by the Premier. The province is represented in the Federal Parliament by 10 senators and 14 members of the House of Commons.

Education.—Each county in the province has a high school or an academy. Among the degree-granting institutions of the province the most important are Dalhousie University at Halifax (including by affiliation since 1922, King's College, Windsor). Acadia University at Wolfville and St. Francis Xavier at Antigonish. The school districts are subdivided into school sections, each administered by a board of three trustees, elected by the ratepayers. Local taxation is supplemented by legislative grants, the total expenditure on education in 1923 being approximately $3,500,000. There were then 114,458 pupils and 3,237 teachers in the schools under public control.

Production and Industry.—The acreage under crops, and consequently the quantity and value of agricultural products, greatly declined during the post-War period. In 1919 the total value of the principal field crops was $63,357,000; in 1924 this value had fallen to $16,359,000, but a slight increase occurred in 1925. The average annual yield, in bushels, of the chief crops for the period 1922–4 was: wheat, 233,533; oats, 4,094,667; barley, 195,700; and buckwheat, 188,100; the average yield of potatoes was 3,372,800 hundredweight. The production and export of apples, for which the Annapolis and Cornwallis valleys are especially suitable, has become a leading industry. The average annual crop exceeds 1,500,000 barrels. The provincial Govt. maintains 35 model orchards in various parts of the province. In 1925 there were 291,912 cattle, 273,499 sheep and lambs, 53,480 swine and 53,352 horses in the province. Dairying has increased in importance; the chief dairy product is butter, the output of which increased from 320,763 lb. in 1911 to 4,094,282 lb. in 1924. Travelling dairy schools giving instructions to farmers throughout the province have been instituted.

The forest area of Nova Scotia is estimated at over 12,000 sq. m., more than half the area of the province. The value of the lumber cut in 1923 was $2,281,949. The production of pulpwood for 1923 was valued at $838,358. The fishing industry is of vital importance: in 1924 there were 18,721 persons employed in the various branches of the industry, and the total value of the products amounted to $8,777,251.

Coal, iron, copper and gold are found, but only coal is produced to any large extent, the output being 4,973,184 tons in 1924. The production of gold has greatly declined, and only 750 oz. was produced in 1924. Colchester County contains valuable oil shales. The total value of mineral products in 1925 was $38,720,000. Extensive manufactures of iron and steel are carried on at Sydney and other parts of Cape Breton Island. The shipbuilding industry has declined steadily, except for the temporary stimulus provided by the exigencies of the World War. Other manufacturing industries of the province include sugar refineries, pulp and paper mills, canneries, textile and boot and shoe factories. The total capital invested in manufacturing industries was $107,000,000 in 1923, the number employed 17,179, and the gross value of production amounted to $82,000,000.

Trade and Communications.—Imports entered for consumption in 1924–5 amounted to a value of $22,068,108. Exports during the same year were valued at $43,487,392. Of 15,190 m. of roads in 1924, 1,255 m. were of gravel. The total expenditure on the highways in 1924 amounted to $1,728,894. The Canadian National Railway system is the chief means of internal communication; the railway mileage in 1925 was 1,434. (*See* CANADA.) (S. LE.)

NOVELLI, ERMETE (1851–1919), Italian actor and playwright (*see* 19.838), died at Naples Jan. 29 1919. His tragedy *La Masque* written in collaboration with Signor Bonaspetti, was produced in 1911.

NURSING.—The science and art of nursing has, like surgery and medicine, made enormous strides since 1910, partly due to the War, but largely owing to the general development of science in this country. Modern nursing had its origin with Florence Nightingale, and she set the standards that have been followed since. But in later years there has been a change in the manner in which the nurse is regarded. She is now looked upon, both as the possessor of a great vocation for which she has to be qualified by years of training, and as a professional woman whose loyalty to that profession should be as true as that of the doctor, and whose duty is to add to her knowledge and professional skill both for her own sake and for that of the profession to which she belongs.

I. IN GREAT BRITAIN

Training of Nurses.—In Great Britain the training of the nurse is regulated by the state through the Nurses' Registration Act of 1919. This Act was only carried into law after years of controversy, which ended with the outbreak of War, when a truce was declared and loyally maintained. The profession has now the right of self-government. There is a General Nursing Council for England and Wales and another for Scotland, and 16 of the 25 members of the English Council must be registered nurses elected by persons registered under the Act.

In addition to the ordinary registration of nurses with a general training (which occupies three or four years) there are five supplementary registers for male, mental, fever, mental defectives and sick children's nurses. Nurses usually begin their general training in recognised training schools at an age not less than 21, though for certain kinds of training (such as those for nurses of fever or sick children) probationers are taken earlier. The nurses usually live in the hospital or in hostels near it; and as a rule, those who remain in hospital retire about the age of 50 or 55, when a pension is frequently provided with or without contribution. Post-graduate teaching is developed in the best schools, as is the system of providing tutor-nurses. There is not as yet much connection with the universities though the University of Leeds grants a diploma in nursing.

Hospital training has thus become highly developed in Great Britain, and the matron of a great hospital holds a very important position as regards her staff, which is divided into sisters, staff nurses and probationers. There are specialists in electric and other technical work, but these have usually first completed their general training. Strenuous efforts have been made to reduce the hours of service and to increase the salaries, which for many years have been extremely low. There is still room for improvement in both these matters.

College of Nursing.—In the year 1916, a college of nursing was established with the view of forming a centre for all nursing activities, improving the nursing service as a whole and the conditions under which nurses work. In 1925 it had a membership of 24,000 with 42 branches and sub-branches throughout the United Kingdom. Connected with it are a student nurses' association for nurses in training, a section for sister tutors and a section for public health workers. It is recognised by the Ministry of Health as an approved centre for the training of health visitors.

Although a large number of nurses serve in hospitals, these are regarded mainly as training schools, where the young nurse is carrying on her studies as well as gaining practical experience. The difficulty with the present hours of duty is to provide the necessary time for her studies and for preparing for frequent examinations, state and hospital. In early days, the importance of the training was not fully recognised, and the nurse was regarded as one who simply performed certain useful functions. Now, the doctor or surgeon looks to the nurse for assistance in his work; he can only see the patient at intervals but she has him always under observation, and the accuracy of her observation and report is a matter of vital importance. It is probable that during the strain of War the matter was pressed home on those in control of hospitals as it never was before. Nurses have become an essential part of the social and economic life of the country and their functions are continuing to increase. It may be well to enumerate the most important of them.

District Nurses.—On completing her general training, usually of four years, a nurse may take her district training and be placed on the roll of the Queen's nurses, which are supervised from head-quarters but supported locally. There are still "cottage nurses," with a short training, but those with a higher standard are rapidly increasing, more especially as they are eligible to do county health work under the medical officer of health. Those who hold the certificate of the Central Midwives Board are frequently employed in infant and child-welfare work. Before many years have elapsed every parish or district should have its own nurse.

Public Health Work.—In addition to child welfare work many nurses are employed under county, burgh or city schemes. The education authorities require a large staff for following up the cases of children who have been inspected by their medical officers. Nurses are also required for fever and isolation hospitals. Poor Law infirmaries give excellent training and have certain advantages over hospitals, which are also training schools for the medical profession. There will probably be changes in Poor Law administration before long.

Private Nursing.—This form of nursing has expanded enormously and though some visiting nurses come in for the day, they are mainly residential. Nurses who undertake this work are to be had either from a hospital which sends out their nurses after they gain their certificates, or from an institution, possibly a co-operative institution or home. Nurses are employed in many private nursing-homes for the well-to-do.

Mental Nurses.—The training for mental nurses is usually conducted in a recognised institution for the treatment of mental disorders where the candidate serves for three years, and enters for the state examination for mental nurses. The nurses and attendants are of both sexes, but women are being increasingly employed even for male patients.

Midwives and Maternity Nurses.—Midwifery is controlled by a Central Midwives Board, established in London, with jurisdiction in England and Wales, and there are separate boards for Scotland and Ireland. The number of midwives now on the roll in England and Wales is approximately 77,791. These boards regulate the issue of certificates and the conditions of admission, and have also the power to remove names from the roll. It was only in 1910 that it was forbidden to any person to attend women in childbirth for gain (otherwise than under the direction of a qualified medical practitioner) unless certified under the Act. An incorporated Midwives Institute has done splendid work in promoting the interests of midwives. Many trained nurses take the midwives' certificate, for which they have to have a six months' special course while a twelve months' course of midwifery is necessary for those who are not trained nurses.

Masseurs and Masseuses.—The Chartered Society of Massage and Medical Gymnastics grants a certificate to those who have taken a prescribed training at a recognised school and have passed an examination. After June 1927 examination on massage as a single subject will cease.

Various Services.—A voluntary advisory nursing board was established in 1921 under the Prison Commission of the Home Office, and trained nurses are now appointed for the care of sick prisoners. A nursing service deals with hospitals under the Ministry of Pensions, and a matron-in-chief is at its head.

The Overseas Nursing Association sends trained nurses to the Crown Colonies and small British communities abroad. There is also an Indian nursing service for Europeans in India.

Queen Alexandra's Imperial Military Nursing Service originated in 1902. A nursing board advises the Secretary of State on matters connected with the service. A matron-in-chief is at its head and principal matrons, matrons, sisters and staff nurses are subordinate to her.

In the first year of the World War there were 2,323 fully trained reserve nurses, in addition to the regular service, and by 1918 the number reached 10,304. There is likewise a service called Queen Alexandra's Military Families Nursing Service. The Territorial Army Nursing Service, established in 1907–8 in connection with the Territorial Army, supplied the largest number of British nurses available on the outbreak of the World War. The probable number required is about 4,000, but the territorial nurses are only called up in case of necessity. Like the Territorial Army, they enrol with overseas obligations.

Queen Alexandra's Royal Naval Nursing Service is a small one, which also has a reserve. The Royal Air Force Nursing Service was established in 1921 and has the same formation—matron-in-chief, matrons, sisters and staff nurses—as the others. (See MEDICAL SERVICE, ARMY.)

(1921); Sir Henry Burdett, *The Nursing Profession* (1915); Lavinia L. Dock and Isabel M. Stewart, *A Short History of Nursing* (1920); Elizabeth S. Haldane, *The British Nurse in Peace and War* (1923); an abridged edition of *The Life of Florence Nightingale*, by E. T. Cook (2 vol.), appeared in 1925, edited by Mrs. R. Nash.

(E. S. H.)

SCIENCE AND TECHNIQUE

Nurses now work for shorter hours, they have greater freedom, optional out-door uniform, a rational and comfortable indoor uniform, better food, private bedrooms, a dining hall and comfortable sitting rooms. They are encouraged to take healthy out-door exercise, to play games for their hospitals, to join musical or literary societies. There has been a further reduction in the minimum age (to 19 years in many hospitals) at which probationers are engaged, in order that girls leaving good schools may pass on to a nursing training without loss of time, and find their position in that nursing training to be on a par with that of their friends, who have passed on to a university.

The standard of living for the patient also has greatly improved. The modernisation of hospital wards, singular 15 years ago, is now an almost universal fact. The introduction of up-to-date apparatus, such as steam heat, electric light, gas or electric cookers, heaters and sterilisers, electric hot air baths, adjustable beds, heated food trolleys, rubber floors, electric lifts, wheeled stretchers, high power reflector lights for operating rooms, powerful magnets, etc., is an advantage; there is a marked improvement in the quality of the patients' bedding, linen, crockery, hospital food and its service, although, in the last respect, England has something to learn from Scandinavian countries. There is a greater personal liberty for patients: in many hospitals, since the World War, smoking is permitted to the men patients within certain hours, and visitors have greater access to their sick friends.

Entirely new methods of treatment have been evolved for diseases and conditions such as diabetes, eclampsia, uraemia, phthisis, cardiac disorder, etc., necessitating, in many cases, complicated and exact diet regulated by an exact knowledge of the chemical constituents of the blood and other fluids. In other cases treatment such as immobilisation of a lung, or measurement of the air capacity of a lung, is regulated by the results of frequent bacteriological and other tests. Again, treatment by means of graduated exercises for the heart, the re-education of muscles and nerves that have lost their power, and the re-education of the brain itself, have been developed and depend for success on careful nursing.

Surgical Cases.—The advance in surgery is illustrated in delicate operations in brain surgery; plastic operations on the face; blood transfusion; tendon transplantation; periscopic examination of the abdominal and other cavities; examination of the intestinal tract, kidneys, spinal canal and brain cavities by means of opaque drugs and X-rays; bone grafts and all the skilled manipulations of orthopaedic surgery; plaster and splint work; and advances in many other special branches of medicine and surgery. In all these investigations and achievements

doctors require the intelligent and skilled co-operation of nurses. The education of modern nurses has been widened and deepened to fit them for their task. (E. E. MacM.)

II. IN THE UNITED STATES

The rapid development of the nursing profession in the United States has been due in large measure to the three national nursing organisations established by the nurses themselves, in the belief that they were responsible for the ethics, standards and educational developments of their profession.

American Nurses' Association.—The "American Nurses' Association" was founded in 1896, according to its charter, "to establish and maintain a code of ethics; to elevate the standard of nurses' education; to promote the usefulness and honour of nurses; to distribute relief among such nurses as may become ill, disabled or destitute; to disseminate information on the subject of nursing by publications in official periodicals or otherwise; to bring into communication with each other various nurses and associations and federations of nurses throughout the United States." This association has been active in legislative measures affecting nursing interests, and since 1917 has been in constructive co-operation with the National League of Nursing Education. *The American Journal of Nursing*, a monthly magazine published continuously since 1900 by the American Nurses' Association, is also the official organ of the "National League of Nursing Education."

The National League.—The "National League of Nursing Education" was organised in 1893 by 18 women superintendents of hospitals to promote nursing education and to raise educational requirements for the profession. Its membership is now open to heads of schools for nurses, teachers of nurses and heads of nursing services, all of whom are also members of the American Nurses' Association. The League has initiated many distinctive movements, the most notable of which are: in 1896, the extension of the hospital training course to three years; in 1903, the inauguration of state registration of nurses, now compulsory in the 48 States of the Union; in 1907, the establishment of a department of hospital economics at Columbia University; in 1917, the publication of a standard curriculum, designed to ensure a minimum standard for all schools of nursing, and now almost universally adopted; in 1925, the classification and grading of training schools, a task now under way. In addition, the League has during the 33 years of its existence published numerous pamphlets and reprints of value in nursing education.

The National Organisation.—The National Organisation for Public Health Nursing was organised in 1912, to establish standards in public health nursing, and to promote a general intelligent understanding on the part of the laity, as well as the nurses, of the needs and importance of well-planned preventive work in the field of public health. It publishes a quarterly journal, *The Public Health Nurse.*

Each of the three national organisations maintains ample headquarters, with secretaries and reference libraries, and in diverse ways lends its support to the body of nurses and their educational experiments. The distinctive service in America performed by these associations because of their special knowledge and experience accounts for the remarkable progress made in the nursing field in the past 30 years.

The American Red Cross.—In 1904, by Act of Congress, the reorganisation of the American Red Cross was effected, and provision thereby made for a flexible nursing reserve, with chapters in every State, ready to provide nurses from the ranks of the profession in times of emergency. The Red Cross has also initiated a peace programme for rural visiting nursing, which has developed into a national service of public health nursing. In 1919, it appropriated $115,000 for scholarships to enable graduate nurses to equip themselves more thoroughly for this service.

Army Nursing Service.—The Army Nursing Service was established by Act of Congress in 1901; the Navy Nursing Service, in 1908. In 1918, the Army School of Nursing was established on progressive lines, with hospital affiliations to give its students the experience necessary for their complete training.

U. S. Public Health Service.—The United States Public Health Service, a branch of the Treasury Dept., employs a staff of nurses under the direction of a woman superintendent, to assist in carrying out its extensive public health programme in hospitals, in foreign and domestic quarantine and in various sanitation projects.

University Courses.—At Teachers' College, New York, the first collegiate course for nurses was established in 1899 through the efforts of the nurses themselves. To-day there are in the United States 22 universities or colleges providing training for nurses. In 1909, the University of Minnesota made its school of nursing a professional school of the university, the principal being responsible to the dean of the medical school, and a member of the medical faculty. Five-year courses have been established by several colleges in order to combine liberal arts with professional training.

In 1919, through the generosity of the Rockefeller Foundation, a study was made of the conditions of nursing and nursing education. As a result of a report based on this study, Yale University established a school of nursing open only to college graduates, to be maintained as an experiment for five years by the Rockefeller Foundation. The ideal of this school is to increase the number of teachers and leaders for new lines of work.

Development of Public Health Nursing.—Perhaps the most unique contribution to nursing in the United States has been the development of public health nursing. The term "public health nurses," originated in 1893, emphasises the community responsibility of the nurse. There are to-day 12,000 public health nurses in the United States actively engaged in public health nursing, which, as now understood, proclaims the twin service of ministration and education, and includes the care of the sick in the homes and the teaching of preventive health measures. Many types of specialised work in the public health field have been developed: school nursing, municipalised in 1902, and now supported by public or private funds throughout the country; work with the tuberculous; maternity clinics; milk stations; infant health centres; prenatal clinics; clinics for the pre-school child; care of cardiac cases; industrial nursing; hospital social service; and treatment of venereal diseases.

Hospital Social Service.—The germ of Hospital Social Service, now highly developed, originated in 1879, when the Ethical Culture Society of New York employed a nurse to associate herself with a visiting physician affiliated with the dispensary. The Massachusetts General Hospital of Boston in 1905 placed new emphasis upon carrying the treatment from the hospital to the patient and utilising the opportunity of education in the home, systematising the co-ordination of the treatment and the complete rehabilitation of the family through public and private agencies. Many hospitals now employ a staff of social workers and nurses for follow-up work among their patients' families and among discharged patients. The nurses in the United States have written most of the text-books used in the schools and in public health nursing, and publish many leaflets, articles and local journals. In this they are encouraged and aided by the medical profession.

Educational Tendencies.—The present tendency in nursing education is to replace the apprenticeship system of training by professional university schools administered independently of hospitals, but affiliated with them to give ward experience to their students.

Statistics.—In 1925 the number of registered nurses in the United States was 250,000, of whom approximately 220,000 were active private-duty nurses, 11,000 public health nurses and 5,000 were in institutions or engaged in teaching. The number of training schools was 1,800, the number of graduates annually 15,000, and the number of colleges giving training courses 22. The growth in number of training schools is striking; in 1873 there were four schools, in 1883 22, in 1900 400, in 1910 1,100, in 1920 1,800. According to the 1920 census, there are 150,000 untrained nurses in the United States.

NYASALAND PROTECTORATE (*see* 4.595).—Area about 40,000 sq. miles. Population (1924 estimate): Europeans 1,462; Asiatics 669; natives 1,210,344. The increase in the native population (10,410 since the 1921 census) was wholly due to immigration from Portuguese Nyasaland.

The five years before the World War were marked by steady progress, notably in the advancement of the natives. In 1913 Mr. (later Sir) George Smith was appointed governor, a position he held for 10 years, guiding the affairs of the protectorate with conspicuous ability. During the War the northern part of the country was invaded by the Germans from East Africa (Sept. 1914) and there was stiff fighting around Karonga on Lake Nyasa. Later, Nyasaland was one of the bases of General Northey in his operations against the Germans. Practically every European of military age joined the Nyasaland Volunteer Reserve; the Nyasaland battalions of the King's African Rifles rendered good service, while over 150,000 natives were employed as carriers.

Chelembwe's Rebellion.—Early in 1915 there was a revolt of some 500 natives in the Shire Highlands. The rebels were led by John Chelembwe, a negro, trained as a teacher by the American Baptist Mission, who had taken a university course in the United States and had subsequently built a church in Nyasaland and preached the independence of Africans. Chelembwe and his followers attacked a planter's house and killed three white men. One, a Mr. Livingstone (a descendant of David Livingstone), was decapitated, and Chelembwe preached in his church with Mr. Livingstone's head placed on the pulpit. The rising was quickly suppressed by volunteers and native soldiers. Chelembwe fled, was tracked by native police and shot dead (Feb. 1915). This revolt, a symptom of Ethiopianism, was no reflection of the attitude of the natives generally. Under the guidance of Christian missions—of which the principal are the Church of Scotland Mission, the Livingstonia Mission of the United Free Church and the Universities Mission—the natives, naturally progressive, made marked progress, both in education and industries. The doyen of the missionaries, Dr. Robert Laws, of the Livingstonia Mission, who exercised a powerful influence throughout the protectorate, celebrated the jubilee of his work in Nyasaland in 1925.

Economic Progress since the War.—A considerable number of white men who came from South Africa or Great Britain during the War settled in Nyasaland as planters. But the development of the country was greatly impeded by the lack of adequate means of exporting produce, and both European and native cultivation suffered severely, though 1924 proved a good year for trade. The shallowness of the Shire and Zambezi made river transport hazardous. To overcome this difficulty a railway, completed in 1915, was built from Port Herald, on the Shire, to Chindi, on the north bank of the Zambezi, and in 1922 another railway, from Beira to the southern bank of the Zambezi, was opened. Until, however, the Zambezi was bridged (which had not been done up to 1926) this means of communication was unsatisfactory. Moreover, as the railway from Port Herald stopped at Blantyre, there was only road communication with Lake Nyasa and the produce of the northern part of the protectorate had practically no outlet.

Most of the whites live in the Shire highlands, the climate rendering the greater part of the country unsuitable for Europeans. As stated by the governor, Sir Charles Bowring, in 1924, " the prosperity of the protectorate depends on the development of its tropical agricultural resources, partly by a limited number of European plantations, but principally by the natives themselves with European instructors." The natives, particularly the Yaos, the Amatonga and the Angoni, are keen agriculturalists, and with the provision of ocean outlets the prosperity of Nyasaland will be assured.

Coffee growing has been almost abandoned, and the chief exports are tobacco, cotton, tea and fibres. Imports, which in 1910–11 were valued at £111,000, had risen to £548,000 in 1924. Exports were valued at £97,000 in 1910–1 and at £583,000 in 1924. Revenue, which was £76,000 in 1909–10, was estimated at £285,000 in 1924–5, while expenditure rose in the years named from £108,000 to £305,000. Revenue was burdened by railway charges under guarantees given to the companies, the net railway revenue being insufficient to meet interest and sinking fund charges.

(F. R. C.)

OAKLAND, Cal., U.S.A. (*see* 19.935), increased in population 44% in the decade after 1910, reaching 216,261 in 1920, of whom 49,895 were foreign-born (including 4,536 from China and Japan). The Census Bureau estimate for 1925 was 253,700. After the World War there was a period of great industrial expansion. Over $150,000,000 worth of building was done in Oakland in the five years 1921–5. Bank debits nearly doubled between 1919 and 1923, increasing from $751,947,000 to $1,450,856,000. The number of ships which docked at the Oakland harbour in 1924 was 7,870. Factory products were valued at $22,343,000 in 1909; $134,756,000 in 1919; $122,491,778 in 1923. Hydro-electric power was furnished by two competing companies. The water supply (from the adjoining Berkeley hills) was still in the hands of a private corporation, but a project had been undertaken by the city, in co-operation with adjacent municipalities, for bringing a supply from the Sierra Nevada mountains (at a cost of $39,000,000) and its completion was expected by 1928. Additions to the public buildings included a city hall, a municipal auditorium, high schools, a health centre and a public library. There were 57 playgrounds, covering 290 ac., with 418 ac. additional in parks, a boulevard skirting Lake Merritt and two municipal camps in the Sierras.

OBERLÄNDER, ADAM ADOLF (1845–1923), German caricaturist (*see* 19.946), died in Munich May 29 1923.

OBSTETRICS (*see* 19.962).—Since 1910 a striking change has occurred in the science of obstetrics and its practice, chiefly as the result of its invigoration by the spirit of preventive medicine.

The term "preventive medicine" does not connote any special creed or peculiar doctrine in medicine. It is, in fact, merely an attitude of mind, which has developed slowly, but with increasing momentum during this century. Lip service has always been given to the ancient platitude that "prevention is better than cure," but till a knowledge of the causes of disease and the manner of its spread was obtained, the translation of these words into action was scarcely possible. With concrete examples, such as those afforded by the adoption of Listerian principles in surgery and midwifery, and generally by the lessened incidence of contagious and infectious diseases as their causation was worked out, the development and diffusion of preventive ideals throughout the whole of medicine has become easier and more general. This fresh mental attitude has produced a change of method throughout medicine, which might be described as the observation of the bodily functions in health and watching for the first sign of departure from the normal, rather than waiting till disease develops. Its first object is to seek out the causes of disordered function and remove them before they can become operative and, in the second place, when these causes are unknown, to detect the early signs of deviation from normality and restore the normal before trouble arises. The maintenance of physiological function in all bodily systems is its aim so that the cure or relief of established disease becomes the final resource of medicine and marks the failure to attain its earlier objectives.

If obstetrics is regarded from this point of view the difference between the new and the old practice will become obvious. Its immediate purpose will be to secure normal reproduction by detecting and removing all known causes of disorder of function and by observing the healthy pregnant woman from conception onwards to discover any sign of departure from the normal. Though a physiological state, pregnancy imposes a strain on the efficient working of every system of the body, and the thorough examination of the state of health of mind and body of the woman early in her pregnancy and further observation to see how she is standing the test seem but reasonable precautions. Apart from those who have some organic weakness and may break down under the strain, there are disorders of function that may develop in those previously of sound physique. A special strain falls on the excretory organs, and the kidneys and the liver may be affected and lead to acute or chronic disease. Hence the need for the routine and repeated examination of the urine. The good health of the mother throughout childbearing increases her resistance to infection (*e.g.*, puerperal fever) and her efficiency in the rearing of her family.

The care of the pregnancy itself is likewise a matter of greater concern than in the older obstetrics, not only because of the loss of prospective life, but because miscarriage is a prolific cause of operative interference, during or after its occurrence, and of infective and other diseased conditions of the reproductive tract and thus of subsequent disability. Premature labour results in the birth of weakly infants difficult to rear and is a prominent factor in the persistent high mortality among new-born infants. Another important object of the supervision of the pregnant woman, that of foreseeing and avoiding difficulties and complications during labour, provides the simplest illustration of the changed outlook in obstetrics.

Earlier Methods.—The usual custom of a generation ago was for the woman to retain her doctor for attendance on her confinement and for the doctor to do little more than note the expected date on which his services might be required. Unless consulted by the patient because of some disturbance of health, he might not see her again until summoned at the onset of labour. He then made a thorough investigation to see if all was straightforward or if there was any malpresentation or other difficulty, and was prepared to do his best to remedy any untoward condition that might be present or arise later, often being exceedingly ingenious and resourceful in so doing. His obstetric training as a student had been directed largely toward teaching him the management of normal labour, the emergency treatment of abnormal presentations and obstructions to the passage of the foetus through the birth canal and other complications during labour, and his reputation as an accoucheur was largely determined by his capacity to cope with emergencies.

New Methods.—The training of the modern student is conducted on other lines, and whenever a complication occurs the first question discussed is, "Could this have been foreseen?" and if so, the next question is, "What should then have been done?" and a comparison of the case as he has seen it with what it might have been had the emergency been anticipated is used to impress on him that the sole criterion of sound obstetrics is the securing of natural parturition and the prevention of unexpected difficulties and complications so far as the present state of our knowledge allows.

To avoid difficulties in labour, examination is begun about six weeks before the expected date of confinement in order to determine that the child is presenting normally and that there is sufficient accommodation in the bony pelvic canal to allow of its easy passage. This examination is repeated two or three times to make sure that no change has occurred in the presentation and position and that the child does not become unduly large to pass readily. For the most part these matters can be determined with a fair degree of accuracy by the ordinary methods of obstetric examination, but in difficult and special cases examination under anaesthesia and by X-rays may be required. Should it be discovered that even at six weeks before full time there will be difficulty in the child being born by the natural passages, because of rickety or other deformity of the pelvic bones, the question arises whether it is better to resign all hope of the delivery of a living child by the natural passages and perform Caesarean section or to induce labour and learn if the natural powers can effect the delivery of a small and premature infant.

If there does not appear to be any obstruction at the time of the first examination but at a later one there is evidence of a tight fit, labour should be brought on then to avoid the risk of the child becoming too large to be born without difficulty. By eliminating difficulties due to disproportion in size between the child and the mother's pelvic canal and such malpresentations as cross births and brow-presentations (which if allowed to

remain instead of being changed would result in complete obstruction) most of the serious difficulties in labour can be obviated in some way or other. The change in presentation and position of the child can be effected by manipulation through the abdomen, if done before the child is too large to be moved readily, and in favourable cases and under anaesthesia sometimes even up to and after the onset of labour, but if left until the waters have broken or labour is advanced, requires internal operative procedures with their additional risks of injury and infection.

In these instances the cause of difficulty can be anticipated and removed before labour begins, but there are also many conditions of which the cause is unknown so that the obstetrician must fall back on the second line of defence, that of discovering the earliest signs of disturbance, taking them as a warning of danger ahead and making the best possible dispositions. Premature detachment of the after-birth commonly shows itself by haemorrhage and all pregnant women whilst under supervision are warned to report at once any bleeding, so that immediate measures may be taken to lessen the chances of serious consequences. Albuminuria, discovered by frequent examination of the urine, oedema, excessive vomiting and visual disturbances are warnings of possible complication.

Prematernity supervision is in its infancy, but with experience of its working much more will be possible in the way of prevention. Many of its problems have scarcely begun to be worked out and an example of one of the most outstanding of them is worth a little consideration as an example of the problems that obstetrics has to face.

Merely to accept the principle that its primary objective is to secure natural reproduction is not sufficient to change practice. It is also necessary to show where the methods hitherto adopted are harmful. By the infusion of preventive ideals the vision is widened beyond the treatment of the individual case and the nation's maternal and infantile mortality and disability are brought under review. The success of obstetric methods must be tested by asking what price the nation pays in maternal mortality and disability for its new lives, and whether it obtains full value in new lives for the price paid.

When those wider questions are looked into, there is little ground for complacency among those responsible for the obstetric practice of the country. There has been no reduction in maternal mortality equivalent to the drop in the general death-rate or to the remarkable fall in the infantile mortality, which has been halved since the beginning of this century. Further analysis of the registrar-general's figures in England and Wales shows that septicaemia, a form of blood-poisoning practically eliminated from general surgery by the antiseptic and aseptic technique, is still too prevalent and still causes (as puerperal sepsis) about a third of the deaths in childbearing. The annual rate of maternal deaths per 1,000 live births registered in England and Wales is a little under four mothers. In the bad years immediately after the War, the rate was over four per 1,000. This may not appear large but it means that about 3,000 women in the prime of life die in childbearing with the loss of their maternal care to many more young children, and of these mothers over 1,000 die from puerperal sepsis, a preventable disease. Its prevention is a more complicated matter than, and a somewhat different problem from, that of surgical sepsis, because septic organisms may be present in the lower genital tract and spread upwards and into the blood stream, apart from any question of failure of aseptic technique on the part of the attendant.

The statistics of all maternity hospitals show that fever in childbed increases with all complications and difficulties calling for internal manipulation, all of which tend to the introduction or upward spread of infective organisms. The more prolonged and the higher up the tract the manipulation, the greater is the incidence of fever. By far the commonest operative interference is delivery by the forceps because it is advocated by many merely in order to shorten the patient's suffering. Instead of trying to secure natural delivery in cases of weak uterine action, a substitute for the uterine power is adopted in the shape of the muscular power of the attendant exerted through the obstetric forceps. The causes of weak uterine power are difficult to determine and often impossible to foresee, but here is a direction in which investigation is necessary. What is the meaning of the enormous increase in artificial deliveries, and, is the shortening of her time of pain worth the price of the additional risk?

Particularly calling for solution are the questions, how far modern social conditions have lessened the power of the woman of to-day to stand the hardship, fatigue, and mental and physical strain of child-birth and rendered her less capable of completing the expulsion of the child naturally than the mothers in the days before anaesthesia and frequent forceps delivery; what are the factors tending to produce this lessened capacity; and, how far are they removable?

The obstetrical centre of gravity has thus been shifted backwards from the care of labour to the supervision of pregnancy and a wider outlook over the reproductive cycle is taken so that the part played by obstetrics is seen as but part of the wider subject that is concerned with securing the health of the new generation at the minimum of cost to the old. The prematernity supervision looks forward to the nursing of the child and the rearing of the family. It anticipates the natural feeding of the infant by removing all causes that may interfere with breast feeding. It has an educational side and endeavours to inculcate sound principles of hygiene in the preparation for, and the care of, the babe when born, because success in this direction will mean a better start for the new generation. The observation of the developing child falls to paediatrics and the two subjects, as maternity and child welfare, have become a duty and charge to local health authorities, and as such are well known to the public.

In conclusion a tribute should be paid to the late Dr. Ballantyne of Edinburgh, as the advocate of prematernity supervision and the pioneer of the antenatal clinic, which more than anything else has served to further the permeation of obstetrics by the spirit of preventive medicine. *See* J. S. Fairbairn, *Gynaecology with Obstetrics* (1926). (J. S. Fa.)

OCEANIA or OCEANICA (*see* 19.988).—This name, in either form, is conveniently and not uncommonly used to cover all the small islands of the South Pacific Ocean which are not closely neighbouring to any of the larger lands, such as eastern Asia and New Guinea. The name is thus approximately equivalent to the former title South Sea Islands. The previous general survey of these islands is given under the heading PACIFIC OCEAN (*see* 20.436).

The War Period.—Oceania was not wholly free of incident during the World War. Very soon after the outbreak (Aug. 30 1914) a New Zealand expeditionary force occupied the former German island of western Samoa; in Sept. Nauru surrendered to a vessel of the Australian Navy; and in Sept.–Oct. the Japanese occupied the German Caroline and Mariana Islands. German vessels of war were at large in the Pacific at this time, and on Sept. 7 1914, a landing party from the "Nürnberg" wrecked the Pacific "all red" cable station on Fanning I.; but communication was restored by the operator. Moving eastward across the ocean, the German vessels bombarded Papeete, capital of the French island of Tahiti, on Sept. 22. Later, the South Pacific was outside the range of naval operations, and the remoteness of some of the islands was exemplified when Lord Jellicoe on H.M.S. "New Zealand" found in Oct. 1919 three Europeans confined on Christmas I., and ignorant of the cessation of the War.

Apart from the occupation of Samoa and the Carolines, certain changes in government took place during the period of the War. The Commonwealth Govt. of Australia took over the administration of Norfolk I. in 1914, and the executive council was made in 1915 to consist of six elected members and six members appointed by the administrator. The Gilbert and Ellice Is., previously a British protectorate, became a colony in 1916. Ocean, Fanning and Washington Islands were included later in that year, and Ocean I. became the seat of government. Christmas I. was included in 1919. The Wallis and Horne Islands, previously a French protectorate, were declared a colony in 1917. This annexation had been proclaimed four years earlier, but opposition was fomented in Fotuna (Horne Is.) by

Roman Catholic missionaries; and even in Uvea (Wallis), where the native chiefs had asked for annexation, French law could be only gradually introduced.

The so-called four-power treaty signed on Dec. 31 1921 by Great Britain, the United States, France and Japan at the Washington Conference, defined the mandated territories and the respective sovereignties in Oceania (Japanese in the Caroline and Marshall groups; Australian in the former German New Guinea and islands east of it; British over Nauru) and specified those areas in which no further fortification should take place. Japanese proceedings in the Carolines under military administration had previously evoked a good deal of criticism, especially in Australia, partly on account of their secrecy and partly on strategic grounds. The civil administration was established under the mandate in April 1922. A substantial influx of Japanese immigrants has taken place.

An administrative system which, it was hoped in some quarters, might be modified in course of the settlements after the War, but was not, was the Anglo-French condominium over the New Hebrides. Opinion has been freely expressed in Australia that the system is cumbrous and makes against progress, and that the French interest should be abolished by purchase or exchange, and the islands brought within the British sphere, under the Imperial Govt. or that of the Commonwealth.

Population.—The populations, according to recent census figures or estimates, of the principal groups covered by this notice are as follows:—

Caroline, Mariana, Marshall and Pelew Is. (Japanese), 52,222 including 3,671 Japanese (1920).
Cook Is., Niué and other oceanic islands belonging to New Zealand, 13,209 (1921).
Easter I. (Chile), est. 300 (1922).
Fiji (British), 157,266 (1921), including 3,878 whites and 60,634 Indians.
Gilbert and Ellice Is. (British), 29,897 (1921).
Marquesas Is. (French), under 3,000 (1923).
Nauru (British), 2,166 (1922), including 110 whites and 900 labourers recruited from other islands, and Chinese.
New Caledonia (French) 47,505 (1921), including 16,794 whites and 3,611 Asiatics. Nouméa, the capital, had 9,614 inhabitants, including 6,238 free whites and a penal element of 600.
New Hebrides (Anglo-French condominium), 55,000–60,000 natives; 275 British, 709 French, Indo-Chinese coolies and other immigrants, 1,032 (1923).
Tuamotu (Paumotu) Archipelago (French—the first is the proper form of the name), 3,715 (1924).
Samoa (New Zealand), 37,299 (1924): (American), 8,194 (1922).
Society Is. (French, including Tahiti), 7,145 (1924).
Tonga (British protectorate), 24,935 (1921).
Tubuai Is. (French), about 3,000.
Wallis Is. (French), about 4,500.

The decrease of native population continues in most of the islands; from whatever cause, the islands under French control, especially the Society, Tuamotu and neighbouring groups, appear to be specially affected. The French administrations have been criticised for lack of care for the wellbeing of the natives: in New Caledonia they are said to make little effort to put native labour to use, and indeed their control is not wholly effective. There was a small native rising there in 1917. Japanese, Tonkinese and Javanese labour is imported. The Fijians and the Gilbert and Ellice islanders also diminish in numbers. In the latter colony the Govt. enforces the prohibition of alcohol; but it is still urged that the adoption of European clothing, as the natives become better educated, weakens their resistance to pulmonary diseases. And not only here, but in many parts of Oceania, an influenza epidemic in 1918 caused many deaths—4,000, for example, in Tahiti, and 1,000 in Tonga.

Nevertheless, there are exceptions to these unhappy conditions. Thus American Samoa was free of the epidemic, and the native population is estimated to have increased over 40% during 22 years of American control. Native education has in some instances become a matter more of government concern and less exclusively in missionary hands. Thus down to 1916 education in Fiji was almost entirely a missionary organisation; but the Govt. then passed an Act rendering all schools which comply with certain conditions eligible for state aid. The Gilbert and Ellice Govt. introduced a new system in 1920, and the New Zealand administrations have taken similar action.

Among immigrant Asiatic peoples, apart from the Japanese, the most important group is that of the Indians in Fiji. Indentured Indian labour was stopped in 1916, though free labourers could still be admitted. Under indenture the general condition of the Indians was good, though isolated abuses gave rise to private philanthropic interference from Australia. But many Indians in Fiji have entered into trade and become well-to-do, and having (on the whole) benefited by residence in the colony proceeded to strikes and seditions, the unrest in India having been reflected in Fiji and fomented by imported agitators. Stern measures by the Govt. have been effective.

Trade.—Copra, phosphates and fruits are the chief articles of export from Oceania. Some of the islands are leased to coconut companies, and in many the industry flourishes, but not in all. The cost of importing labour and collecting the produce proves too heavy in some instances, as for example Christmas I., which has changed ownership more than once, and in 1923 employed only two Frenchmen and 18 Tahitians under a British company. Some of the copra-yielding islands are liable to occasional hurricanes which may almost wreck the industry—there was one such in Niué in 1915; but as a practical method of celebrating the end of the War 15,000 nuts were planted there. Drought also may be a deterrent of the copra industry. Thus in the Gilbert Is. in 1915–8 there was a shortage of rainfall, with only 14 in. in the driest year; the normal ranges from 80 to 140 in. annually. The fruit-growing industry of the Cook Is. is believed capable of great expansion. Fiji exports principally sugar and molasses, copra, bananas and trocas shell. Rubber is grown, but the industry could not withstand the low prices of 1920–1. An interesting attempt to acclimatise the mocora palm is contemplated in Niué, with a view to making Panama hats from the fibre; the natives are skilled weavers of pandanus hats, but the trade has declined.

Nauru is the chief producer of phosphates (*see* NAURU). The excellent quality of the nickel and chrome ores of New Caledonia has attracted attention, but there is no great development owing to difficulty in obtaining labour, and only companies established under French law are permitted. Makatea in the Tuamotu group has become a phosphate ground of some importance, and is administered separately from the rest of the group. But the trade of the eastern French islands generally is somewhat stagnant, and the development of Tahiti as a holiday resort from America (an attractive consideration being the absence of prohibition) has been seriously discussed. (*See* ARCHAEOLOGY: *Oceania*; GUAM; FIJI.)

OCEANOGRAPHY (*see* 19.967).—In 1912 the results of the South Polar expeditions became known. Roald Amundsen landed on the great Antarctic Ice Barrier (at the Bay of Whales, in south lat. 78°, and west long. 165°) and travelled over the land towards the Pole, which he reached on Dec. 14 1911. Capt. Robert Scott had left England before Amundsen and in ignorance of the intention of the latter to seek the South Pole. Scott took his previous route, *via* the Beardmore Glacier, towards the Pole, not the easiest way, but much the most interesting one from the scientific point of view. The party (Scott, Wilson, Oates, Bowers and Evans) reached the South Pole about a month after Amundsen and, on their return, encountered a series of blizzards in which all perished.

After Scott's last voyage Shackleton made two further expeditions to the south polar regions. In the first one he left England

in the "Endurance" (in 1914); reached south lat. 76° 34′, drifted north, was beset in the ice and lost his vessel, the crew being landed on Elephant Island (in south lat. 62° and west long. 55°). This voyage is famous for the fine boating cruise made under the command of Capt. Worsley. A small party left Elephant Island in a whaleboat and, after a voyage of 14 days, reached South Georgia from where they sent assistance to the wrecked crew of the "Endurance." Shackleton again sailed for the Antarctic in Sept. 1921, in the "Quest" but died (of angina pectoris) at South Georgia on Jan. 4 1922. These voyages have roughly fixed the notions at present held about Antarctic geography (*see* POLAR EXPLORATION).

An important expedition set out (Oct. 1925) for the Antarctic regions on Scott's old vessel, the "Discovery," strengthened and refitted for special work. This is the eighth exploring vessel bearing that name—the first one having gone to Hudson Bay in 1602. The voyage is primarily intended for the investigation of the whaling industry and it will be supplemented by the continuous work of a laboratory on the Island of South Georgia. The cost of this well-found expedition is largely borne by the Government of the Falkland Islands, and important scientific results are confidently expected (*see* WHALING).

Arctic Expeditions.—The first and most notable Arctic expedition since 1913 is that of Stefansson, who left Alaska in 1913 with a vessel called the "Karluk." Stefansson demonstrated, for the first time, how Arctic investigators could trust themselves freely to the ice, finding food there and being able to keep themselves perfectly healthy (*see* ARCTIC RESOURCES). He investigated part of the Beaufort Sea, the huge inaccessible region of frozen ocean lying between the Pole, Alaska and Western Siberia. He explored some of the Parry Islands and supplemented Nansen's observations on the drift of ice in the North Polar Ocean: this takes place in a large cyclonic eddy having its centre in north lat. 83° 50′ and west long. 160° tending to leave the Arctic region through the wide passages between Greenland and Iceland and between Iceland and Europe.

It is now known (though no formal results have yet been published) that important fishery and oceanographic investigations have been made by the Russian Govt. on the Siberian Continental Shelf. Off the coast, from Novaya Zemlya to the Behring Straits there is an enormous region of flat shallow water (the greatest in the world) and some great rivers (such as the Lena, Obi and Yenesei) open into the sea here. It is stated that the fishing grounds in the neighbourhood of these estuaries are unusually productive. An American expedition (the Macmillan one) is working in the Arctic regions.

Roald Amundsen made an attempt in 1925 to reach the North Pole by aeroplane. Starting from Kings Bay, in Spitsbergen, a small party reached north lat. 87° 44′ (in west long. 10° 20′) but were then forced to descend. After abandoning one of the planes, they returned to Spitzbergen in the other. A small expedition led by Algarsson left Liverpool for Arctic investigation in 1925 but returned after some three months. Two small but very successful expeditions to Spitzbergen were organised by some Oxford scientists. Thus there have been several investigations during the post-War period, but these have added little to our knowledge of the oceanography of the North Polar Ocean beyond that resulting from Nansen's highly productive voyage with the "Fram" in 1895.

A good deal of general marine biological and oceanographical investigation is now being carried on in the shallow seas of the north-west of Europe by the various maritime states. This work is mainly concerned with questions of the productivity of the sea fisheries, with the search for new trawling grounds and with the investigations necessary for the elaboration of regulations of methods of fishing both within the territorial waters and on the high seas.

Physical Oceanography and Geodesy.—The tendency in oceanographical investigation is towards research into the physics and geology of the ocean floor; towards the physical and mathematical study of currents and tides; and towards the investigation of oceanic meteorology.

Permanence of the Ocean Beds.—There has always been much discussion as to whether or not the great oceanic depressions have always been permanent features of the face of the earth. In the latter half of the 19th century, this was generally believed. Nowhere on the dry land are there any sedimentary rocks that appear to have been deposited at the bottoms of oceans comparable in depths with those we know—that is, there are no formations known that resemble, for instance, the Globigerina Ooze now being deposited on the Atlantic floor. On the other hand the geographical distribution of many species of plants and animals points very decidedly towards the existence in the past of land connections between the various continents, and this evidence cannot be put aside. It is now believed that, in the North and South Atlantic, in the central part of the Indian Ocean, and possibly in the central part of the Pacific, there were, during the Mesozoic period, extensive land regions that have now subsided. Thus there are indications that large regions of continental land have been depressed to form the floors of deep oceans, but there are no clear indications that deep ocean beds have ever been elevated to form dry land. It is possible that the quantity of water on the surface of the earth has been increasing throughout geological time. It is known that fluid heated rock (volcanic magma) contains much water and it is probable that, in the course of geological time, large quantities of water have thus reached the surface as these magmas, are extruded, cool down and weather away (*see* GEOLOGY).

Age of the Oceans.—Fairly satisfactory data now exist for the formation of estimates of the age of the oceans. The evidence comes partly from the study of radioactivity (*q.v.*): it is known that helium and lead are the end-products of radioactive disintegration of certain minerals and from the ratios of these materials to their parent substances it is believed that a period of several thousands of millions of years must have elapsed since the first solid and cool earth-crust was formed. Some cosmographic investigations (due mainly to Jeans and Jeffreys) suggest pretty clearly that at least about 1,300,000,000 years have elapsed since the first oceans were formed.

Formation of the Ocean Floors.—Oceanic soundings are gradually accumulating (though they are still very few in comparison with what are needed) and a general idea can now be made as to the forms of the great oceanic depressions.

Geosynclines.—In general an ocean bed is a great, flat plain and there are few marked elevations or depressions on it. But, in general, the marginal regions are deeper than the central ones and there is a tendency for the arrangement of mountain chains running parallel to the ocean coast (as along the whole western sides of North and South America). Also the marginal regions of oceans tend to be regions of volcanic and earthquake disturbance. (The coast of Japan and the coastal part of California, for instance.) Jeffreys has shown how very probable it is that the central part of the earth has still a very high temperature; that a relatively thin outer shell is cold and has ceased to contract and that the hot central mass is still losing heat to the outside. Therefore the ocean floors must warp downwards at the margins, but must tend to rise slightly at their central regions. Our knowledge of oceanic depths supports this conclusion. In the Pacific notably, but also in the Atlantic and Indian Oceans, the "deeps" (that is, the regions of over 3,000 fathoms in depth) all tend to be situated near to the continental lands.

Relative Ages of the Oceans.—These features of high mountains, formed by foldings of the earth, and running parallel to the oceanic margins, are well exhibited on the American side of the Pacific. On the Asiatic side we have chains of islands (the Aleutians, Kuriles, Japanese, Philippines, etc.) which form the natural boundaries of the ocean bed. In many places these islands (the "insular arcs") can be shown to be formed by earth-foldings. They are often volcanic and earthquake regions. Thus the Pacific Ocean is bounded by geosynclines—that is, the coastal mountain foldings and, outside of these, the marginal oceanic depressions. These geosynclines exhibit great activity, which is indicated by faulting of the strata, earthquakes and volcanic eruptions. Therefore the Pacific Ocean is still in the making, so

to speak. Indeed among the island archipelagoes there are evidences of continued subsidence. The Atlantic is a much older ocean for, except in the West Indian region, there is not much evidence of activity as in the Pacific, while the geosynclinal land elevations and depressed marginal oceanic deeps show signs of being smoothed out. The Indian Ocean is probably still older, in the geological sense.

The Theory of Isostasy (*see* ISOSTASY).—When the intensity of gravity was measured at many places on the surface of the earth, some remarkable results were obtained. The measurements are made by observing the rate of swinging of a standard pendulum (on the land) or by observing the barometric pressure simultaneously with the temperature of boiling water (on the sea). Where necessary corrections are made, the intensity of gravity is everywhere the same (with the exceptions of small deviations). Yet it ought to be less over the ocean bottom (where some two to three miles of earth crust are replaced by water) than over the continental land. Therefore, again, the materials of the earth crust must be heavier on the ocean floor than on the continental plateaux. At a certain depth beneath the surface all rocks are exposed to such enormous pressures that they are in a potentially self-crushed condition so that "flowage" of their materials must take place when there are stress-differences. There is a continual adjustment of pressure so that when shallow sea regions near the land are loaded with sediments from great rivers, material beneath this loaded region flows to underneath the continental plateau (which has undergone erosion).

The Wegener Hypothesis.—Connected with the theory of isostasy is Wegener's hypothesis of the mode of origin of the oceanic and continental earth-features. Beneath the continental plateaux and the ocean beds there is the "plastic," crushed, earth-crust layer, and the hypothesis is that the great continental land elevations actually slip on this crushed layer. The Atlantic has been formed, it is stated, by the slipping westward of the Americas and when the outlines of Western Eur-Africa and eastern North and South America are compared it is seen that the one continental land mass would approximately fit into the other. The coastal mountain ranges on the Pacific margin of the Americas are said to have been formed by the crumpling of the crust under the horizontal pressure set up by the westward drift of the American continents, and so on. The hypothesis requires that there should be evidence of progressive change of longitude. This has been claimed but the observations are doubtful. It also requires a motive force—some stress-difference under which the continental land masses yield and shift place relative to the earth-axis. This is difficult and no satisfactory verification of the Wegener hypothesis has been made (*see* GEOLOGY).

Tidal Investigations (*see* TIDES).—Much fine work, both on the theory of the tides and on the methods of tidal prediction has been done at the Liverpool Tidal Institute. The methods of prediction have been greatly improved and methods of forecasting deviations from the predicted results (which may be due to winds) are being worked out.

Long-period Tides.—The work of Otto and Hans Pettersson on the occurrence of long periodic variations in the tide-generating force due to the sun and moon has important oceanographic consequences—should the theory be confirmed and established. The Petterssons have shown that there are absolute maxima of tide-generating force recurring at intervals of about 1,600 years. The last maximum was in 1433A.D. and the next will be in 3300 A.D. Important effects preceded the last maximum—thus the coast of Greenland was relatively free from ice during the period of the Norse voyages related in the Sagas. Iceland was nearly free from volcanic eruptions during the period 800 to 1250 but such phenomena were relatively frequent during the period 1290 to 1348. During the 13th and 15th centuries, the Baltic was frequently frozen over between Denmark, Germany, Sweden, Gothland and Esthonia. About 1287 the Zuider Zee was formed. The Pettersson Theory relates many of these occurrences to the changes in the North European ocean current system set up by the high tides during the periods of maximal force (that is, at intervals of 1600, 93, 19, 9 and 4½ years).

Marine Biology.—The most important result of oceanic biology during the post-War period is the completion of Dr. Johs. Schmidt's fine investigations on the life history of the freshwater eels. It has now been demonstrated that all the eels of Europe and America migrate out into the region of the Atlantic Ocean roughly coincident with that of the Sargasso Sea. There they spawn and, after this single reproductive act of their life-times, they die. The eel-larvae, or *Leptocephali* take several years to migrate towards the continental shores where they undergo metamorphosis into the well-known elvers and then ascend the rivers. Having attained maturity after 4 to 7 years they return to the Atlantic Ocean to spawn and die.

References to most of the matters treated in this article will be found in J. Johnstone, *Introduction to Oceanography* (Liverpool, 1923).
(J. J.)

OCHS, ADOLPH SIMON (1858–), American newspaper proprietor, was born in Cincinnati March 12 1858, of Jewish parentage. His father, who had left Bavaria for the United States in 1846, settled in 1865 with his family in Knoxville, Tenn., where the son studied in the public schools and during his spare time delivered newspapers. At the age of 15 he became a printer's devil on a Knoxville paper. Advancing rapidly in newspaper work, he moved to Chattanooga in 1877 and in 1888 gained control of the reorganised Chattanooga *Times*, which soon assumed a high position among the papers of the South. He was one of the founders of the Southern Associated Press and served as president. In 1896 he obtained control of *The New York Times*, then in financial difficulties and with circulation greatly diminished. He formed the New York Times Co., and having placed the paper on a stronger financial foundation after four years became the majority stockholder. With a daily issue on Aug. 18 1896 of 18,900 (of which over half was returned unsold), the circulation increased rapidly, reaching an average of 392,695 in 1926, (360,000 daily and over 600,000 on Sundays). The annual receipts exceeded $22,000,000 in 1925, probably equalling those of any other American paper. In 1920 the staff of *The New York Times* numbered 2,800. It was classed as an independent Democrat publication, an advocate of sound money and tariff reform, and consistently opposed William Jennings Bryan in his presidential campaigns. By the fairness and comprehensiveness of its presentation of news, editorial moderation and ample foreign service, it made secure a high place in American journalism, becoming widely read and influential throughout the country.

The *Times* has been a pioneer in many fields of newspaper publishing: in the introduction of rotogravure printing to the United States, in the reception of a new service by wireless, in the improvement of advertising typography and in the censoring of advertising to protect its readers from dishonest and misleading offers. It is also worthy of note that in an age of syndication, or exchange of news features among a great many newspapers, the *Times* has pursued a wholly different course, preparing its news and other articles solely for its own columns. The *Times* Co. also publishes the *Book Review and Magazine* (sections of the Sunday edition); the *Annalist*, a financial review appearing on Fridays; the *Times Mid-Week Pictorial* on Wednesdays; *Current History Magazine*, a monthly, started during the World War. The *Index* of the *Times*, begun in 1913 and published quarterly, forms an invaluable guide to contemporary events, to be compared only with the similar Index to *The Times* of London. In 1901 Mr. Ochs became proprietor and editor of the Philadelphia *Times*, later merged in *The Philadelphia Public Ledger*, of which he was sole owner from 1902–12, when he sold it to Cyrus H. K. Curtis. The Times Co. also has in the Wide World service a news photograph agency covering the entire world. (L. WI.)

O'CONNELL, WILLIAM HENRY (1859–), American cardinal, was born at Lowell, Mass., Dec. 8 1859. He graduated from Boston College in 1881, and then went to Rome where he studied theology at the North American College (1881–4), being ordained priest June 8 1884. He became rector of the North American College in 1895 and was consecrated Bishop of Portland, Me., May 9 1901. In 1905 he was selected as special papal envoy to the Emperor of Japan. He was appointed co-adjutor to Bishop

Williams of Boston, Mass., Feb. 8 1906, taking the titular archbishopric of Constantia. He became Archbishop of Boston Aug. 30 1907, and was created cardinal by Pope Pius X., Nov. 27 1911.

ODER (*see* 20.2), a European river. The Oder rises in Czechoslovakia, flows through the mining area of Upper Silesia, and crosses Germany, receiving a number of tributaries, of which the chief are the Warthe and the Netze,[1] both rising in Poland.

It is utilised by three main currents of traffic; traffic between Berlin and Stettin; goods transported to or from the mining area of Upper Silesia (this traffic has diminished since the partition of Upper Silesia between Germany and Poland); and traffic to and from Poland via the Warthe and the Netze, thence by the Bydgoszcz (Bromberg) canal and the Brda (Brahe) river towards the Vistula. Poland has placed on the navigation of these two tributaries certain restrictions based on her conception of their legal status.

Problem of International Status.—The Oder and all the navigable portions of its system, which provide natural access to the sea for more than one state, were declared international under Article 331 of the Treaty of Versailles. Article 341 places the Oder under the administration of an international commission consisting of three representatives of Prussia, and one each of Poland, Czechoslovakia, Great Britain, France, Denmark and Sweden. Under Article 343 it was the duty of this commission at once to prepare an act of navigation. As the commission failed to reach an agreement regarding the territorial extent of its powers, the British Govt. on Aug. 23 1924, brought the dispute before the League of Nations, in virtue of Article 376 of the Treaty of Versailles.

The advisory committee of the communications section of the League appointed a commission of inquiry consisting of M. J. Hostie, president, Gen. H. O. Mance and Prof. L. Babinski, which studied all the legal aspects of the question and also examined the situation along the Warthe at Poznań (Posen), along the Netze (Notéc) at Naklo, and along part of the Old Netze between Naklo and Lisi-Ogon. The majority of the commission reported that "Oder" in the sense of Article 341 should be taken to mean the whole international system; moreover it was of opinion that although Article 331 only includes in the system the navigable parts which naturally provide more than one state with access to the sea, the sphere of territorial application had been extended as a result of Article 338, which provides that the provisional definition given in Article 331 shall ipso facto be replaced by the general definition of the Barcelona Convention on the régime of navigable waterways of international concern. As regards consideration of fact, the Warthe, from its junction with the Oder as far as Pogorzelice, indubitably fulfils the conditions of the general definition laid down in the Barcelona Convention. The Warthe, as far as Luban, carried considerable traffic before the War. It was navigable for craft of 400 tons, which could proceed with full cargoes at mean water level. The sector between Luban and Pogorzelice was navigable for craft of 150 tons and carried an appreciable amount of traffic, although mainly of local character. The Netze, which has been canalised between Kreuz and Naklo, is navigable for craft of 400 tons. In pre-War years this waterway carried a considerable amount of traffic—mainly transit traffic proceeding from or towards the Bydgoszcz canal. The commission considered that the Netze below Naklo should be regarded as naturally navigable; the portion of this river above Naklo should not be presumed, in its natural condition, as being navigable in the sense of the Barcelona Convention.

Transit Committee's Suggestion.—The committee for communications and transit suggested on Nov. 27 1924, that the jurisdiction of the international Oder commission should extend upstream on the Warthe to and above Poznań (Posen), and upstream on the Netze as far as Ujście (Usch), from which point as far as its confluence with the Vistula through the Bydgoszcz canal, the waterway should be subject to the régime of the Barcelona Convention. In the opinion of the committee this solution, while it takes account as far as possible of the various legal and technical standpoints, is also in the general interests of navigation. The choice of the limit on the Warthe needs no comment; for purely technical reasons the limit on the Netze might have been Naklo, but this would have represented in fact a decision regarding the legal controversy. The committee preferred to reach an agreement on a practical basis. Thus Ujście was chosen; but on the other hand, realising the importance before the War of the transit traffic over the junction between the Oder and the Vistula, the committee desired to guarantee to international navigation, including floating, the benefits of an international régime on this waterway. Existing treaties guarantee to Germany freedom of transit across Poland, along all means of communication for traffic to and from East Prussia. Consequently, for a certain category of traffic, this waterway already enjoys an international régime as regards transit. It was thought that under the circumstances the proposed extensions of the international régime would not encounter any serious opposition.

However, at its eighth session in July 1925 the advisory and technical committee felt bound to note the fact that the opinion given with a view to conciliation had been accepted by all the governments represented on the Oder commission except those of Germany and Poland. The German Govt. expressed no opinion, while the Polish Govt. definitely refused to accept the solution. (R. Rn.)

[1] The Netze is a tributary of the Warthe.

ODESSA (*see* 20.3), in the Ukrainian Soviet Republic, had a population of 434,857 in 1920 as compared with 631,040 in 1912. The city was bombarded several times by the Turks during the World War, taken by German forces in 1918 and occupied by the Bolsheviks in 1920. A new mole and a special ice-breaker were built for the harbour before the War, but Odessa's share in the trade of Russia was then declining and plans had been made for further improvements in the harbour. A scheme was reported to be again under consideration in 1925, whereby it is proposed to construct a grain harbour, an additional mole and warehouse accommodation. Ground was being reclaimed and dredging carried on in 1925 and Odessa was made a free port by the Russian Govt., in the hope of improving trade. The quay accommodation in 1926 allowed 12 or 13 steamers to unload at once.

O'DONOVAN, WILLIAM RUDOLF (1844–1920), American sculptor and painter (*see* 20.9), died in New York City April 20 1920.

OFFICE APPLIANCES.—Many office tasks, being of a repetitive character, naturally adapt themselves to the principle of "division of labour," and consequently to the use of machinery also. But these facts alone are not sufficient justification for the purchase of appliances. Four purposes are considered by good office management in deciding when the use of machinery is advisable. These are:—

Objects of the Appliances.—1. To save labour. This saving should be evidenced in a reduced pay-roll. Hypothetical savings of "half a man" are seldom realised.

2. To save time. In many cases this is more important than the saving of labour; to speed up a slow routine, extra expenditure is often an economic advantage.

3. To promote accuracy. Mechanical methods are advisable when accuracy is vitally important and otherwise difficult to obtain.

4. To avoid monotony. The substitution of a machine for manual repetitive movements will usually achieve this.

Inventive skill and genius have not been lacking to meet these needs, and the list of available devices is very long, machinery being now extensively used.

Adding and calculating machines are largely used for the promotion of accuracy, and save time by avoiding extended search for errors. The ordinary clerk is usually incapable of correctly handling a large amount, even of simple calculations, with a fair degree of accuracy by the mental-manual method, and these machines have therefore become a practical necessity for the modern business office.

Adding Machines.—All adding machines may be used for addition, subtraction, multiplication and division; but as certain types are better adapted for multiplication and division, a technical distinction has grown up in the trade between adding and calculating machines, the latter being used more extensively for multiplication and division.

There are two principal types of adding machines: those which print on paper the amount being added, and those which do not—the former being known as listing, and the latter as non-listing machines. The listing machines are again divided into two classes, the first being the full keyboard model carrying a row of keys numbered from 1 to 9 for each column, and the machine of the second class having 10 keys arranged in two or three rows. Each of these keys represents a digit, and the depression of a key for an item automatically causes progressive columnar position. Thus, if 23 is to be added, the 2 is first depressed, then the 3, and the mechanism takes care of the numerical order. The items are printed either on a roll of narrow paper or on a wide form held in the carriage of the machine.

Some models have two sets of adding dials—one for accumulating individual totals, the other for accumulating a grand total. On some machines a " split " feature provides for splitting the printing mechanism into two or more sections, so that several columns may be listed and added at the same time and the total of one or more columns printed. On others, subtraction is accomplished by means of complementary numbers, a " complement " being any number which, added to another, makes a full number. Thus if the digits are changed to 9's—as 9, 99, 999 and so on—and a 1 then added, we can convert any number into a full or complementary number on the keyboard of any adding machine. The complementary numbers are usually indicated by small figures on the keys, the two digits on a key, if added, invariably making nine. Other machines perform subtraction by depressing a subtract key. Multiplication is consecutive addition. Thus, if 26 is to be multiplied by 5, it is merely added five times. For division, the divisor is subtracted from the dividend as many times as it is contained in that dividend, the number of subtractions being automatically registered on the counting wheels as a quotient. There is also a small portable adding machine, weighing about seven pounds, operated with a pull-down lever keyboard. A very small adding device, known as a vest pocket machine, is operated by inserting a pick, or stylus, in positions for the amounts.

Calculating Machines.—Where rapid addition, multiplication, subtraction and division are required, and no need for a printed record exists, calculating machines are used. They do not print a record of the items, but indicate the result on total dials. One type, known as the key-driven, causes the items to appear immediately on the dials when the keys are depressed, the operation of a crank clearing the figures off the dial faces again. As with adding machines, the four arithmetical operations are all performed as variations of simple addition. In another type, known as the key-set, the amounts are first set up on the keyboard and operation of the machine, either by hand or by motor, effects the calculation. The total dials, located in the laterally moving carriage above the keyboard, show the total in addition, the product in multiplication, the minuend or remainder in subtraction and the quotient in division. Proof dials, located in, above or below the carriage, show the multiplier in multiplication and the divisor in division. An extra set of dials is sometimes provided, which furnish an additional check for accuracy by showing the amounts set up on the keyboard. The dials are cleared by various means, distinctive with each make of machine.

For subtraction, the amount from which the deduction is to be made is set up, the operation of the machine causing that figure to appear on the total dials. The figure to be subtracted is then set up and the machine operated, and the answer appears on the total dials. Multiplication is consecutive addition, though in some models multiplication is by means of a plus bar; in others, by means of an extra row of multiplying keys. Division is consecutive subtraction, some models dividing by means of a minus key, while another model provides for setting up amounts by means of levers pulled down to the desired numbers, this machine otherwise conforming to the key-set type.

Book-keeping Machines.—The so-called book-keeping machine is in reality a device for posting on loose ledger sheets or cards. The amount is not merely entered to the account as in hand book-keeping—to be added and balanced at a specified period—but a balance is struck each time a posting is made. The original entry from which the account is posted is usually a sales ticket, credit slip or copy of the invoice (*see* BOOK-KEEPING).

All such machines are designed to print and add an old balance, print and add debit items, print and subtract credit items and compute the new balance, in some cases printing it automatically, in others showing it in the adding and subtracting mechanism so that it may be copied in the proper column by the operator. Proof of the correctness of posting varies with the type of machine. One type is an adding machine which subtracts directly; it is equipped with means for printing dates, folio numbers, characters and abbreviations, and with a tabulating carriage which moves automatically to the next column as each amount is computed and printed, and in some cases returns automatically to any required position on the printing line. Both vertical and horizontal columns are added, subtracted and computed. Items are set up as on an adding machine, the operation of the motor causing them to be printed, added or subtracted. When a new balance is printed, the accumulator clears, ready for the next operation. Some models have two counters, thus making it possible to compute individual balances and accumulate a total of all postings. The keyboard may be split into two sections so that both ledger and statement can be inserted in the carriage and posted at the same operation—that posting being automatically repeated.

The design of a second class of book-keeping machine embodies a typewriter—on which any description may be typed—and a calculating machine, built as one unit. Some machines add and subtract in vertical columns; others compute amounts across the sheets as well. The typewriter carriage moves to correct column positions by means of a decimal tabulator. Typing the amounts on the number keys effects addition or subtraction. The amounts are visible in registers or totalisers placed either on the carriage truck, in positions corresponding to the columns to be added or subtracted, or at the front of the machine below the keyboard. In posting, a new balance is computed, and the operator types in the proper column the amount appearing in the register which functions to compute across the sheet. If the typing is correct, this register clears. Ledger and statement are made at the same time, in some cases by means of a carbon and in others by the split-platen method, one machine of this class being unique in that its typewriter section is mounted on a carriage which moves from left to right across a flat printing surface on which the forms are held, a back and forward motion providing line spacing. Registers are mounted on the rear of the typewriter section, and ledger and statement are posted at one operation by means of carbon.

A third class of machine carries, below the typewriter keyboard, a 10-key keyboard which controls the calculating mechanism. Here the split-platen method is used for making ledger and statement at the same time. Still another class, used for ledger posting and instalment accounts, follows cash register design, amounts being set up on a push-in key-set keyboard, and turned into the mechanism by the operation of the motor. There is a sliding printing table on which the forms to be posted are inserted. Two forms may be posted at the same time, the amount being printed on one and repeated on the other. This machine automatically computes and prints the amount of the balance outstanding on each account. Debits and credits are classified and a total of each is accumulated, as many as 18 individual and two group totals being obtainable. A detailed record of all postings is printed on a strip of paper inside the machine.

Billing Machines.—The writing of an invoice for goods sold, by means of a carbon duplication, can be made to serve other purposes also, and it is quite common at one writing to make the invoice, the original sales record, the shipping notice, the shipping record and other memoranda required for various kinds of business. By means of calculating devices, the amounts of the items may be computed, and totals accumulated for controlling accounts. Combination typewriters designed to do this work are known as billing machines. These are designed to write, at one operation, the several necessary copies of orders, invoices, bills of lading and other forms, and in some cases to compute amounts as they are written. Cut forms, printed and padded in individual sets so that each set is torn off and loose carbon inserted between the sheets to make the necessary copies, are used with some machines. Others use continuous-length forms, which provide multiple copies of the same or related forms, in rolls or folded flat, these forms being fed through the machine with the carbon interleaved between the copies, so that it is not necessary to insert new forms after writing each set.

Among the billers which write, but do not compute, is an ordinary correspondence typewriter equipped with an inbuilt carbon-changing device which removes the carbons from a set of continuous-length forms just written and inserts them in

another set. Another non-computing biller has a standard keyboard typewriter mounted on a carriage which moves from left to right across the flat writing surface over which the forms are fed. Cut forms may be used with this machine, and it may be equipped to add in vertical columns and to cross compute as well. Book-keeping machines which combine a typewriter with a calculating mechanism have been adapted to billing work which requires the adding or subtracting of amounts as they are typed. One such has an inbuilt carbon-changing device which provides for the use of continuous-length forms; another uses cut forms and may be equipped with a split cylinder so that billing and ledger posting can be done simultaneously.

Still another embodies a typewriter and a calculating mechanism which handles addition, subtraction and multiplication, and is operated from a separate 10-key keyboard below the typewriter keyboard. By means of a split-platen, billing and ledger posting can be done at the same time.

Accounting and Tabulating Machines.—The preparation of statistics requires, first, the sorting of data, and, second, the accumulation, by classes, of the amounts involved. Machines for this work were first used by the U. S. Census Bureau, but are now being rapidly adapted to business uses, such as cost work, sales analysis and similar work.

Cards printed with vertical columns numbered from 0 to 9, or from 0 to 12, and separated into fields of one or more columns, each field representing an item, such as department, job number and so forth, form the basis of two systems. Facts are expressed in figures, letters or symbols, and are recorded by perforations on the card at the proper numerical positions, made by a punching machine which operates like a typewriter. The cards are then arranged by a sorting machine, according to a predetermined classification. Contact—electrical or mechanical, depending on the make of the machine—sets the mechanism in motion. The cards are next fed through the tabulating machine, which makes a printed final report, in multiple if so desired. Contact through the perforations causes the machine to designate and add what has been perforated into the cards—listings, sub-totals, totals or grand totals being obtained, depending upon the arrangement desired for the report. When detailed listing and printing is not required, a non-printing tabulator registers the quantities in counters which accumulate the totals, the figures being posted by hand to report forms.

Another type of machine is built on the same principle as the book-keeping machine of cash-register design. Twenty-seven keys, each representing a classification, accumulate individual totals, and as many as three grand totals can be obtained and the number of items in each classification counted. A continuous permanent record of all operations is made within the machine on a roll of paper called a visible audit sheet, and notations may be hand-written opposite any printed item. This record may be used as a posting medium, a proof sheet or a permanent record. A ticket may be issued on any operation, showing the date, serial number, identifying numbers, symbols for the totals used and the amount. It may be used as a voucher, pay ticket, receipt, requisition, or posting medium, or for filing purposes. The same information may be printed on any form inserted in the printing-table.

Duplicating Machines.—In offices there is much need for devices that will quickly produce multiple copies of typewriting or handwriting, for the time and labour thus saved is an important economy. Sometimes only a few copies are needed, sometimes many. For a limited number of copies, say up to five or six, the carbon method of duplication is perhaps the cheapest in most cases; but where from 5 to 100 copies are required, the hektograph process is preferable.

Stencils.—For a still larger number of copies, the stencil methods and type methods are available. With the former, the stencil was originally made on a sheet of wax-covered paper, which was written upon either with a stylus or with a typewriter from which the ribbon was removed—a system that had many defects. The modern method utilises a specially prepared sheet of tough, flexible tissue, which can be filed away after using and used many times. One manufacturer provides a glass-topped, electrically illuminated table for making stencils by hand with a stylus. Typewriting, handwriting and drawing may all be combined on one stencil sheet. The duplicator consists of a hollow revolving cylinder, partially covered by an ink pad, over which the stencil is fastened. Each revolution brings the stencil sheet in contact with the paper, and the ink, passing through the characters or design, makes the impression. From 1,500 to 5,000 copies can be made in an hour, depending on whether the model is hand- or motor-operated and whether it is automatically fed.

Hektographs.—The hektograph is many years old, and its operation is based on the principle of absorption. The original writing is done on a sheet of hard bond paper with a water-soluble ink or with a typewriter ribbon impregnated with such ink. This sheet is then placed in contact with a moist surface of gelatin or clay composition, and the writing is absorbed from the paper and appears in reversed form on the gelatin or clay surface. Then, by placing a sheet of blank dry paper on this moist surface, the impression is transferred to the paper. The gelatin was originally used in flat tin pans, and in this form the hektograph was of little use in the office, as registration was difficult. The clay form of hektograph was, and is, extensively used for the reproduction of drawings by architects and draftsmen, because it is a simple matter to prepare this composition for large sizes of work. The modern hektograph uses the old principle, but the gelatin is coated on a long band, a small portion of which is exposed at a time. This band runs over a flat iron surface. Registration is accomplished by a special feeding device. The unique feature of the hektograph duplicator is its use in routines of order or billing systems, in which from 10 to 15 copies of the same writing (or any portion of it) may be transferred to sheets of various sizes and shapes. Such copies are much clearer than carbons, and the paper does not have to be thin. The hektograph can also be used for bulletins of which 100 or less copies are desired.

Type Reproduction.—There are several devices which duplicate from type, the principal feature of most being a simple method of setting the type, which does not require a trained typesetter, the printing also being simplified by means of a revolving drum. The style of type most used is the imitation typewriter face, and the chief use is for the reproduction, through a ribbon, of facsimile typewritten letters, there being also a special device which may be used for the reproduction of the signature. A printing-ink attachment makes possible the use of printer's type and of electrotypes or stereotypes curved to fit the drum. Some models are hand-fed and operated; those which are automatically fed and motor driven attain a speed of 2,400 to 4,800 pieces an hour. Another machine produces letters from typewriter type cast on a linotype machine, at the same time filling in the name, address and salutation from slugs—one for each name on the mailing list—which change automatically as each letter is printed through a ribbon, the slugs being filed for future use. The speed is 1,000 letters and envelopes an hour, the latter being addressed from the same slugs. Certain machines which print from typewriter type are really small presses adapted to the printing needs of the layman, and print from printer's type, electrotypes, linotype, monotype, flat zincs and half-tones.

Automatic Typewriters.—The automatic typewriter is designed to produce actual typewritten letters at three times the average speed of a typist. Its mechanical movements are controlled by a paper roll, similar to that of a player-piano, in which perforations representing characters on the typewriter keys are made by a perforator. When an entire letter has been thus perforated, the paper is cut from the roll, and its ends are cemented together to form an endless belt, which is then placed over the drum of the automatic typewriter. The operator writes by hand the name and address and starts the automatic device. Pins dropping through the perforations into slots, as the roll is carried forward by the revolution of the drum, actuate the typewriter keys, causing the typing of the words; when all the perforations have passed over the drum, the operator removes the finished letter and then repeats. Insertions of special words or sentences may

FIG. 1. Photostat. This machine copies photographically any written or printed material, and automatically develops, fixes and washes the photographic copy. A machine used to save the labour of keeping documents. FIG. 2. Electric Printing, Tabulating and Accounting Machine. This machine tabulates data which have been previously sorted on another machine, not shown in illustration, and prints the tabulation automatically on a suitable sized sheet. FIG. 3. The Protectograph. A machine for printing the amount, and at the same time shredding the paper on cheques, to avoid the possibility of forgery. FIG. 4. Graphotype. On this machine, a metal stencil is embossed, which is later used for addressing. Fig. 5. Brunsuiga Calculating Machine. FIG. 6. Bookkeeping Machine. Used for posting debit and credit items on ledger sheets. Accounting is balanced with each posting. FIG. 7. Postal Permit Printer. FIG. 8. Postage Meter Machine. A device which seals the envelope and prints indicia which take the place of the ordinary postage stamp. The meter is locked by the postmaster, and postage is paid for the amount shown on the meter. FIG. 9. Addressograph. Prints from metal stencils made by the Graphotype. Addresses envelopes, statements and the like automatically.

be made by hand at any desired point. One operator can, without difficulty, control three or four machines.

Photocopying Machines.—A special photographic machine, in which a roll of sensitised paper coated on rag stock is used as a negative, photographing directly without the intervention of plates, has of late years been highly developed and used extensively as an office device. It offers a means of quickly producing a fac-simile copy of any document, and has therefore to a great extent eliminated the laborious hand copying of records, deeds, insurance applications, contracts and the like. The equipment consists of a large camera combined with a developing machine, so that after an exposure is made the sensitised paper is carried first to the developing bath and then to the fixing bath. Dials and levers control all operations, and the machine is so scientifically adjusted that an office boy can turn out perfect copies. The colours are reversed in the first print, called a "black print;" that is, the whites in the original are black and the blacks are white. As the photograph is made through a reversing prism, the letters appear exactly as in the original. A white positive print is made by re-photographing the black print. By continuing to photograph the original, as many black prints as desired can be made; and as many positives as required can be made by photographing the black prints.

Addressing Machines.—These are in reality devices designed for duplicating small pieces of writing. Originally designed for duplicating names and addresses—hence the name—they now have many other uses, such as the making of invoices, statements, receipts and other office records. They are of especial value in businesses where the same list of names and addresses must be repeatedly used. Each name and address must first be impressed upon a metal plate, cut on a fibre stencil or set in type, according to the character of the machine. The metal plate is prepared by an embossing machine operated by hand or electric motor; a blank plate is inserted in the machine, and the required characters are selected by an indicator and stamped into the metal. Some embossers have a typewriter keyboard, the embossing being performed by depressing the keys. Some metal plates carry a name card and others a record card for recording relevant data. A fibre stencil consists of a frame in which is mounted a panel of semi-transparent paper coated with a gelatinous material, some frames having spaces for the insertion of relevant data. The name and address are cut by means of a typewriter from which the ribbon has been removed, a special device holding the stencil while it is cut. When printer's type is used, slugs with the names and addresses are cast on a linotype machine.

Addressing machines, despite many structural differences, operate on the same general principle. The metal plates, stencils or slugs are fed from a magazine to the printing point where the envelope or other matter to be addressed is placed either by hand or by a mechanical device. Directly over the printing point is a stamping arm which comes down on the envelope when the machine is operated, thereby bringing it into contact with the plate, stencil or slug either directly, in case ink is used, or through a ribbon. As the arm rises, another plate comes to the printing point, the one just used passing to a receiving machine, where it re-files itself in original order. Models are hand, foot-treadle or motor operated, the speed varying from 1,000 to 15,000 impressions an hour. Special models are designed for publishers addressing on large envelopes, on mailer strip or directly on the margins of newspapers and magazines. The adaptability of addressing machines is greatly increased by attachments, some of which are so common as to be considered standard equipment. The metal plates and fibre stencils are filed like index cards in drawers kept in cabinets, slugs being filed in galleys and stored in cabinets. One machine is unique in that its metal plates are linked together to form an endless chain; they pass to the printing point from a reel on which they are wound and they are then re-wound on another reel, the reels being stored in cabinets.

Hand Stamp Affixers.—Stamps provided in rolls of 500 by the post-office are locked in a stamp affixer and applied to envelopes by the downstroke of a plunger, moisture being applied in some cases to the stamp, in others to the envelope. Extra containers, allowing for quick change from one denomination to another, are furnished with some models. Some machines are spring-locked; others are key-locked to guard against unauthorised operation; still others furnish the further protection of counting the stamps used, the number appearing in figures on a recorder.

Sealing Machines.—These are designed for the rapid sealing of large quantities of envelopes. The envelopes are fed to the machine one at a time, either by hand, semi-automatically by holding them against revolving feed rollers or automatically from a hopper—depending on the type of machine. The gummed flaps come in contact with a moistening device—a wick, a roller or a metal disk—which receives its water supply from a reservoir or by a position feed suction. The envelopes then pass between sealing rollers and are ejected from the machine.

Permit Mailing Machines.—An office having occasion to mail a thousand or more letters a day could greatly expedite their passage through the routine of mailing if the office were permitted to cancel the stamps or to print some indication that postage was paid. For this purpose, a U.S. Post Office regulation, passed in 1920, provides for the printing of the permit, or indicia, as it is called, directly on the envelope in the office of the mailer. Permit mail is of two kinds—metered and non-metered; for either, the licence must be obtained from the Post Office Dept. through the local postmaster, the mail being delivered to the post-office by the sender, as such mail is handled separately. Machines which handle non-metered mail print the indicia, seal the envelopes and count the pieces. The impression must show the postmark—city and state, month, day and year, denomination and sender's permit number. The number shown in the counter of the machine after a mailing is completed, multiplied by the denomination, gives the amount of postage to be paid. Payment is made either with each individual mailing or by a cash balance carried at the post-office. Certain machines will print the indicia without sealing, seal without printing, or count without either sealing or printing.

The basis of the meter system is a printing and recording mechanism demountable from the machine with which it is used, so that it can be taken to the post-office to be set for a given number of impressions, payment being made at that time, and the mechanism locked and sealed. Two sets of registers indicate how much postage has been used. A separate meter is used for each denomination, and any number of meters can be secured for one machine. The indicia are the same as those printed by the non-metering type, except that the sender's meter number is shown. The speed of such machines varies from 150 to 200 a minute. One type of machine is adapted for use with either the metered or the non-metered system. In 1924 the U.S. Post Office Dept. issued a regulation permitting first-class mail to be sent out with pre-cancelled stamps attached. The stamps, obtained in coils from the post-office, are applied by a hand stamp-affixer and the envelopes are then passed through a non-metering permit machine which seals and counts them and prints the postmark and additional cancellation required. Where bulk of mail does not warrant a permit machine, the postmark and additional cancellation are applied by a rubber stamp bearing a changeable date. One sealing machine is adapted to metered, non-metered and pre-cancelled systems, without mechanical alteration.

Cash Registers (*see* 5.446).—Motor-driven models are now available.

Autographic Registers.—On many occasions it is necessary to make by the carbon method several copies of pencil memoranda. The autographic register is a device for making at one writing an original and from one to six copies of sales slips, bills of lading, requisitions and other business records on continuous forms. These, interleaved with carbon, are retained within the register and fed across a writing table or platen. Some registers use rolled forms, one roll for each copy of the record; others use flat folded forms. Various type of registers have various methods of aligning the several copies that make up a set. As a written

set is issued from the register, either by pulling out by hand or by the turn of a crank, and is torn off against a knife edge, another set, automatically leaved with carbon, is brought into a writing position.

Coin-handling Devices.—In all business houses where large amounts of coin are handled and packaged daily, the use of mechanical devices for sorting, counting and packaging saves time and labour. Coin-counters simply sort mixed coins into denominations. The usual type of machine has a disk revolving in a hopper, and the coins are carried by the disk to a rail finger from which they roll by gravity and are sorted by dropping through slots of various diameters into separate boxes. From 1,000 to 12,000 coins can be separated in a minute, depending on whether the model is hand or motor operated. Coin-counting and packaging machines count the coins and deliver them into bags or wrappers, and, in specific cases, check pre-determined amounts into bags. One denomination of coin is dumped into the machine and a revolving disk throws the coins to the outer edge of the hopper, where they pass under a register which counts them.

In some models the coins fall through a stem into a tubular wrapper which the operator has previously placed there; other models wrap with continuous rolls of paper, fed down as the coins are counted; when the required number of coins are in place, they are carried over to the paper and tightly wrapped, the machine automatically locking off further passage of coins. Coin-counters and separators serve the dual purpose of counting and sorting coins of mixed denominations at the same operation. The registering devices of some machines provide for a totalled sum in connection with each separate adding counter; others have a sub-total and a total register. Other coin-handling devices are bag-loading machines; proving and bagging machines which recount and bag coins that have been previously separated; continuous counting and bagging machines, which count and bag coins at a high rate of speed; counting machine heads, which handle one denomination at a time and handle metal tokens also; manual counters and packagers, which combine in one operation hand-counting and wrapping.

Dictating Machines.—By means of the cylinder phonograph the time of a stenographer taking notes may be saved. The executive who uses this system speaks into the mouthpiece of a small machine which records his voice by engraving on a revolving wax cylinder. He may pause in his dictation, correct an error, and at any time listen back to what he has said. When the cylinder is full, a typist puts it in a transcribing machine placed alongside her typewriter, and the reproduction of what has been dictated is carried to her by receivers placed over her ears, she typing the words as she hears them. The engraved surface of a used cylinder is removed by a shaving machine so that it may be used again and again.

Typewriters (*see* 27.501).—One machine which has been on the market a comparatively short time is practically noiseless in operation, because the principle of pressure printing instead of percussion printing is utilised. Another is electrically powered and can be operated either from a direct or an alternating current; the keys are touched lightly—about one-quarter of an inch depression—and electricity takes up the burden. Portable typewriters serve the need of the individual for a personal writing machine. Their construction embodies many features of standard office typewriters. The machine is usually secured to the bottom of the case in which it is carried, a permanent base being thus provided, making its use convenient under all conditions. The weight varies from 7 to 12 pounds. A wide selection of special keyboards and type arrangements for engineers, doctors, chemists and all those requiring special symbols and extra characters is available.

Cheque Writers and Protectors.—Besides writing the permanent and unchangeable amounts on cheques, thereby protecting, as far as it is mechanically possible, against losses from raised and forged cheques, these devices save time and labour in concerns which issue large quantities of pay-roll cheques and in banks and establishments which issue dividend cheques periodically. Protection is afforded by printing, by shredding or by perforating the amount, using acid ink in one or two colours. The amount is written in words, in figures or in words and figures. Certain models protect the payee's name as well, by "crimping" or shredding an un-inked design over it. After a cheque is inserted in the machine, the amount to be written is selected by slide levers set in vertical columns, by a hand wheel or by an indicator on the dial, depending on the type of machine. Some models require one stroke of the operating handle for each word or number; others print the whole amount at one operation. In some models the amount is visible before and after printing, and in certain cases the name of the user is also printed. Repeated writing of the same amount on a number of cheques, without change of set-up, is a feature of some cheque writers. An interesting development is the cheque writer with many combinations of foreign denominations for use in foreign banking.

Cheque Certifiers.—These devices print a form of acceptance on cheques, either through a ribbon from a bronze die or from steel wheels inked by a felt pad. Some number the cheques with consecutive serial numbers. Certain models are locked against unauthorised operation.

Cheque Endorsers.—Motor-driven machines are used for endorsing large numbers of cheques. Impressions are made from either a rubber or a metal die inked from rollers and having movable type for dates and batch numbers. Cheques are fed by hand, one at a time, to those models designed for use alongside an adding machine, so that as each cheque is listed for clearing-house, transit, or deposit, the operator turns it over and drops it into the endorser, which prints the endorsement and places the cheque in its original order in a tray beneath the machine. Other models provide for feeding a large number of cheques held at the feeder guide by the operator's hand.

Cheque Cancellers.—Enduring and inerasable evidence that a cheque has been paid, together with the date of payment, is provided by machines which perforate the cancellation through cheques, and if desired, the bank's American Bankers Association number. Dating of deposit slips, notes, mortgages, and other papers may also be done. Hand models cancel from 100 to 225 cheques a minute; motor-driven models are speedier.

Cheque Signers.—Pay-cheque signing is speeded by devices which sign from five to 10 cheques at once. A sheet of cheques is placed on an extension table under a writing frame to which are attached five to 10 fountain pens controlled by a monitor penholder. As the operator signs a sheet of cheques they are pushed into a tray and another sheet is brought into position.

Finding and Filing Devices.—Simplification of filing and locating data compiled in digest form is achieved by three mechanical devices differing in construction, operation and purpose. The purpose of one is to find a single card by number. It is a metal, desk-like affair, in the top of which are 10 trays, each holding numerically filed cards numbered from 0 to 999—1,000 in all. A card is found and filed according to its number. By depressing the proper number-keys of the finding mechanism, the corresponding card is instantly raised above the others in the file. In filing a card, the operator raises the card immediately following to indicate the filing position. Means are provided for finding misfiled cards.

Another device finds a single card by means of the general class or name under which it has been classified. This system uses a steel drawer, on the front of which are two rows of keys marked with the classifications, such as "Farm Lands," "West Side Property," etc. The keys are connected with rods extending back through the drawer. One card can be filed under many classifications, by means of clips placed in position along its lower edge, which correspond to the classifications desired. Pressure on the proper key raises the desired card, together with all those having a clip corresponding to the key. A tap returns the card to position.

A third system provides for the automatic selection and segregation of cards according to any number of classifications, the basis of the system being the card. The top carries a brief summary of the record, or can be extensive enough for a posting

record. The body of the card is perforated, two vertical perforations constituting a " position " to which some classification is assigned. Each card is prepared for automatic selection by converting the two holes of significant positions into a slot by means of a hand-operated slotting punch. The cards are placed in a file drawer, which has a brass front perforated to conform to the cards. If, for example, the device is used for a list of garages, and all garage cards are to be selected, a steel rod is placed in the position designating garages. If all garages having service stations for a particular motor-car are to be selected, another rod is placed in the position designating that information. The more rods, the finer the classification. The drawer is then inverted, and the cards that are suitably slotted drop down. A rod inserted at the bottom of the drawer locks them in place, and when the drawer is held upright, the desired cards are held above the others in the file. When the work is finished, the locking rods are removed and the cards fall into place.

Visible Index Systems.—An operation on a card system may be divided into several parts: (1) locating and removing the card; (2) making the record or noting the information; and (3) returning the card to place. If the second part is a small proportion of the whole time required, the total operation may be greatly simplified by using the so-called visible system.

The cards are usually mounted on panels in such manner that they overlap, showing only the title line, a slight lifting movement revealing the whole card. The panels are housed in several ways. Sometimes they fit into steel cabinets and may be pulled out at a convenient angle for posting or removed entirely. In other cases, the panels—with cards inserted on both sides—are hung vertically, either on a circular track which rotates at the touch of a finger to bring the panel with the desired card before the eye or on a straight track so that they turn like the pages of a book. Another type of visible index is in book form, the cards being either held on panels inserted between the covers or fastened into the binder, as in a loose-leaf binder. Still another kind, which looks like a card drawer with the sides and ends cut down, consists of an aluminium tray in which cards tabbed at different heights so that a portion of each tab is always visible are held by a lock rod. Aluminium guides permit indexing. Pulling forward a guide exposes the tabs of a group of 24 cards, and the full surface of any one is visible when the intervening ones are thrown over. With each type of visible index colour signal systems may be used to call attention to pertinent facts.

Electric Paging Systems.—By audible code signals sounded throughout the premises, this equipment immediately locates individuals who are away from their desks. The central station is usually located near the telephone switchboard, and the telephone operator sends the signals.

Telegraph Typewriter.—An electrically operated typewriter used in hotel offices, banks and other businesses where information is daily transmitted to distant points, transmits messages in written form to any number of distant stations. As the message is typed on the sending typewriter, the words are written simultaneously and automatically by the distant receiving typewriter. The paper is fed from a roll mounted on a frame behind the typewriter. Tabulated forms and duplicated copies can be written. The telautograph is used for a similar purpose, but the message is handwritten instead of typed.

Credit Authorising Systems.—Three distinct types of systems are used for transmitting to a department making a charge sale, the credit department's O.K. on the sale. One is an electric telephone system with a switchboard in the credit department and a telephone in each sales department. As the sales person calls the credit department, she places the slip in an aperture in the telephone, and the credit authoriser causes his approval to be printed on it if the sale is approved. (W. H. L.*)

OFFICE MANAGEMENT.—The office is that part of an enterprise which is devoted to the direction and co-ordination of the various activities of the enterprise. It is characterised by the gathering, classification and preservation of data of all sorts; the making, using and preservation of all kinds of records; the analysis and utilisation of these data in planning, executing an determining the results of operation; the preparation, issuin and preservation of instructions and orders and the compositio copying and filing of written messages.

Though clerks and clerical work have existed for centuries, an large groups of clerks for decades, it is only in recent years that th management of clerks, or office management, has become a proble of importance. This is wholly due to the rapidity of industrial chang which is best shown in the United States. In 1880, when there we but 172,575 clerks in that country, mostly book-keepers and accoun ants, the problem might be considered as practically non-existen but in 1920, when the number of clerical workers of all kinds ha grown to 2,951,008, it assumed proportions that could not b ignored. In 1920, one in 10 of all persons engaged in "gainf occupations" was a clerical worker. The change was necessitate by the exigencies of an ever-growing large-scale industry. Whi business organisations were small, and direct contact existed betwee producer and consumer, beyond simple bookkeeping few record were required, there was little written communication betwee sections of an organisation, and consequently few clerks were needed All this has changed, and to-day the office has attained a position major importance in business.

Many offices employ more than 100 clerks each, and a considerab number employ several thousands. Evidently the employment such numbers of workers requires management of a high order, y it is only recently and among the most progressive companies tha the subject has received the attention it deserves. Ingenious systen of record keeping and filing have been invented, scores of clev appliances and marvellous office machines are available (*see* Offic Appliances), but the problem of securing the greatest result for th least expenditure of effort has not been given the attention in th office that it has in other lines of endeavour. This is due to the new ness of the problem, but there are signs that this condition is su to change as time passes.

Frederick Winslow Taylor (*q.v.*), the "father of scientific manag ment," was himself probably the first person to apply—at least in limited measure—scientific principles to office work. In Copley biography of Taylor is shown a "Time Note," dated about 188 giving "piece-work" rates on 17 clerical operations, the implic tion being that Taylor had at least studied these operations, foun the best method of performing them and controlled them to th extent that he offered an incentive wage for their accomplishmen

The Human Element

The major divisions of office work are given herewith, but no necessarily in the order of their importance.

Organisation.—The most essential factor here is clearly define lines of authority, and its lack is the greatest defect to be foun in many companies. In the struggle for advancement it seem difficult to prevent officers from claiming more authority tha is granted them, and where confusion of this kind exists, loss morale invariably results. Functionalisation—one of the leadin principles of scientific management—is as efficacious in th office as elsewhere. The office manager himself holds a func tional position—that of managing clerks, wherever locate Where this principle is fully carried out, work, instead of bein departmentalised, will be functionalised, and therefore performe much more effectively. Thus, a stenographer employed exclu sively in taking notes and transcribing letters, will do much mor effective work than one who also keeps and files records, answe telephone calls and performs other miscellaneous work. Func tionalisation, however, is to its fullest extent only feasible i large offices. It is uneconomical to have too many department under the charge of one officer. A chart of the organisation, an an organisation diagram, both giving not only the position each individual in the office but his duties and relation to other are necessities. Also there should be standard methods for pe forming each task, and written standard practice instructio so that the carefully devised methods may be perpetuate Otherwise great loss of output will result.

Personnel Methods.—Progressive records of each employee performance are necessary as they serve as a basis for futur advancement. Special tests for ascertaining the ability of ne employees will prevent to a large extent the great wastage continuous hiring and discharging. Many psychological test special ability and trade tests have been prepared, extensivel used and found advantageous (*see* Intelligence Tests). Whil there are many clerical positions which demand the very highes intelligence, all clerical work does not, and much of the simple

clerical work is found irksome when allotted to those capable of a higher grade of activity. Training is extremely important, though often sadly neglected. In some offices the various lines of promotion are laid down and made known to all employees, so they can prepare themselves for advancement. Some offices also have officers who devote their activities wholly to employment, and all persons who are to be discharged are referred for final adjudication to this officer—the employment manager. The advantage here is that competent employees are not lost to the organisation solely because of the personal pique of some hasty or temperamental officer. The employment manager also ascertains by tactful questioning the reasons why employees leave, and by a careful, classified record of such reasons is enabled to check bad practices, and to determine any other causes for dissatisfaction.

Turnover.—The "rate of turnover," that is, the ratio of employees leaving to those on the pay-roll, is a most important factor in good office management. An average cost of over $100 is represented in the training of a new employee who replaces one who has left, so that it is evidently desirable to retain employees for long periods. Turnover is dependent upon many factors. If employees are not properly selected, many replacements will be needed; if salaries are not right, physical conditions bad, or the relations of officers not as they should be, there will be many voluntary separations. A minimum turnover is considered to be about 10% annually. Length of service depends upon much the same conditions as rate of turnover.

Routines and Methods.—A routine is a collection of separate operations through which a piece of work successively passes. Division of labour has been highly developed in office work, and few operations are complete in themselves. Routines as a rule are seldom consciously developed but come into existence gradually through the use of machinery combined with hand-work. As a result, operations wholly or partially useless and of little or no value to the "finished product"—the result desired—are frequently found. Methods also have generally speaking a similar evolution, and yield great results from scientific research. Unless both routines and methods are carefully studied, there is apt to be much waste.

Control of Output.—To secure maximum results for minimum effort, a continuous and uninterrupted flow of work is necessary, and this is one of the most difficult achievements in office work. In the manufacturing of any material commodity the work can be precisely scheduled, step by step, and the maintenance of a steady flow is largely a mechanical problem, as every piece of similar character goes through precisely the same steps. But in the office there is the added difficulty that office work of similar character does not always take the same course; and even in some work of exactly the same nature, the flow is governed by conditions beyond the control of the office manager. Because of this fact it was, until very recently, considered impossible to plan and schedule office work. Peaks, that is, periods demanding intensified and additional work, were handled either by overtime work, or by the permanent maintenance of a sufficient force of clerks to handle them, both plans being evidently wasteful. Analysis of this matter, however, showed that in many cases they could be adequately met by pre-planning. The office force should be well balanced, and sufficiently large to handle average conditions; but a sufficient number of clerks should be trained in several operations. Then by utilising the idea of the "flying squadron"—a selected group of clerks that can be used almost anywhere in an emergency—most of the minor peaks can be handled without difficulty. Major peaks can be dealt with by a re-adjustment of working force and the employment of extra clerks for positions which require only a minimum of training.

Clerical Output.—On this subject all the major factors of office management converge, and all have a bearing upon it. Under conditions where all factors have been scientifically studied, clerical output is invariably much greater than in organisations in which they are largely ignored. Thus in the office of the latter character the average output of a stenographer will rarely exceed 100 sq. in. per hour, while in a scientifically managed office this particular output will be increased to an average of 200 sq. in. per hour. The maintenance of the latter rate does not depend alone upon the skill and application of the stenographer—for 200 sq. in. per hour is but 30 words a minute, while the world's typewriting record is over 800 sq. in. per hour—but largely upon other factors outside the control of the operator and decidedly within that of the office manager. As with typewriting, so it is with all other clerical operations; the output usually depends much more upon the efforts of the management than upon those of the individual clerk. The effort should not be to obtain the highest possible output from any individual, but that which should be expected from a first-class worker.

The Incentive Wage.—Still another factor which aids in obtaining a high clerical output, is an incentive wage of some kind, wherever it is possible to measure the work. The various methods of incentive wage used in other lines of business endeavour have all been tried in the office, some with considerable success, others with disastrous results. In the cases of failure the main causes generally are that (1) work was not properly standardised; (2) not properly measured; (3) steady flow not obtained; (4) work not properly controlled; and (5) no adequate check upon its quality. Piece-work in the office is not so generally applicable, because the worker must have a guaranteed minimum wage, and it is not always possible to supply him with sufficient work to make that wage on a piece-work basis.

The Mechanical Side

The preceding factors deal almost wholly with the management of the human element, and now other factors must be considered—those physical factors without which efficient management is not possible.

Arrangement.—The physical arrangement of an office affects all other factors of management. As most offices are in large cities, rentals are high, and therefore space must be conserved. For this reason the cubicles of the old-fashioned office are giving way to the open office. Departments having relations with each other should be contiguously located, and the seating of the workers in each department be regulated also on this principle. Work should flow in straight lines. Adequate light, both daylight and artificial, should be provided, the standard of the latter being placed by experts at not less than 10 foot-candles (*see* Illumination Engineering). The totally indirect system, in which the light is thrown from its source to the ceiling, and from thence reflected down, is considered the best. Ventilation is an important matter also. Experiments show that the best ventilating system is that which brings in fresh air from the outside without altering it in any way, this being superior to the elaborate washed and heated air systems (*see* Heating and Ventilation). Excessive noise is also detrimental to good work, and noisy machines, if numerous, should be segregated.

Equipment.—Under this head are included desks, tables, chairs, filing cabinets and similar furnishings. The old-fashioned roll-top desk is being rapidly eliminated, and as the present tendency is to the extended use of small loose-leaf books and cards, the high-standing book-keeper's desk has largely disappeared. At present the usual office desk is too large and contains too many drawers, and as clerks have little need for more than one or two drawers, a table is generally preferable. The size of a desk depends naturally upon the character of the work, but a desk larger than 54 in. x 30 in. is rarely needed, though no desk should be smaller than 40 in. x 30 inches. Chairs to be comfortable require designing to fit the human anatomy in an upright seated position. A few good anatomical chair types are available, but most of the others are uncomfortable.

Office Machinery.—Here the greatest development has taken place, office appliances being now available for almost every occasion (*see* Office Appliances). There was a tendency to use machines to the exclusion of competent brainwork, but office managers are beginning to see that this is a mistake.

Correspondence.—This is naturally an extremely important part of office management, not only between the company and outside correspondence, but within the organisation itself. The present tendency is toward brevity and clarity, and the florid style and redundant expressions of the so-called "business English" are in process of elimination.

Filing.—The vertical system of filing has almost entirely superseded the old-fashioned flat file, and elaborate systems have been greatly simplified. Its greatest present misuse is the filing of valueless and superfluous material. The filing problem requires not only adequacy in equipment and system, but also accuracy, which necessitates adequately trained operators, for misfiled papers may easily cause great loss.

Stock-keeping.—In a large office the maintenance and issue of an adequate stock of all forms in use becomes a problem in scientific stock-keeping. Order and neatness are necessary, and an adequate location system, so that material can be found with a minimum loss of time. Stores should be classified according to some well-devised system, and there should be a perpetual inventory and a systematic method of issuing stores to, or on the order of, authorised persons.

Intercommunications.—This factor is a most important one in large offices. The telephone is of course the most common method, but there is usually a large transfer of papers from one part of the organisation to another, and this must be taken care of by well-organised messenger systems with regularly scheduled trips. In many offices automatic belt systems or other forms of conveyors are used. Mechanical devices of other kinds are automatic signalling systems, automatic telephones and so forth.

Forms.—Most office work is performed by writing upon some kind of blank form, whether they be detached or loose-leaf forms. The quality of paper selected for any form should be governed by the use to which it is put. If it is to be written upon with pencil it is wasteful to use a high-grade paper designed for writing with ink. When forms have a temporary value only, the paper should be of a cheaper quality than that of forms to be kept for a number of years. Selecting standard qualities of paper for these various purposes requires considerable study. A large variety of colours should not be used, as many of them—particularly the reds and blues with their varying shades—are difficult to read under artificial light. Not more than nine standard sizes of forms are usually needed.

Salary Standards.—In most offices salaries vary widely and often unreasonably, clerks doing similar work frequently receiving widely different salaries. Some of the best-managed organisations have made a careful gradation of salaries, with a maximum and minimum for each class of worker. The minimum is that salary which a clerk is entitled to as soon as he is assigned his position, and the maximum the highest salary which the company can afford to pay for that type of work. Such gradation eliminates gross inequalities, gives more equitable payment for results and minimises dissatisfaction among the office force.

Summary

Office management is highly complicated, and requires a specialist—a manager of high order who at the same time thoroughly understands clerical work. The scientific approach to the factors of office management may be briefly defined. First it is necessary to define thoroughly the purpose of any work about to be undertaken, for if this is neglected the path of the subsequent investigation is likely to follow incorrect lines. Then the problem should be carefully analysed by dividing it into its factors. These preliminary steps, though simple in a statement, are by no means so simple in fact. The next step involves a careful search for all the facts in the situation which govern each and every factor in the analysis. It is a very common oversight to gather an abundance of facts on one part of a problem, and ignore or minimise other parts. To infer, without investigating, is a most prolific source of error, the method of actual test being by far the best. These three steps are precisely those of experimental science, and may be called the scientific method of thinking out a problem. By its use, the office manager can correctly approach each problem and devise the right method, otherwise known in management as "the one best way." With the best method secured, it is then necessary to select the person best fitted to perform it, for all cannot be equally proficient in the same things. The person best fitted for any particular task will invariably produce better results than the so-called "average" person. When found, it then becomes necessary to teach the person who has been thus selected.

These six steps constitute the basic procedure in any form of scientific management and lead up to the seventh, which is planning. Without careful planning, all the scientifically designed work which has gone before will be wasted. Finally, to secure the best results it is vitally important to win the co-operation of the workers. An office force labouring without interest or enthusiasm will accomplish some results, but certainly not of the type desired by a competent office manager. The management which does not and cannot secure co-operation is necessarily defective. These eight steps cover the basic principles of scientific management in all activities. There is also a considerable tendency toward the simplification of office methods and the entire elimination of much that has been done in the past, on the ground that it is either superfluous or not worth the effort expended. These tendencies are continuously accelerated by economic conditions. Scientific management will be the principal means of reducing the numerical growth of office workers.

Galloway, *Office Management; its Principles and Practice* (1925); J. W. Schulze, *Office Administration* (1919). (W. H. L.*)

OHIO (*see* 20.25), a State of the United States of America. In 1924 Ohio had a population of 6,219,330, an increase of 20·8% in the decade 1910–20 or of 30·5% since 1910. The density of population rose from 117 per sq. m. in 1910, to 141·4 in 1920. There was a marked increase in the negro population of the cities owing to migration from the South, and also of the foreign element. More significant was the drift from rural districts to cities. In 1910 the urban population in cities and incorporated villages of 2,500 inhabitants or more, formed 55·9% of the total; in 1920 it was 63·8%. In 1925 eight cities had a population in excess of 100,000.

Cities with 100,000 Inhabitants or Over (1925).

Akron	208,435[1]	Columbus	292,222
Canton	114,648	Dayton	178,642
Cincinnati	418,792	Toledo	288,792
Cleveland	922,864	Youngstown	159,870

[1] 1924.

Communications.—A flood in 1913 wrecked the two principal canals, the Miami and Erie from Cincinnati to Toledo, and the Ohio and Erie from Portsmouth on the Ohio river to Cleveland: They had not been restored by 1926. The lower part of the Muskingum river and that part of the Ohio bordering the State has been canalised. The chief development in transportation has been the expansion of interurban traction service and the establishment of motortruck lines. In 1919 there were 4,223 m. of electric railway. In steam-railway mileage there was no significant change between 1900 and 1920. In order to meet the demand of the motor-car for improved roads large State expenditures have been made, and in 1918 31,800 m., or 36·8% of the rural public roads had been surfaced.

Agriculture.—The total value of all farm property in 1920 was $3,095,666,336, as against $1,902,604,589 in 1910, an increase of 62·7%. The total value of live stock in 1920 was $287,655,118. In 1919 the value of all crops was $607,037,562, an increase of 174·6 over 1909. The following table shows the quantity and value of the chief agricultural products according to the United States Census.

Agricultural Production 1919

Crop	Quantity in bushels	Increase % over 1909	Value in $	Increase % over 1909
Corn	149,844,626	− 4·9	217,274,709	163·9
Oats	46,818,330	−18·7	39,795,590	71·4
Wheat	58,124,351	89·6	127,873,574	311·0
Hay and forage	7,661,890[1]	..	130,187,929	..
Tobacco	64,420,472[2]	−27·3	13,528,302	50·3

[1] Tons. [2] Pounds.

The total acreage harvested in 1919 was 11,780,554, an increase of 3·1% over 1909.

Mineral Products.—From 1900–18 there was an increase in the annual output of bituminous coal from 16,900,000 to 40,900,000 short tons; in 1923, 40,546,433 short tons were produced. The coal of Ohio is produced mainly in the southeastern part of the State. The fire-clay mines of Tuscarawas, Jefferson, Columbiana Stark and Carroll counties supply the raw material for a rapidly rising industry. In 1917 3,694,302 net tons of coke were produced: in 1918 the output of natural gas was valued at $24,234,741. The production of crude petroleum has fallen; the total for 1918 was 7,285,005 bar. with a value of $23,465,197 (*see* Petroleum).

Manufactures.—According to the preliminary report of the biennial census of manufactures, 1923 (Dept. of Commerce), the manufactures of Ohio have nearly returned to the War-time level. The table below gives the development from 1914–23.

The most notable advance was in the production of motor-cars and in the manufacture of motor-car tires. The value of all tangible property in Ohio was estimated in 1922 at $18,489,000,000. The *per capita* wealth increased from $1,076 in 1890 to $3,048 in 1922.

History.—The chief political advance has been the progress in adapting the constitution and the system of administration to the new needs of the State. At the election of 1910 a general constitutional convention was approved by a large majority. Delegates were chosen in Nov. 1911, and the convention sat Jan.–June 1912. The delegates, of whom the majority were Democrats, represented the progressive elements of both major parties. Forty-two amendments were submitted to the voters on Sept. 3 1912, of which 34 were ratified; among those defeated were the abolition of capital punishment, woman suffrage, and a $50,000,000 bond issue for a state system of roads. The tax-reformers secured for the general assembly the power to impose inheritance, income and franchise taxes as well as taxes upon the production of coal, oil, gas and other minerals. A tax commission created in 1910 succeeded in bringing out for taxation the property of corporations at something near a true valuation, and in obtaining the adoption of the 1% rule as the maximum rate for taxation. The League for Direct Legislation secured the initiative and the referendum, the liquor interests a licensing system. In 1918, on the eve of Federal prohibition, an amendment incorporated state prohibition in the state constitution.

A law of 1910 centralised the taxing power in a small state tax commission, bringing to an end an expensive system of decennial boards of equalisation. The following year all the charitable and penal institutions were placed under a board of administration. In 1911 the old railroad commission became the public service commission. The act of 1911 gave the public service commission the same power over public utilities in general which the railroad commission had had over railways and telegraphs. In 1913 the legislature changed the public service commission to a public utilities commission. At the same session of the general assembly a state industrial commission was created to assume the functions of the older boards of awards, departments of inspection, etc. In 1911 the Workmen's Compensation Act substituted "a system of compensation for industrial accidents, which compensation is to be paid out of a state insurance fund, to which both employers and employees contributed (90% and 10% respectively) in lieu of the civil action for damages." A law of 1913 made compulsory the system of state insurance. Employers were required to guard the safety of employees and also to arrange reasonable hours of work. Ohio under the Act maintains its own state insurance fund. By 1918 the premium income to the state fund amounted annually to $9,000,000. At a cost of 4½% of the premium receipts the industrial commission gave protection to more than 1,500,000 workmen.

In 1913 the Department of Agriculture, the State Experiment Station and the College of Agriculture, together with the dairy and food commissioner and the fish and game commissioner, were brought under an agricultural commission with four members. Two years later, the legislature undid the reform in part, making the experiment station and the agricultural college independent institutions, and restoring the large Board of Agriculture of 10 members without a salary. A change in political parties occurred again in 1917 and the legislature, while retaining the large Board of Agriculture, made its functions those of an advisory council. The position of Secretary of Agriculture was created.

One of the constitutional amendments of 1912 instructed the legislature to make provision for a state-wide public-school system, and substitute for the commissioner elected by the people a superintendent of public instruction, appointed by the governor. In 1914 the legislature enacted a Rural School Code; and in 1917 created a State Board of Education. The reorganised Department of Education was instructed to emphasise rural agricultural education, and to co-operate with the Federal Govt. in vocational education. The old State Board of Health was reformed at the same session. In the Act of 1917 a State commissioner of health was supported by an advisory public health council of four members. A statute of 1919 created a state-wide system of municipal and general health districts and the powers of the Department of Health were greatly increased. The General Assembly in 1915 created a state highway commissioner, and in an Act of 1919 authorised the development of a state system of highways and co-operation with the road-making enterprises of the Federal Government.

In 1921 an Act was passed which combined the numerous departments and commissions into nine departments—finance, commerce, public works, agriculture, health, industrial relations, examinations, education and public welfare. If the Act stands the test of constitutionality Ohio will have a system of administration analogous to that of the Federal Government. Other legislation included a children's code (1913), providing a state-wide juvenile court and a mothers' allowance system, and a pension system for teachers in the public schools (1919). In 1921 the legislature authorised a World War compensation fund of $25,000,000, and the establishment of co-operative marketing associations. In 1925 it once more undertook, with only slight success, to adjust an antiquated tax system to modern conditions.

A disastrous flood in 1913, affecting especially the inhabitants of the Miami, the Scioto and the Muskingum river valleys, led to a measure for the protection of the river valleys from future damage of the kind. By 1921 the Miami Conservancy District had practically completed a series of dry reservoir dams costing $25,000,000.

Governors since 1913 have been Judson Harmon (Dem.), 1909–13; James M. Cox (Dem.), 1913–5 and 1917–21; Frank B. Willis (Rep.), 1915–7; Harry L. Davis (Rep.), 1921–3; Victor A. Donahey (Dem.), 1923– . (E. J. B.*)

OHIO RIVER: *see* MISSISSIPPI.

OHNET, GEORGES (1848–1918), French novelist and man of letters (*see* 20.35), published in 1908 *La route rouge*, and in 1912 *La serre de l'aigle*. His last work was *Journal d'un bourgeois de Paris pendant la guerre de 1914* (1914–5). He died May 5 1918.

OIL: *see* PETROLEUM.

OILS AND FATS (*see* 20.43).—Long experience in the construction and use of hydraulic presses led to something approaching a state of perfection early in the present century. The process of extraction of oils by means of solvents is, however, a more recent introduction into the industry.

I. THE MANUFACTURING SIDE

Solvent Processes.—In the earlier extraction plants losses of solvent were often high, extraction of oil from seed was incomplete, and the oil obtained was of inferior quality and frequently unsuitable for edible purposes. The methods of construction and operation of extraction plant have been improved to such an extent that the losses of solvent (generally light petroleum spirit) only amount to about 1% of the weight of seed treated. The oil content of the residual meal can easily be reduced to 2%, or even less, and oil of excellent quality is produced, the oil being quite equal to that prepared by expression.

There is, therefore, at the present time but little to choose between pressing and solvent extraction, and the choice of the process rests

	1914	1919	1921	1923
Average number of wage earners . .	510,435	730,733	494,288	699,031
Wage payments . .	$317,923,000	$944,651,000	$627,033,000	$979,660,000
Value of products .	$960,811,000	$5,100,308,000	$3,300,693,000	$5,046,504,000

rather on the kind of seed to be treated than on grounds of cost of working or efficiency. Where the maximum yield of oil is desired, and the residual meal is not required to contain more than traces of oil, solvent extraction is obviously better. In a good many cases seed is pressed first and the residual cake afterwards extracted by solvents. In the oil seed crushing industry it has always been an aim to devise continuous methods of operation. Several machines for the continuous expression of oil seeds have been devised and patented, but so far only one such machine, the Anderson "expeller," appears to have met with commercial popularity. Patents have also been taken out for continuous processes of solvent extraction, but it does not seem that any of these have been put into actual commercial operation.

Refining and Bleaching.—Many of the chemicals formerly used or proposed are not now employed. In practice treatment of certain oils (*e.g.*, linseed and rape oils) with sulphuric acid is effective, while treatment with caustic soda, which neutralises free fatty acids, and in many cases also removes colouring matter and other impurities, is largely employed. The use of caustic soda for neutralising oils has certainly increased in late years with the growing use of oils for edible purposes. Outwardly the principles of the process are simple, neutralisation of free fatty acid by soda and the removal of the soap formed from the neutralised oil. Actually the problem is one of some complexity from the physico-chemical point of view, involving as it does the formation of emulsions.

Various processes have been devised with a view to obtaining better or more rapid separation of the soap from oil, and also to lowering the loss of neutral oil carried away with the soap, such as that of C. Baskerville (*J. Ind. Eng. Chem.* 8, 118, 1916) in which about 2 % of prepared cotton fibre is added with the soda to the oil, enabling the soap (and cotton) to be separated from oil by means of a filter press. In other processes a vacuum is employed to assist removal of water after neutralising, so as to obtain the soap in a dry form, which can be separated from oil by filtration.

Filtration.—The methods of removal of insoluble suspended impurities from crude oils have been improved, and the use of filter presses, which assist filtration and also cause clarification of the oil, is common. High speed centrifugal clarification is in many cases advantageous, while the introduction of a new type of filter—the Hele-Shaw "stream-line" filter—may have far-reaching applications. Considerable advances in the methods of "bleaching" oils by means of various decolourising materials such as natural fullers earths, chemically treated earths, and charcoals, have been made and the use of such materials, particularly in the edible oil industry where freedom from colour is desirable, has undoubtedly increased.

Activation.—Methods of "activating" vegetable carbons so as to render them highly efficient as decolourising agents which can compete with animal or bone charcoal, formerly the most efficient variety of decolourising charcoal have been developed. The methods of activating vegetable decolourising charcoals owe a good deal to the investigations carried out during the War on methods of producing vegetable charcoal with a high absorptive capacity for gases such as was required in gas masks. The nature of the physical reactions of carbon treated in various ways was thus elucidated. While the removal of colour is due chiefly, if not entirely, to physical adsorption of the colouring matter, further investigation is desirable, both in the direction of elucidating more fully the *modus operandi* of the decolourising effect and also towards further improvement of decolourising agents.

Chemical methods of bleaching oils and fats generally involve treatment by oxidising agents, and are seldom, if ever, employed in bleaching oils for edible purposes. Oils for technical use, *e.g.*, for soap manufacture, are still generally bleached by air or by bichromate and acid or by hypochlorites, but various other oxidising agents such as certain organic peroxides and metallic per-salts are also used.

Deodorisation of Oils.—Practically all processes depend on the passage through the heated oil of a current of steam, which carries off the more volatile substances to which odour is due. In the earlier processes steam at comparatively low temperature was employed, and as much as 2 lbs. of steam was often required to deodorise 1 lb. of oil. Deodorisation is still to some extent regarded as a trade secret, but modern development has all been in the direction of employing superheated steam and higher temperature of oil assisted by high degree of vacuum. Deodorisation is now much more efficient than formerly, both in degree and in consumption of steam. The use of inert gases, such as carbon dioxide or hydrogen, in place of steam has also been tried.

Artificial Oils and Fats.—The conversion of hydrocarbons from petroleum into fatty acids by processes of oxidation has attracted a good deal of attention, by reason of the large difference in price between hydrocarbon oils and fatty acids (which may be converted to oils by reaction with glycerol). Fatty acids undoubtedly can be produced from hydrocarbons, but so far it does not appear that any process has been devised which shows a likelihood of commercial success.

Fatty acids are in many cases by-products of the oil industry; they also frequently exist in a free state mixed with neutral oils in crude oils, and have to be removed before the oil can be used for many purposes. The conversion of fatty acids into neutral oil by esterification with glycerol is the subject of certain patents. Technically the conversion of fatty acids into neutral glycerides has been suggested. (1) for the purpose of converting fatty acids of low value into neutral oils of higher value, (2) for the neutralisation of free fatty acids naturally present in crude oils, (3) for the production of glycerides having certain desirable properties, *e.g.*, mixed triglycerides containing definite fatty acids. Esterification has certainly been carried out technically but, owing to the reticence of manufacturers, it is not possible to indicate its technical importance.

Hydrogenation of Oils.—In principle the process is one of great simplicity, involving the combination of hydrogen with a liquid oil containing unsaturated fatty acids, the resulting product being a solid fat containing saturated fatty acids. Thus liquid olein, the triglyceride of oleic acid, a common constituent of liquid oils, is converted to solid stearin, the triglyceride of stearic acid, according to the chemical equation $C_{17}H_{33}COOH + H_2 = C_{17}H_{35}COOH$.

This reaction is effected by bringing the liquid oil into contact with hydrogen gas in presence of small amounts of catalytic metals. Metals such as platinum and palladium are active hydrogenation catalysts at low temperatures, even at ordinary atmospheric temperature, but these metals are too expensive to be used on the large scale demanded by modern requirements, and have been displaced in the oil industry by nickel catalysts. Many patents dealing with the production of suitable catalysts, machinery for carrying out the reaction, and other details, have been taken out. The process consists as a rule in heating the oil and nickel powder catalyst to 150–200° C., in a closed vessel with hydrogen under pressure of 50 lb. per sq. in. or more, thorough agitation being effected either by stirring gear or circulation of hydrogen through the oil by pump or by both these means. After hydrogenation to the desired degree, *i.e.*, after sufficient hydrogen is combined to produce an oil of the required hardness, the mixture of oil and catalyst is run out of the reaction vessel and the catalyst removed by filtration.

The catalyst most usually employed is a mixture of nickel and some inert material such as kieselguhr (siliceous earth), the latter being used to afford a large surface of catalytic material. The catalyst is produced by precipitating an insoluble nickel salt in presence of the inert material; nickel carbonate is commonly employed and this is formed by adding the requisite amount of sodium carbonate solution to a suspension of the inert material in a solution of nickel salt (generally nickel sulphate). The precipitated nickel salt, etc. is collected and washed in filter presses until free from soluble salts; it is then dried and reduced in a current of hydrogen, generally at a temperature of 300° C. or over. After reduction the catalyst is kept from contact with air either by admixture with oil or by keeping in an atmosphere of inert gas.

The reduced catalyst powder has generally a content of nickel of about 20 per cent. In the hydrogenation of oils of good quality an addition to the oil of as little as 0·1% of actual nickel is sufficient to bring about hydrogenation, but lower grades of oil may require considerably more, while very low grades of oil cannot be treated economically owing to the presence of impurities which "poison" or render the catalyst ineffective. This powder catalyst process has been developed to a very high degree of efficiency, and the process of hydrogenating oils has grown to a very large extent.

The powder process is not continuous and the powder catalyst must be removed from the oil by filtration. Further the nickel catalyst can only be recovered for re-use by costly processes. By a recently developed process metallic nickel in the form of fine turnings is employed as catalyst. These turnings are packed permanently in cages which fit into the reaction vessels. In this process of hydrogenation the oil flows continuously through heated reaction vessels containing cages of nickel turnings in presence of hydrogen; and hydrogenated oil entirely free from nickel and requiring no filtration is delivered from the plant. The degree of hydrogenation is readily controlled by the rate of flow of oil, while the nickel catalyst is regenerated without loss in weight, and at low cost by a simple process of electrolytic oxidation (*Eng. Pat.* No. 203,218).

The process of hydrogenation has led to much important work on the mechanism of the reaction, the effect of "poisons" on catalysts, and the nature of the catalytic action of metals. Oils hydrogenated under such conditions as obtain in technical practice as a rule contain considerable amounts of iso-oleic acid, a solid unsaturated acid isomeric with ordinary liquid oleic acid. This facilitates the identification of hydrogenated oils in compounded oils (K. A. Williams and E. R. Bolton, *Analyst*, vol. 49, p. 460 1924), which was otherwise difficult or even impossible.

Speaking broadly, the hydrogenation of oils may be looked upon as the most important advance in the oils and fats industry during the present century, and hydrogenated or hardened oils are used to a very large extent chiefly in edible oil and in soap manufacture. By it liquid oils may be converted into solid fats of any desired degree of hardness and many oils which are of low value on account of odour and flavour, such as fish and whale oils, can be rendered odourless and tasteless.

Oil Analysis and the Constituents of Oils.—The general tendency has been to increase the delicacy and reliability of the various tests, and from increased knowledge obtained as to the "constants" of various oils to render more easy the detection of admixtures or adulterants. The task of the analyst has increased considerably in difficulty owing to the improved methods of refining oils employed in commercial practice, to the increased complexity of mixtures of blended oils and to the widespread use of hardened oils. Much work has been done on the nature of the fatty acids present in oils and fats, and the relative proportions of the different fatty acids occurring (as neutral glycerides) in commercial oils and fats are now generally known with a desirable degree of exactitude.

There is a lack of information as to the exact forms of triglycerides existing in most oils and fats. Mixed triglycerides, such as oleodistearin, have been separated from natural fats, but so far such substances can only be separated by tedious methods of fractional crystallisation, which do not afford accurate quantitative evidence. The importance of mixed triglycerides is certainly great, for example, their influence on the consistence and general physical properties of fats. The inner structure of the molecule of various fatty acids has received attention, by the application of the X-ray spectrograph (*e.g.*, A. Müller, *Chem. Soc. Trans.*, vol. 123, p. 2043 1923).

New Constituents of Oils.—In the liver oils of certain sharks and other marine animals large amounts of unsaponifiable matter, consisting of highly unsaturated hydrocarbons, have been discovered, thus spinacene—$C_{30}H_{50}$—was isolated from the liver oils of *Centrophorus granulosus* and *Scymnus lichia* by A. C. Chapman (*Chem. Soc. Trans.* vol. 111, p. 56 1917). Similar or identical hydrocarbons have been obtained from many other marine animal oils by A. M. Tsujimoto.

Soap (25.296).—An interesting example of the application of scientific methods to the technique of soap making is the work of K. Maclennan (*Chemistry and Industry*, 1923, 393 T) dealing with the microscopical character of the soaps of individual fatty acids, and with the structure of the soap during different stages in the manufacture.

A general improvement in technique and machinery is evident. Machines for artificial cooling of soap enable the soap to be obtained in the form of solid slabs ready for cutting in about two hours, compared with the four or five days formerly necessary when spontaneous cooling in frames was employed. The oils used by the soap maker in recent years have to some extent changed, and the increased demand for oils for edible purposes (*e.g.*, margarine) has caused a rise in price in some cases, and such oils have consequently been replaced by other cheaper oil for soap making. Soya bean oil has proved useful to the soap maker as a substitute for more expensive materials. Hardened oils have also come into use in soap making, while full use has been made of the increasing quantities of by-products obtained as a result of the removal of free fatty acids in the refining of crude oils for edible and other purposes (*see* under REFINING).

In refining oils with caustic soda the soap formed together with any excess of caustic soda and associated neutral oil is deposited as soap stock; this forms a useful raw material for the soap maker on the spot, if not used in the same factory the soap stock is generally converted into "acid oil" (by treatment with an excess of mineral acid) so as to obtain a more homogenous material and to save cost of transport by removal of water. The production, improvement and use for domestic as well as technical purposes of dry soap in the form of powder or flakes; are noteworthy. Investigations into the colloidal and other physical properties as well as to the chemical nature of soap and soap solutions, have resulted in a better understanding of many problems connected with soap; for example, methods have been devised for measuring the detergent action of soaps.

II. THE DISTRIBUTING SIDE

The trade in oils and fats has always been important, but it was not until the War period that any systematic attempt has been made to compile statistics. During the War industry was brought temporarily under Governmental control in Great Britain, in Germany and some other countries, and the need for more accurate information as to available supplies was acutely realised. The International Institute of Agriculture, Rome, began to collect statistics from the various producing and exporting countries, and these have been published in *Oleaginous Products and Vegetable Oils.*

Figures dealing with production are in most cases largely guesswork. The bulk of the oilseeds are shipped from tropical countries, many of which are still in a primitive state of development. Moreover, a considerable proportion of the production is consumed in various ways in the countries of origin, and in most of them are numerous small native mills producing oils for local use, and using up in many cases as much as half the total crops. The difficulties therefore in the way of obtaining complete statistics are very great. Since the War, however, a considerable advance has been made in the method of estimating crops, and Government reports for the principal producing countries are now issued at regular intervals for most of the oilseeds prominent on the international markets.

The pioneers in the oilseed industry were the soap manufacturers, who, as they found their supplies of raw material being encroached upon by the demands from the edible oils trade—demands which steadily increased with the development of better refining methods—were driven to search in new directions. The effect of the War was to arrest this expansion, to divert available supplies to Allied countries, and to favour those sources of supply which lay nearest to hand. The blockade cut out Germany as an importer, and many seeds and nuts which previously had gone mainly or exclusively to the Continent, such as groundnuts, sesame seed, palm kernels and copra, were diverted to Great Britain. Moreover, economy of freight space being essential, and oil occupying much less room than seed, a considerable stimulus was given to the erection of oil-mills in countries of production, and to the development of the export from there of oil in bulk. Particularly was this the case with copra and coconut oil. In both the Philippines and Dutch East Indies extensive crushing plants were put up, and shipments of oil increased in the one case from 5,000 tons in 1913 to 140,000 tons in 1919, and in the other, from 1,000 tons in 1913 to 75,000 tons in 1919. After the War former conditions were gradually restored, though Great Britain continued to import palm kernels, copra and groundnuts to a much greater extent than before.

The War helped the development of refining processes. The vital necessity of finding supplies of oils and fats for the armies and the civil population gave a great impulse to research, and many oils which had hitherto been regarded as purely industrial, became available for edible purposes as a result of improved methods of refining and deodorising; rape oil, which had previously been used for burning and lubricating, and palm oil for soapmaking, took a place in the list of important potential edible oils. Another process—hydrogenation, whereby a liquid oil is enabled to absorb hydrogen and is hardened—was greatly developed. This process brought whale oil to the margarine manufacturer.

The general effect of these changes has been to increase very considerably the interchangeability of oils. While each oil may be said to have a particular purpose for which it is most suited, it can be readily turned to other purposes if the price factor is right. Whereas previously there were wide differences in prices the tendency now is for all refined oils to approximate in value.

The production of oilseeds is liable to very considerable fluctuations, but in a normal year the following estimates of the main crops may be taken as approximately correct:—

Product	World's Production Oilseeds	Exportable Surplus from Producing Countries	Approximate Oil Equivalent of Exportable Surplus
	Tons	Tons	Tons
Linseed	4,000,000	2,000,000	600,000
Cottonseed	11,000,000	900,000	162,000
Ground Nuts	2,500,000	800,000	280,000
Rape and Mustard	1,500,000	380,000	133,000
Sesame	600,000	300,000	135,000
Soya Beans	4,500,000	1,000,000	100,000
Sunflower	2,000,000	30,000	9,000
Copra	1,500,000	600,000	390,000
Palm Kernels	500,000	450,000	202,000
Castor Seed	300,000	150,000	63,000
Oil			
Olive Oil	700,000	120,000	120,000
Total			2,194,000

Linseed.—The main producing countries are Argentina, India, U.S.A., Canada and Russia. About 50% of the total is now produced in Argentina, where expansion has been steady over the last 20 years, and was largely unaffected by the War. The seed is mainly exported to the crushing mills in Europe, though America imports considerable quantities, varying according to the fluctuations in the home crop. Production in Canada and the United States has varied largely. Normally America consumes about 1,000,000 tons of seed and any deficiency in the home production has to be made good by imports of seed from Argentina or of oil from Europe. In 1922, 64,000 tons of linseed oil were exported from Europe to America. In India, flax is cultivated for the seed and not the fibre. Production of linseed amounts to from 500,000 to 600,000 tons, of which about 80% is exported, almost entirely to Europe. With the increasing competition from Argentina there has been a tendency to diminish production. Russia as a producer and exporter of linseed was practically eliminated during the War and subsequent revolution, but is now again resuming exports. Production in 1925 reached 600,000 tons, which is about normal. Pre-War exports amounted to approximately 150,000 tons a year.

Cottonseed.—The main producing countries are the United States, India and Egypt, but cultivation has extended to other countries, *e.g.*, South America (Brazil, Peru, Argentina), East and West Africa (Nigeria, Uganda, Sudan) and Australia. With the increasing demand from the textile industry for cotton, a great expansion in cultivation is inevitable and with it the production of cottonseed, one of the greatest sources of edible vegetable oil. Up to 1870 cottonseed in the United States was a useless encumbrance to the planter. With the discovery and development of refining, numerous oil-mills were erected, and now some 4,000,000 to 5,000,000 tons of seed are crushed annually, producing about 600,000 tons of oil. Up to a few years ago 150,000 tons of oil were exported annually to Europe, but owing to increasing home consumption the exportable surplus has now diminished to about 28,000 tons, with every probability of a further decrease.

Europe has had to depend for its supplies of cottonseed mostly on Egypt and India, though with the extension of cultivation to other countries many varieties are now coming on to the European market. Egypt normally produces about 600,000 tons and exports to Europe 400,000. India produces rather over 2,000,000 tons, but exports only from 200,000 to 300,000 tons. Figures relating to China are difficult to obtain, but it is estimated she produces about 1½ million tons, practically all of which is consumed locally. The striking fact about cottonseed is that out of a total production of about 11,000,000 tons of seed, only some 900,000 tons find their way to the international markets, the rest being disposed of at home.

Groundnuts.—The main producing countries are India, West Africa China and the U.S.A., the two first being the principal sources of supply for the world markets. In all arens production is continuously expanding to meet the demand both for the purposes of oil production and for direct use as food. The chief importing country is France, which takes about 500,000 tons annually.

India produces well over 1,000,000 tons, more than half of which is retained for home consumption. The nuts are shelled before exporting. West Africa produces well over 500,000 tons and exports about 350,000 tons, practically all in shell. Figures are not available for China, but production is probably very large. Exports amount to only about 60,000 to 70,000 tons. The U.S.A. consumes all it produces, viz.: about 350,000 tons.

The pre-War export trade in ground-nut oil was confined mainly to France, the Netherlands and China. During the War French and Dutch exports were reduced to a minimum, and China became the chief source of supply, increasing its export from 15,000 tons in 1913 to 75,000 tons in 1919—mainly to America. Since then the pre-War position has gradually been restored.

Rapeseed.—India produces four-fifths of the world's supply, the remainder being grown in Japan, Rumania, Russia and other European countries. European cultivation has decreased considerably. The great bulk of seed produced in India is consumed locally, exports even before the War showing a marked tendency to diminish. In recent years exports have fluctuated widely, varying from 56,700 tons in 1921 to 271,500 tons in 1924 and 165,000 tons in 1925.

Soya Beans.—The chief producer of soya beans is China, the normal crop being estimated to be between four and five million tons. The soya bean has long been one of the staple foods of the East; since 1904 when the first shipment was made to Europe there has been a very rapid expansion in trade. Some 500,000 tons are now exported to Europe, a similar quantity being exported locally—mainly to Japan. In addition, a large number of mills have been erected in Manchuria to crush the soya bean, the oil being exported mainly to Europe and the cake to Japan for use as a fertiliser for the rice crop. Exports of oil amount to over 100,000 tons a year.

Sunflower Seed.—This is produced mainly in Russia, but to an increasing extent in Rumania, Hungary, Bulgaria and Poland. In 1913 some 180,000 tons of oil were produced practically all of which was consumed locally.

Copra.—The two main zones of cultivation are the Southern Asiatic, including Dutch East Indies, Philippines, Ceylon and Malay States, and Oceania, comprising the various Pacific Island groups. The former is the more important, supplying about four-fifths of the total. During the War the export trade to Europe in copra suffered severely. In the case of the Dutch East Indies, exports fell from 230,000 tons to 65,000. The United States, however, increased its imports both of copra and coconut oil. A marked revival took place in 1919, total exports amounting to 650,000 tons of copra.

Palm Kernels.—West Africa holds practically a monopoly of the production, although plantation cultivation is being extended to other tropical countries, notably the Dutch East Indies. Practically the whole of the production is exported to Europe. The War diverted supplies from Germany to Great Britain. In 1909 only about 20,000 tons were brought into England, as against 240,000 tons to Germany. After the War Germany gradually recovered her position. In 1924 the respective figures were 280,000 as against 102,000 and in 1925 226,000 against 225,400 tons.

In addition to palm kernels, West Africa produces large quantities of palm oil, *i.e.*, oil from the palm fruit. It is difficult to estimate total production owing to the large local consumption. The method of producing the oil is still primitive, and the free, fatty acid content is high. The oil, therefore, is used principally for soapmaking in importing countries, though the best qualities can be made edible by refining. About 180,000 tons are exported annually to Great Britain, the Continent and America.

In the same group of oil nuts may be mentioned the cohune, babassu, ucuhubu, all of which have only come on the international market so far in small quantities. The producing country is Brazil, which is known to be rich in oil seeds.

Castor Seed.—India has practically a monopoly. During pre-War years the average export amounted to about 120,000 tons, the chief importing countries being Germany and Great Britain. During the War Brazil began to cultivate this seed, and in 1918 exported 4,000 tons and in 1924 15,000 tons. After the War exports from India fell heavily, due to the accumulation of Government stocks in Great Britain. Since then recovery has set in and in 1925 100,000 tons were exported. The United States has become one of the chief importing countries. Small quantities are also exported from Dutch East Indies and Portuguese West Africa.

Olive Oil.—Cultivation of the olive has not undergone any material change during the last 25 years. The principal producing countries border on the Mediterranean, *i.e.*, Spain, Italy, Greece, Algeria, Tunis, and, to some extent, France and Turkey. Annual production amounts to 700,000 tons, of which over 100,000 tons are exported, mainly to Argentina, the U.S.A., Great Britain and Germany. The War reduced the exports of Italy, Greece and Tunisia and doubled those of Spain. As much as 87,000 tons in 1916 and 110,000 tons in 1919 were exported from Spain. Pre-War conditions however eventually re-asserted themselves.

Animal Fats.—In addition to the vegetable oils, considerable quantities of animal fats, such as lard and tallow, are produced for edible and industrial purposes. The United States produces some 700,000 tons of lard, of which about one-half is exported. The main exporting countries for tallow are Argentina and Australia, which between them account for about 100,000 tons. The United States consumes practically all its production which amounts to about 170,000 tons.

Marine Oils.—The principal marine oil is whale oil. These oils were used only for burning until the hydrogenation process was developed; since that time all the whale oil is used in soap and margarine manufacture. The total production of marine oils is approximately 200,000 tons, whale oil accounting for about 130,000 tons (*see* WHALING).

See International Institute of Agriculture, Rome, *Oleaginous Products* (1923); *International Crop Report and Agricultural Statistics* (monthly.) (J. W. P.)

OKLAHOMA (*see* 20.57).—A State of the United States of America. The population in 1920 was 2,028,283; in 1910 it was 1,657,155; an increase of 371,128, or 22·4% as compared with 866,764 or 109·7% in the preceding decade. The urban population increased from 320,155 in 1910 to 539,480 in 1920. During the same period the density of population increased from 23·9 per sq. m. to 29·2. Indians decreased from 74,825 to 57,337. Negroes increased from 137,612 to 149,408. The population in 1920 of the larger cities was:—

Oklahoma City	91,295	Okmulgee	17,430
Tulsa	72,075	Enid	16,576
Muskogee	30,277	Shawnee	15,348

The population of the State in 1925 was estimated at about 2,250,000 persons.

Mineral Production.—The most important development between 1910 and 1920 was in the production of oil and gas. In 1924 there were 50,000 wells producing either oil, or gas, or both, and 43 counties were classed as oil and gas producers. Tulsa is the centre of the oil and gas area of the State: its population increased from 18,000 in 1910 to 72,075 in 1920. The production of oil increased from 52,028,700 bbl. of crude oil in 1910 to 161,000,000 bbl. in 1924, and its value from $19,227,000 in 1910 to $279,000,000 in 1924. In 1924 Oklahoma produced 3,500,000 tons of coal, 178,000,000,000 cu. ft. of gas, 67,000 tons of lead, 242,000 tons of zinc, 290,000 tons of gypsum and 2,000,000 bbl. of Portland cement. The total value of Oklahoma's mineral production increased from $33,000,000 in 1910 to $410,600,000 in 1924.

Agriculture.—The total area of farm land in 1910 was 28,859,353 ac. of which 17,551,337 ac. were improved; in 1920 the total area was 31,951,934 ac. of which 18,125,321 were improved. The value of farm property in 1910 was $918,148,882; in 1920 it had increased to $1,660,423,544. In 1909 the total value of all crops was $131,522,220. In 1919 it was $550,084,742, but, owing to the drop in prices, in 1924 the total value was only $427,934,000. Dairy products in 1924 were valued at $25,000,000, as against $20,878,920 in 1919. The following tables show the quantities and values of cereal production in 1909, 1919 and 1924, and the numbers of live stock in 1910, 1920 and 1924:—

Cereal Production

	1909	1919	1924
Wheat: quantity	14,008,334 bu.	65,761,843 bu.	54,870,000 bu.
Value	$13,854,322	$140,730,350	$68,048,000
Corn: quantity	94,283,407 bu.	53,851,093 bu.	65,600,000 bu.
Value	$48,080,554	$72,698,979	$58,384,000
Oats: quantity	16,606,154 bu.	45,470,191 bu.	38,880,000 bu.
Value	$7,172,267	$36,376,150	$20,606,000
Kafirs: quantity	4,658,752 bu.	17,901,096 bu.	29,614,000 bu.
Value	$2,531,036	$23,271,427	$22,803,000
Barley: quantity	127,641 bu.	1,781,839 bu.	4,675,000 bu.
Value	$75,059	$2,049,119	$3,273,000
Rye: quantity	37,240 bu.	705,124 bu.	518,000 bu.
Value	$30,364	$1,022,434	$523,000

Live Stock

	1910	1920	1924
Horses	786,700	790,670	633,000
Mules	258,152	358,200	330,000
Dairy Cattle	1,765,346	870,690	565,000
Other Cattle		1,284,753	1,044,000
Sheep	49,157	106,024	8,300
Swine	..	1,366,722	841,000

The chief industries are the manufacture of flour and meal, smelting, oil refining and meat packing. The following table prepared by the U.S. Census Bureau gives a comparative summary for 1914 and 1921:—

	1914	1921
Number of establishments	2,518	1,398
Proprietors and firm members	2,464	1,262
Salaried employees	2,793	5,443
Wage-earners	17,443	22,241
Capital	$ 65,477,654	..
Salaries	3,202,332	$ 11,801,000
Wages	11,011,043	29,532,000
Cost of Materials	70,969,750	203,803,000
Value of products	102,005,693	283,764,000
Value added by manufacture	31,035,943	79,961,000

Education.—During the period 1910 to 1924 great progress was made in education. The enrolment of pupils in 1910 was 415,116, and in 1924–5 it was 654,742. The number of accredited four year high schools increased from 29 in 1912 to 508 in 1924. The total expenditure for public schools in 1910 was $8,600,450.32, as against $30,187,233 in 1924–5. Similar growth has been shown in the higher educational institutions supported by the state. The six state teachers' colleges, the Agricultural and Mechanical College and the secondary agricultural schools as well as other State secondary schools have made progress. The University of Oklahoma, which in 1907–8 had 40 instructors and 790 students, had in 1924–5 264 instructors and 5,561 students, inclusive of the summer session, but exclusive of correspondence and extension work. In 1916 the industrial institution at Chickasha was re-organised and renamed the Oklahoma College for women. It is the only school maintained by the state that is not co-educational.

History.—At the time of its admission in 1907 Oklahoma contained more than one-third of the Indian population of the United States. These Indians came from numerous tribes that had moved to Oklahoma in the 19th century, and their absorption into the general body of citizens has proceeded increasingly since 1910. The Indians of Oklahoma had by 1920 practically no separate history, and such tribal organisations as were maintained were not for governmental purposes, but were business corporations for the control of tribal property. The great mineral output has made many of the Indians extremely wealthy. The Osage tribe in particular continued to hold much of its land as tribal property, and its members receive very large royalties. This was not true of certain other tribes, as the lands assigned to them are valuable only for grazing purposes, and the individual allotments under such circumstances bring small incomes. The fact that a large part of the land, especially in the eastern half, has been allotted to the Indians, serves to account for the large number of tenant farmers in a state. The governors of Oklahoma between 1910 and 1925 were Lee Cruce (Dem.), 1911–5; Robert L. Williams (Dem.), 1915–9; James Brooks Ayres Robertson (Dem.), 1919–23; John Calloway Walton (Dem.), 1923; Martin Edward Trapp (Dem.), 1923– .

OKLAHOMA CITY, U.S.A. (*see* 20.61), the capital of the State of Oklahoma and its commercial centre, continued to grow

rapidly after 1910, reaching a population of 91,258 in 1920 (of whom 8,241 were negroes and only 3,477 foreign-born), and 139,947 on Jan. 1 1925, according to an official census made by the city.

In a zone 50–100 m. from Oklahoma City lie (1925) most of the 250 producing oil-fields of the state. The nearer territory, within a radius of 50 m., is believed to contain oil far below the surface, and its development may be expected with the exhaustion of the more accessible supplies and improvement in methods of reaching lower levels. In 1924 the assessed valuation of taxable property in the city was $119,000,000; bank clearances amounted to $1,283,152,000; building permits represented a value of $8,060,845; the volume of wholesale business was estimated at $175,000,000; and freight originating in or destined for the city amounted to 1,880,426 net tons. The value of products manufactured within the city increased from $7,868,000 in 1909 to $69,071,000 in 1919. In 1925 there were 431 manufacturing establishments with an output valued at $150,000,000, the principal industries being packing, flour-milling, cotton-pressing and ginning.

The commission form of government was adopted in 1911. By 1925 a new water supply system costing $5,500,000 had been completed; and 2,200 ac. had been laid out in public parks and playgrounds. Oklahoma City University (established in 1911 and superseding Epworth University) had a roll of over 1,300 students.

OKUMA, SHIGENOBU, MARQUESS (1838–1922), Japanese statesman (*see* 20.61), emerged from his retirement in 1914 to become Prime Minister, in which capacity it was his fortune to guide the country through the opening months of the World War. In Oct. 1916, Count Okuma retired from office owing to his failing health. In the same year he was raised to a marquessate. He died at Tokyo Jan. 10 1922.

OLD AGE PENSIONS: *see* INSURANCE, SOCIAL.

OLDENBURG, SERGEI FEDOROVICH (1863–), Russian orientalist, was born Sept. 14 1863 at Bjankino, Siberia, of a family of German origin. Oldenburg learnt Greek and Latin at a secondary school in Warsaw and later entered the University of St. Petersburg (Leningrad) to study oriental languages. He specialised in Indian dialects under Professor T. P. Uinajer, graduated in 1890 and went to England where he did research work at Cambridge. In 1894 he published his *Buddhist Legends*. In 1903 became a member of the Academy of Sciences, of which in the following year he was elected permanent secretary. In this capacity he controlled the official and scientific correspondence of the academy, its publications and their exchange, the academical archives, the scientific expeditions and the regional surveys of the country. He also became director of the Asiatic Museum, founded by the academy in 1818, which contains many valuable oriental manuscripts. Oldenburg took a leading part in two archaeological expeditions to Chinese Turkistan, which discovered a whole library of ancient Mss. buried in sand among ruins of a deserted town. He was appointed professor at the University of St. Petersburg in 1895 and still occupied the chair of Indian languages and literature in 1926.

OLD TESTAMENT: *see* BIBLICAL CRITICISM.

OLLIVIER, OLIVIER ÉMILE (1825–1913), French statesman (*see* 20.89), died at St. Gervais-les-Bains, Savoy, Aug. 30 1913.

OLNEY, RICHARD (1835–1917), American statesman (*see* 20.91), died in Boston, Mass., April 8 1917. He declined, in 1913, President Wilson's offer of the ambassadorship to Great Britain.

OLYMPIC GAMES (*see* ATHLETIC SPORTS, also 2.846).—The modern revival of the Olympic Games of ancient Greece is due to a Frenchman, Baron Pierre de Coubertin, whose personal admiration of the English public school and English ideals of sport determined him to impart those ideals both to France and to the rest of the world by organising an amateur meeting of all nations in athletic rivalry every four years. The Baron succeeded in his efforts so far that by the fourth celebration of Games in 1908 he saw collected in London the representatives of 20 different nations competing in 20 different forms of sport, involving more than 100 separate events, with a complete illustrated code of rules for each of them, accepted by more than 2,000 athletes. In 1924 he saw in Paris an even longer programme, in which 45 different nations contributed a total of competitors three times as large as that of 1908.

As it is therefore clear that the modern Olympic Games have become, in all human probability, a permanent feature in the world's calendar of sport, it would serve no good purpose to say more concerning recent developments than that they appear to be more warmly welcomed by the Americans and by other nations in Europe and elsewhere than by the population of Great Britain as a whole, which has been for long accustomed to an annual round of organised competitive sport quite unfamiliar to any other country.

Early Meetings.—It was by the British Olympic Committee, headed by Lord Desborough and the Rev. R. S. de C. Laffan, that the first real organisation of these Games was successfully carried through in 1908 in London. Previous meetings, though recorded, were neither representative nor properly organised. The third celebration at St. Louis in 1904 had attracted hardly any competitors from outside the United States. The second, in Paris in 1900, had suffered from inadequate preparation and control. The first of the revival, appropriately held in Athens in 1896, where the famous Marathon Race was standardised, was made possible by the munificence of a private citizen (M. Averoff); but the marble stadium built at his expense, though splendidly adapted to local festivals, did not permit of a running-track suitable for the athletic championships of the world.

After the success of the London meeting in 1908, that of Stockholm in 1912 carried on the movement with all the enthusiasm to be expected from the compatriots of Sir Viktor Balck; and their wonderful stadium combined with thoroughly skilful organisation in all directions to make the future of these Games still more firmly assured. The meeting of 1916, originally fixed for Berlin, was impossible owing to the World War; and it was the opinion of many that neither Belgium nor the rest of the world were ready for the Games of 1920 in Antwerp. The Belgians were unable to produce the usual official report, and therefore certain details about the Games of 1920 cannot here be given; but both in the total of entries and in the standard of achievement these Games maintained an unexpectedly high level. The Games of 1924 were again celebrated in Paris.

Organisation.—Of the International Olympic Committee Baron Pierre de Coubertin was for many years president, being succeeded by Count Baillet-Latour. It is the central body by which the general policy of the Olympic movement is (or should be) controlled. In 1910 the representatives of the United Kingdom were Lord Desborough, the Rev. R. S. de Courcy Laffan and Sir Theodore A. Cook. In 1924 they were Lord Cadogan, the Rev. R. S. de Courcy Laffan and Brigadier-General R. Kentish, C.M.G., D.S.O. The American members in 1924 were Professor Sloane, Mr. W. M. Garland, General Charles Sherrill and Dr. David Kinley. Forty-four nations are represented by one or more delegates each. It is hoped that by degrees this influential committee will crystallise such ideals as a world-wide amateur definition which will cover every sport; an Olympic programme restricted to those first-rate forms of sport in which at least half the competing nations have personal experience; a prize schedule of permanent medals and certificates alone, with an official list of properly constituted challenge cups; a universally accepted code of laws to govern every competition in the Games; and a body which will appoint juries and officials with power to inflict penalties that cannot be evaded.

Besides this central committee, on which all nations are represented, each nation has its own Olympic association and its own Olympic council. The British Olympic Council, which may be taken as typical of the rest, contains one or more representatives of every association governing every sport in Great Britain, and a few other co-opted members chosen for their special knowledge or experience in organisation. Through this committee the association controlling each sport selects the best representatives in that sport. By this committee the funds necessary for British participation in Olympic meetings are collected.

Finance.—The Olympic Games in Great Britain are not assisted by any grant of public money, as is the case with nearly every other competing nation. It was necessary in 1908, for instance, to build a stadium in London that would hold 70,000 spectators, and would contain a first-class cinder track with three laps to the mile, a cement cycle track outside it, a swimming bath inside it 100 metres long by 50 ft. broad and 12 ft. 6 in. deep; and a central oval of turf 700 ft. by 300, suitably laid out for all the different contests arranged in it. In this stadium 27 athletic events were decided; and six other forms of sport, archery, fencing, cycling, gymnastics, swimming and wrestling, also took place. The cost of this stadium was over £60,000 in 1908. The marble erection in Athens may have cost more. The permanent stone stadium in Stockholm cannot have cost much less. As an indication of the rise in expenses since the War, it may be added that the huge stadium built at Wembley in 1924 cost over £500,000. The Games were planned to be held in Holland in 1928 and in the United States in 1932, and these two countries had thus to incur this particular expense. But there is gradually rising throughout Europe a series of permanent buildings, fitted for Olympic Games, which will by degrees greatly reduce this item of expenditure in the organising country.

Those countries, however, which are not obliged to build a stadium have always before them the expense of sending teams, totalling from about 50 to as many as 500, to the country in which the Games are being held. The problem of these expenses has not been satisfactorily solved, but the shortening of the programme has been suggested as one solution. There were 109 first prizes in 1908, 102 in 1912, 100 in 1920 and 111 in 1924. In addition to the sports mentioned as taking place in the London Stadium in 1908, there are such events as lawn tennis, shooting of every kind, rowing, yachting, football and boxing. This by no means exhausts any possible list. In 1924 a whole series of winter sports was added to the Paris programme of 111 events. Clearly the Games should not be confined to track and field events in athletics alone. It is equally clear that some standard programme must be laid down for the future by the international committee.

Records.—A comparison of the events to which most importance is popularly attached in the various Olympic Games from 1896 to 1924 will show the following Olympic records, (Table I.) to which the world's records have been added in a separate list (Table II.) for purposes of comparison:—

TABLE II. WORLD RECORDS.

Race	Date	Winner	Time or Distance
(1) 100 metres	1921	C. W. Paddock	10 3/5 sec.
(2) 200 metres	1921	C. W. Paddock	21 1/5 sec.
(3) 400 metres	1924	E. Liddell	47 3/5 sec.
(4) 400 metres relay	Metric world's record not available.		
(5) 800 metres	1917	J. E. Meredith	1 min. 51 9/10 sec.
(6) 1,500 metres	1924	P. Nurmi	3 min. 52 3/5 sec.
(7) 1,600 metres	Metric world's record not available.		
(8) 3,000 metres steeplechase	1924	W. Ritola	9 min. 33 3/5 sec.
(9) 3,000 metres team	1924	Finland (P. Nurmi 1st)	8 min. 32 sec.
(10) 5,000 metres	1924	P. Nurmi	14 min. 28 1/5 sec.
(11) 10,000 metres	1924	P. Nurmi	30 min. 6 sec.
(12) 10,000 metres walk.	Metric world's record not available.		
(13) Marathon	1924	C. de Mar	2 hr. 29 min. 40 1/5 [sec.]
(14) Hurdles (110 metres)	1920	E. J. Thomson [1]	14 4/5 sec.
(15) Hurdles (400 metres)	1924	F. M. Taylor	52 3/5 sec.
(16) High jump	1925	H. M. Osborne	6 ft. 8 1/4 in.
(17) Long jump	1925	de Hart Hubbard	25 ft. 10 3/8 in.
(18) Pole jump	1925	C. Hoff	13 ft. 10 1/2 in.
(19) Weight	1909	R. Rose	51 ft.
(20) Hammer (16 lbs.)	1913	P. Ryan	189 ft. 6 1/2 in.
(21) Javelin	1924	H. Lindstrom	218 ft. 7 1/4 in.
(22) Discus	1925	G. Hartranft	157 ft. 1 3/8 in.
(23) Hop, step, and jump	1924	A. W. Winter	50 ft. 11 1/4 in.

[1] In 1920 E. Thomson set up a World's record of 14 3/5 sec. for 120 yards over 10 flights of 3 ft. 6 in. hurdles.

The division of victories, as opposed to records, in the 23 events given above since 1896, has been as follows:—(1) U. S. A. 1896, 1900, 1904, 1912, 1920. Great Britain 1924. South Africa 1908. (2) U. S. A. 1900, 1904, 1912, 1920, 1924. Canada 1908. (3) U. S. A. 1896, 1900, 1904, 1912; Great Britain 1908, 1924. South Africa 1920. (4) Great Britain 1896, 1900, 1920, 1924. U. S. A. 1904, 1908, 1912. (5) Great Britain 1896, 1900, 1912, 1920. U. S. A. 1904, 1908; Finland 1924. (6) Finland 1912, 1924. France 1920. (7) Finland 1920 1924. U. S. A. 1904, 1908. Greece 1896. South Africa 1912. (8) U. S. A. 1896, 1900, 1904, 1908, 1912, 1924. Canada 1920. (9) U. S. A. 1900, 1904, 1908, 1920, 1924. (10) U. S. A. every year. (11) U. S. A. every year except 1920, Sweden. (12) U. S. A. every year. (13) U. S. A. every year except 1920, Finland. (14) U. S. A. every year. (15) U. S. A. every year except 1896 and 1900, no contest. (16) U. S. A. every year. (17) U. S. A. every year except 1920, Sweden. (18) U. S. A. every year. (19) U. S. A. every year except 1920, Finland. (20) U. S. A. every year except 1896, no contest. (21) Sweden 1908, 1912, Finland 1920, 1924. No contest in 1896, 1900, 1904. (22) U. S. A. 1896, 1904, 1908, 1924, Finland 1912, 1920. Hungary 1900. (23) U. S. A. 1896, 1900, 1904. Great Britain 1908, Sweden 1912. Finland 1920. Australia 1924.

TABLE I. OLYMPIC RECORDS.

Race	Date	Place	Winner	Country	Time or Distance
(1) 100 metres	1912	Stockholm	D. F. Lippincott	U.S.A.	10 3/5 sec.
	1924	Paris	H. M. Abrahams	Great Britain	10 3/5 sec.
(2) 200 metres	1904	St. Louis	A. Hahn	U.S.A.	21 3/5 sec.
	1924	Paris	J. V. Scholz	U.S.A.	21 3/5 sec.
(3) 400 metres	1924	Paris	E. Liddell	Great Britain	47 3/5 sec.
(4) 400 metres relay	1924	Paris	U.S.A.	U.S.A.	41 sec.
(5) 800 metres	1912	Stockholm	J. E. Meredith	U.S.A.	1 min. 51 9/10 sec.
(6) 1,500 metres	1924	Paris	P. Nurmi	Finland	3 min. 53 2/5 sec.
(7) 1,600 metres relay	1924	Paris	U.S.A.	U.S.A.	3 min. 16 sec.
(8) 3,000 metres steeplechase	1924	Paris	W. Ritola	Finland	9 min. 33 3/5 sec.
(9) 3,000 metres team	1924	Paris	Finland	Finland	8 min. 32 sec.
(10) 5,000 metres	1924	Paris	P. Nurmi	Finland	14 min. 31 1/6 sec.
(11) 10,000 metres	1924	Paris	W. Ritola	Finland	30 min. 23 1/5 sec.
(12) 10,000 metres walk	1912	Stockholm	G. H. Goulding	Canada	46 min. 28 2/5 sec.
(13) Marathon	1920	Antwerp	H. Kolehmainen	Finland	2 hr. 32 min. 35 5/8 sec.
(14) Hurdles (110)	1920	Antwerp	E. J. Thomson	Canada	14 4/5 sec.
(15) Hurdles (400)	1924	Paris	F. M. Taylor	U.S.A.	52 3/5 sec.
(16) High jump	1924	Paris	H. M. Osborne	U.S.A.	6 ft. 5·95 in.
(17) Long jump	1912	Stockholm	Gutterson	U.S.A.	24 ft. 11 1/4 in.
(18) Pole jump	1920	Antwerp	F. K. Foss	U.S.A.	13 ft. 5 in.
(19) Weight	1912	Stockholm	Macdonald	U.S.A.	50 ft. 4 in.
(20) Hammer (16 lb.)	1912	Stockholm	M. J. McGrath	U.S.A.	177 ft. 7 in.
(21) Javelin	1920	Antwerp	J. Myrra	Finland	215 ft. 9 1/4 in.
(22) Discus	1924	Paris	C. Houser	U.S.A.	151 ft. 5 1/16 in.
(23) Hop, step and jump	1924	Paris	A. W. Winter	Australia	50 ft. 11 3/16 in.

It should be noted that 100 metres = 109·3 yards; 200 metres = 218·7 yards; 400 metres = 2·6 yards less than a quarter of a mile; 1,500 metres = 119·6 yards less than a mile. 110 metres (hurdles) is nearly 11 inches over 120 yards. The Marathon Race is 42·263 kilometres or 26 miles 385 yards.

These 23 events all occur in the department of athletics, which is only one division of the Games. In 1908, the United Kingdom, with 839 entries, scored 57 first prizes and five more went to the Dominions; the United States, with 160 entries, scored 22 first prizes. The remaining 22 first prizes went to the 1,529 entries from all other nations. In 1912, the United Kingdom, with 526 entries, scored ten first prizes and eight more went to the Dominions; the United States, with 572 entries, scored 24 first prizes; Sweden, the organising country, with 881 entries scored 24 first prizes; the remaining 36 first prizes went to the 3,651 entries from all other nations. Sufficient records were not kept of the next two Games to continue the comparison in full. But in 1920 the United States won 22 first prizes; Great Britain took eight; the Dominions four; Belgium, the organising country, one; and the remaining 65 first prizes were divided among all the other nations. In 1924, with 424 entries, the United States won 27 first prizes; Great Britain, with 443 entries, won six; and the Dominions, four; France, the organising country, won four. The remaining 69 first prizes (without counting winter sports, in which Norway won easily with Finland second) were divided among all the other nations. These figures are not taken from victories in the athletic sections only; but from the full programme.

Some Reflections.—On these statistics a few words of explanation are necessary. There is not supposed to be a winning nation of any particular Olympic year. But human nature insists on classification of results, and this may be roughly obtained by scoring ten for a first prize, five for a second and four for a third. Even then, it is clear that the Marathon Race is really worth more than the 100 metres; or a sculling-race than a miniature rifle. The Americans have done wonderfully well by specialising in athletics, and their all-round ability is shown by the fact that at Paris in 1924 H. M. Osborne won the Decathlon comprising ten events, and also set up a new world's record for this particular competition.

But the country that has made the most extraordinary progress of all is Finland. In estimating the percentage of victories to entries it must be remembered: (1) that not all athletes entered were actually competing, (2) that gymnastic and other teams absorb a large number, (3) that women have entered, since 1912, for certain events like swimming and lawn tennis, (4) that some (though few) athletes compete in two or more events, (5) that the organising country in which the Games are held can invariably count on producing, if she desires, the full number of competitors legally permitted to enter for every event.

The art competitions have not been considered in these statistics. But it may be noted that in 1920 the silver medal in literature was awarded to Sir Theodore Cook (Great Britain) for his poem on "Pindar and the Olympic Games," and in 1924 the same prize was won by Miss D. Margaret Stuart (Great Britain) for her "Sword Songs." For the guidance of future organisers, it may be added that out of £27,183 available for the expenses of the British team of 1924, a surplus of £1,458 was left in hand on Dec. 31 of that year for the purposes of the British Olympic Association.

The Games in 1924.—The winter sports began at Chamonix on Jan. 25 1924, and 39 entries represented Great Britain. There were 14 events in all, in skating (speed and figure), ice hockey, curling, bobsleighing and ski-racing. The programme in Paris was opened at Colombes on July 5 1924 and consisted of athletics (27 events), swimming (ten events for men and seven for women), boxing (eight events), cycling (six events), wrestling (two styles, 13 events), shooting (eight events), lawn tennis (five events, including ladies), gymnastics (two events), fencing (four events), rowing (seven events), weight lifting (five events), the modern Pentathlo and polo. Association football was held in Paris from May 15 to June 9 1924, Uruguay beating Switzerland by three goals to nil in the final. Rugby football was held in Paris from May 3 to 18, the United States defeating France in the final by 17 points to three. Neither baseball nor cricket has been included in the Games. In 1924, in polo, Argentina won four games, the United States three, Great Britain two, Spain one and France none. Many other sports were omitted. The programme was very much too long for practical purposes, and a standardisation of the Games, in this and other directions, became a pressing necessity for the Olympiad of 1928 in Holland. The Games of 1932 will be held in the United States (*see* ATHLETICS).

A. M. Webster, *The Evolution of the Olympic Games*, (London 1925).

(T. Co.)

OMAHA, Neb., U.S.A. (*see* 20.98), 34th city in size in the United States, and the principal retail trading centre between Chicago and Denver, ranked first (1924) in the production of dairy butter and of pig lead, first as a primary grain market and disputed with Kansas City for second place in packing-house products and as a live stock market. South Omaha, the site of the Union stock yards (*see* 25.514), which had a population of 26,250 in 1910, was annexed in 1915; Benson, Florence and Clontarf in 1917; thus increasing the area to 37 square miles. The population was 191,601 in 1920, of whom 35,381 were negroes and 35,645 foreign-born; and the census bureau estimate in 1925 was 211,768. The products manufactured within the city limits were valued at $60,854,000 in 1909; $452,237,000 in 1919 (when South Omaha was included); $315,971,430 in 1923; and, according to a local compilation, $388,018,541 in 1924. The 550 wholesale and retail houses distributed merchandise valued at nearly $500,000,000.

The packing industry, employing 14,000 persons, dealt with 70% of the 8,697,690 head of live stock received in the city in 1924, producing an output valued at $198,392,582. Industries next in importance were smelting, principally of lead and silver (value of products, $42,708,485); butter and other dairy products ($24,331,395); automobiles, trucks and accessories ($19,007,475); flour and grist-mill products ($11,180,808). Omaha is the headquarters of the Union Pacific system, central station of the transcontinental air-mail route, and national headquarters of the air-mail branch of the postal service. It is an important centre for insurance. The percentage of homes owned is high and increasing: (1910) 39·8%; (1920) 48·4%; (1925) 55%. The public schools included 58 "grade" and five high schools in 1925, representing an investment of $20,000,000 and an annual expenditure of $4,000,000. The combined budget of the philanthropic institutions financed by joint appeal was about $400,000. With the completion of projects under way in 1926, the parks will comprise over 2,000 ac. and the city will have 50 m. of boulevards. A new "home rule" charter was granted by the Nebraska legislature in 1923.

OMAN, SIR CHARLES WILLIAM CHADWICK (1860–), British historian, was born at Mozufferpore, India, the son of a tea planter, Jan. 12 1860. Educated at Winchester and New College, Oxford, he distinguished himself at both seats of learning, and in 1883 was made a fellow of All Souls College. In 1905 he became Chichele professor of modern history at Oxford and he was chosen a fellow of the British Academy in the same year. He was president of the Royal Historical Society 1917–21. In 1919 he was elected M.P. for the University of Oxford and in 1920 he was knighted. As a historian Oman won his spurs by his studies on the art of war, the result being his *History of the Art of War in the Middle Ages* (1898, new ed. 1924). His other works include a *History of Greece* (1890); *A Short History of England* (1895, new ed. 1920); and six volumes of a *History of the Peninsular War*. Sir Charles is an authority on coins, on which subject he writes in this Encyclopædia.

OMAN (*see* 20.99) roughly comprises the extensive and mountainous promontory which forms the eastern extremity of Arabia, extending from Ras Musandam on the Gulf of Oman to the eastern limits of Hadhramaut at Ras Sajar (*lat.* 16° 8″ N.) on the Indian Ocean. Its capital, Muscat (*see* 19.43), was before the

War an important centre of the traffic in arms, which was in 1912 subjected to control by the establishment of a warehouse at the instance of the British Government. The Sultan of Muscat, Saiyid Taimur, who succeeded his father, Saiyid Faisal ibn Turki, in 1913, enjoyed a nominal authority over the whole of Oman, but his rule is effective only on the coast.

The tribes of the interior are practically independent under the loose control of an Imam of the 'Ibadi sect, whose centre is at Rustaq. A rising of the 'Ibadis in 1913–4 against the Sultan resulted in the occupation of Bait al Falj near Muscat by a British Indian force, which remained there throughout the War, defeating the rebels in 1915. Since the War the Sultan's administration has given rise to much dissatisfaction and in 1920–1 the British Govt. intervened to patch up an understanding between him and the 'Ibadi Imam. Shortly afterwards the Sultan had to agree to the creation of a sort of council of regency for the administration of the State and since then he has taken no active part in the government of his dominions, residing partly in India and partly on his personal estates. The administration is controlled by the Govt. of India. (*See* ARABIA.)

O'NEILL, EUGENE GLADSTONE (1888–), American dramatist, was born in New York City Oct. 16 1888. His early education was received at Roman Catholic schools and at the Betts Academy, whence he proceeded to Princeton University, remaining for one year. At different times he worked as sailor before the mast, actor and reporter. In 1914–5 he attended Harvard University. He rapidly became the most conspicuous of the younger American dramatists, and twice was awarded the Pulitzer Prize: in 1920 for his play, *Beyond the Horizon*, and in 1922 for *Anna Christie*. He finds his dramatic material among simple people, often sailors, and he deals in terms of tragedy with their conflicting passions and dreams and inner questionings. Among his works are: *Thirst and Other Plays* (1914); *The Moon of the Caribbees and Other Plays of the Sea* (1919); *Emperor Jones* (1921); *Straw* (1921); *Gold* (1921); *The Hairy Ape* (1922); *Welded* (1924); *All God's Chillun's Got Wings* (1924); *Desire Under the Elms* (1924). A complete edition of his plays in two vol. was published in 1924. His *Fountain* and *The Great God Brown* were produced in 1926.

ONNES, HEIKE KAMERLINGH (1853–1926), Dutch physicist, was born in Groningen Sept. 21 1853. He studied mathematics and physics in his native town, where in 1879 he took his doctor's degree on presenting a dissertation entitled *New Proofs of the Earth's Rotation*. He became professor of experimental physics at Leyden in 1882, and devoted himself especially to the study of properties of matter at low temperatures. As director of the Cryogenic Laboratory, founded by him at Leyden, he succeeded, in 1908, in liquefying helium. He later carried out important investigations on the influence of low temperatures on nickel and manganese iron alloys. He also demonstrated that the resistance of electric conductors disappeared suddenly at a certain temperature and that electric current could exist without electromotive force. In 1913 the Nobel Prize for physics was conferred on him. He became a foreign member of the Royal Society in 1916 and a corresponding member of the Prussian Academy of Sciences at Berlin in 1923, the year in which he resigned his chair at Leyden. His published work includes *Algemeine Theorie der Vloeistoffen* (*General Theory of the Fluids*, 1881). He died at Leyden Feb. 21 1926. See J. P. Kuenen, *De Toekenning van den Nobelprys aan H. Kamerlingh Onnes* (*Chemisch Weekblad, 1913*).

ONTARIO (*see* 20.113), a province of the Dominion of Canada. Through the addition in 1912 of Patricia, formerly part of the northwest territories, the area of Ontario was increased to 407,262 sq. m., of which 41,382 sq. m. are water. In 1921 the population was 2,933,662, an increase of 16·08% in the preceding decade. Sex distribution showed an excess of 30,118 males over females: 77% of the population were of British, 8·4% of French and 4% of German origin. The number of Indians in the province in 1921 was 26,654. The chief towns and their populations in 1921 are Toronto, the capital of the province, 521,893; Hamilton, an important manufacturing centre, 114,151; Ottawa, the federal capital, 107,843; and London, 60,959. The Government consists of a lieutenant-governor and a legislative assembly with a single chamber, the term for members being four years. The province is represented in the Federal Parliament by 24 senators, and by 82 members of the House of Commons. Women may vote, and are eligible for election to the Legislature.

Education.—The increased range of compulsory attendance and the more efficient enforcement of the law provided for in the provincial Education Act of 1919 led to increased numbers of pupils, especially in the secondary schools. The school age having been raised from 14 to 16, increased attention was devoted to technical education, which has shown considerable progress. In 1924 there were 7,022 elementary schools, with an enrolment of 610,322, an increase of nearly 10,000 over the preceding year, 189 continuation schools, and 183 high schools and collegiate institutes, with an aggregate enrolment of 66,784. The University of Toronto and its affiliated colleges had a total staff of 583 in 1924.

Agriculture.—Ontario is the chief mixed farming province in the Dominion. The value of all field crops in 1918 was $363,900,778, but by 1924 it had fallen to $260,534,000. The table below shows the yield in thousands of bushels and value in thousands of dollars of the principal field crops in 1922–5.

Dairy farming has steadily increased in importance, the gross revenue of dairy products reaching a value of $71,000,000 in 1918 and $95,005,000 in 1924. An intensive programme of agricultural education has been carried on by the provincial Government. Live stock in 1924 included 2,917,000 cattle, 1,807,903 swine and 870,279 sheep; horses numbered 673,371 in 1923.

Forests and Lumber.—The total area of forests in Ontario in 1924 was estimated at 240,000 sq. m., the chief timber being spruce, pine and poplar. The production of lumber, laths, and

shingles in 1922 was valued at $25,687,380. Pulp production in 1923 was 877,921 tons, valued at $33,481,035; the manufacture of paper is increasing in importance.

Fur and Fisheries.—The fur trade of Ontario is the most important in the Dominion. In 1922–3, 838,249 pelts were purchased by traders at a value of $3,616,692. The fisheries of Ontario, due to its wealth of lake shoreline and inland waters, were valued at $3,159,427, which was just $1,000,000 greater in value than the fisheries of Quebec.

Mining.—Northern Ontario has become increasingly notable as one of the world's great mining areas. The production of petroleum fell from 226,165 bar. in 1913 to 154,317 bar. in 1924. Construction materials, including Portland cement, and stone, increased in value from $5,866,775 in 1913 to $10,833,670 in 1924.

Manufactures.—Ontario is the leading manufacturing province of Canada, 9,174 establishments in 1922 employing 237,319 persons with an annual production of $1,274,424,000. The leading manufactures are pulp and paper, textiles, iron and steel, boots and shoes, and sugar refining. The rapid expansion of the industrial activity of Ontario has been greatly stimulated by the development of hydroelectric power, chiefly at Niagara Falls. The Queenston-Chippawa development, begun in 1917, was completed in 1925 at a cost of over $60,000,000; there are eight units, totalling 440,000 horse-power. On Feb. 1 1924 the available 24-hour power at 80% efficiency at ordinary minimum flow was 18,225,316 H.P.: the developed water power was 1,445,480 horse-power.

Communications.—The province is well provided with railways for internal communication and for connecting all the leading industrial centres with neighbouring provinces and with the United States. There were 10,956 m. of steam railways in operation on Dec. 31 1923; several electric railways were also in operation. The greater part of the 117·2 m. of canals of Canada are situated in Ontario, the most important system being that which connects Port Arthur with Montreal through the Great Lakes. While the number of Canadian vessels using this system has shown a steady increase since 1917, the number of American vessels has declined proportionately, as also has the freight originating in the United States. Ontario possesses the best road system in the Dominion. Of its 64,258 m. of highway in 1924, 22,127 were of gravel, 11,446 were macadamised, and 185 were of concrete (*see* CANADA). (S. LE.)

OPERA (*see* 20.121).—In spite of the World War, the first quarter of the 20th century was fruitful in the production of new operas. But there is a distinct cleavage between the works of the pre-War period and those written after the War. Before the War restlessness and impatience with the old methods were the exception. They became the rule after 1919. Opera which conforms to the commonly accepted rules and standards is found only in the case of composers who belong more properly to the preceding era, like Boito, Puccini and Stanford. The general tendency is towards innovation and experiment—innovations of a radical nature affecting not only the technique of musical composition but also the whole conception of opera, and experiments in which the relation between the component parts, their worth and usefulness are questioned.

There are examples of opera in which music appears to have resigned all claims in favour of poetry, and examples in which both poetry and music give precedence to some far-fetched idea of scenic presentation. The change cannot be ascribed to the War. The most famous modern composer before 1914, Richard Strauss, never found one form of composition more congenial than another; he turned from the sonata to the symphonic poem, from symphonic poem to Biblical and classical opera, from opera to ballet, and from ballet to comedy. But this restlessness, like the innovations of Strauss, pales by comparison with the impatience and the boldness of the post-War generation.

The war, naturally, exercised a disastrous effect on opera. In Great Britain operatic enterprise was, during these years, entirely in the hands of Sir Thomas Beecham, who did much to raise the standard of opera in English. Beecham and the British National Opera Company (formed on his retirement) are mainly responsible for the production of the new British operas—Dame Ethel Smyth's *The Boatswain's Mate*, Gustav Holst's *The Perfect Fool* and *At the Boar's Head*, and Vaughan Williams's *Hugh the Drover*. These ventures attracted considerable attention, and various schemes were suggested for establishing British opera on a less precarious footing. The full international season was resumed at Covent Garden in 1924, when a German company was readmitted for the first time since the War.

Opera in Germany

Strauss.—Richard Strauss's first essays in opera came when he was at the height of his fame, and audiences were ready to accept and to welcome anything he chose to give them. The remarkable success of *Salome* and of *Elektra*, however, does not seem likely to stand the test of more critical days. Certainly neither of these, nor *Ariadne auf Naxos* (revised version in 1916), has increased his reputation. *Der Rosenkavalier* (1911) based on a libretto by Hugo von Hofmannsthal, is more likely to stand the test of time. That certain scenes are coarse rather than immoral cannot be doubted, but the skill shown in the drawing of characters is beyond question. The librettist has provided a comedy of manners which gives Strauss every opportunity to display his special genius for portraying comic and pathetic situations.

Although he has evolved no new theories, Strauss has given us in *Der Rosenkavalier* a whole gallery of characters every one of which is drawn with extraordinary felicity, varying from the sketch of a negro page boy to that of the provincial baron—the gross and material Ochs von Lerchenau; from the full length portrait of the heroine to the caricature of the adventurers who seek her patronage. Light comedy has induced him to adopt a frankly melodic style, often in waltz rhythm, which stands at the opposite pole to the declamatory style of *Elektra*. The dance melodies are as fluent as those of Johann Strauss, and much more subtle. It is Strauss's greatest asset that he can turn from laughter to tears, revealing at once the pathos that underlies laughter and the oddities and whimsicalities of a quasi-dramatic situation. The librettist may not convince us that the sorrows of a heroine who has resigned her lover to a younger rival and who trembles at the thought of a lonely old age are very deep or undeserved. The musician, however, is perfectly convincing, and just as in his symphonic poems he asked us to sigh for as well as to laugh at Don Quixote, so in *Der Rosenkavalier*, he depicts humanity in its pathetic and its ludicrous aspects. The scene which describes

the arrival of the Rosenkavalier bearing the token of betrothal to the bride, like the ensemble of the third act, is an admirable example of his power to describe different emotions at the same time.

Die Frau ohne Schatten (1919) tempted both composer and librettist (Hofmannsthal) into obscure symbolism, which, perhaps, cannot be expressed effectively in terms of music. While making the fullest use of his great skill in instrumentation, Strauss sought here as in *Ariadne* and in the ballet *Joseph's Legende* to make use of broad, diatonic melodies. These, owing to their gorgeous orchestral colour, may seem impressive at first, but soon betray inherent weakness and artificiality.

Some success attended the performance in Germany of two operas by Hans Pfitzner, *Das Christelflein* and *Palestrina*—both produced in 1917. These, like the operas of Erich Wolfgang Korngold—*Der Ring des Polykrates*, comedy in one act; *Violanta*, opera in one act (1917); and *Die Tote Stadt* (1920), and of Franz Schreker, *Der Ferne Klang* (1912), *Das Spielwerk und die Prinzessin* (1913), *Die Gezeichneten* (1918) and *Der Schatzgraber* (1920) leave the main problems of opera untouched. More originality was shown by Walter Braunfels in his adaptation of the " Birds " of Aristophanes (1920).

Busoni.—The contributions to opera of Ferruccio Busoni are intended for the German stage, and must be taken in conjunction with the art of Germany rather than with that of Busoni's countrymen the Italians. This remarkable artist was 46 years of age when he first turned his attention to the theatre. Two short operas—*Turandot*, founded on Gozzi's fairy play, and *Arlecchino*, based on a libretto written by himself—added considerably to his reputation as composer. But his most remarkable contribution is *Doctor Faust*, the libretto of which, dealing with the legend from an entirely new point of view, was first published in 1921. The music unfortunately was not finished at the time of his death in 1924, but the score was skilfully completed by Philipp Jarnach, and performed in Dresden in May 1925. It made a deep impression, both on account of the ideas embodied in the play and of the manner in which they were presented.

Busoni's *Faust* differs from Goethe's, as it differs from Marlowe's, in that the central idea is not the strife between good and evil, but the continuity of the human effort towards a goal which, hidden from our knowledge, is embodied in a Divine Will incompatible with the traditional conception of God and the devil. This idea is presented in a set of scenes derived from an old puppet play, and connected by unity of style and a single purpose. The music is not a symphony on which the action has been imposed, but it springs from the same source as the words and the action. Considered apart from the play, it reveals an instinct for classic dignity combined with the freedom of a modern. Although he never falls into extravagance, Busoni's power of suggesting atmosphere, mood and emotion is as considerable as the variety and resource of his orchestration. His profound knowledge of the classics gives breadth and depth to a style which is never heavy or unduly complex, but alert, elastic and free from the influence of prevalent schools. Whether in time *Doctor Faust* will rank with the acknowledged masterpieces, or whether its finer points must escape the average theatre audience, may be doubted, but Busoni is certainly the musicians' musician.

Opera in Italy

The composer who in some ways most nearly approaches Busoni, is Arrigo Boito, whose *Nerone*, first begun when the composer was a young man, was left unfinished at his death in 1918. It was completed under the supervision of Arturo Toscanini, and performed at La Scala, Milan, in May 1924. There is one important point of divergence between Busoni and Boito. Busoni was first and foremost a musician who wrote his own libretto because of the obvious advantages to be gained by unity of control. Boito was equally pledged to both poetry and music. The profound learning found in Busoni's music and in Boito's poetry resulted in an entirely different conception of music drama. In *Nerone* Boito attempted to place on the same level all the arts which constitute opera. He meant it to be spectacular enough to please the audience by a striking stage picture; he devoted great care, skill and an extraordinary wealth of information to the writing of the libretto, so that poetry should be duly honoured; he restrained the lyrical impulse in music with the double object of allowing complete freedom to scenic and poetic art and of giving prominence to the dramatic effects of a musical accompaniment which was in the main descriptive.

It may be questioned whether the idea of perfect equality between sister arts originated in Boito's mind, or whether he arrived at it after balancing the claims of other systems. He was a close observer of artistic movements, and it is possible that he became early acquainted with Moussorgsky's *Boris Godnov*, which is the best example of this theory. But while Moussorgsky adopted it because it seemed the only possible form for a musician of his temperament, Boito's lyrical reticence may have been the outcome of deliberate choice. It is not surprising, however, that opera based on the equality of the arts should have some of the faults of the ideal state based on the equality of men. However admirable, logical and just the theory, the practice is likely to result in a weakening of power and interest. So far, the greatest operas have been those in which music predominates.

The musical value of *Nerone* is far from negligible. The scene in which the early Christians learn the doctrine from the lips of their leader Fanuel has a delicate beauty that is very rare in Italian music, and there is a poignant pathos in the death scene of Rubria. On the other hand, in almost the whole of the first and second acts there is little genuine musical interest, apart from the adaptability of the music for the stage. The libretto has many lines of good poetry, and the historical learning amassed in its few pages constitutes probably a record of compression. Unfortunately, much of this is inevitably lost when put to the test of the theatre. The demands made on stage appliances make it impossible to contemplate a performance in any theatre not equipped with modern resources. If the system has proved far from flawless, the opera leaves us in no doubt as to the genius of a composer whose chief failing was the inability to choose between the claims of two arts he loved with equally deep devotion—music and poetry.

Puccini.—A less thoughtful and more popular composer, Puccini, after the early successes, touched the lowest point of his career with a comic opera *La Rondine* (1917), and rose to the highest with the comedy *Gianni Schicchi* (1919), which revealed a freshness and humour hitherto unsuspected in his music. Neither the failure nor the success owes anything, however, to a development of artistic ideals. *Gianni Schicchi* marks if anything a return to the old system, and contains a typical *aria* or two of the old pattern which won the warmest approval of his admirers. His technique shows a great advance on his previous work.

Pizzetti.—From the point of view of the development of music drama, the work of Ildebrando Pizzetti is more interesting. He began by accepting the criterion of his Italian contemporaries, and then, dissatisfied with what he conceived to be the dramatic ineptitude of lyricism, evolved a style which seeks to give to the melody of the singer beauty, but consistent with greater freedom than is possible in music which aims entirely at lyrical expression. In this he comes near to *Pelléas et Mélisande*, but with the important reservation that while Debussy envelops the drama in an atmosphere of mystery and shadows, Pizzetti expresses himself with absolute directness, and asks of music only that it should have the pliability, if not the swiftness, of words. These theories are exemplified in *Fedra* (1915) and perfected in *Debora e Jaele* (1922).

Malipiero.—More daring but also more questionable are the theories advanced by G. Francesco Malipiero, and exploited in works representing a complete reaction from all accepted ideas of opera. In *Pantea* the singers are not seen, and the action is expressed in the movement and gesture of a dancer whose mimicry is stressed by the music. *Sette Canzoni* consist of episodes unconnected by anything like a plot, and relying for their appeal not in any development of events but in the contrast between

the characters or between the moods of each picture. Greater prominence is given to the musical elements in *Le Baruffe Chiozzotte*, a free adaptation in one act of Goldoni's comedy for which Malipiero has evolved a "spoken" recitative, while the duty of the orchestra is to provide mood and atmosphere. *Orfeo* is satire, uncompromising in its music and in the action. The value of such works is negative, but it shows clearly enough the trend of musical ideas in Italy.

Wolf-Ferrari.—Quite traditional, on the other hand, are the operas of Ermanno Wolf-Ferrari, whose best work is comedy. A lurid melodrama, *I Gioielli della Madonna*, has made Wolf-Ferrari known beyond Italy and Germany; it is not equal to *Il Segreto di Susanna*, or to the charming arrangements of Goldini's comedies, *Le Donne Curiose* and *I Rusteghi*. Wolf-Ferrari combines some of the virtues of the Germans, such as solid, well-balanced workmanship, with an Italian bias for lyrical expression. This combination is not without its drawbacks, and is inclined to blunt the individuality of his music.

The English Revival

The general revival of interest in music in Great Britain has had a remarkable effect on opera, and operas by native composers written and performed in the first quarter of the 20th century exceed in number and in interest those of any other period in the history of English music. Although the greatest musician of the time, Sir Edward Elgar, has never written for the theatre, a group of gifted musicians has sprung up not only willing to devote themselves to a form which still offers scant chances of performance and reward, but also, in some cases, determined to make it the vehicle of new and individual expression.

Stanford and Ethel Smyth.—Sir Charles Stanford belongs on the whole to an older generation, yet his last work (which he did not live to see performed) was an opera, *The Travelling Companion* (1914: produced at Liverpool, 1925), in whose fantastic adventures some trace may perhaps be seen of the influence of the Russians. Dame Ethel Smyth, devoted to opera from the early days of her career, was writing for the theatre at the beginning of the century. But it was only with the comic opera *The Boatswain's Mate* (based on a story of W. W. Jacobs, performed by the Beecham Company during the War) that she made her mark. It has been pointed out that her music lacks unity of style, and the charge cannot be easily brushed aside. But, whatever its defects, the opera has the rare merits of speedy action, a whimsical story, and music which, however indebted it may be to other sources, has intense vitality and comic verve. Another work, *Fête Galante*, had a favourable reception when first performed at Covent Garden in 1923.

Boughton.—High hopes were aroused by Mr. Rutland Boughton's *The Immortal Hour*, which, performed first at the Glastonbury Festival in 1914, did not come into its own till eight years later, when it was given in London with considerable success—first at the "Old Vic." Theatre, and later at the Regent and Kingsway theatres. The unusual story, steeped in Celtic romanticism, the easy flow of the melodic themes, the genuine, glowing passion of the love scenes, the well-built choric sections, made a deep impression, and led some to expect even better things from Mr. Boughton.

These expectations, however, were not realised in the immediate future. Mr. Boughton's next essay was more ambitious, for it meant nothing less than the translation into opera of the *Alcestis* of Euripides in the English version of Professor Gilbert Murray. It is much to the composer's credit that he refused to be bound by archaeological considerations, and aimed rather at music which could bring home to a modern public the rich pathos and humanity of the Euripidean drama. In this he partly succeeded. The chorus is treated with skill and sympathy, and many scenes have great beauty. There is a delicate tenderness in the account given by the Handmaid of the grief and resignation of the dying Queen; the funeral procession moves to a strain that is at once expressive and dignified; and the music of Herakles lacks neither vigour nor originality. Yet on its performance at Covent Garden (1924) the work was found, on the whole, disappointing. An inadequate performance, and, still more, the barrenness of the orchestral setting, may be held partly responsible for this impression. But the revival of a Greek play in a modern theatre is apt to show to disadvantage the vaunted resources of the modern stage. The intimate relation possible between spectator and performer in an amphitheatre becomes impossible as soon as the modern stage sets up its barrier. This becomes all the more evident when music inevitably retards the course of the action and the speed of the words. No doubt for this reason *Alcestis* was found much more impressive accompanied by the piano in a small hall at Glastonbury than at Covent Garden, where the composer had at his service a vast stage and a large orchestra. A somewhat riper dramatic style was shown by Mr. Boughton in *The Queen of Cornwall*, a musical version of a play by Mr. Thomas Hardy.

Perhaps greater musical accomplishments are to be found in Mr. Granville Bantock's *The Seal Woman* (Birmingham, 1914), a "Celtic" opera which unfortunately suffers from a libretto which is neither convincing nor well constructed.

Holst.—The greatest interest was aroused by the performance of Mr. Gustav Holst's one-act opera *The Perfect Fool* at Covent Garden (1923), soon after the composer had made a great reputation with the symphonic suite "The Planets." The libretto (written by Mr. Holst) is highly fantastic. The value of *The Perfect Fool*, however, lies not in the text or in the story, both of which reveal obvious inexperience, but in music which lacks neither ingenuity nor dramatic expression. The choral writing is exceedingly effective, and thus well in keeping with the high traditions of British choral music. Such a chorus as that of the peasants flying the country ravaged by the Magician and his imps compares not unfavourably with the great choruses of *Boris Godunov*. Mr. Holst's mastery of instrumentation, the marked individuality of his orchestral colour, stand him in good stead and give considerable point to every bar of the score, irrespective of the action which takes place on the stage.

The libretto, were it to be extended to three or four acts, would be wholly inadmissible, and even in its present form it is not free from errors of construction as well as instances of verbal infelicity. But the music bears evidence to a dramatic talent which, directed to a more worthy purpose might, in the end, produce something more important than *The Perfect Fool*. Originality is evident in both text and music. But the originality of the music is easy; it is part of a temperament; its influence permeates every component element—harmony, counterpoint, orchestration. The originality of the story is purely negative, and contributes nothing to the success of the opera.

If the weakness of *The Perfect Fool* is a libretto unworthy of its music, the weakness of Mr. Holst's next opera, *At the Boar's Head* (1925), is a libretto to which music can add little or nothing. *At the Boar's Head* consists of various scenes from Shakespeare's *King Henry IV.*, with Falstaff as the central character. Mr. Holst, out of reverence for the poet, has adopted every word without alteration or excision, and also without allowing sufficient latitude for the inevitable retarding effect of music applied to words. Perhaps he hoped to neutralise this defect by the adoption of folk melodies, most of them derived from Chappell's *History of Popular Music in England*, or from *Country Dance Tunes* and *Morris Dance Tunes* (edited by Cecil Sharp), and the Folk Song collection of G. B. Gardiner. He has also deliberately given music a less important part than has been the custom of the great opera composers and, with considerable ingenuity, made the words bear the very lightest of musical burdens. In conformity with this purpose, the orchestra has been reduced in numbers, and there are not a few pages in which the vocal part proceeds unaccompanied or is reduced to a recitative, enabling the singer to pronounce his words with the greatest speed. Of actual action there is practically none, and the dramatic interest is limited to such traits of characterisation as these brief scenes reveal.

The value of *At the Boar's Head* lies for us in the extraordinary skill with which Mr. Holst has woven together some forty folk-tunes and in the novelty of an opera where the usual relation

between words and music is reversed. In spite of care and cleverness, there are moments when the listener cannot but feel that the notes are holding back the pace of the dialogue. When one good joke caps another, or when a period of prose makes for a definite climax, even the lightest music becomes an impediment. Mr. Holst's stimulating and vigorous freshness and ingenuity are never absent from his music. But they are the gifts of the musician in general rather than of the composer of opera in particular.

Vaughan Williams.—In the libretto of *Hugh the Drover* Dr. Vaughan Williams was more fortunate, for Mr. Harold Child has provided him with a story which possesses human interest, moves swiftly and logically to an appointed end, and is told in words which are never too sublime or too homely for musical treatment. It was produced in 1924 by the British National Opera Company, and made an immediate appeal. It is based, like the music of Mr. Holst's *At the Boar's Head*, on folk tunes. Dr. Vaughan Williams has used them very deftly to emphasise the simple and direct nature of the story. It may be said here that the use of folk songs in opera by these British composers owes more to the researches of Mr. Cecil Sharp than to the example of continental musicians. Abroad the general tendency has been to add splendour and brilliancy to a folk-tune used in opera. Mr. Holst and Dr. Vaughan Williams appear to be mainly concerned with keeping fresh the fragrant flavour of these native wood notes wild. The question of the fitness of a subject has to be considered afresh when the musician means to draw his raw material largely from the vast wealth of folklore. It is obvious, for instance, that such a play as "Othello" would gain nothing if it were set to music derived from popular melodies. *Hugh the Drover*, on the other hand, is admirably adapted for such treatment.

Mention must yet be made of the graceful light work of Mr. Nicholas Gatty, whose *Prince Ferelon*, first produced at the "Old Vic." theatre in 1921, has been repeatedly performed since with conspicuous success by the Carl Rosa Company.

Revivals.—Characteristic of this period is the number of revivals. J. S. Bach's *Phoebus and Pan* has been revived and prepared for stage presentation by the company of Sir Thomas Beecham. Later the same composer's *Coffee Cantata* was put on the stage by the British National Opera Company. Cambridge witnessed a revival of Handel's *Semele* in the form of opera, and to Oxford must be given the credit for the first performance in England in modern times of Monteverde's *Orfeo*. Most fortunate of all was the revival of Gay's *The Beggar's Opera*, which had a run of three and a half years in London, during which 1,453 performances were given. Its sequel, *Polly*, has also been produced, though not with the same good fortune.

Opera in other Countries

France.—Apart from Debussy's *Pelléas et Mélisande*, which remains an isolated example of individual genius, French contributions to modern opera are, generally speaking, copious rather than notable. The promise of Gustave Charpentier's *Louise* was not maintained in the sequel *Julien*. The operas of Alfred Bruneau, of Charles Marie Widor and Gabriel Fauré are little known abroad, where Massenet and Thomas remain the representative composers of French music drama. A far more brilliant achievement is Maurice Ravel's one-act opera *L'Heure Espagnole*, the orchestral score of which may be described without exaggeration a marvel of wit and skill. Indeed, its worth is mainly in the felicity and deftness of the scoring. The plot and the scenic action are nothing more than a *jeu d'esprit* of typical Parisian flavour. At the opposite pole stands Vincent d'Indy, who attempted a new compromise between opera and oratorio in *La Légende de St. Christophe* (1920). In this a narrator is made to tell the story of St. Christopher, who is shown in various scenes, embodying, at first, pleasure, then repentance and ending with death. D'Indy's music, like his text, offers the strongest possible contrast to Ravel's. While the former is severe and restrained the other is wordy and whimsical; Vincent d'Indy stands for the classics and, in particular, for the traditions of César Franck, while Ravel is the apostle of modernity, intolerant of restrictions and of scholastic canons. Both in France and out of France Ravel has the larger following.

Of the novelties produced later at the Opera in Paris the most notable is perhaps Albert Roussel's *La Naissance de la Lyre* (1925), the music of which has a certain distinction, not however without artificiality.

Russia.—The only important addition to Russian opera since the death of Rimsky-Korsakov has been Igor Stravinsky's *Nightingale* (1914), which is described as a "lyrical tale." There is, however, as little "lyricism" in the music as there is in the story, which is derived from Hans Andersen's well-known tale. It belongs to the kind of opera of which the finest example is Rimsky-Korsakov's *Golden Cockerel*. The *dramatis personae* are no more than puppets, and the purpose of the musician is not so much to bring home the pathos or wit of a dramatic or comic situation as to emphasise the artificial nature of the story, and in this the highly sophisticated music of Stravinsky succeeds admirably. The atmosphere is cold and unemotional, the play appears to evolve at considerable distance from the spectator, who is asked not to follow in sympathy the adventures of the characters, but to admire the artistry and the aptness of the performance. The action is reduced to a minimum. Stage pageantry takes the place of stage action, and *The Nightingale* may be placed, as an entertainment, half way between opera and ballet. It is true that the actors sing and do not dance. But if the action were to be presented by mimes or marionettes and the singers used as a complement to the orchestra the loss would be trifling.

The opera aroused at first keen interest on account of its music and of the novelty of its scenic presentation. However much we may doubt the real value of innovations which tend to deprive opera of its surest means of appeal—that is, dramatic action—there is no questioning the extraordinary skill and ingenuity of Stravinsky in the domain of harmony and orchestration.

United States.—America has made so far no contribution to international opera, nor can it be said that a school of national opera is already firmly established, even though some original works have been produced with fair success. The conditions are undoubtedly favourable. The nation as a whole appears to be passionately devoted to its music; musical institutions are supported with a generosity which has no parallel in Europe, and every effort is made to keep the public constantly in touch with the best that the Old World produces. If the results have not fully justified the hopes of the patrons who more than once have offered valuable prizes for American operas, the reason probably is to be found in the fact that the absence of a tradition or of national schools adds considerably to the difficulties of the composer. Having nothing of this nature to guide him in the choice of model or style, even the comprehensive knowledge of other schools which may otherwise nourish his mind and individuality is apt to leave him perplexed, and to suggest a hopeless attempt to balance their virtues and combine them in himself. Such, for instance, is the case of Mr. De Koven's, in many ways, able opera *The Canterbury Pilgrims* (pub. New York, 1917), the style of which owes something—on the composer's own admission—to Verdi, to Wagner and to Massenet. Genius, no doubt, is not to be hired, and the inducements which it is in the power of patrons to offer are, at best, a poor substitute for friendly rivalry and example.

But if there are no American operas of the first rank, works have been produced which deserve attention and are of good omen for the future. The accomplished conductor of the New York Symphony Society, Mr. Walter Damrosch, has written a musical version of Rostand's *Cyrano de Bergerac* which was received on its first production (New York, 1913) with every mark of favour. Horatio William Parker aroused unusual expectations with *Mona* (New York, 1912) and *Fairyland* (Los Angeles, 1915). Other composers have produced operas of some merit, amongst them C. W. Cadman (*Shanewis* New York, 1918); J. A. Hugo (*The Temple Dancer*, New York, 1919) and V. Herbert (*Natomah*, Philadelphia, 1915). (F. Bo.)

OPHTHALMOLOGY (*see* 10.91 and 28.130).—The science of ophthalmology deals with the processes by means of which the images of external objects are brought to our consciousness. It is therefore concerned:

(*a*) with the eye itself; (*b*) with the nerve paths and tracts which convey visual impulses originating in the eye, through the different parts of the brain to the brain cortex, where these impulses are converted into conscious impressions; (*c*) with the eyelids which cover and protect the eyes; (*d*) with the tear glands and ducts; (*e*) with the muscles that bring about the movements of the eyes and keep them trained in the desired direction; (*f*) with the nerves and their complicated cerebral connections which supply these muscles; (*g*) with the bony walls which comprise the boundaries of the orbit; (*h*) with the blood-vessels and lymph paths which maintain the nutrition of all these structures.

It concerns itself with diseased conditions of these parts and derives particular importance from the fact that many diseases of the central nervous system and many general constitutional diseases of the body manifest themselves by some derangement of function or structure which is to be discovered by the various means of investigation which are available to the ophthalmic surgeon.

Many of these investigations are capable of an accuracy and a minuteness which is possible with no other structure in the body, and the eye, as an organ, is unique in the body in the important particular, that its retina is, in essence, a portion of the brain itself which is available to minute examination by means of the ophthalmoscope, and is the only portion of the brain which is available to inspection during life. The arteries and veins which supply the retina can also be minutely examined during life, the diseases of them observed and followed in all their changes, and they are the only arteries and veins in the body which can be seen clearly during life. The value of these observations is enhanced by the fact that the eye itself acts as a sort of low-power microscope, providing a magnification of about 15 diameters for the examination of these structures. The eyes are the subject of a number of hereditary diseases, and form one of the most convenient media for the study of transmission of such diseases.

Affections of the Eye.—The whole function of the eyeball itself is to provide that a clear image of external objects shall be formed upon the retina, but, considered as an optical instrument, in certain cases it departs from the normal, with the result that the acuity of sight is lowered. Thus it may be too long, so that the retina comes to be behind the point at which the images of external objects are formed; this condition is known as myopia or short-sightedness, and may be compensated by the wearing of concave lenses in the form of spectacles.

In other cases, the eyeball is too short, so that the retina comes to be placed in front of the point at which the image of external objects is formed. This condition is known as hypermetropia or long sightedness; this can be compensated by the use of the focusing muscle of the eye, making the lens more convex; or, what is preferable, by the wearing of appropriate convex lenses in the form of spectacles. In astigmatism the refractive power of the eye varies in different axes, so that, for instance, in an extreme case the vertical axis may be myopic whilst the horizontal axis is hypermetropic.

Normally the visual axes of the two eyes are parallel, so that images of external objects are formed upon corresponding points of each retina. This arrangement is largely responsible for the phenomenon of stereoscopic vision, which enables us to judge the position of objects in space with great accuracy. Should this parallel arrangement of the two eyes become upset by any means, such for example as paralysis of some of the muscles, the power of stereoscopic vision is lost and double vision usually arises.

Eyeball and Camera Compared.—The eyeball may with considerable aptitude be likened to a photographic camera. Roughly speaking it is globular in shape and is an inch long in all dimensions. The front part, or cornea is curved, is perfectly transparent and functions as a lens. Behind it is a chamber filled by the aqueous humour—little more than water. Further back is the iris—the coloured part of the eye—which in infants, up to about three months of age, is always of the same bluish-grey colour, and afterwards attains the different tints and colours which produce the blue, the grey, the green or the brown eye. The hole in its centre forms the pupil, and by contraction or dilation of the tissues of the iris the pupil can be varied in size through a wide range; it may be compared to the stop in the camera. In bright lights the pupil is small, and it becomes large in dull illumination. The iris rests behind upon the lens.

The lens is bi-convex, its back surface having a greater curvature than the front. It is perfectly transparent, and the focusing of the eye for near or distant objects is brought about by alteration in its curvatures by contraction of the ciliary muscle. Here is an essential difference between the eye and the photographic camera, whose focus is adjusted by shifting the position of the lens. As age proceeds, opacities frequently develop in the lens, until at the age of 60 very few individuals have lenses which are entirely free of opacities; almost everyone, then, at the age of 60 or over may be said to have the beginnings of cataract, though the sight is quite unaffected thereby. When, however, these opacities have so increased as to involve markedly the central part of the lens, and so render sight very imperfect, the term of cataract becomes applicable to the condition; in such a case the cataract can be removed by operation and the sight restored.

Vitreous Chamber and Retina.—Behind the lens is the largest chamber of the eye, the vitreous chamber, which is occupied by a perfectly transparent, colourless substance, much like the white of an egg. Clothing the back part of the eye, and extending forward some distance in front of its equator, is the retina. It rests upon a highly vascular membrane which is responsible for the nutrition of the greater part of it, namely the choroid; in man, however, the retina has blood vessels of its own, which are seen with great distinctness by means of the ophthalmoscope. These vessels supply the inner parts of the retina with their nutrition. The retina is the sensitive layer of the eye and may be likened to the sensitive plate of the camera for upon it images are formed which initiate impulses which, when conveyed to the cortex of the brain, give rise to the sensations of sight. Its sensitive layer is placed posteriorly, and is composed of very delicate structures known as the rods and cones.

At the central spot or yellow spot of the retina, the point of distinct vision, cones alone are present. The rods are believed to be concerned with lights of lower intensities, and in accordance with this they alone are present in night-flying birds (*see* COLOUR VISION).

Optic Nerves.—The nerve fibres from all these tissues converge upon the optic disc, and leave the eye by means of the optic nerve, which traverses the orbit to enter the skull. Inside the skull the two optic nerves meet and each is divided into two parts, one part continuing to the mid-brain on the same side, the other part crossing over to the opposite side. This crossing forms what is known as the chiasma; in many animals, the birds for instance, the whole of each optic nerve crosses over in this way. Beyond the chiasma the nerve fibres are again collected into a compact bundle known as the optic tract, which terminates in the mid-brain. From here nervous impulses are relayed in two chief directions; some connect up with the nerves which control the movements of the eyes and others, forming the so-called optic radiations, make a long sweep backwards to reach the cerebral cortex, where, as already stated, the impulses are transformed to sensations of sight.

Cerebral Cortex.—The exact area of the cerebral cortex, in which these fibres end, is known with great accuracy and forms the visual cortex. It is placed at the extreme hind end of the brain, and the adjoining mesial surface of each hemisphere, in the region of the calcarine fissure (*see* 4.408). Should a minute portion of this cortex be cut out as the result of injury or blocking of its blood supply, the precise area of the defect which will be found in the vision can be stated with certainty. This accurate localisation was much advanced as a result of observations made during the War.

Amongst the general diseases of the body in which important manifestations occur in connection with the eye a few may be mentioned.

Clinical Symptoms.—In brain tumours or abscesses, swelling of the optic disc is seldom absent, and forms perhaps the most important sign in the diagnosis of the condition. In addition the ocular nerves may have their functions interrupted, so that the movements of the eyes are interfered with, they no longer move in unison and double vision occurs. If nothing can be done for the brain tumour the optic nerve atrophies and blindness ensues. In advanced renal disease changes in the retina develop and convey a particularly grave prognosis, for patients seldom live so long as two years after their discovery. In diabetes a similar change may also arise, which may greatly spoil the sight, and although of less serious import than in renal cases, it must be considered a bad omen. Syphilis frequently attacks the eye, whether in the early or late stages, and is perhaps the most prolific single source of blindness. Tuberculous disease occasionally occurs. In diseases of the blood in general, eye signs are very common, and there are many other diseases where the diagnosis may be greatly assisted by the discovery of changes in some part of the ocular apparatus. The introduction of what is known as the " slit lamp " has made many investigations possible which previously were quite outside our scope.

OPIUM, TRAFFIC IN (*see* 20.130).—It was first realised in 1906 that if the Chinese Govt. were to be able to suppress the opium evil, she must be assisted by other nations. In 1909 President Roosevelt proposed that an international investigation should be made. As a result an international opium commission met that year at Shanghai at which 13 Powers were represented. The recommendations made at this meeting formed the basis of the First Opium Convention, which was drawn up at The Hague in 1912. The articles of this convention may be summarised as follows:—

1. The distribution of raw opium to be controlled and the use of prepared opium to be gradually suppressed.
2. The export of raw opium to countries prohibiting its entry to be stopped and its export to countries restricting its import to be controlled.
3. The export and import of prepared opium to be prohibited except to those countries not yet ready to suppress its use.
4. The use of alkaloids of opium and its derivatives to be confined to medical and legitimate purposes; a Government licence to be obtained by all persons engaged in the manufacture, sale, distribution, import and export of the drugs.
5. The last chapter of the convention consisted of clauses dealing with assistance to China and with certain obligations undertaken by China herself.
6. Before the convention came into effect the adherence of the 34 non-signatory Powers in Europe and America was required.

International opium conferences were held at The Hague in July 1913 and June 1914, at which a number of Powers ratified the convention. During the War all action in this connection was suspended until the Paris Peace Conference in 1919. In the peace treaties of 1919–20 the signatory Powers agreed that the ratification of these treaties should constitute a ratification of the convention of 1912 and the protocol adopted by the Third Opium conference of 1914 (according to which the convention should come into effect upon its ratification regardless of the non-signatory Powers).

Opium and the League of Nations: Appointment of Advisory Committee.—Under the Covenant (Article 23 c), the duty of supervising the execution of agreements with regard to the traffic in opium and other dangerous drugs devolved upon the League of Nations. In order to carry out this obligation, the first Assembly of the League constituted a committee on opium and other dangerous drugs to be advisory to the council. This committee consisted of representatives of the countries chiefly concerned in the production of raw opium or manufacture of the drug, assisted by three assessors appointed for their special knowledge of the opium question. To the governments originally invited to nominate members, *i.e.*, Holland, India, Siam, Great Britain, Japan, Portugal, France and China, have since been added the United States of America, Bolivia, Germany, the Kingdom of the Serbs, Croats and Slovenes and Switzerland. The first assessors to be appointed were Sir John Jordan, Mrs. Hamilton Wright and M. Brenier.

The advisory committee, which sits only once a year, except in special circumstances has obtained certain important and definite results, such as additional ratifications to the Hague Convention (56 states have now ratified, 50 of these states being members of the League) and the adoption by a very large number of countries of an import certificate system. Under this system no government may allow the export from its territories of any dangerous drugs covered by the Hague Convention, except on the production by the exporter of a licence from the importing country, certifying that the drugs in question are required for legitimate purposes. The committee also encourages the use of the secretariat as a centre for the exchange of information concerning seizures of drugs within the territories of the different states. As a result, it is more possible to know the extent of the illicit traffic which takes place and the main sources and centres of the traffic. The committee receives and examines annually reports from the states as to the exports and imports which have taken place in the current year and of the amounts manufactured.

Annual Requirements of Drugs for Legitimate Purposes.—The council, on the recommendation of the advisory committee, invited the governments and the members of the League to prepare an estimate of total annual requirements for the inhabitants of their territories for medical, scientific and other uses with a view to proposing at some future date to the states concerned a new distribution of production which would limit the total output of raw material to the amount required for legitimate medical and scientific purposes.

The representative of the United States of America urged on the advisory committee the recognition of the principles that the use of opium products for other than medical and scientific purposes is illegitimate and they further urged the necessity, in order to prevent the abuse of these products, of exercising the control of the production of raw opium in such a manner that there would be no surplus available for non-medical and non-scientific purposes. The advisory committee expressed its agreement with this view, the representative of India, however, stating that, in the opinion of the Indian Govt., the use of raw opium according to the established practice in India and its production for such use are not illegitimate under the convention. The council and the assembly also approved the principles laid down by the representative of the United States of America.

International Opium Conferences of 1924 and 1925.—A number of replies had been received from governments giving estimates of their annual requirements of drugs for legitimate purposes when the committee decided to recommend to the council the calling of two international conferences. One, at which the producing and manufacturing states were to be represented, was to deal with the limitation of the production of raw opium and cocoa leaf for export to the amount required for medical and scientific purposes, and with the limitation of the amounts of morphine, heroin and cocaine to be manufactured; the other was to be a special conference to consider the suppression of opium smoking. The council forwarded this proposal to the assembly without comment, and after discussion by that body it was decided to ask the council to take the necessary action to put these resolutions into effect.

The assembly suggested, when forwarding the recommendation to the council, that the conference which was to deal with the problem of raw material and manufactured drugs should include all countries who are members of the League and parties to the convention of 1912, and not only representatives of producing and manufacturing States. This proposal was approved. The two conferences met during the latter part of 1924 and the early months of 1925, the conference on the use of prepared opium sitting first. This included representatives of the British Empire, China, France, India, Japan, Netherlands, Portugal and Siam.

The following 41 states attended the second conference: Albania, Australia, Belgium, Bolivia, Brazil, Bulgaria, Canada, Chile, China, Cuba, Czechoslovakia, Danzig, Denmark, the Dominican Republic, Egypt, Finland, France, Germany, Great Britain, Greece, Hungary, India, the Irish Free State, Italy, Japan, Luxembourg, the Netherlands, Nicaragua, Persia, Poland, Portugal, Rumania, the Serb-Croat-Slovene Kingdom, Siam, Spain, Sweden, Switzerland, Turkey, United States of America, Uruguay and Venezuela. The United States and China withdrew before the close of the conference, as they were unable to obtain the support of the conference on certain principles which appeared to them to be vital.

The Agreement of 1924.—The 1924 conference did not find it possible to recommend the immediate complete suppression of the use of prepared opium, but drew up an agreement which embodied the substitution of government monopoly for other systems in force. No general agreement could be reached regarding any provisions for registering or rationing addicts, nor was it found possible to embody in the agreement provisions for uniform prices or uniform penalties for the infraction of law or for the limitation of imports. It was held by the majority of members of the conference that no rationing could be enforced or total suppression imposed so long as a large illicit supply of opium remained uncontrolled. To this the representative of China objected, protesting against the refusal of the majority to take immediate steps to suppress opium-smoking until producing countries should find it possible to control smuggling. The conference, in a protocol to the agreement, decided to take any necessary measures not already taken for the entire suppression within a period of 15 years of the consumption of prepared opium in the territories under their authority, this period to begin so soon as the effective execution of the measures required to prevent illicit exportation of raw opium from their territories had been undertaken by the poppy-growing countries. Provision under the agreement is made for a League Commission to decide when these measures have been effectively executed. The agreements reached took the form of an Agreement, a Protocol and a Final Act. Instruments of ratification have been deposited by Great Britain, France and India only.

The Convention of 1925.—The result of the deliberations and discussions of the conference of 1925 was a convention providing for the more effective restriction of the production and manufacture of narcotics, and establishing stricter control and supervision of the international trade. This convention has been ratified by the following states: Australia, Great Britain, India, New Zealand, Sudan, Union of South Africa and the Govts. of Egypt Rumania and Salvador have adhered to it.

Among the more valuable suggestions were the creation of a central board, whose task it would be to follow the course of international trade, and the general acceptation of the export and import certificate system. The conference also drew up a protocol by which the signatory states, recognising their obligations to establish such control over the production, distribution and exportation of raw opium as would put a stop to illicit traffic, agreed to take within five years of the date of the coming into force of the protocol such measures as might be required to prevent the smuggling of opium seriously interfering with the effective suppression of the use of prepared opium in those territories where such use is temporarily authorised. A Final Act, containing further recommendations, was drawn up. Among these special mention may be made of a request to the council to consider the possibility of sending a commission to various opium-producing countries to study the difficulties connected with the limitation of the production of opium in those countries, and to advise as to what measures should be taken to make it possible to limit the production of opium in those countries to the quantities required for medical and scientific purposes. The result of this Final Act is shown in the League of Nations commission of enquiry sent to Persia to report on the possible substitution of crops for the existing opium crops. Half the money for this investigation was contributed by the League of Nations, the remainder by the American Social Hygiene Bureau.

OPPENHEIM, HERMANN (1858–1919), German physician and neurologist, was born Jan. 1 1858 at Warburg in Westphalia. He studied at Göttingen, Berlin and Bonn and graduated in 1881 with a thesis: *Beiträge zur Physiologie und Pathologie der Harnstoffausscheidungen.* From the beginning of his scientific career Oppenheim devoted himself especially to investigations concerning illnesses following upon dreams and to the rebuilding of the central nervous system. His monograph *Die traumatischen Neurosen* (1889, 2nd ed. 1892) attracted wide attention, but also evoked much opposition from Charcot, Schulze, Seeligmuller, Mendel and others. In 1894 appeared his *Lehrbuch der Nervenkrankheiten* which has been translated into English (1910) and other languages and is a work of international importance. It was followed by two other highly important works: *Die Encephalitis und der Hirnabscess* (1894) and *Die Geschwülste des Hirns* (1896). Oppenheim was the first to initiate the use of operative methods in the treatment of abscesses. His investigations in connection with spinal abscesses were very successful. Here his mastery of diagnosis stood him in good stead. The World War turned his attention anew to traumatic neuroses, and he published *Die Neurosen infolge von Kriegsverletzungen* (1916), *Beiträge zur Kenntnis der Kriegsverletzungen des peripherischen Nervensystems* (1917) and *Stand der Lehre von den Kriegs und Unfallsneurosen* (1918). Oppenheim died in Berlin May 26 1919.

OPTICAL GLASS (*see* 12.87).—Although prior to 1914 the manufacture of optical glass in Great Britain had been steadily, but very slowly, making headway, the research work carried out by Abbe and Schott at Jena, stimulated by the facilities afforded by the German Govt., resulting in a lengthy list of glasses both suitable and available for optical purposes, did not encourage any other European maker to take any decisive steps towards exhaustive scientific investigation of the supply of optical glass.

War Developments.—The ready supply thus afforded by Germany at the beginning of the War found the belligerent nations other than Germany unprepared both with information and supply for military needs. In 1914 there was one maker only in Germany; in France and in Great Britain, and although the quality of the British glass even then was beyond question, yet the small list of British glasses available at the outbreak of hostilities with the still smaller list in France, made decisive action on the question of manufacture imperative. At that time only 26 optical glasses were listed by the British maker, a number quite insufficient for the needs of the modern optical instrument maker, whereas the list of the same manufacturer now shows over 112 varieties. Dense barium crown glasses are now made in England, possessing more extreme properties than any ever before made. Progress has also been made in the fluor crown varieties.

In addition excellent material is produced in England in sufficient quantities and varieties to meet a world demand. Undoubtedly the necessity for the use of good optical glass in military, naval and aerial operations stimulated its manufacture both in England and France and it is unlikely that in future contingencies either of these countries will be found unprepared. British manufacture of optical glass owes much to the very strong financial support and encouragement given by the British Government.

Features of Manufacture.—Optical glass differs from other commercial and domestic purpose glass in that it is not produced in large masses and rolled out in sheets as is window glass, but is melted in smaller quantities in crucibles, allowed to cool, the crucible cracked, the resultant mass broken up and certain comparatively small pieces selected and approved. It differs from commercial and domestic glass in the need of care in its manufacture and the many factors which tend to make the results uncertain. Variation in results in commercial glass or those required for domestic purposes are of little importance; but with optical

glass, even when every care is used in the batches and the meltings, the occurrence of double-refraction and iridescence causes the resultant mass when annealed and examined by a refractometer sometimes to show variations which make final selection of each piece necessary before the results of the batch can be classified. Optical glass is much more costly, ranking from 7s. a lb. in the case of barium crown glasses to about 40s. a lb. for some flint crowns. For some optical instruments large pieces or slabs of perfect purity, homogeneity and durability are necessary, as in the case of two 41-in. disks for the large telescope made in Great Britain since the War.

Economic Difficulties.—Its manufacture by small firms, as is possible in the case of glass used for domestic purposes, is not feasible and rarely successful. Access to special sands for the silicate constituents, the services of a highly specialised chemical laboratory staff and substantial financial resources are requisite. Such restrictions obviously confine its production to very large firms with unusual technical resources. In Germany the list of useful glasses issued by Schott of Jena has been extended, and the Sendlinger Works have also placed certain glasses on the market. Conditions in France have prevented any extension by other firms than the Paris works of Parra-Mantois. In America, although other firms, such as the Spencer Lens Co., entered upon its manufacture, the bulk of optical glass is made by Bausch and Lomb of Rochester. Most of the ophthalmic spectacle glass used in the United States is made in England, by the firms of Chance Bros. of Birmingham, the Parsons Glass Co. of Derby and Barr and Stroud of Glasgow.

During the War the manufacture of optical instruments, especially range-finders, binoculars and telescopes, fulfilled all requirements. Since the War, their production has naturally decreased, although there is still a large field of useful work being done in surveying instruments and especially in research against disease. Notable improvements have been made in the manufacture of refractometers, ophthalmic instruments and slit-lamp microscopes (*see* MICROSCOPY; TELESCOPE).

Anti-actinic Material.—But by far a greater field has been explored in Germany, America and Great Britain in the development of glasses suitable not only for refraction purposes, such as lenses and prisms, but in the important direction of anti-actinic and anti-caloric material.

Although certain research work has been done on the Continent in this direction, it was not until Sir William Crookes turned his attention in 1909 to the question of adding various metallic oxides to the constituents of glass, in an endeavour to discover a combination which would absorb the invisible rays of the infra-red and ultra-violet regions of the spectrum without obscuring too much light or materially affecting the colours of objects seen through the glass when fashioned into spectacles, that this question of anti-actinic glass began to receive serious consideration. The result has been that a series of crown glasses of index 1·523 has been made with a very appreciable ultra-violet and heat cut-off, transmitting at the same time about 88% of light, and yet without imparting any appreciable unpleasant tint to the glass.

Special Varieties.—Until recent years spectacle manufacturers were content to use good quality white ordinary glass, but the demand for such special varieties as bi-focal, tri-focal, aspherical and special ophthalmic lenses has been so enormous as to result in the production of a large variety of glasses with definite indices and dispersions.

Other Developments.—Improvements have also been made in the transparency of certain glasses for the ultra-violet spectrum, perhaps one of the greatest advances made in recent manufacture, due to the research work carried out on glass annealing. Formerly more or less a lengthy and uncertain process, due to a tendency to fracture and double refraction unless a lengthy time of about 14 days for a period of cooling was given, the annealing period has now been reduced to about three days. The quality of the glasses has been improved, so much so that since the War it has been possible for a British manufacturer to introduce the first anastigmatic lens, having the hitherto unheard of aperture of F.2, which makes it possible to photograph a stage scene without flashlight and with the help of ordinary stage lighting (*see* PHOTOGRAPHY). One of the principal economical strides made in the manufacture of optical glass has been the possibility of moulding small plates of glass to practically any desired size and thickness, or into flat disks or disks with specified curves. ***See also*** GLASS.

OPTOPHONE.—The optophone is an instrument for enabling totally blind people to read ordinary letterpress, such as a printed book or newspaper, without the necessity of printing it in raised type to be read by touch. The instrument was invented in 1914 by Dr. E. E. Fournier d'Albe, then a lecturer in physics in the University of Birmingham. It is based upon the properties of selenium, an element which is a better electrical conductor in light than in darkness. A beam of light is rendered intermittent by the interposition of a revolving siren disc and is then concentrated into a small bright point on the paper to be read. If the point on the paper is white, it will reflect the light; if it is black it will not. A selenium cell placed close to the paper, on receiving the reflected beam of intermittent light, will respond to each flash by a change in conductivity, and if the frequency of the flashes is of the "musical" order (between 30 and 30,000 per second), a telephone receiver connected with the selenium and a battery will sound a musical note. A blind person could thus tell whether the paper is black or white.

That is the principle of the optophone. In practice a small row of luminous points is substituted for a single point, and each point in the row is given a different frequency by suitably perforating the siren disc. The row, usually of five or six points, just fills up the size of the tall letters of the print to be read. When the whole row falls upon the black stem of a letter there is silence in the telephone. As the letters pass their various shapes are indicated by the sounding or silence of the different notes, and after some practice the blind person learns to recognise letters from their sounds, and so to read ordinary type.

The first reading test was given by the inventor in March 1917, the matter read being a leading article in *The Times*. In Aug. 1918, Miss Mary Jameson, a blind pupil from Norwood, gave the first public reading demonstrations, reading an unknown page from a book at a speed of about two words per minute. Later, with an improved instrument, she attained a speed of about 20 words per minute. A new type of optophone was brought out in 1920 by Barr & Stroud, of Glasgow. In this instrument two selenium cells were used, balanced against each other in such a manner that white paper produced silence, and the black letters themselves made the musical sounds. Reading demonstrations were also given with this instrument, a maximum of 85 words per minute being attained by a blind reader at the meeting of the British Association in Liverpool in 1923. The new type is known as the "black-sounder," and the original type is termed the "white-sounder." The latter type was approved by the Inventions and Research Committee of the National Institute for the Blind in 1921 after an exhaustive series of tests. The optophone is intended to place the world's printed literature once more within reach of the blind. It is applicable, without special preparation, to any language, and can also be used for reading typescript, but not handwriting.

See "A Type-reading Optophone," *Roy. Soc. Proceedings* (1914); "The Optophone," *Journal of Roy. Soc. of Arts* (1921); "The Optophone," *St. Dunstan's Review*, No. 55 (1921).

(E. E. F. D'A.)

ORANGE FREE STATE (*see* 20.151), since 1910 a province of the Union of South Africa. The area is 49,647 sq. m.; according to a recomputation made in 1924, the population (1921) was 628,827, of whom 188,758 were whites, an increase in the white

population since 1911 of 13,381. Of the non-whites, only 395 were Asiatics. Agriculture, including stock raising, is the chief occupation of the people, the Orange Free State being essentially a pastoral region. There are, however, diamond fields, including the Jagersfontein and Koffyfontein mines, and coal mines by the Vaal river near Vereeniging. The only big town is the capital, Bloemfontein (*q.v.*). The great majority of the inhabitants are of Dutch descent.

Dr. A. E. W. Ramsbottom was the first administrator, being succeeded by Mr. (later Sir) Cornelis Wessels. Both had been members of the Ministry during the brief period (July 1907—May 1910), when the province had been a self-governing colony. In 1924, on the death of Sir. C. Wessels, Senator E. R. Grobler was appointed administrator. Education occupied much of the attention of the provincial council. In 1912 the provincial council adopted, in the main, the proposal suggested by the Union Parliament that up to standard IV. instruction in the schools should be given in the "home language" of the scholar. In 1920 an ordinance was passed recognising "Afrikaans," *i.e.*, South African Dutch, as equivalent to Netherlands Dutch as a medium of instruction. In most respects the provincial administration was progressive. For the provincial system *see* CAPE PROVINCE.

The province was the stronghold of the Dutch Nationalists. Up to his death in 1916 ex-President Steyn, who lived near Bloemfontein, though he held no office, exercised very great influence on public affairs. In the crisis caused by the World War Steyn opposed operations against German Southwest Africa. There followed the rebellion of General De Wet, the Free State being the principal theatre of the campaign. General Hertzog, the parliamentary chief of the Dutch Nationalists and, after Steyn's death, their undisputed leader, was supported by the Free State in the general elections of 1915, 1920, 1921 and 1924. (*See* SOUTH AFRICA, UNION OF.)

ORCHESTRATION (*see* 20.168 and INSTRUMENTATION, 14.651). —The orchestration of the 19th century is dominated by the names of Berlioz, Liszt, Wagner and Strauss, and it is not without significance in regard to the continuity of its evolution that the last of these re-edited the treatise written on the subject by the first. Berlioz was in fact the true creator of the orchestra employed by Strauss, and even the tendency to increase its dimensions was initiated by him. This tendency in the end became its weakness. Beyond a certain point it was still possible to increase the richness of an orchestra, but only at the cost of merging its individual hues, so that, however polyphonic the invention of the composer, its orchestral expression tended towards a more highly coloured homophony. To a certain extent this was consistent with the ideals of the Romantic movement, which were generally best served by the blending of tone-colours, and only in special situations welcomed their sharp impact one upon another.

Rimsky-Korsakov's Orchestral Theory.—Even in the 19th century this tendency in orchestration was not allowed to pass unchallenged. The founders of the Russian school were not at first differentiated, except in idiom, from the general trend of European music, but their less sophisticated colour sense, and congenital delight in bright and sharply defined colours, were bound to affect their orchestral method. Thus arose a new movement, at the head of which stands, so far as orchestration is concerned, the name of Rimsky-Korsakov. His method is imperfectly expounded in a treatise, but is clearly discernible in the numerous examples from his own works. So far from aiming at the harmonious fusion of the various timbres of the orchestra, he is often at considerable pains to prevent it, and make them stand out clearly one from another.

The first step in this direction was the dispersal of the groups. Though there had been considerable freedom in the orchestration of the Romantics, they were still almost instinctively disposed to regard the principal homogeneous groups, of strings, wood-wind and brass, as the three manuals of an organ, to be used alternately or combined (*tutti*) as opportunity arose. The occasional soli were mere incidents in the flow of sound. With Rimsky-Korsakov and his followers, on the other hand, it is the occasional use of homogeneous groups that is incidental, the general conception of the orchestra being that of an assemblage of solo instruments. That, at least, appears in the light of recent developments to have been the end towards which Rimsky-Korsakov was striving, though he only partially attained it. His method spread to other countries, mainly through the medium of Debussy, who quickly influenced the entire French school. It has been consciously or unconsciously assimilated by the majority of modern composers in England (*e.g.*, Holst) and elsewhere, and is now in such general use that for the first decades of the 20th century it may be regarded as the new orthodoxy in succession to that of the 19th. This, of course, does not preclude the existence of many intermediate methods. In orchestration most composers are, and will always be, eclectics. Hence any too rigid classification of methods would be confronted with a multitude of contradictory instances.

The most important outcome of the Rimsky-Korsakov orchestration is the impetus it gave to the study of individual timbres and the corresponding instrumental idioms. Compared with other branches of musical technique this study had proceeded slowly. In the 18th century composers did not discriminate very strictly between instruments. There are numerous examples, by Bach and others, of works which exist as piano concertos and also as violin concertos. Even more frequent is the indication "flute or violin." But though in the 19th century composers were more definite in assigning to particular instruments everything they wrote, in adapting their ideas to the respective instruments they were more often guided by considerations of executive technique than by the implications of timbre. Some characteristics, such as those of the oboe and its relatives, were too marked to escape notice and there are passages in Wagner which cannot be imagined as conceived for any other instrumental medium. But in general usage a passage was entrusted in turn to any instrument on which it was practicable. It is in the fullest sense a modern discovery that for each timbre there is a corresponding dialect of the melodic language, into which the musical idea should be translated if it is to be adequately expressed. The procedure of composers being mostly empirical, this matter still awaits the investigation of the theorist but it will most likely be found dependent upon the relative intensity of the overtones, which varies in each timbre. Already J. M. Hauer has published some interesting speculations bearing on the point.

The Reaction Towards Counterpoint.—The most prominent composer who has proceeded on these lines is Stravinsky. Starting from the basis of Rimsky-Korsakov's teaching, he soon began to explore the idiomatic qualities of individual instruments and the world-wide reputation he enjoys for clever scoring, even among those who do not appreciate his music, largely rests upon this feature of his practice. He is not content that a passage should be effective, for instance, on the clarinet, but he demands that its inflections should be those implicit in the tone-colour of the clarinet and foreign to any instrument not akin to it. This led him at first to advocate an enlargement of the wind sections of the orchestra, to permit of full harmony in any timbre, while the strings were to be reduced on the ground that the duplication of parts, though increasing their tone, weakened their character. The question of balance he regarded as a matter involving the orchestral skill of the composer. Soon, however, he found that the assertion of the individual character of an instrument made much of the background superfluous, and this led him to turn from harmony to counterpoint, and from large orchestras producing the former to small combinations of contrasted timbres producing the latter. Thus originated the newer tendency, still regarded as heterodox in relation to the prevalent allegiance to Rimsky-Korsakov, but possibly destined to take the place of the latter, just as that has succeeded to the Berlioz-Wagner-Strauss tradition.

Though the name of Stravinsky is most prominent in this connection, the same principles are behind many contemporary manifestations, such as Schönberg's *Pierrot Lunaire*, and have gained many adherents. The younger French composers, among

whose critics one encounters the term *art dépouillé* (*i.e.*, music stripped of its harmonic envelope), Hindemith and many others in Germany, Bliss in England and, in general, the younger generation everywhere, have come under the spell of this movement, which replaces the multiplication of instrumental means by the intensive exploitation of small numbers. It is a strange coincidence that this tendency, which set in two or three years before the World War, should develop in a period of general impoverishment, whereby an economy of means which was originally dictated by artistic considerations has become financially expedient. As, however, the spread of new musical forms is always very slow, the larger and more expensive orchestra is, despite adverse conditions, still the standard.

A further result of the contrapuntal character of the new orchestration is that it has added a kind of neo-classicism, which consists in a return to old, pre-romantic conventions. It is, for instance, safe to say that never since the 18th century have so many composers been attracted to the older type of instrumental concerto. Schönberg's chamber-symphony for solo instruments came before this revival, but in its instrumental complexion it is prophetic of much that has followed. In 1926 there is a growing literature of *concerti grossi* revealing a somewhat sophisticated affinity to the period of Bach and Handel.

At the same time, a corresponding "stripping" of the texture has affected the normal orchestra, especially when used by composers of the same school, such as Auric in France and Rieti in Italy. It generally produces an impression of austerity, not to say acidity, a deliberate casting away of all orchestral brilliance as too liable to distract attention from the music. This new sobriety, curiously enough, has led in some instances to a qualified reinstatement of the old grouping system. The wheel has come full circle, and it looks as if we shall presently be practically where we were rather more than a century ago, but with a vast fund of technical experience garnered in the interval and a medium of expression more sensitive to the creative impulse than could ever have been foreseen by the classics. It is no exaggeration to assert that, thanks to this experience and the teaching based upon it, any student of average talent leaves a good conservatoire to-day as proficient in this one subject of orchestration as any of the great masters. (E. Ev.)

ORDERS OF KNIGHTHOOD: *see* KNIGHTHOOD AND CHIVALRY.

ORDNANCE (*see* 20.189).—The chief developments in ordnance that have occurred since 1911 are in the nature of increased range and shell power. To these must be added the new guns required to meet the special conditions of the World War: the anti-aircraft gun, the tank and anti-tank guns, the trench mortar and the long-range guns.

I. THE GUN

Gun Construction and Design.—The period since 1911 shows a tendency towards the use of steels of a higher yield point and a consequent increase in the use of alloy steels. The immense demands for alloy steels during the War and the difficulty of obtaining sufficient supplies led to a reversion to the use of carbon steel for small and medium guns with a consequent shortening of the life of these guns. Since the War, however, there has been a demand for increased range without increase of weight of the equipment. To meet this it is necessary to use steels of great strength such as nickel chrome molybdenum and chrome vanadium. The general design of guns has altered but little. Great Britain retains the wire wound gun for almost all types, with a slight modification in breech end construction. Fig. 1 is typical of present day British practice. Continental nations retain the all-steel system of construction.

Manufacture.—The great expenditure of ammunition and consequent rapid wear of guns in modern warfare renders the question of rapid and easy repair of guns a matter of paramount importance. British wire wound guns from 4 in. calibre upwards are fitted with removable liners known as inner "A" tubes, a feature which increases the weight of the piece, but facilitates repairs. Other European nations retain the all-steel designs on the lines of the French or Krupp systems (*see* 11.217). These, on account of the heavy shrinkages necessary, are difficult to reline. Many expedients have been adopted to speed up manufacture and repair. The British 60 pdr. and similar guns were manufactured without inner "A" tubes, being subsequently bored out and fitted with the latter. Short liners were fitted extending from the rear of the chamber, and over the worn region of the bore. These were, however, unsatisfactory and were abandoned. The

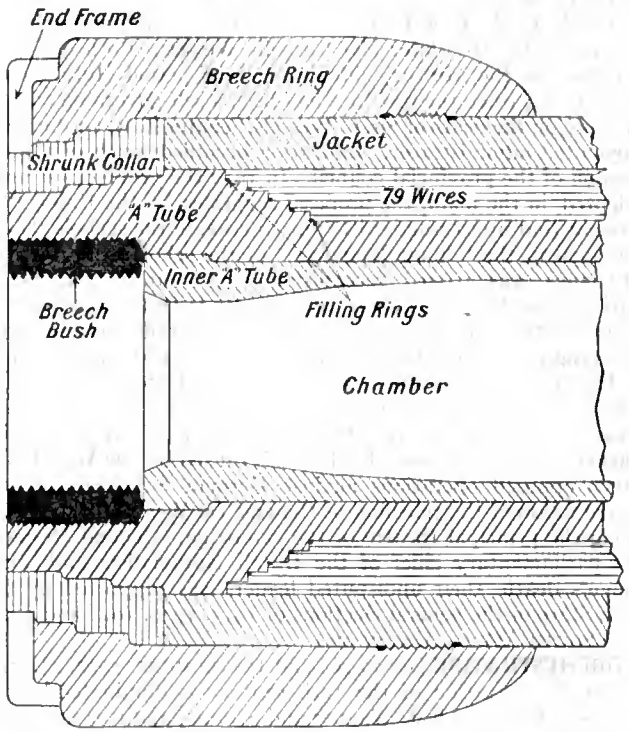

FIG. 1.—Sectional view of breech end of B.L. 15-in. gun.

French in some cases adopted the system of boring out worn-out guns to a larger calibre. A 145 mm. gun was bored out after its first life to 155 millimetres.

Auto-frettage.—A new method of building a gun termed "auto-frettage" (self hooping) has been tried by various nations. In a single tube gun pressure applied to the bore produces a tension in the various layers of the wall. This tension is at a maximum on the inside and decreases continually towards the outside of the tube. The successive layers will be deformed, the greatest deformation taking place at the surface of the bore. If the elastic limit of the steel is exceeded the deformation will be permanent. The metal of the layers least deformed, *i.e.*, those at a greater distance from the axis of the bore, acts elastically on the layers beneath, producing a graduated shrinkage on those layers.

It is argued that if a pressure equal to, or less than, that which has caused the deformation is subsequently applied to the gun no further deformation will take place. In the auto-frettage system the wall is permanently deformed by the application of hydraulic pressure to the bore. The advantage claimed for this system is that it will be possible to make small and probably medium guns of single tubes, thereby effecting savings in time, skilled labour and material. It is possible that the process may be applied to the relining of existing types, and to the manufacture of large guns, using two or three tubes. The limiting factor appears to be the size of sound forging that can be produced.

Trench Mortars.—The trench mortar was a weapon originally designed for the destruction of wire, and short range bombardment in the siege of fortresses. Prior to 1914 these weapons had been developed only by Germany which used them with considerable success when trench warfare commenced on the Aisne in Sept. 1914.

The ordnance plants of the Allies being fully occupied in the manufacture of guns, it was necessary to turn to the ordinary

engineering firms for the supply of mortars. This necessitated a simple design capable of speedy manufacture with existing machines. Three types have been employed:—

1. The stick bomb type firing a large spherical bomb with cylindrical stalk from a smooth bore gun of small calibre. This type was used by the British and German armies, but was discarded on account of its inaccuracy.
2. Smooth bore mortars either muzzle or breech loading. The Stokes mortar is of the former type, and the French 165 mm., in which the bomb is loaded from the muzzle while the propellant charge is loaded from the breech in a small case, is of the latter.
3. Rifled muzzle loading mortars. These were much used by the Germans but require the use of special plants in their manufacture.

The conditions of the War tended to crystallise the trench mortars into two main types: (*a*) a heavy mortar for bombardment purposes and (*b*) a light mortar to accompany attacking infantry for dealing with machine-guns and providing smoke screens. The former has been practically discarded under the conditions of mobile warfare contemplated by European nations; the value of the latter is a matter of controversy, but it is retained in some armies.

Long-Range Guns.—In 1918 Germany produced a gun of 21 cm. calibre which shelled Paris at a range of 45 miles. Similar guns of great range were constructed by various nations. These guns must be of great length which results in excessive wear and stripping of the copper driving band. Shell for the German guns were provided with steel ribs to take the rotational thrust in addition to a gas check driving band. The effect of these guns was almost entirely moral. Owing to their great cost and short life it is unlikely that they will be extensively employed in future wars.

Breech Mechanism.—With the introduction of the breech loading 6 in. 26 cwt. howitzer in 1916, a new type of mechanism known as the Asbury type (see fig. 2) was introduced. It was

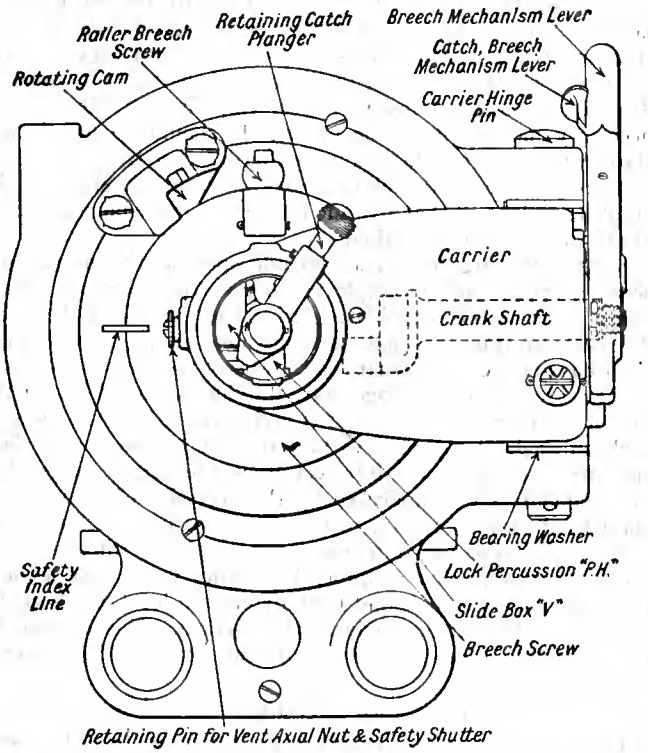

FIG. 2.—General arrangement of breech mechanism of B.L. 6-in. 26 cwt. howitzer.

subsequently adopted for the majority of medium and heavy guns in the British Army. The breech screw is of the Welin type with arm carrier. The rotation of the breech screw is effected by a vertical lever with crank connection to the breech screw. It is claimed for this mechanism that the lever is more conveniently situated for operating the breech than in the normal type with horizontal lever. The obturator is positively unseated by a special cam on the breech face, and the breech screw is positively locked when the breech is open. Semi-automatic mechanisms were introduced owing to the advent of aeroplanes and coastal motor-boats which demand guns that can fire extremely rapid bursts to counter them. The speed of loading these guns is increased by automatic ejection of the fired case and automatic closing of the breech.

These mechanisms are usually of the sliding block type; as the gun returns to the firing position a rod on the mounting fouls a pawl on the crank shaft of the mechanism, causing the latter to rotate and the breech to open; at the same time a spring is compressed. The spent case is ejected by the extractors which engage with the block and hold it open. On the loading of the next round the rim of the cartridge clears the extractors from the block which is then closed by the spring (see fig. 3).

Obturators.—Prior to 1914 the German Army relied solely on the quick firing (Q.F.) system in which the charge is contained in a brass cartridge case which effects the obturation. The British and French Armies used the quick firing system for light guns

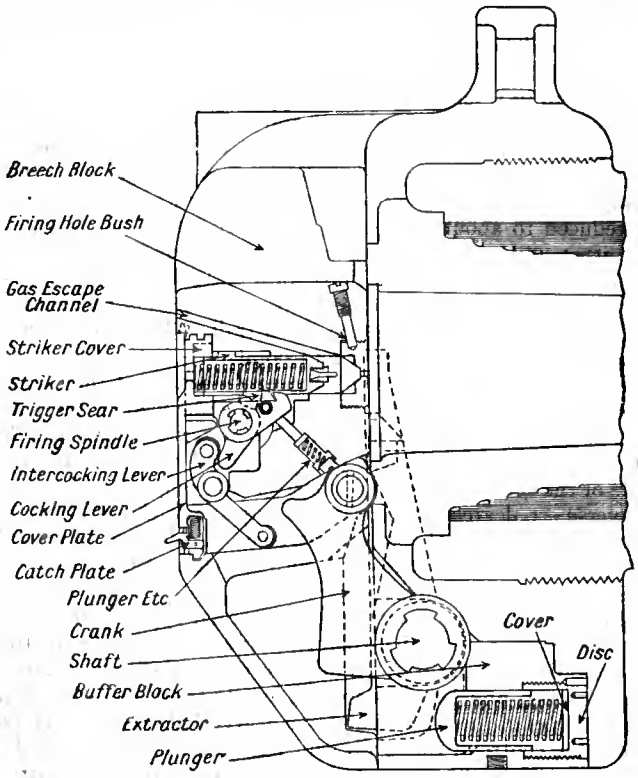

FIG. 3.—Section of breech end of Q.F. 3-in. 20 cwt. Mark I. Gun.

and the "B.L." or de Bange system for medium and heavy guns. The large expenditure of ammunition in the World War rendered the supply of brass cartridge cases a matter of great difficulty, so that an increasing tendency towards the "B.L." system is noted. Germany still retains the "Q.F." system as the sole method of obturation.

Improvements have been effected by the British, French and American armies in the de Bange obturator with the effect of giving it a longer life. The latest design in the British service consists of an asbestos (with rape oil) pad enclosed in a brass gauze casing. The pad is protected in front by a thin copper disc with a split steel ring about its periphery. A similar ring protects the edge of the pad in the rear and a solid ring forms a bearing for the pad on the vent axial. (E. A. W.)

II. THE CARRIAGE

All artillery carriages must be designed primarily, to provide a support for the gun during firing, and to allow of three separate movements:—

(*a*) Right and left in the horizontal plane . . . . traverse
(*b*) Up and down in the vertical plane . . . . elevation
(*c*) Axially back and forward . . . . . recoil

All carriages, therefore, are built up on the same general lines, and consist of two main portions:—

The basic structure provides the support, and should remain fixed during firing.

The super-structure provides for the three firing movements, and is divided into:—

1. Carriage body, which is pivoted on the basic structure and is capable of movement in the horizontal plane to a greater or less extent according to the type of carriage. It consists of two steel side pieces joined by transoms. On the top of each side piece is a bearing to receive the trunnions, one on each side of the cradle.

2. Cradle, which is pivoted by its trunnions in the carriage body, and can be elevated and depressed in the vertical plane. It is so constructed that the gun can slide backwards and forwards through it, if it be a ring-shaped cradle; or on it, if it be trough-shaped.

3. Recoiling parts, which connect the gun to the cradle and govern its movements.

The superstructure, having in all cases the same functions to perform, does not alter greatly, except in size and weight for different carriages. The type of basic structure depends altogether on the purpose for which the equipment is designed. Guns of the fixed defences, for instance, which are securely anchored to the ground, and may have to traverse in any direction, have their basic structure circular in shape. Semi-mobile equipments, which are moved to a temporary position in separate loads, cannot be anchored as firmly as fixed guns and have the basic structure a rectangle with its long sides in the line of fire, so as to provide support in the line of greatest shock. In this case the carriage body is pivoted near the front of the basic structure, and traverse is reduced to about 25 degrees each way. The mobile gun, or howitzer, must be ready to come into action at short notice, and so its basic structure must form a travelling as well as a firing support. Thus, the basic structure in this case consists of a pair of wheels, an axletree and a trail. The mobile carriage may be supported at three or four points.

Three Point Support.—Only the two wheels and the point of the trail, which is secured by a spade embedded in the earth, are in contact with the ground. To preserve lateral stability the force of the recoil must not be allowed to act far to either side of the centre of the trail; consequently only a small angle of traverse—4 degrees each way—is possible without lifting the spade and moving the whole carriage. A wide space must be left, in the centre of the trail, into which the gun may recoil when firing at high angles of elevation.

Mention must be made here of a special type of three point support carriage, in which traverse is given by moving the front of the trail along the axle. In this case the carriage body becomes unnecessary, and bearings for the cradle trunnions are formed on the sides of the trail. The force of recoil always acts straight down the centre of this trail, which gives great lateral stability. A disadvantage, however, is that the spade forms the centre of the circle in which the front of the trail must move, and it follows that when the gun is traversed to the right, the right wheel must move back and the left wheel forward, and vice versa. This makes traversing very hard work on any but the most favourable ground and necessitates a somewhat complicated traversing gear. Examples of this type are the British Q.F. 18 pr. mark IV and the French 75 mm. guns.

Four Point Support.—The amount of traverse given by ordinary three point support carriages is quite insufficient for dealing with rapidly moving targets such as tanks and armoured cars. The need for more traverse is met by using a split trail, the halves of which can be splayed out for firing, each half having a spade at its rear end. This greatly widens the support in rear, and allows of traverse up to 25 degrees each way, while maintaining stability. At high elevations the gun is free to recoil between the legs of the trail. For travelling the legs are pinned together and hooked to a limber in the usual way.

Anti-aircraft Equipments.—For defence against aircraft, the first requirements are all round traverse and extreme elevation. This necessitates a carriage approximating in design to the fixed mounting. The basic structure consists of a base ring bolted down to the travelling platform. The carriage body, built specially high to allow of great elevation, has a circular race on its underside to fit over a "live roller ring" which revolves on the base ring and so facilitates rapid traverse. The travelling platform can be lowered from its wheels to the ground and anchored for firing.

Possible Developments.—The rapid advance of mechanical transport and the increased use of tracked in place of wheeled vehicles for cross country work give an indication of the lines on which mobile carriages of the future may develop. Tractor drawn artillery is now common, and it is easy to imagine that the mobile gun of the near future will leave its wheels, and fire either from the tractor itself, or from a tracked vehicle towed by the tractor. In either case the basic structure will probably be a circular pedestal clamped to the floor of the vehicle and capable of all-round traverse.

Gears.—To provide the necessary movements of the parts of a carriage in relation to one another certain gears are used. They are traversing gears, elevating gears and sight actuating gears. Traversing provides for the movement of the carriage body on the basic structure in the horizontal plane. In its simplest form this gear consists of a nut and screw, the nut being held on a pivot at the rear of the carriage body, and the screw carried in a pivoted bearing on the trail in such a way that it can revolve but can have no lateral movement. The screw being turned by a handwheel, forces the nut to one side or the other, thus traversing the carriage body about its pivot. For heavy equipments and those requiring wide traverse, a more complicated system is employed; and may include one or more driving shafts with spur, bevel and worm gearing.

Elevating Gear.—This provides for the elevation and depression of the cradle in the bearings of the carriage body. It is effected by a toothed arc or arcs attached to the cradle, and actuated by spur pinions on a cross shaft carried in the bearings in the carriage body. On one end of the cross shaft a worm wheel is keyed. A handwheel on the carriage body, working through spur or bevel gearing, if necessary, turns a worm which rotates the worm wheel and with it the horizontal shaft and its pinions. The pinions, being in mesh with the elevating arcs, impart the necessary movement to the cradle. It should be noted that the elevating arcs can, in many cases, be detached from the cradle, and are provided with hollow bosses which fit loosely over the cradle trunnions, so that arcs and cradle may move independently of one another when required.

Sight actuating gears may include spur, worm or nut and screw gearing, and are employed to give the necessary movements to the axis of the sight, relatively to the axis of the piece. At the same time the angle, or equivalent range, at which the sight has been set with regard to the axis of the piece is recorded.

Sighting.—A gun carriage must provide means of laying the line of sight on the target, and of laying the axis of the piece at such an angle (tangent elevation) relative to the line of sight that the trajectory will intersect it at the target range. The arrangements are complicated by the necessity of allowing for the lateral movement of a projectile due to its spin, known as "drift" and for any difference in level of the wheels due to uneven ground. The reciprocating sights used with modern carriages allow for drift and for difference in level of wheels by tilting the sight at an angle to the vertical. This is done by cross levelling a bubble mounted on the bracket which carries the telescope.

Two main sighting systems are used with mobile carriages:—

1. *Rocking bar system.* In this case, the axis of the sight is first moved relatively to the axis of the piece, through the angle of tangent elevation. This is done by the sight operating gear. Next, the gun and sight are moved together, by the elevating and traversing gears, until the line of sight is on the target. One man performs these two separate operations, a process much too slow for the engagement of rapidly moving targets.

2. *Independent line of sight.* Here the laying is done by two men. One, by means of the elevating and traversing gears, keeps the line of sight continuously on the target. The other, using the range gear, which moves the gun independently of the sight, keeps the axis of the piece continuously set at the angle of tangent elevation. As these movements can be carried out simultaneously and independently, much time is saved.

III. BUFFERS AND RECUPERATORS

The kinetic energy acquired by the gun on firing is absorbed by the buffer, recuperator and friction, and in this way the velocity of recoil is diminished, and the gun finally brought to rest. The recuperator is designed to store up energy so that it may return the gun to the firing position and retain it there at the maximum elevation. The buffer must absorb energy not accounted for by the recuperator and friction.

In mobile carriages, to preserve stability, the heavier portion of the recoil system recoils with the gun, and a long recoil is provided for the same reason: further, as the gun recoils, the stability moment decreases, so the resistance to recoil must be correspondingly decreased. Hence the system of graduated resistance is employed with mobile carriages. While the gas is acting on the gun, recoil should be as free as possible to preserve the aim, and reduce the couple on the recoiling parts. The

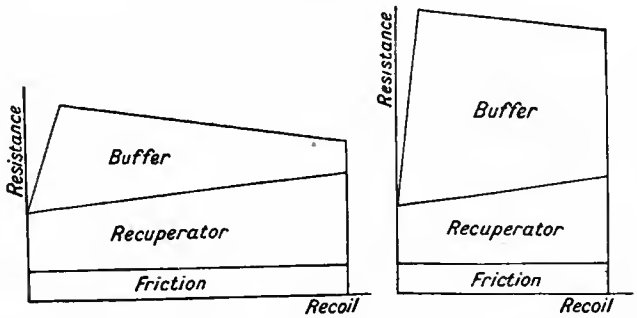

FIG. 4.—Resistance space diagrams. Graduated recoil (left) and controlled recoil (right).

maximum resistance to recoil comes into action at the end of the period of free recoil, and then diminishes. Fig. 4 (left) is a typical resistance space diagram for graduated recoil.

The length of recoil is determined from the condition that the maximum recoil energy with free recoil (calculated from the ballistics of the gun) must equal the work done by the total resistance to recoil, *i.e.*, the area of the diagram. The buffer resistance can be obtained from the diagram, for the recuperative and frictional resistances can be calculated reasonably accurately. British mobile equipments have centre trunnions, so recoil must be shortened as elevation increases in order that the recoiling parts may not foul the ground. Recoil is then said to be controlled. The resistance-space diagram for such a system will be similar to that shown in fig. 4 (right). Since recoil is shorter and the total area must be the same, the resistance due to the buffer is greater than in graduated recoil (fig. 4 left). This increase in resistance does not affect the question of stability, since the stability moment increases with the elevation.

With fixed mountings the question of stability does not arise, so short recoil is generally employed. Further, the total resistance to recoil is a minimum when retained constant, and the system of equalised resistance is therefore adopted.

The Buffer.—This consists of a cylinder filled with liquid in which works a piston and rod: either the cylinder or rod recoils with the gun; between piston and cylinder is a flow space for the liquid which decreases during recoil. The resistance to the flow of liquid through this flow space retards and finally checks the motion, and the resistance can be varied by suitably varying the flow space. The withdrawal of the piston rod at full recoil leaves a partial vacuum in the cylinder which assists the initial stages of recuperation, but before the buffer can act as a control to recuperation, the liquid must be banked up on the face of the piston remote from the rod. At this instant the recoiling parts have their maximum recuperative velocity: further, the flow space is increasing, and the resistance is insufficient to absorb the surplus energy. A further controlling device is therefore fitted to ensure the gun coming quietly to rest in the firing position.

The flow space, calculated and afterwards corrected experimentally, is varied by the following methods:—

(*a*) A circular piston and longitudinal grooves of constant width and varying depth cut in the cylinder walls.

(*b*) Rectangular ports in the piston sliding over valve keys, metal bars contoured to give the required flow space, fixed to the cylinder walls.

(*c*) A hollow piston rod with circular piston sliding over a tapered control rod fixed to the cylinder. Ports in the piston provide a passage for the liquid.

(*d*) A valve with ports cut in it is rotated on the piston rod by feathers upon it engaging spiral feather-ways in the cylinder walls. It rotates against a valve having similar ports which is fixed to the piston rod.

Systems (*a*) and (*b*) are suitable for short recoil. System (*d*) is particularly adaptable to controlled recoil and is used in modern mobile carriages. Controlled recoil necessitates cut off gear to reduce the flow space automatically as the gun elevates. A link or cam gear placed between cradle and carriage body rotates the piston rod through bevel or spur gearing. Cut off therefore occurs earlier in the recoil stroke.

Control to recuperation is necessary to prevent a metal to metal blow, as the flow space in the buffer increases with recuperation. The following devices are in use:—

(*a*) A control plunger with a flat on it displaces liquid from a control chamber, the chamber having filled with liquid on recoil. The most modern equipments combine an additional adjustable exit for the liquid with this system to suit special conditions. Thus recuperation takes place in three stages: (1) unresisted except by friction; (2) resisted by the buffer and friction; (3) resisted by the buffer, plunger and friction.

(*b*) Two separate valves, one to control recoil, the other to control recuperation, the former being idle when the latter is functioning and vice versa. The system is best applied to the rotating valve type of buffer and affords two-stage control to recuperation.

(*c*) A valve on the tapered control rod allows the hollow piston rod to fill with liquid on recoil. On recuperation the valve closes and the rod displaces the liquid through shallowing grooves in the hollow piston rod. Recuperation is thus controlled from the outset.

The Recuperator.—This consists of a set of springs either in a single or a double column, or of a chamber containing compressed air; in either case it must be under sufficient initial compression to retain the gun in the firing position at the maximum elevation. Part of the recoil energy is stored in the recuperator by further compressing either the air or springs, and this energy returns the gun to firing position.

Spring Recuperator.—A single column consists of one or more spiral springs, separated by parting plates, placed end to end on a compressor rod secured to the gun. The system is mounted in a case fixed to a cradle, so that on recoil the springs are compressed by the compressor rod. The telescopic system consists of two banks of springs separated by a hollow tube, but connected to each other by a flange at each end of the tube. The outer bank bears against the casing in rear, the inner bank against the compressor rod in front. On recoil the action is telescopic, so that the compression per column is reduced. For this reason the system is more suitable for long recoil equipments than a single column. In any case the life of a spring is limited and it is liable to fatigue.

Air Recuperator.—Air, initially compressed, is in contact, either directly or through liquid, with a piston, which on recoil further compresses the air. Recuperators are thus classed as pneumatic or hydro-pneumatic, the latter class being subdivided according as the liquid and air are in contact or separated. Liquid is used on account of the difficulty of sealing air at a high pressure. With pneumatic recuperators the air is sealed by a liquid gland, the liquid pressure being intensified in order to effect the seal. With the hydro-pneumatic system, one cylinder contains liquid acting on the face of a packed piston connected by its rod to the cradle cap, and communicates through a retard valve, port and pipe to another cylinder containing liquid and compressed air, the cylinders recoiling with the gun. The retard valve permits a free flow of liquid during recoil, but closes to control the rate of recuperation; the outlet of the pipe is arranged to be always below the liquid level, to prevent the air passing to the liquid cylinder.

This system is liable to aeration, and in a more modern design, liquid and air are separated by a packed floating piston having a tail rod which intensifies the liquid pressure, reducing the tendency for air to escape. The tail rod also acts as an indicator for the quantity of liquid in the system, as it is visible from the front of the cradle cap through which it projects.

The compression ratio should be low to reduce the final pressure and heating effect, and usually lies between 1·5 and 2. To give a low compression ratio the piston area should be small relative to that of the air cylinder, but, at the same time, it should be as large as possible to reduce the initial pressure for convenience in charging and sealing. From a knowledge of the compression ratio, piston area and length of recoil (which is the working length of the recuperator) the volume of the initially compressed air can be estimated. Low initial pressure and low compression ratio entail bulky construction, particularly of the air cylinder; the design of the cradle limits the size of the system, and for this reason the initial pressure in a mobile equipment is generally higher than that in a fixed mounting.

Air recuperators, compared with springs, have the advantages that, firstly, an increase in power can easily be obtained without an increase in weight; secondly, run up can be controlled by the recuperator as well as by the buffer; and, thirdly, troubles due to fractured or fatigued springs are eliminated. On the other hand, air systems require skilled attention for their proper maintenance, and as they absorb a greater proportion of recoil energy than springs, a loss of pressure is much more likely to overload the buffer than a spring breakdown; correct charging is therefore essential.

The air used in recuperators must be dry and free from dust to prevent rust and abrasion and to preserve the mirror surface

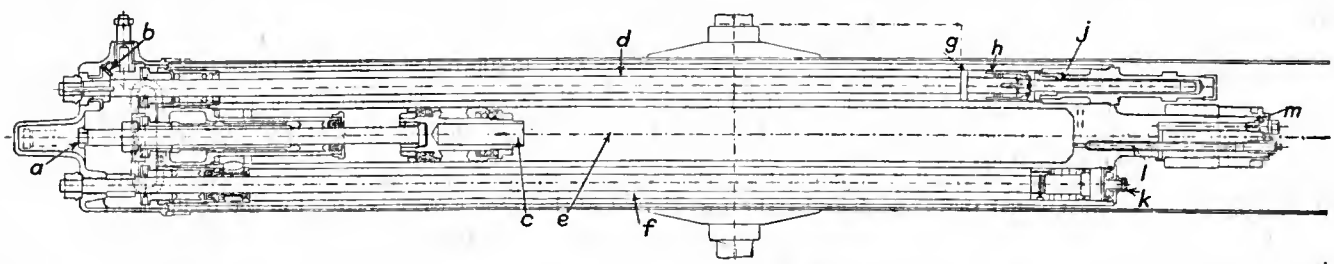

FIG. 5.—General arrangement of buffer and recuperator. *a.* Tail rod (leakage). *b.* Cut-off gear segments. *c.* Floating piston. *d.* Buffer cylinder. *e.* Air reservoir. *f.* Recuperator cylinder. *g.* Recoil valve. *h.* Rotating valve. *j.* Control plunger. *k.* Dust cover. *l.* Air valve. *m.* Air filling plug.

necessary on the rods and cylinders; the use of air bottles charged with specially dried air instead of pumps minimises the risk of allowing moist air to enter a system, while the French favour the use of nitrogen instead of air. Some experimental recuperators of stainless steel are being tried, but certain manufacturing difficulties remain to be overcome. A special liquid mixture is used in buffers and recuperators; it should be non-freezing in any climate, acid-free, non-inflammable and of slight viscosity which should be little affected by temperature change. Only the specified liquid should be used, as it is for that liquid that the flow space is designed, but glycerine may be used in emergency.

Packings.—These may be distinguished as joint rings, soft packings and high pressure packings. Joint rings, copper, leather or vulcanised fibre are used with plugs, stuffing boxes, etc., for standing joints. Soft packings of asbestos, lead and hemp moulded to shape are used in stuffing boxes to seal under normal pressures, and to centre the rod. High pressure packings in the form of rubber or leather rings of " U " or " L " section are used to seal under high pressures. Generally a combination of soft and high pressure packings is used. Fig. 5 shows the general arrangement of a modern rotating valve type of buffer and hydro-pneumatic recuperator with floating piston as fitted to a mobile carriage. (E. J. C.)

IV. NAVAL ORDNANCE

War experience has proved that, at sea, victory will always rest with the side that can hit the hardest at the longest range, and recent years have seen a steady increase in the size of the guns carried by warships of all types.

The 12-inch Gun.—In 1911 the 12-in. gun, which for over 10 years had been the standard heavy gun for the navies of the world, had, in the British Navy, reached the limit of its development in the 12-in. mark 11 50 calibre gun. This gun formed the main armament of the six battleships which followed the first " Dreadnoughts " and of the contemporary battle cruisers. In the first three battleships (" Vanguard " class) the guns were placed as in the " Dreadnought," but in the " Colossus " class the midship turrets were placed " en échelon," so that all 10 guns could be fired on either broadside. This disposition of the main armament marks the transition stage to the centre line arrangement, which by 1915 had been adopted in the capital ships of all navies. In the secondary or anti-torpedo boat armaments, the 12-pdr. Q.F. gun was replaced by a 4-in. Q.F. or B.L. gun in all these ships.

In contemporary ships in foreign navies the 12-in. gun still held its place as the main armament, but the desire to increase the heavy gun power was shown by both the United States and Japan, who mounted 12 of these guns as against 10 in the British ships. The secondary armament in foreign navies was usually greater at this period than in the British ships. The Japanese used a mixed armament of 6-in. and 4·7-in. guns and the United States employed the 5-in. gun.

By 1912 the demand for an increase in range combined with greater hitting power became insistent and a new gun—the 13·5 breech loading mark 5 was introduced into the British fleet. This gun, which weighs 68 tons and fires a 1,400 lb. projectile with a velocity of about 2,500 fs., shows a very marked advance in power over the most highly developed gun of 12-in. calibre. Ten of these 13·5 guns formed the main armaments of the " Orion " and " King George V." classes which were completed in 1912–3, and the battle cruisers of the " Lion " class, built at the same time, mounted eight. In these battleships and battle cruisers, and in all subsequent capital ships built for the British fleet, the heavy guns are mounted on the centre line. Thus the whole armament can be brought to bear, through a very large arc of fire, upon either broadside, and the maximum gun power is developed. In all these ships the 4-in. gun was retained as the secondary armament, but a change was made in the next class—the " Iron Duke " completed in 1914. The main armament of these ships remained the same but the 6-in. B.L. gun displaced the 4-in. in the secondary armament.

The 15-inch Gun.—The year 1915 marked another great step forward in the gun power of the British fleet by the introduction of the 15-in. gun. This gun weighs 100 tons and fires a 1,920 lb. shell with a muzzle velocity of 2,500 foot seconds. The muzzle energy developed is thus twice that of the most powerful 12-in. gun, and as the rate of fire of the 12-in. and 15-in. guns is the same under battle conditions, upon this count alone the hitting power of a British battleship may be said to have been doubled between 1912 and 1915. In addition, the heavier gun has a greater range—and what is most important of all—considerably greater accuracy at extreme ranges.

The 10 battleships of the " Queen Elizabeth " and " Royal Sovereign " class each mount eight of these 15-in. guns in their main armament, supported by a powerful battery of 6-in. guns. The battle cruisers of the " Renown " class have six 15-in. guns,

with a reversion to the 4-in. gun, mounted in triple mountings, as a secondary armament. The "Hood," which was the first capital ship completed whose design embodied the lessons learnt at the battle of Jutland, carries eight 15-in. guns and a battery of 16 5·5-in. B.L. guns. The armament of this ship is arranged in the same way as that of the "Queen Elizabeth," but the ship is much longer and faster.

The 16-inch Gun.—A further advance has been made in the size of the guns of the capital ships now being completed—the "Nelson" and "Rodney." These ships carry nine 16-in. guns of a new pattern in three triple turrets, all in the centre line forward in the ship, and the secondary armament consists of 12 6-in. guns in double turrets, three on each side in the after part of the ship.

In other navies during the period 1911–25 a similar general increase in the size of the guns, both for the main and secondary armaments, has taken place. In both the United States and Japanese navies, the 12-in. gun was replaced by the 14-in. in all ships built after 1914, and this gun remained the standard weapon in both navies until the ships projected in 1921, wherein a 16-in. gun has been adopted, the general arrangement of the armament being similar to that of the British "Queen Elizabeth." For the secondary armament, the United States retained the 5-in. gun, until 1921, when the 6-in. gun was adopted. Japan, on the other hand, after adhering to the 6-in. gun as the secondary weapon in her later ships, has now reverted to a gun of 5·5-in. calibre.

The German Navy was always one step behind other fleets in the size of the guns mounted in the main armament. The early German "Dreadnoughts" were armed with the 11-in. gun, which had for many years been the heaviest weapon employed in the German fleet. After 1912, the 12-in. gun became the standard weapon for the capital ships and remained so until the battle of Jutland in 1916. At this date, a few ships mounting 15-in. guns were approaching completion, but they were not finished in time to be actually employed. The guns employed in the secondary armament of the German ships were similar to those in the British Fleet—a 4·1-in. gun in the earlier ships or a 5·9-in. gun in the later ones.

Heavy Guns and Mountings.—Recent years have not brought about any very drastic changes in the main principles by which heavy gun turrets are worked. The most recent designs of twin turrets in the British Navy show no very great difference in general arrangement from those in which the 12-in. guns were mounted in the earlier "Dreadnoughts." The guns have increased from 12 in. to 15 in. in calibre, their weight and that of their ammunition has been more than doubled; consequently there are additional and more powerful machines, and many alterations in detail, but the general design has not been altered. The power used in the British Navy for working the turrets is entirely hydraulic, supplied by hydraulic pumps which are situated outside the structure of the turret. The hydraulic system is heavy, but it is reliable and successfully withstood the severe test imposed upon it during the War, in the very large number of turrets afloat in the British fleet. Any other system will have to be proved to be very reliable before it can be expected to supplant it.

The Japanese follow the British system, but in other navies electrical power has been used almost entirely for working the turret machinery. Electrical machines have made great strides in efficiency and reliability in recent years, and the combination of electric motors and hydraulic transmission (cf the type of the Williams-Janney and Hele-Shaw machines) has rendered electric power peculiarly adaptable to turret machinery. This system has been used in all recent United States designs and the increased use of electrical power for the auxiliary and possibly for the main engines of warships, may lead to the electro-hydraulic system being generally adopted in power-worked gun mountings.

Triple Turrets.—Triple turrets have appeared in most navies, but the British Navy has been slow to adopt the innovation. The development is due to the desire to increase the gun power of the ships, without unduly increasing the size of the ships themselves. By the agreement made at Washington the size of capital ships is limited to 35,000 tons and of guns to 16-in. calibre. All nations therefore began to try to place the greatest gun power possible into ships of this size without sacrificing protection and speed and having due regard to the radius of action required of the units of each particular fleet. Six guns mounted in two triple turrets occupy less length of the ship, which is one of the most important factors, than do the same number of guns in three twin turrets. Weight of heavy armour is thus saved which can be used for other purposes. Designs of quadruple turrets have been made, but it is not clear that economy of space results from their adoption, chiefly owing to difficulties in the ammunition storage and supply. There appears to be little doubt that the triple turret will be adopted by all navies in the near future.

Medium Heavy Guns and Mountings.—No modern capital ships now mount medium heavy guns in either their main or secondary armaments. Guns from 11 to 7-in. calibre are not powerful enough to be of any real use at long range against armoured ships, and, since their ammunition is too heavy to be manhandled, they cannot be used for rapid fire, and would consequently be out of place in the secondary armament. The relative weakness of the medium calibre gun was well illustrated at the battle of the Falkland Islands, when the German armoured cruisers, armed with 8-in. guns, speedily fell victims to the greater range and hitting power of the 12-in. guns of the British battle cruisers.

In the mountings of 6-in. and smaller guns a general change has taken place as the result of war experience, from the old pedestal (P.) mounting to the central pivot (C.P.). This was necessitated by the demand for greater ranges and therefore increased elevation. In the P. mountings the elevation was limited to about 20°, as the bottom of the cradle carrying the gun then fouled the pedestal. In the C.P. mountings a circular plate is bolted to the deck, having a low pivot in the centre; on this plate is carried, on rollers, a revolving platform, the pivot being only used to prevent lateral motion. On the platform are built two transoms, on the top of which are the trunnion bearings, in which the gun and cradle swing in elevation between the transoms. The latest C.P. mountings for 6-in. and 4·7-in. guns admit of elevation of 30° or more. The C.P. principle has also been adopted for all anti-aircraft mountings in which elevations up to 85° are necessary.

Anti-aircraft Guns.—The rapid development of aircraft has called for a new type of armament in the form of the high angle gun. The commencement of the War found all nations unprepared to meet the new form of attack. The menace had been realised, but none of the belligerent nations had advanced much beyond the experimental stage in the development of an anti-aircraft armament. Consequently a large number of improvised equipments were produced, none of which were satisfactory. The problem of hitting an airship or aeroplane is a difficult one, since the target is moving in three planes at high speed. A vast amount of experience was obtained on shore during the War and high angle gunfire succeeded in making aircraft fly at a greater height and therefore the attainment of their objective became more difficult. At sea, much less experience was gained and the problem is a much more difficult one, since the platform upon which the gun is mounted is a moving and unstable one, thus adding greatly to the complications.

All warships now carry two or more anti-aircraft guns. In the British fleet a 3-in. Q.F. semi-automatic gun was used at first, but this has now been replaced by the 4 in. Q.F. mark 5 gun on a specially designed high angle mounting. The tendency is to increase the size of anti-aircraft guns. The first essential, however, for an efficient gun for this purpose is extreme rapidity of fire and a limit is imposed upon the size of the gun by the weight of the ammunition. A round of fixed ammunition for a 4.7-in. gun weighs about 80 lb. and this is as much as can be handled by one man with any degree of rapidity. It does not appear therefore that high angle guns will increase above this calibre unless a complicated power worked mounting is introduced, and this does not at present appear probable. (*See* GUNNERY: WASHINGTON CONFERENCE.) (S. H. W.)

OREGON (*see* 20.242), a State of the United States of America. The population in 1920 was 783,389 as against 672,765 in 1910, an increase of 16·4%: at the end of 1925 it was estimated at 1,007,725. The 1925 population of the 33 cities and towns with more than 2,500 inhabitants was 51% of the total population, as against 49·9% and 45·6% in 1920 and 1910 respectively.

Forestry.—In 1922 the virgin forest area was 21,344,000 ac., or about 34% of the total area. The timber stand in 1923 was 395,776,229 mill board feet. The total annual depletion of merchantable stand by fire and cutting during the years 1920–5 was about 1·2%. There were 14 national forests with an area of 24,086 sq. m. within the boundaries of the State. Oregon ranked first in the nation as a timber-bearing State and second in lumber production. In 1923 it produced 12·61% of the nation's soft-wood lumber; its cut was 3,800,000 mill board ft., valued at $110,000,000. The number of sawmills was 685; 45,000 men were employed and the lumber industry pay-roll was 65% of the entire industrial pay-roll of the State: 80% of the outgoing products were lumber and wood.

Agriculture.—Of the total land area 22·1% (13,542,318 ac.) was in 1920 included in the 50,206 farms; in 1925 14,170,043 ac., of which 4,984,375 ac. were improved, were in 55,909 farms. The gain in the total farm acreage during the decade 1910–20 was 15%, and from 1920–5, 4·3%; the gain in the improved acreage during the decade was 14·9%, but from 1920–5 the shrinkage of tillable land in the farms was nearly 2%. The average value of farms and buildings was 12·4% less in 1925 than in 1920. The total value of farm property in 1910 was $528,243,782, and in 1920 was $818,559,751: 81% of the Oregon farms were, in 1920, operated by the owners. The crop values in 1920 were 192·7% higher than in 1910. The conspicuous increases in production in

the decade 1910–20 were in forage, ensilage and fruits. The total field crops in 1920 were worth $131,884,639. Live stock in 1925 consisted of 2,002,378 sheep, 483,813 beef cattle, 312,518 dairy cattle, 225,350 horses and 223,287 swine. In 1924, 16,250,000 lb. of wool were produced.

Mining.—The mineral output includes gold, silver, copper, lead, platinum, quicksilver, Portland cement, lime, clay products, monumental and building stone, coal, crushed rock, sand and gravel, diatomaceous earth, gypsum and mineral water. The total annual value is about $5,500,000, and in the years 1920–5 increased at the rate of about $250,000 a year. Its most valuable mineral products are sand and gravel for building and highway construction and the common clay used in the manufacture of brick and drain tile. The expansion of mining activity has centred in the production of copper east of Baker, and that increase adds to the production of the precious metals associated with copper ores.

Industries.—Oregon has distinct advantages for special lines of industry, including an abundance of raw materials, an equable and moist climate favourable to the production of textile fabrics, and readily available hydroelectric power. The relatively high transportation cost has been the main factor handicapping development. In 1914 Oregon's manufactured products were valued at $109,761,951 and the average number of wage-earners employed was 28,829: in 1925 the volume of output had increased to about $363,912,328, and employment was furnished to some 62,655 workers. The chief industries arranged in order of value of products were lumber and timber products, slaughtering and meat-packing, dairy products, woollen goods, printing and publishing and canning and preserving.

Transportation.—In the years 1910–25 there were two distinct periods of transportation improvement. In the decade 1910–20 there were the opening of the main waterways, the extension of the railways (increasing the mileage by more than one-half), and a thorough commitment to the construction of a system of State highways with a consistent development. During the five years 1920–5 there was the maintenance of the channel depths of the waterways, the projecting and partial construction of the extensions needed to complete the Oregon railway network, and the continuation of highway construction. With the completion of the Celilo canal in 1915, the Columbia and its tributary, the Snake, were made navigable to Lewiston, Idaho. Through the construction of this canal above the city of The Dalles a fall of 80 ft. in a stretch of 9 m. was overcome. With the transference to the Federal Govt. in 1915 of the canal and locks around the Willamette Falls at Oregon City, the free use of the Willamette was secured. The co-operation of the Federal Govt. and the port authorities of Portland secured a deep-water channel in the Willamette and Columbia from Portland to the sea.

The railway construction during the decade provided:—

(1) Lines to the Pacific coast, from Portland to Tillamook and from Eugene to Coos Bay; (2) extensions into central Oregon with parallel lines up the Deschutes river to Bend and westward from Vale in the Snake river valley; (3) construction on the gap between Natron and Klamath Falls as part of a double line for Oregon-California traffic; (4) an electric line from Portland to Eugene and a steam line from Corvallis to Eugene.

The railway mileage in the State in 1910 was 2,413·61; in 1920, 3,626·77; in 1925, 3,347 steam and 589 electric.

In the period 1920–5 a 30-m. extension into central Oregon by the Oregon short line was completed, and construction activity on the Natron-Klamath cut-off has brought it almost to completion. Notwithstanding these additions to the railway mileage in Oregon in the 15 years 1910–25, a complete lack of railway lines still existed in the large southeastern section of the State, comprising about one-half its area. Not only is the possible development of this section thus hindered, but the timber-covered area to the west has no direct transportation route to the great lumber market of the prairie states to the east. The development of a state highway system, begun in 1917, has been regularly carried forward: at the close of the year 1925 the total mileage was 4,463, of which 889 m. were paved and 2,188 m. had macadam surfacing. A definite market road system for each county has been approved.

Education.—In 1920 the total enrolment of grade-school and high-school pupils was 148,412; in 1925 it was 187,982. Funds for the maintenance of the schools increased 69% in the years 1920–5.

History.—During 1910–20 recourse was freely had to the "Oregon system" of direct legislation to enact constitutional amendments and statutory laws. Through initiative petition, referendum petition and by vote of the Legislature, 174 proposals were submitted to the people; of these, 73 were approved. The people of Oregon by this procedure established prohibition, woman suffrage and a rural credit system. Citizenship qualification for the franchise, the right to veto single items in appropriation bills, the abolition of the poll tax, classification of property for taxation and State-wide limitation of the rate of increase of taxation and indebtedness were also thus enacted. Legislation also included the establishment of a minimum wage, workmen's compensation and pensions for widows and a "blue-sky law" licensing sales of corporation securities. While three-fourths of the voters usually vote with the Republican party, the representative leaders of the State during 1910–20 were two Democrats, George E. Chamberlain as U.S. Senator and Oswald West as governor. Mr. Chamberlain was promoted from the governorship to the Senate. During the period 1920–5 the majority party was better able to maintain its unity, electing two governors in succession and sending a solid delegation of Republicans to Congress. In 1922, however, the Democratic governor, Walter M. Pierce, was elected by a decided majority on issues of retrenchment and revenue reforms.

In the decade 1910–20 the people of Oregon began to demand more active progress in their State Government. While there had been before 1910 a half-hearted venture in railway regulation, later repudiated, and institutions of higher education had been receiving meagre support for some decades, the spirit of the constitution of 1857 was still dominant. Later, however, the desire for an early realisation of an adequate highway system, and the assured prospect of regular revenues from automobile licences, led to the authorisation in 1917 of a State bond issue for the building of a State highway system. The limit of indebtedness then fixed was 2% of the assessed valuation. This limit was raised in 1920 to 4% for the State. The counties are authorised to borrow up to 6% of assessed valuation to secure funds for highway improvement. The governors during 1911–25 were Oswald West (Dem.), 1911–5; James Withycombe (Rep.), 1915–9; Ben W. Olcott (Rep.), 1919–23; Walter M. Pierce (Dem.), 1923– .

(F. G. Y.)

ORELLI, HANS KONRAD VON (1846–1912), Swiss theologian (*see* 20.251), died at Basle Nov. 8 1912.

ORINOCO (*see* 20.275).—During the 15 or 20 years ending in 1926 economic conditions in the region of the Orinoco and its tributaries have passed through three states: normal, depressed during the World War years and a subsequent revival. The improved conditions are largely caused by Europe's renewed demands for raw materials. Ciudad Bolivar (pop. 20,000), the metropolis of the region, has extended modern sanitation and improved health conditions, paved some streets, installed electricity, initiated motor-car service, extended telegraph and telephones and constructed some modern homes. Beer, ice, candles, macaroni, lumber, fishing and mining are local and regional industries. Cattle business, largely north of the Orinoco and Apure rivers, is expanding, and estimates place the number of head at several million. British interests in the San Fernando region are active in breeding and shipping to Port of Spain for slaughter and re-export. Ciudad Bolivar is increasing the export of hides; tonka-bean shipments range from 70,000 to 600,000 pounds yearly; exports of egret feathers to France and of balata largely to England are increasing. The indications of petroleum in the Orinoco delta are promising. German, British, French and American companies, in the order given, represent foreign investments. There is some gold mining and much prospecting is carried on in the region.

ORLANDO, VITTORIO EMANUELE (1860–), Italian politician and jurist, was born at Palermo March 19 1860. Becoming a barrister and a law professor, he was first elected deputy for Partinico in Sicily in 1898. He was Minister of Education in the Giolitti-Tittoni Cabinet of 1903–5, and of Justice in the Giolitti Cabinet of 1907–9, and again under Salandra in Nov. 1914. Although a Giolittian at heart, he was in favour of Italian intervention in the World War. On the resignation of the Salandra Cabinet in June 1916 he remained in office under Boselli as Minister of the Interior, and when the latter resigned Orlando was entrusted with the formation of a new Cabinet. After the Armistice he went to Paris as president of the Italian peace delegation. When President Wilson launched his appeal on Fiume to the Italian people over the heads of their delegates, he returned to Rome, where he was triumphantly received, but after his return to Paris without the guarantees he was supposed to have secured, and without obtaining any satisfactory solution of the Adriatic problem, the Chamber voted against him and he resigned on June 19 1919.

On Dec. 2 1919 he was elected President of the Chamber. He at first supported Fascism and the Mussolini Govt. and was re-elected deputy in 1924 on the Government list; but after the Matteotti affair he withdrew his support, without, however, abandoning the Chamber. At the municipal elections of Palermo in Aug. 1925 he mobilised all his adherents in favour of the anti-Fascist list but upon the subsequent triumph of the Fascists Sig. Orlando retired from Parliament.

ORLEANS, LOUIS PHILIPPE ROBERT, DUKE OF (1869–1926) (*see* 20.285), died at Palermo March 28 1926.

ORPEN, SIR WILLIAM NEWENHAM MONTAGUE (1878–), British painter, was born at Stillorgan, County Dublin, Nov. 27 1878 and studied at the Dublin Metropolitan School of Art and at the Slade School, London. He was elected A.R.A. in 1910 and R.A. in 1919. He first exhibited at the New English Art Club, of which he became a member in 1900, his early work being marked by preoccupation with spacing and silhouette and the use of quiet harmonies of grey and brown, with a note of vivid red or blue. He soon turned to the use of bright colour and the study of light, seen in a series of brilliant portrait interiors such as the "Hon. Percy Wyndham" (1907), "Myself and Venus" (1910, now in Pittsburgh Gallery, U.S.A.). About this time he became well known for his vigorously characterised portraits. During the World War Orpen received an appointment as official artist and in 1918 an exhibition of his war pictures was held in London. Many of these are now in the Imperial War Museum. He was created K.B.E. in 1918. He wrote *An Onlooker in France* (1921) and *Stories of Old Ireland and Myself* (1924).

ORTHODOX EASTERN CHURCHES (*see* 20.333).—As regards the ecclesiastical position in the Near East, this article deals only with the "Orthodox" Churches—an adjective used in its technical sense, and having here no bearing on the question of right or wrong belief—and not with the uniats (the Churches which acknowledge the Roman obedience but keep their own rites), or with the separated Churces of the East—the Armenians, Nestorians, Jacobites and Copts. It is necessarily dependent on literature of a fugitive nature, such as magazines and newspapers, and on the observation of recent travellers. One preliminary remark, which throws light on many of the problems to be discussed, must be made. A marked feature of Orthodox Christianity is that political independence has usually led to ecclesiastical independence. This is a fact of great importance.

THE POSITION BEFORE THE WAR

Position at the Outbreak of War.—Russia, with Georgia, is reckoned to have had nearly 100,000,000 Slavonic Orthodox.[1] Georgia, an exarchate once independent, was gradually being Russianised; the exarch was a Russian and an *ex officio* member of the Russian Holy Synod since 1801, while his suffragan bishops were Georgians. The effects of Tsarism on the Russian Church have been described by a learned observer as not good.[2] "Under the guise of protecting the Church, the state in reality had enslaved it." The Church was, he continues, in a state of paralysis, and the Russian educated classes were estranged from it.

The Orthodox Church in Turkey (Greek), under the Ecumenical Patriarch, Archbishop of Constantinople—often erroneously in the West called the Patriarch of Constantinople—is believed to have numbered 2,500,000 in Europe—counting in those transferred to the kingdom of Hellas in 1912—and 2,000,000 in Asia Minor and the islands.[3] In Greece proper, where the autocephalous position of the Church was recognised by the Ecumenical Patriarch in 1850, there were about 2,000,000 orthodox (*ib.*)

In the Austro-Hungarian Empire there were several orthodox Churches, chiefly Slavonic, with some 3,000,000 souls: The Karlowitz Serbian Church; those of Dalmatia and Cattaro, joined to the Ruthenian Bukowina, though far distant from it; of Bosnia and Hercegovina; of Transylvania; and a certain number of orthodox scattered in various districts. The Bulgarian Church was made autocephalous by the Sultan in 1876, when the Bulgarian exarch resided in Constantinople; but the Ecumenical Patriarch did not recognise its independence. It numbered about 4,000,000.

In Rumania the old Church of Okhrida was suppressed in 1767, and the Orthodox then became subject to the Ecumenical Patriarch till recent times. They numbered about 4,500,000. The same state of things obtained in Serbia (1,500,000), where the old Church of Ipek was suppressed in 1766.

The little Church of Montenegro (about 200,000 souls) was made independent in 1766 and governed by a metropolitan who had one suffragan bishop.[4] (Note that in some of the separated Churches of the East the metropolitans have no suffragans.) In addition there were the Orthodox in the patriarchate of Antioch, that of Jerusalem, that of Alexandria, Cyprus, autocephalous since 431, and the monastery of Mount Sinai, autocephalous since 1575, the archbishop of which usually resides in Egypt

THE POSITION AFTER THE WAR

The alterations in the boundaries of the various states have necessarily had a great effect on the Church.[5] But a much greater effect has been produced by the internal convulsions in Russia and Turkey.

Russia has lost Poland and the Baltic provinces; but this has not affected the Orthodox Church to a very great extent, as the bulk of the population was of other faiths. Poland has still 3,000,000 Orthodox; Lithuania has 23,000 Orthodox and 35,000 "Old Believers;" Czechoslovakia has very few orthodox, 90% of the population being Roman Catholics or Uniats.[6]

In Russia proper and in Georgia the effect has been most disastrous. At first the revolution promised well for the Orthodox. A Holy Synod of 12 bishops and a council of bishops, priests and laymen were established in 1917; the office of Chief Procurator—a layman who had represented the Tsar, and who wielded very great powers—was abolished; the patriarchate, discontinued by Peter the Great since 1700, was revived (Nov. 1 1917) in the person of Tikhon, Patriarch of Moscow and all Russia, who was enthroned on Dec. 4 1917. But the Bolshevist régime dashed all the hopes of the Church. The new rulers set themselves to oppose Christianity in all its forms. The patriarch was imprisoned, and only liberated, owing to the general expression of civilised public opinion, after a long incarceration, in May 1923.

All teaching of religion in public schools was forbidden; parents were not allowed to teach their children religion; only candidates for the priesthood, if over 18 years of age, might learn theology. No minister of religion could enjoy full civil rights. No religious association could hold property, and all property of existing religious associations was confiscated to the State,

[5] The new frontiers, as far as they are fixed, may be seen in the *Royal Geographical Society's Journal*, 53. 370, 54. 188, 55. 160, 65. 90.
[6] *Goodwill*, pp. 135–139.

which might at its pleasure lend buildings for religious worship. Monasteries were to be converted to useful purposes.[1]

A great persecution of the Orthodox has broken out, and according to the official figures, within a period of less than two years, 1,275 bishops (and priests?) and 6,775 other persons have been executed for their religion.[2] Most of the remaining bishops who have not escaped from Russia have been interned in or about Moscow, or in monasteries in the Far North. And the only organisation that has been found possible is a synod of 15 Russian bishops which holds its sessions outside Russia, at Belgrade. The patriarch Tikhon died in 1925, and a makeshift for the patriarchate has been devised in the shape of a locum tenens. The passive resistance of the Russian peasantry has been the great obstacle to the Government's endeavour to suppress Christianity, and the so-called reformed Russian Church, a body encouraged by the Soviet power, has so far been a failure for the same reason. In Georgia, the Church is in as great confusion as in Russia; since the first revolution the tendency has been towards independence in ecclesiastical matters.

The Ecumenical Patriarchate.—Post-War Turkey, with its curtailed frontiers, has as its aim the creation of an entirely Moslem State; and among other things the Turkish Govt. desires the abolition of the Ecumenical Patriarchate. But the European Powers, while restoring Constantinople to Turkey, prevented this, and at Lausanne the Turkish delegates made a formal declaration of their Government that the Patriarchate would be allowed to continue.[3] Yet, as far as Turkey is concerned, the Patriarchate is little more than "the shadow of a shade." By the Treaty of Lausanne all Greek Orthodox residents in Constantinople before Oct. 30 1918 are exempt from expulsion. All other Greeks in Turkey, however, are liable to expulsion, and those in Asia Minor have been settled in the new Greece and elsewhere, in many cases in exchange for Moslems. Only Turkish subjects can be metropolitans in Turkey, and therefore the episcopate has to be recruited from the comparatively few Greek residents in Constantinople. Outside modern Turkey the Ecumenical Patriarch, not the Metropolitan of Athens, has jurisdiction in Macedonia, Western Thrace, Epirus, Crete and the Aegean Islands, and this is an exception to the rule about ecclesiastical independence mentioned above.[4]

Yugoslavia, called in the Treaties the Serb-Croat-Slovene State, is now re-organising its Church, which includes the former Serbian Church, the Karlowitz Serbian Church, that of Dalmatia and Cattaro, that of Bosnia and Hercegovina (these three formerly in Austro-Hungary) and Montenegro. During the Great War many Serbians were in England; over 600 refugees, young ordinands, were there instructed and prepared for the Orthodox priesthood under Serbian priests.[5] Many others were in France, engaged in secular pursuits, and in other countries. This will be a convenient place to remark on the changed ecclesiastical conditions in both Yugoslavia and Rumania. Before the War Rumania and Serbia were inhabited practically by Orthodox alone. But the enlarged boundaries have brought in many Roman Catholics and Lutherans, and this has complicated the problem of national religions. The former idea of one country, one church, has to be given up, and religion and politics cannot have the same close connection that they had before. Moreover, the greatest hindrance to the reorganisation of the Orthodox Church in the Balkans and in Rumania is the exaggerated national feeling and jealousy of each country against the others. This jealousy is much more felt between the different branches of Orthodoxy than between them and the Roman Catholics or Lutherans.[6]

Rumania.—To the former Rumanian Church, with its two metropolitans, is now added the Transylvanian Church (formerly in Hungary), with its Metropolitan at Hermannstadt, and suffragan bishops at Arad and Kazansebes; and also the Churches of Bukowina and Bessarabia. The United Church now numbers some 11,000,000, out of a total population of about 12,500,000.[7]

Greater Greece.—The old metropolitanate of Athens has not been greatly affected. For Macedonia, etc., see above; but it is hard to see how the Ecumenical Patriarch in Constantinople can under the changed conditions exercise an effective supervision over these districts. Salonika has now become once more a Christian city, and the mosques which had originally been Christian churches have now been restored to Orthodox worship.

Bulgaria has lost the Aegean coast to Greece, and part of the Dobruja to Rumania. Otherwise the Church has not been much affected. It has, by the official census of 1920, about 4,000,000 members, almost all of Bulgarian nationality, out of a total population of nearly 5,000,000, of whom about 700,000 are Moslems, chiefly Turks.[8]

We now pass to the smaller communities in Asia and Africa which were once under Turkish rule. The orthodox patriarchate of Jerusalem, now under British mandate, consists of about 30,000 Arab and Greek Christians and a few Russians. The chief obstacles to progress are the jealousies between Arabs and Greeks, and the financial difficulties of the monasteries. There is now no orthodox theological seminary in Palestine.

The orthodox patriarchate of Antioch, now under French mandate, suffers from the same difficulties as that of Jerusalem. It has some 300,000 members. The orthodox ("Melkite") Patriarch of Alexandria has only a small following of about 100,000, as has been the case since the Monophysite schism in the 5th century. Under him is the Archbishop of Nubia. The autocephalous Churches of Cyprus (with about 200,000 orthodox) and Mount Sinai have not been greatly affected by the War.

(A. J. M.)

ORTHOPAEDIC SURGERY.— The influence of the War upon the practice of orthopaedic surgery is related to organisation, and to lessons learnt in technique from the handling of large groups of cases. Efficiency at the front and at the hospitals in England was attained only when segregation of various types of injury became established. The treatment of fractures during the early part of the War was attended not only by unnecessary deformity, but also by a high mortality, and remained unsatisfactory until special hospitals were started, manned by teams of expert surgeons. In compound fractures of the femur an initial mortality of 80% was ultimately reduced to 25%. This dramatic change was accomplished by immediate reduction and fixation of the fracture, by segregation and by continuity of treatment both at the seat of war and at home. Knowledge thus gained has formed the basis of the efforts to place the organisation and teaching of fractures upon a different basis with a view to minimising the disabilities of industrial accidents. Reform lies in the simplification of apparatus, and in an intensive education in their application, in segregation of fractures in special wards and in appointing surgeons with special qualifications to teach the student.

Technique.—The World War supplied us with exceptional opportunities of acquiring an improved technique in certain reconstructive operations which have an important bearing upon civil surgery. Amongst these stand prominently injuries to the peripheral nerves, tendon transplantations, bone grafting and bone infections. The enormous number of complete nerve lacerations enabled a finished operative technique to be built up, which was largely wanting before the War. Many misconceptions were corrected, such as the worthlessness of complete transplants of nervous or other tissue to bridge gaps in peripheral nerves, and the doubtful value of lateral nerve anastomosis. In cases of irreparable destruction to nerves, healthy muscles were transposed to take the place of paralysed ones. These operations proved singularly successful where large tracts of the musculospinal nerve were irreparably damaged.

Certain flexor muscles of the forearm were attached in such a way that extension of the wrist and fingers became assured. Bone graft surgery received a great impetus during the War and has since been extended. This has led to considerable research on the viability of transplanted tissue, and in the case of the bone it is held that the transplant is a scaffold along which the fresh bonelaying cells creep from the embracing bone and deposit new bone, the scaffolding itself being ultimately removed by absorption. War experiences have permanently affected the treatment of virulent infections. The Carrel-Dakin method has permanently established itself as well as the procedure of laying open infected bone cavities so that the soft tissues fall in easily to obliterate the gap when the infection is at an end.

Care of Cripples.—The most notable advance in orthopaedic surgery following the War is in the organisation for the care and cure of cripples. This consists in the establishment of well-equipped open-air hospitals in various parts of Great Britain, known as hospital schools, fully staffed by surgeons specially trained to deal with deformities of every kind. These schools provide treatment and education for the cripple, and are associated with what are known as after-care clinics situated in small towns covering an area of from 40 to 50 m. distant from the hospital in every direction. These after-care clinics are visited by the hospital staff at stated times, and are attended by out-patients who have been inmates of the hospital school, and by cases from the district, who are often seen at a sufficiently early date to prevent deformities from arising. These hospitals and clinics are run in close association and agreement with the local practitioners, the education authorities and the Ministry of Health. This scheme, in association with preventive measures, promises practically to eliminate the cripple. Its aims are to secure the potential cripple at the earliest moment, to give him expert institutional treatment in fresh air and sunlight and to secure continuity of treatment until recovery is complete.

Artificial Light.—Of the special advances in knowledge that have taken place since the War, the evolution of the artificial light treatment as an auxiliary form of therapeutics for tuberculosis of bones and joints and of rickets may be instanced. The work of Rollier, Leonard Hill and others has given prominence to the therapeutic value of sunlight (*see* HELIOTHERAPY), and in the absence of sun extended observation favours the conclusion that we have in various forms of artificial light a promising substitute. This treatment, as in the case of heliotherapy, must be looked upon merely as an accessory measure in surgical tuberculosis. It is most effective when used in combination with other surgical procedures. It should be pointed out that there is grave danger in spreading a belief that other forms of treatment are unnecessary and subsidiary.

Infantile Paralysis.—The serious epidemic of infantile paralysis has resulted in a more widespread knowledge of the early symptomatology and important work has been done, especially by the late Prof. Lovett of Harvard from 1916 onwards. It has now been proved that complete rest and immobilisation and the elimination of meddlesome therapeutics have resulted in lessening the severity of symptoms by limiting the paralysis. The mass of material rendered available by these epidemics has thrown new light on the actual treatment of deformity. Tendon transplantations for various deformities of the feet have given place to operative stabilisation of the flail foot, and transplantations when practised are now associated with reconstructive operations upon bone. This combination has resulted in more satisfactory function.

Rickets.—Rickets and allied nutritional diseases, largely as a result of starvation diets during the War, have received close investigation by many observers abroad and at home. Considerable work on the aetiology, particularly with reference to diet, exercise and sunlight, has been carried out at Johns Hopkins Hospital, the Lister Institute and by Findlay of Glasgow, Mellanby and Chick. Much has been discovered regarding "vitamines" or "accessory food factors" (*see* VITAMINES). The report of the Research Committee provisionally deals with only two varieties; one known as vitamine A, or fat soluble A, and the other as anti-rachitic vitamine. Both are essential to the diet of growing animals. Defect in the one leads to arrest of growth and loss of weight; in the other a deficiency in the deposit of lime salts. The committee conclude that an anti-rachitic vitamine is a central factor in the prevention of rickets; and that a deficiency of calcium and phosphorous, in conjunction with a deficiency of anti-rachitic vitamine, hastens rickets. The greater the discrepancy in the calcium phosphorus intake the greater need for an appropriate anti-rachitic intake. It has now been proved that sunlight and ultra-violet rays act as an antidote to a deficiency diet, and can ward off the on-coming of rickets. This work has added considerably to the knowledge of orthopaedic surgeons, and has rendered unnecessary a good deal of the operative treatment for rachitic deformities.

Spinal Treatment.—The writings of Hibbs, Calve, Girdlestone and Waldenstrom have enabled us to place in accurate perspective the bony fixation of the vertebral column in tubercular disease of the spine. Forcible correction and fixation of the spine in lateral curvature is being abandoned in favour of less drastic measures, and bony fixation of the flail spine in paralytic cases is being performed with promising results.

Other Operations.—Operative treatment in osteoarthritis, especially in the non-articular type, is being more widely practised. This consists in stabilising the joint by exercising the joint surfaces and in the complete removal of diseased synovial membrane in the knee joints. The so-called operations of arthroplasty, or mobilisation in ankylosis of joints is becoming more common, and the results more encouraging. They mainly consist of the loosening and reconstruction of the bone ends, and the introduction of transplanted or living tissue between the bone ends to secure movement.

The treatment of fractures of the neck of the femur by wide abduction of the limb with internal rotation have been still further perfected by Royal Whitman of New York, and a large percentage of recoveries in this obstinate type of fracture occurring in old age is reported. The pathology of the rarer bone diseases such as "cysts of bone," "myeloid sarcoma," "Paget's disease" have been closely studied by many observers, resulting in valuable information in relation to operative procedure.

ÖRTZEN, GEORG, BARON VON (1829–1910), German poet and prose writer (*see* 20.342), died in Freiburg May 26 1910. His later works include: *Nebensachen* (1910); *Auf Schwarzwaldwegen* (1910).

ORZESZKO, ELIZA (1842–1910), Polish novelist (*see* 20.343), died at Grodno May 18 1910.

OSAKA, Japan (*see* 20.344), brought several suburban districts within its boundaries in 1925 and had a population of 1,252,972 in 1920. It was a busy industrial centre with over 7,000 factories in 1921; the cotton manufacture, in particular, has developed rapidly. There is an acute shortage of houses and rents are high. Many people migrated from the north to Osaka after the earthquake in 1923, since the southern and south-western districts are believed to be immune from severe shocks. In 1909 one-third of the city was destroyed by fire and though it was rebuilt with wider streets and better buildings, there are still many wooden houses and bridges, dangerous in case of fire, and its factories and warehouses compare less favourably with European and American standards than those of Tokyo. Work on a drainage system was started in 1909, but is still incomplete. Railways in the neighbourhood are in process of electrification, and there were 51 m. of tramways in 1925.

Trade has grown very largely, but most goods are loaded and discharged at Kobe, as the river is only navigable for small vessels. A programme of port improvements was, however, undertaken in 1906 to make the harbour suitable for ocean-going ships, including the erection of jetties and warehouses, and the protection of the shore was practically completed in 1914; and further work on land reclamation has been undertaken. A fourth

shipbuilding yard was opened in 1911. A pharmaceutical school was opened in 1917 and in 1919 the university of medicine was made into a general university. The spread of pulmonary tuberculosis has caused alarm and a tuberculosis laboratory has been opened. In 1919 a municipal home for workpeople, including an employment bureau and a children's clinic, was inaugurated.

OSBORN, HENRY FAIRFIELD (1857–), American palaeontologist, was born at Fairfield, Conn., Aug. 8 1857. Graduating from Princeton University in 1877, he was appointed assistant professor of natural science there in 1881, becoming professor of comparative anatomy in 1883. He went to Columbia University as Da Costa professor of biology in 1891 and was professor of zoology there from 1896 to 1910, in the latter year being appointed research professor of zoology. He was also curator of the department of vertebrate palaeontology of the American Museum of Natural History from 1891 to 1910. He was appointed vertebrate palaeontologist to the U.S. Geological Survey, 1904. From 1894 to 1916 he was connected with the Brearley School for Girls as director and president. He served as chairman of the executive committee of the New York Zoological Society 1896–1903, and assisted in founding the fine Zoological Park in the borough of the Bronx, New York City. (*See* EVOLUTION; PALAEONTOLOGY.)

Osborn's works include *From the Greeks to Darwin* (1894); *Evolution of Mammalian Molar Teeth* (1907); *The Age of Mammals* (1910); *Huxley and Education* (1910); *Men of the Old Stone Age* (1915); *Origin and Evolution of Life* (1917); and *The Earth Speaks to Bryan* (1925).

OSLER, SIR WILLIAM (1849–1919), British physician, was born at Bond Head, Canada, July 12 1849. He was educated at Trinity College School, Port Hope, Trinity University, Toronto and at McGill University, Montreal, where he took the M.D. degree in 1872. He studied medicine in London, Leipzig and Vienna and was in 1874 appointed professor of medicine at McGill University. From 1884 to 1889 he was professor of clinical medicine in the University of Pennsylvania, and from 1889 to 1904 professor of medicine at Johns Hopkins University. In 1905 he was appointed regius professor of medicine at Oxford, where he also served as a curator of the Bodleian Library, as a delegate of the University Press and as one of the Radcliffe trustees. In 1911 he was created a baronet. Sir William Osler carried out original and valuable researches on the diseases of the spleen and blood and also made eminent contributions to the study of infections of the heart, of angina pectoris, of malaria and of many minor maladies. He was the author of many medical works, of which the most important is *The Principle and Practice of Medicine* (1892, latest edition 1916), and of a volume of essays entitled *Aequanimitas*. Sir William died at Oxford Dec. 29 1919.

OSLO, formerly CHRISTIANIA (*see* 6.279), the capital of Norway, changed its name as from Jan. 1 1925, Oslo being the original appellation of the city. The population was 258,483 in 1920. Between 1912 and 1921 large sums were spent on building and equipping quays. Vessels up to 10,000 tons can be built in the ship-building yards. Garden suburbs have been erected by the municipality at Ullevaal, where there is the largest municipal hospital in the country, and at Töien. At the latter place are three buildings, the first erected in 1908, which house the mineralogical and palaeontological, zoological and botanical collections. A third Viking ship, that of Oseberg, has been added to the others in the historical museum. The Margaret church, built by the Swedish colony in memory of the late Crown Princess of Sweden, was consecrated in 1925. Three new theatres have been built since the World War. A trade intelligence bureau was founded in 1910, and the central bureau of statistics reorganised in 1918. A beginning has been made with the electrification of the state railways, from Oslo to Drammen. The Dovre railway, connecting Oslo with Trondhjem, was completed in 1921, and the Östbane station has been extended. The joint scheme of the state and the municipality for deriving power from the Glommen river has been delayed, but three units of 13,000 kw. were in use early in 1925.

OSSENDOWSKI, FERDINAND ANTHONY (1876–), Polish traveller and writer, was born May 27 1876 in the government of Witebsk. He studied at the University of St. Petersburg (Leningrad) and at Paris, where he received the degree of docteur des sciences and officier d'Académie for his work entitled *The Allotropy of Silver*. He was appointed lecturer of physics and physical chemistry at the Tomsk Polytechnic and then became successively a lecturer in chemistry, physics, geography; a manufacturer, a commercial manager, a journalist, a novelist, a physician, a draughtsman, a teacher of languages, and a mineralogist. Ossendowski was twice imprisoned for supposed political offences. While at the university he was sentenced to five months' imprisonment for taking part in a manifestation against capital punishment, and, at the time of the Russo-Japanese War, he was brought before a Russian law court for leading a patriotic organisation in the Far East with the object of preventing civil war after the defeat of the Russian Army. He was sentenced to death but the sentence was later commuted to 20 months' imprisonment. During this period Ossendowski's books on prisons appeared, which aroused a great deal of controversy and led to a revision of the Russian prison system.

After the outbreak of the Communist revolution, Ossendowski held office as financial adviser to the Government of General Kolchak in Siberia. After Kolchak's Govt. fell, he made his way through the forests to Mongolia disguised as a peasant. His journey through Central Asia is recounted in *Beasts, Men and Gods* (1923), and his other works on Asia include *Man and Mystery in Asia* (1924), and *The Shadow of the Gloomy East* (1925). His play *The Living Buddha* had a successful run at the National Theatre in Warsaw.

Ossendowski also published a number of scientific books, including *The Theory of Fermentation, Vegetation of the Pacific Ocean and the Extraction of Iodine; The Origin of Petroleum according to Scientific Hypothesis, Contribution to the Hydrography of the Ussuri Territories; Contribution to the Oceanography of the Pacific, The Coal Industry in Russia and Its Possibilities.* See Sven Hedin, *Ossendowski und die Wahrheit* (1925).

OSTEND, Belgium (*see* 20.356), had a population in 1923 of 44,271. Large sums have been recently spent in enlarging and improving the town and suburbs, which is one of the most popular watering places in Europe. It is computed that it is visited by nearly 1,000,000 people yearly. It is also a port for cross-channel services and the chief Belgian fishing port. The new fishing harbour includes a wet dock for steam trawlers, a tidal dock for sailing boats and a slipway. Extensive harbour and dock works were completed before the World War.

The War Period.—Ostend was occupied by the Germans for four years during the War, and was at first, until it was rendered untenable by aerial bombardments, a base for destroyers and submarines. In May 1918 the entrance channel to the harbour and the canal to Ghent and Bruges were blocked to all craft except the smallest submarines by the sinking of the "Vindictive." After the War she was raised and broken up. Parts of the "Vindictive," "Intrepid" and "Thetis" have been made into a memorial on the Digue. During the German occupation over 2,000 bombs were dropped on the town, and an enormous amount of damage was done. The new marine station and the locks were blown up, and the Central station badly damaged. Restoration, however, was so rapid that two years after the Armistice hardly a trace of the havoc was left. A new lighthouse, in place of the large one destroyed in 1916, was finished in 1924. In 1922 a monument to commemorate the work of the people of Ostend among refugees fleeing to England was unveiled in front of the church of St. Peter and St. Paul, and in the English church is a plaque in memory of those who were killed in the raid on Zeebrugge. (*See* ZEEBRUGGE.)

OSTEOPATHY.—According to its advocates, osteopathy is that system of the healing art which regards the structural integrity and adjustment of the mechanism of the body as the most important single factor in maintaining the organism in health, in contrast to the older systems which regard the chemical intake of the body as the most important factor. In other words osteop-

athy is based on the belief that the human body is a vital mechanism, a living machine, which, given wholesome physical and mental environment, good food, proper exercise, pure air and pure water, will be healthy—that is, will function properly, so long as all the cells and parts of that vital mechanism are in normal adjustment. Osteopathy teaches that structural derangement of the body is the predisposing cause of disease. Such structural derangement causes functional perversion of the vascular and nervous system, weakening the nutritional processes and lowering the powers of resistance of the body; on the one hand, producing congestion, either general or local, active or passive; on the other, depriving tissues of an adequate blood and lymph supply. This perversion impairs the rebuilding of cells after waste due to active functioning and retards the elimination of waste products through body drainage, thus making the body unable to withstand climatic changes or unhygienic and insanitary surroundings, and offering a hospitable medium for the invasion and propagation of pathogenic germs. Integrity of mechanical structure determines the normality of functioning. That structural perversion is the basic cause of functional disturbance or disease is a distinctive and fundamental principle of osteopathy.

Diagnostic Methods.—Osteopathic diagnosis includes examination of the whole body and its excretions, especially the articulations and alignments of the vertebrae, ribs and pelvis. Symptoms are noted, and chemical, microscopic, hygienic, sanitary and other findings are studied to aid in determining the existing conditions of tissue, viscera and function. Of supreme importance, however, is the physical examination to discover existing mechanical tissue lesions.

Therapeutic Methods.—Osteopathic therapeutics may, and usually does, consist in the specific manipulative removal of the lesion or structural perversion, by effecting tissue adjustments, which free the remedial anti-toxic and auto-protective resources of the organism itself; or it may consist in correcting hygienic, dietetic, environmental and psychic conditions; or in the application of operative surgery for fractures, lacerations, and the removal of abnormal growths or organs so diseased as to be dangerous to life; or it may be the administration of antidotes for poisons and other dangerous substances. In osteopathic therapeutics the fundamental principle is, " Find the lesion, adjust it, and let it alone."

Historical Matter.—The founder of osteopathy, Dr. Andrew Taylor Still, was born in Virginia Aug. 6 1827, and died at his home in Kirksville, Mo., Dec. 12 1917. He was a practising allopathic physician at the beginning of the American Civil War, served as a Union officer, and at the close of the war returned to his home in Kansas and resumed the practice of his profession. Gradually his confidence in the efficacy of drugs as a means of healing weakened, and his faith in the inherent curative power of the body strengthened, until June 22 1874, when he publicly announced that he would henceforth discard the use of drugs as a curative measure and would dedicate the remainder of his life in aiding nature in the alleviation of disease by the mechanical readjustment of the disordered body. The American School of Osteopathy was opened at Kirksville, Mo., in 1892. There were in 1925, over 9,000 graduate practitioners of osteopathy in all parts of the world.

Legal Recognition.—In addition to the school at Kirksville, there were in 1921 six others in the United States devoted to the teaching of osteopathy. The curricula of the osteopathic colleges embrace all the subjects taught in other medical colleges, except *Materia Medica*, in place of which there is included " Principles and Practice of Osteopathy " and " Osteopathic Therapeutics." Osteopathy was by 1925 recognised and regulated by law in 47 states of the United States. The one remaining state, through court decisions, makes its practice legal.

There is an international organisation, The American Osteopathic Assn., having some 4,000 active members; an osteopathic association in each state in the Union; associations in Canada; the New England Osteopathic Assn., the Western Osteopathic Assn., the Eastern Osteopathic Assn., the South Atlantic States Osteopathic Assn., Osteopathic Women's National Assn., a British Osteopathic Association, the Academy of Osteopathic Clinical Research, and the American Society of Ophthalmology and Oto-Laryngology. There are 10 or 12 magazines and periodicals published by the profession.

OSTWALD, WILHELM (1853–), German chemist, was born in Riga Sept 2 1853 and educated at the University of Dorpat. In 1882 he became a professor in Riga, and five years later was appointed professor of physical chemistry in the University of Leipzig, where he was later director of the Physico-chemical Institute. In 1906 he resigned his university appointments and subsequently lived in retirement in Saxony. Ostwald will be chiefly remembered for his discovery in 1900 of a method of oxidising ammonia to form oxides of nitrogen; a mixture of air and ammonia being passed over a platinum catalyst with a specially treated surface. By means of this process and by later developments in connection with it, Germany was enabled to continue the manufacture of explosives during the World War after the Allied blockade had been enforced. In 1909 Ostwald was awarded the Nobel Prize for chemistry. His published works include *Lehrbuch der allgemeinen Chemie* (2nd ed. 1884–87) and *Grundlinien der anorganischen Chemie* (5th ed. 1922) which have been translated into English.

OTIS, HARRISON GRAY (1837–1917), American journalist, was born near Marietta, O., Feb. 10 1837. He became a printer's apprentice, working in various offices in Illinois, Iowa, Ohio and Kentucky. He served throughout the Civil War, and rose to be lieutenant-colonel. He was in the Government printing office at Washington, D.C., 1867–70, and in 1870 moved to California, where he managed the Santa Barbara *Press*. In July 1882 he became connected with the Los Angeles *Daily Times*, obtaining control of that paper in 1886. He served in the war with Spain as brigadier-general in the Philippines 1898–9. In 1910 the *Times* building was dynamited, 21 employees being killed. He died at Los Angeles July 30 1917.

OTTAWA (*see* 20.369), the capital of the Dominion of Canada, had a population of 107,843 in 1921; a later estimate gives it as 126,000. The population is about half British and half French. Ottawa is the headquarters of the Air Force and the Royal Canadian Mounted Police, and contains the National Victoria Museum, the National Art Gallery, the Royal Observatory and the Royal Mint; while the Central Canadian Experimental Farm is in the vicinity. Parliament buildings were almost completely destroyed by fire in 1916; the magnificent library and the Senate House fortunately escaped. Reconstruction was started at once. The main front of the new buildings is the same length as that of the former one, but the height is double; in the main tower is a War Memorial chamber. Other buildings erected since 1911 include the Grand Trunk (now Canadian National) Union station, on the east bank of the Rideau canal and the south side of Rideau street, and the Château Laurier hotel facing the Parliament buildings. The Canadian War Memorial, an arch 45 ft. high, was in course of erection in 1926. A colony for the use of civil servants has been built close to Rockliffe Park. The city possesses 2,000 ac. of park lands. Ottawa in 1924 had 452 industrial establishments, largely for wood products, including one of the biggest lumber factories in the British Empire. Electric power is generated at Chaudière Falls.

OTTOMAN EMPIRE, THE (*see* 27.426).—After an existence lasting well-nigh six centuries and a half the empire founded by Osman (1288–1326) expired on Oct. 29 1923 when the Great National Assembly at Angora by an unanimous vote constituted the Turkish Republic. Since the death of Suleiman the Magnificent in 1566 the Ottoman Empire had been gradually decaying, and throughout the 19th century its demise from time to time had been almost hourly expected. Successive wars had shorn it of its outlying provinces, especially in Europe, and from being an empire that extended in the 16th century from Budapest to the Sudan and from Oran to the Caspian Sea it was left by the Treaty of Sèvres (*q.v.*) with an area of no more than 175,000 sq. m. and a population of barely 8,000,000.

Contrary to expectations, it received its *coup de grace* not from one of the great Christian Powers but from a section of

its own subjects. It fell before the democratic movement inaugurated at Angora in 1919 by Mustafa Kemal Pasha (*q.v.*), and in the following year the Parliament at Constantinople held its last meeting. Two years later Mehmed VI., last Sultan of the House of Osman, fled from Constantinople on board a British ship of war. In consequence the Great National Assembly at Angora decreed his deposition both as Sultan and Caliph in a *fetva* passed on Nov. 19 1922. As Caliph the Assembly elected Abdul Mejid Effendi, a son of the late Sultan Aziz; but in less than two years even the Caliphate was swept away and the House of Osman finally banished (March 2 1924) from the lands over which it had for so long held sway. (*See* CALIPHATE; TURKEY.)

See Lord Eversley's *The Turkish Empire* (2nd ed., 1923), probably the best general survey of the history of the Empire. See also W. Miller, *The Ottoman Empire, 1801–1913* (1913).

OUSE (*see* 20.380).—The question of the navigation of the English river, the Great Ouse, between Bedford and King's Lynn was raised in 1913 at Bedford and a committee was formed to inquire into the subject, but no further steps were taken until the Land Drainage Act of 1918 made it possible to deal with the problem. The Ouse is a long and difficult river, largely artificial, and in 1913 the locks were decayed and unworkable between Bedford and St. Ives. Parts of the stream had never been adequately cleared and the cutting called the New Bedford river, which carries one arm of the river to the sea, was suffering from a long period of neglect In 1920 an Act was passed superseding various minor authorities and placing the drainage of the Ouse in the hands of a board. The decision to rate the owners and occupiers of land adjoining the river in the upper reaches above Earith, where it enters the Fen country, as well as the Fen dwellers, for the purpose of making drainage and tidal channels in the Fen area, aroused opposition from the first. The "uplanders" considered that their assistance should be confined to the portion of the river above Earith, and the comparatively small area of land adjoining it. The Ministry of Agriculture, as the result of an inquiry held in 1924, decided that it was impossible to relieve them of their liabilities under the Act, unless the Government undertook comprehensive works on the tidal portion of the river. A suggested grant of about £1,500,000 was refused as insufficient and a long dispute followed between the drainage board and the upland farmers, who refused to pay the rate levied for administrative purposes. Distraints were carried out in Jan. 1925 and the goods sold at Cambridge.

Protests from the Upland Riparian Owners and Occupiers' Association and continued refusals of payment led to further negotiations with the Ministry of Agriculture, which resulted in the passing of a temporary suspension order in April, with the proviso that no fresh rate should be levied or drainage work done in the "upland" area (except by consent of a sub-committee of the board consisting of representatives of that area) until the end of 1926; that the Ouse district should be surveyed; and that a commission should be appointed to investigate the whole problem. The Upland Riparian Owners' Association adopted a fighting policy, stating that they did not require a drainage commission in their area; and that the river could be surveyed for obstacles and these removed, if necessary, by the National Farmers' Union. They also put forward the suggestion that with co-operation between the millers and the county surveyors the flood waters could be passed through more rapidly. Efforts were being made later in the year to induce the "uplanders" to pay their arrears of rates. A new bridge over the old Bedford river was begun in 1925, but difficulties were caused by the floods. It was decided to approach the county authorities with a view to their taking responsibility for the bridges, many of which were inadequate for the traffic.

OXFORD (*see* 20.405).—The population of the city increased from 53,048 in 1911 to 57,052 in 1921. The garden suburbs on the Cowley and the Iffley roads are only small, but others are in progress. In 1925 the city adopted a town-planning scheme, by which arrangements are made for diverting through traffic round the city, and to preserve its amenities.

The War Period.—The two most important facts in the history of the university since 1911 have been the World War and the two commissions. In the War 14,561 Oxford men served in the British Forces, and 2,660 lost their lives. But the greatest service rendered by the university was the supply of officers. Thanks to the O.T.C., nearly 2,000 Oxford men received commissions in the first two months of the War. After this, Oxford became one of the main training grounds for officers; for the last three years of the War, there always were nearly 2,000 cadets in Oxford and the examination schools and those colleges which were not given up to cadets became hospitals. The number of undergraduates fell to 1,087 in Jan. 1915 and 550, 460 and 369 in the same months in 1916, 1917 and 1918 respectively. The tide began to turn in the latter part of 1918; in Jan. 1919 there were 1,357 men in residence; and in the following 18 months the entries were so heavy that by Oct. 1920 there were about 4,500 men and 650 women actually in residence. Since that time, all the men's colleges have striven to reduce their numbers; so that the figures for undergraduates in Oct. 1925 were about 3,400 men and 750 women. These figures indicate clearly one of the indirect results of the War, the admission of women as full members of university. This change was made in 1920.

New Statutes.—The royal commission, set up in 1919, reported in 1922; most of its recommendations had been embodied in Statutes by the end of 1925, by the statutory commission appointed in 1923, although the actual changes made by the commission will only begin to come fully into effect in Oct. 1926. It was satisfactory to Oxford men to find that a commission appointed by a reforming government, and composed of men of all political parties, reported so favourably on the work of the universities as a whole; so far from being pronounced to be homes of idleness, the main complaint made against most of the teachers was that they worked too hard (see *Report*, pp. 26, 39, 48). To remedy this, and to allow for the extension of university activities, the royal commission recommended a grant to Oxford and to Cambridge of £110,000 a year each; only £60,000 was given at first, but in the spring of 1925 this was increased to £85,000.

It is hard to say what the effect of the new statutes will be. They seem likely rather to carry on the developments which the old universities were already making, than to introduce revolutionary changes. At Oxford, for example, there has been a growing tendency since about 1900 to lay ever-increasing stress on the necessity of research work. To encourage this, the degrees of Bachelor of Letters and Bachelor of Science were set up in 1895, the Doctorate of Philosophy in 1917; the regulations for the B.Litt. are now being remodelled in the light of experience. In the examination, too, for the honours degree in natural science, students of chemistry can only obtain a class if they spend a year on a piece of research.

Another important line of change is that in future the full emoluments of college entrance scholarships will be given only to those who show actual need for help. It remains to be seen how this change will work; but in this, as in other matters, the commissioners have done as little as possible to interfere with the independence of colleges, and great care has been taken to prevent the lowering of standard for scholarships and to see that scholarships do not become merely eleemosynary.

The machinery of government of the university has also been developed since 1900, mainly by voluntary action, but in part by the commissioners. The hebdomadal council has been made more representative of the whole university; university finance management has been remodelled, first in 1912 in one of the reforms carried out by Lord Curzon, and then by a statute of 1920. The studies of the university too are now put under a general board of the faculties, which was set up in 1913 and is elected by the resident teachers. A further instance of development is the change in the theological degrees, which in 1920 were thrown open to students of all denominations, and made to depend, so far as the D.D. is concerned, on the production of a "serious contribution to learning."

Benefactions.—The material resources of Oxford have also been steadily increased by the generosity of benefactors, espe-

cially old members. Natural science has been the chief gainer, with new laboratories for engineering (1912), for chemistry (thanks mainly to Mr. Dyson Perrins) in 1913, for pathology from the Dunn trustees and for biochemistry from Mr. Whitley and the Rockefeller Foundation. The Welch bequest (1915) has added another £50,000 to the resources of biological science, and the Govt. by placing at Oxford the Institutes of Agricultural Engineering (1923) and of Imperial Forestry (1924), has shown its confidence in the oldest university as the fittest place to provide for the newest needs of the empire.

Next to the development of natural science, the most marked feature of the decade 1915–25 has been the growth of modern language teaching. Professorships of French and Italian have been founded by Sir Basil Zaharoff and Mr. Arthur Serena respectively; Sir Heath Harrison has provided scholarships for undergraduate travel (1919), and Mr. Laming has founded travelling fellowships in connection with his old college, Queen's (1924). Closely allied with this development is the increasing number of fellowships for study in the universities of the United States, which are being founded by Americans as a counterpart to the work of Cecil Rhodes.

The Bodleian continues to receive gifts, not only of books and pictures as in Lord Curzon's Napoleonic Collection (1925), but also in cash, as Walter Morrison's £50,000 in 1920. Mention should also be made of Barnett House, founded in 1914 in memory of Rev. S. A. Barnett.

OXFORD AND ASQUITH, HERBERT HENRY ASQUITH, 1ST EARL OF (*see* 2.769).—The opening of the session of 1911 may be taken as the crowning moment in Mr. Asquith's public career. The issue of the constitutional struggle with the Lords was not yet decided, but it was no longer in doubt. It had been practically settled by the events of the previous autumn. The round table conference, which had been called in the hope of reaching an agreed settlement, had broken down, and Mr. Asquith had decided to appeal once more to the country. The election took place in December and the Govt. returned with a commanding majority of 126.

The decisive mandate which the country had given in December dictated the issue that immediately occupied the new Parliament. A bill abolishing the veto of the House of Lords was introduced into the House of Commons and, despite energetic opposition, passed all its stages by the beginning of the summer. But the real crisis had yet to come. The battle had still to be won in the Lords and there the opposition were entrenched in overwhelming power. There was only one way to victory. Ever since the emergence of the struggle it had been evident that the attainment of Mr. Asquith's goal depended on whether he could in the last resort invoke the authority of the Crown to dilute the House of Lords with new peers sufficient to change its complexion. It had been assumed that he had armed himself with this authority after the first election in 1910; but the assumption was unfounded. What was the position now? The question was answered on July 20. The Parliament bill, now in the House of Lords undergoing its second reading, was so amended as to deprive it of any utility for the purpose for which it was framed. Mr. Asquith therefore addressed to Mr. Balfour, the leader of the opposition, a letter stating that the Govt. had decided, if the bill in its essential form could be passed in no other way, the Crown would be advised to create a sufficient number of peers to ensure its passage, and that the Crown had signified its willingness to accept such advice.

The publication of this letter aroused an unprecedented storm, and on July 24, on rising in the House of Commons to make a statement, Mr. Asquith was greeted with a demonstration without parallel in living memory. For the best part of an hour he stood speechless before the roar of anger that issued from the Opposition benches, and at last resumed his seat without having uttered a continuous sentence. What became known as "the pothouse brawl" inaugurated the last stage of the struggle. The Govt. was accused of "dragging in the King," and the Opposition organised an uncompromising resistance in the belief that the Govt. would not dare to carry its threat into execution. The issue, however, was determined on Aug. 10, when the final debate was taking place in the House of Lords, by a statement of Lord Morley confirming the Government's previous intimation of His Majesty's intention. Up to this point the "Die-Hards" seemed to be assured of a majority, but in the division they were defeated. The bill was passed. On Aug. 18 the Parliament Act received the Royal Assent, and the House of Lords stood shorn of its historic privileges.

From this victory Mr. Asquith proceeded to his next great task, with the ground sensibly cleared for action. Gladstone's successive Home Rule adventures had broken on the rock of the Lords' veto. Mr. Asquith now approached the subject with the advantage that that rock no longer obstructed the channel. But before the Irish issue was fully launched another controversy absorbed the Prime Minister's activities. From that controversy the country has not yet emerged. Discontent had long been growing prevalent in the mining industry, and at the end of Feb. 1912, having failed to secure the concessions and advances they demanded, the miners' union declared a strike. Vast dislocation followed and unemployment became widespread. From the outset the Govt. endeavoured to bring the conflicting parties to agreement and Mr. Asquith took on himself the personal charge of the negotiations. A month's fruitless efforts left the country on the brink of paralysis, and the Govt. thereupon introduced the Miners' Minimum Wage bill, which, by providing a half-way solution, forced the hands of both sides and brought the immediate struggle to an end, although the issue incidentally raised—that of the reorganisation and control of the coal industry—was to perplex Parliament and the country for many years to come.

Meanwhile, the Home Rule bill had been introduced and with the Government majority behind it there was little difficulty in securing its passage through the House of Commons, while the Parliament Act provided adequately against the resistance of the House of Lords. That House fought the delaying action, which was all the opposition now in its power. On Jan. 30 1913 it rejected the Home Rule bill at the second reading. Under the Parliament Act the Lords' power of rejection is limited to two successive sessions. The bill was introduced again and in July 1913 it was again rejected by the Lords. After its next passage through the Commons it would have overridden opposition and automatically become law. By this time, however, the political atmosphere was heavy with forebodings from other quarters. The opposition to the measure took an extra-parliamentary shape. The notorious Ulster Covenant had been promulgated in the previous Sept. and talk of open rebellion, should Home Rule be passed, was already current. In June arms had been discovered both at Belfast and Dublin. As the year wore on the outlook became still more serious and a speech by Mr. Bonar Law, the leader of the Conservative party, at Blenheim, seemed to give encouragement to the idea of resistance by force. On Sept. 25 the Ulster Unionist Council appointed a provisional Govt. and prominent Conservatives openly preached armed resistance. Sir Edward Carson, the leader of the Ulster Unionists, left no doubt that in the last resort Ulster would fight.

With the close of the session of 1913 there came a brief lull, and during the recess conversations with the Opposition leaders were opened by Mr. Asquith, who throughout preserved an attitude of patience and forbearance. It will always be matter for controversy whether, when the policy of violent resistance had been adopted, he was justified in ignoring so direct a challenge to constitutional government. His natural disposition was to allow the utmost scope for the play of discussion and the influence of the time element; but it is an open secret that he would have taken up the challenge but for the persuasions of Mr. John Redmond, the leader of the Irish Nationalists, who believed that the prosecution of the Ulster leaders would prejudice the prospects of friendly relations with Ulster when Home Rule was

actually on the statute book. In any case, the conversations of the autumn were futile, and on March 9 1914 the Govt. announced the provisions of their amending bill, their last word of compromise. The chief provision of this bill was that any county in the north of Ireland was to be allowed to vote itself out of the operation of Home Rule for a period of five years.

The offer was rejected by the Opposition and now events rushed forward to an apparently unavoidable catastrophe. Sir Edward Carson was hastening to and fro, reviewing the rebel army of Ulster which had now assumed alarming proportions. On the night of April 24–5, 55,000 rifles were landed at Larne from a German port for the use of the Ulster army. On the other side of the border the Nationalists were beginning to enrol a volunteer army and to make counter-preparations. Meanwhile a more sinister menace appeared. In the debate on the vote of censure on the Govt. on March 19 Mr. Bonar Law, speaking on the Home Rule issue, had used the ominous phrase "soldiers are citizens like the rest of us." There had been much talk of disaffection in the army in regard to the coercion of Ulster, and on March 20 it took shape in the Curragh incident (*see* IRELAND) which led to the resignation of Col. Seely, the Secretary for War. For a moment it seemed that the loyalty of the army was imperilled and the situation that confronted the Govt. looked desperate. But the announcement by Mr. Asquith next day that he would assume the Secretaryship for War created a profound impression in Parliament and stopped for the time being at all events what had seemed like a riot in the army. Following the mutilation of the amending bill by the House of Lords and Sir Edward Carson's challenge to the Govt. to "give us a clean cut or come and fight us," the King, on Mr. Asquith's advice, summoned a conference at Buckingham Palace on July 20 to see if some agreement was still not possible. It broke down four days later and the last hope of avoiding a violent issue seemed gone.

What Mr. Asquith would have done to avert a civil war while maintaining the authority of the constitution was not to be revealed, for on the day that the Buckingham Conference broke up Austria sent her ultimatum to Serbia, and within 10 days the British Army was embarking not for Ulster but for Flanders. In the feverish struggle within the Cabinet that preceded the entry of Great Britain into the World War Mr. Asquith's position was never in doubt. He had throughout been a party to the ambiguous military understandings and conversations which had been in progress with France since before the fall of the Balfour Govt. in 1905, and when the War came he did not waver in his conviction that both the duty and the interest of this country lay in throwing the country's whole weight into the scales against what he considered to be the calculated design of the Central Powers to establish a military despotism over Europe.

The invasion of Belgium by Germany saved his Govt. from disruption, and he addressed himself, free from domestic disquietudes, to the heaviest task ever imposed on a British Prime Minister. For the moment even the Irish trouble subsided, all political differences were shelved and Mr. Asquith became the voice of a united nation in a measure unequalled in modern Parliamentary history. The speeches he delivered in the early days of the War have taken their place beside the classic orations of Pitt during the Napoleonic wars, and his constancy of mind and freedom from all personal ambition played a dominating part during the next two years in laying the foundations of the ultimate victory. It was not to be expected that in the presence of so vast a convulsion discontents would not develop. They became clamant as the true character of the struggle emerged and as the popular idea of a swift decision gave place to the certainty of a long war of attrition. Mr. Asquith had made no change in the political constitution of his Cabinet at the outbreak of war, although he had taken the leaders of the Opposition into his confidence and private counsels, but by the spring of 1915 it became clear that this informal relation would have to yield to a formal coalition.

In Feb. Mr. Bonar Law and Lord Lansdowne intimated that they could accept no responsibility for the way in which the War was being conducted, and in the popular Press—which Mr. Asquith had no talent for flattering—a powerful and ceaseless agitation arose, directed mainly against Mr. Asquith, Sir Edward Grey and Lord Haldane and inspired by the inevitable shortage of munitions which the progress of the War had revealed. Coincidentally, a violent disagreement as to the employment of the navy in the Gallipoli adventure had arisen between Mr. Churchill, the First Lord of the Admiralty, and Lord Fisher, the First Sea Lord, and on May 26 Mr. Asquith reformed his Cabinet on a Coalition basis, bringing in the leaders of the Opposition and excluding Lord Haldane. To meet the growing need for munitions, a special Ministry of Munitions was set up with Mr. Lloyd George at its head.

The reconstruction of the Ministry did not allay dissatisfaction. Within the Cabinet friction developed, and, outside, the Press agitation grew in violence. There was a persistent leakage of Cabinet secrets, certain newspapers betraying a knowledge of most confidential government business with such regularity as to suggest inspiration. A phrase, "Wait and See," which Mr. Asquith had used in reply to a question in the House of Commons years before, became the daily gibe of the malcontent Press, and Sir Edward Grey, then in the midst of the most delicate situation with the United States, was accused of "feeding Germany" because of his attitude on the subject of contraband from America. The war-weariness that had overtaken the country provided an atmosphere in which this propaganda of discontent flourished, and the head of the Govt. was the easier target for attack because he neither "squared" the Press nor hit back at his critics. The inevitable rupture came in the autumn of 1916, when the German raid into Rumania—now seen in its true proportions—served to drive home the attack, and at a time when Mr. Asquith was severely stricken by the loss of his eldest son in the War.

It arose over a question of Cabinet reorganisation. For some time the formation of an inner Cabinet had been under discussion. At the beginning of Dec. 1916 Mr. Lloyd George, who upon the death of Lord Kitchener had become Secretary for War and whose prestige with the Press had long been in the ascendant, submitted a definite scheme for the formation of such a body. From this body the Prime Minister was to be excluded. His right to control policy was not challenged, but he would not direct the deliberations of the inner Cabinet. The *coup* burst upon the country with the announcement of the popular newspapers that Mr. Lloyd George was "packing up" in sheer despair at the inefficient conduct of the War. His highly confidential challenge to the position of Mr. Asquith was under consideration when an article appeared in *The Times* (then owned by Lord Northcliffe) giving full details of the supposed arrangements and suggesting that Mr. Asquith had already agreed. Mr. Lloyd George denied any knowledge of this article; but Mr. Asquith, after consulting with his friends, decided to reject the proposal. Upon this Mr. Lloyd George resigned, and his resignation being followed by that of other influential members of the Cabinet—including some who hoped that their action would give the Prime Minister the opportunity of reforming his Cabinet on a new basis—Mr. Asquith informed the King that he could no longer be responsible for carrying on the business of the Govt.; and within a few days the second Coalition Govt. was formed with Mr. Lloyd George as Prime Minister.

Thus ended Mr. Asquith's long and memorable tenure of the Premiership. This is not the place to pass judgment upon his career or upon his conduct of the War, but it may be pointed out that the hopes of an early victory as the result of a change of Govt. were not realised, and the subsequent disclosures have thrown an entirely different light on the military position at the end of 1916 from that which prevailed at the time. For the remainder of the War he occupied a seat in the front Opposition bench, speaking rarely and only on occasions when the interest of the nation seemed to demand his intervention. At the election of 1918, when Mr. Lloyd George swept the country with an appeal for the maintenance of the Coalition, he did not escape the general wreck of the Liberal party, losing the seat of East Fife which he had held throughout his parliamentary

career. In 1920 he returned to the House of Commons as member for Paisley and resumed his position as head of the remnant of the Liberal party in that House. This position he occupied during two succeeding Parliaments. In 1924, after an election fought on the issue of Protection, he, as the head of a pivotal majority, was responsible for the accession to power of the first Labour Govt., and later in the year for the Government's overthrow on a question of alleged governmental interference with the prosecution of a Communist. At the election which followed he was defeated at Paisley, and he retired to the House of Lords as the Earl of Oxford and Asquith.[1] (A. G. G.*)

[1]On May 26 1926, consequent on the General Strike, correspondence was published between Lord Oxford and Mr. Lloyd George with reference to the failure of the latter to consult his colleagues. This led to a breach in the party. (See LIBERAL PARTY.) (Ed. *E.B.*)

OXFORD AND ASQUITH, MARGOT, COUNTESS OF, the sixth daughter of Sir Charles Tennant, 1st Bart., married, in 1894, as his second wife, Herbert Henry Asquith, later the Earl of Oxford and Asquith. Previous to her marriage she was well known as a member of the coterie known as the "Souls," and afterwards continued to be one of the wittiest and most brilliant women in London society. In 1922 she published *The Autobiography of Margot Asquith* (2 vol.), which attracted considerable attention and a certain amount of criticism owing to the writer's frankness of expression. It is generally acknowledged to be, however, one of the most valuable chronicles of the time. After its publication she undertook a lecture tour in America, and in 1925 published *Places and Persons*.

OYAMA, IWAO, PRINCE (1842–1916), Japanese soldier (*see* 20.424), died on Dec. 12 1916.
