High capacity fixed condensers are generally made of rectangular sheets of tinfoil bet een somewhat larger sheets of paper impregnated with paraffin wax. Each tinfoil sheet is provided with a projection or lug at one side, and alternate sheets have their lugs projecting in different places so that they can be connected together. Where a sufficient number of tinfoil land paper sheets have been laid together to give the required capacity the whole condenser is pressed between hot plates so as to form a solid block when cold, the alternate lugs are soldered together and connected to the terminals, and the whole block inserted in a wooden or metal case which is filled up solid with paraffin wax. For highly accurate standards thin sheets of the best ruby mica are substituted for the paper, and these sheets are frequently silvered on one side, the silvering being removed around the edges. A number of such paper or mica condensers are frequently included in a single case and can be used singly or in parallel, and dial condensers resembling resistance boxes, enabling the capacity to be adjusted from 0·001 to 1·111 microfarads are now commonly used.

Variable vane condensers consist of two sets of thin metal plates. usually of semicircular form, but of different diameters. The larger or fixed plates are built up on a frame so as to be accurately parallel to one another and equally spaced, while the smaller are threaded on a spindle with distance pieces between them so as also to be parallel and similarly spaced. The spindle is mounted in the frame so that the movable plates or vanes can turn between the fixed plates without touching them, and the two systems of fixed and moving plates are insulated from one another. An insulating handle provided with a pointer or a rotating dial enables the spindle to be turned, and the capacity varies continuously, from a low minimum value when the moving vanes are outside the fixed plates, to a maximum when they are completely inside them. By inserting the whole system in a case filled with oil both the capacity and maximum safe P.D. of the condenser may be considerably increased. The vanes are sometimes made of various forms in order to obtain a "square law" variation of capacity with angle, or a uniform frequency scale, etc.

Standard air condensers are only used for fundamental measurements and usually consist of a number of concentric accurately turned and measured cylinders on an insulating base so that their capacity can be calculated from the dimensions.

The most simple method of comparing the capacity of condensers is by the direct deflection method using a ballistic galvanometer (*q.v.*). If a condenser of capacity C is connected to a battery of e.m.f. E, it suddenly becomes charged with a quantity Q=CE, so that if two condensers of capacities C_1 and C_2 are connected successively to the same battery $Q_1=C_1E$, and $Q_2=C_2E$; thus $\frac{Q_2}{Q_1}=\frac{C_2}{C_1}=\frac{D_2}{D_1}$, where D_1 and D_2 are the corresponding swings of the ballistic galvanometer.

Inductance standards may be either fixed or variable, and of self or mutual inductance. Fixed self-inductance standards are simply coils wound on rigid insulating bobbins, so as to have constant conformation. Marble is used for the most accurate, and carefully seasoned paraffined teak or boxwood for the ordinary standards. The first accurate variable inductance standard or variometer was that of Ayrton and Perry, and consisted of two coils each of about ten inches diameter wound in single layers on circular wooden or ebonite formers curved so as to be parts of spheres and to enable one to fit as closely as possible inside the other. The inner coil was mounted on a spindle passing through the outer coil and having a pointer reading on a large dial at the top. The two coils were connected in series through flexible leads, and when they were parallel but the current passed round them in opposite directions their inductance was very low as the magnetic effects of the two coils almost neutralized each other, while on turning the inner coil round, the magnetic field (and therefore the inductance) increased steadily to a maximum when it was again parallel to the fixed coil. By careful construction a tenfold range of inductance was secured.

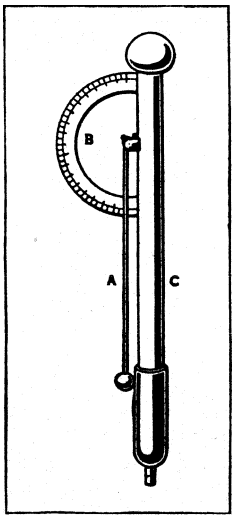

FIG. 21.—HENLEY'S ELECTROSCOPE

Variable mutual inductance standards are, however, to be preferred, as they can easily be made of very long range. The best known is that of Campbell who employs three circular coils on marble formers and with their planes parallel. The centre coil is mounted on a spindle at its edge so that it can be swung like a vane between the two fixed coils, and this spindle is provided with a handle and pointer travelling over a scale calibrated in microhenries. The winding on the fixed coils is of ten insulated wires stranded together so as to have equal magnetic effect. In addition there are a number of fixed bobbins with primary and secondary windings which can be thrown into the circuit when this is desired.

Capacity and inductance measurements are now most commonly made by bridge methods using alternating current and telephones or vibration galvanometers, and such bridges allow of condensers, self, or mutual inductances to be compared in any combination. The best known forms of such bridges are those of de Sauty, Maxwell, Campbell, Drysdale and Schering.

VII. ELECTROSTATIC INSTRUMENTS

Electroscopes **and** Electrometers. — As their names indicate, these instruments are intended respectively for the detection and measurement of electric charges or differences of potential. Electroscopes were the first electrical instruments to be devised, and take their origin from William Gilbert (1544–1603), who first developed the knowledge of electrical phenomena from the isolated fact known to the ancient Greeks, that amber could be electrified by friction. His electroscope consisted simply of a light pivoted metallic needle, either end of which was attracted on the approach of an electrified body. The next step was to utilize the repulsion of two similarly electrified bodies. Benjamin Franklin, employing two linen threads hanging close together, and du Fay, Canton, Henley and Cavallo double straw or pith ball electroscopes. Henley's electroscope (fig. 21) was a crude form of electrometer, and consisted of a pith ball suspended at the lower end of a light pivoted arm and normally just touching a metal sleeve. When the latter was charged, it imparted part of its charge to the pith ball and repelled it, and the amount of the charge was roughly indicated by an arc divided in degrees with its centre at the pivot. Cavallo's electroscope (c. 1770) was the prototype of the modern repulsion electroscopes, having a glass bell jar with a metal stem sealed into its neck (fig. 22). At the top of this stem was a bell-shaped metal cap A, which served as a charging knob and also protected the glass and insulation of the stem from rain if the instrument was used in the open air; while at the bottom of the

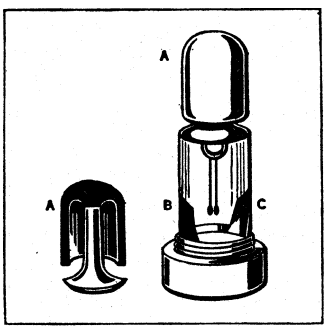

FIG. 22.—CAVALLO'S ELECTROSCOPE

stem two pith balls were suspended by fine silver wires. Two metal strips, B and C, were cemented on the inner surface of the bell jar and connected to earth. In 1782 Volta increased the sensitiveness of this form of electroscope by adding a condenser, and Faraday showed that for its indications to have a definite meaning the interior of the glass vessel should as far as possible be covered with metal, leaving only small spaces for the observations of the movements of pith balls. In 1787 Abraham Bennet substituted gold leaves for the pith balls, the form of electroscope shown in fig. 23, in which the stem carrying the gold leaves and charging knob is supported on a rectangular glass frame inside the bell jar which is coated on the inside by a number of strips T of tinfoil, all connected to a terminal on the base, which can be connected to earth. The interior of the instrument is kept perfectly dry by means of a vessel containing calcium chloride and sulphuric acid, and an ebonite plug slides on the upper part of the stem. This plug normally closes the jar, but when the instrument is in use, it is slightly raised, leaving a small air space between the stem and the cap of the bell jar.

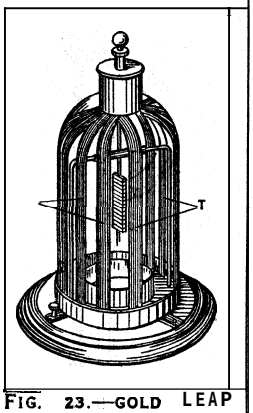

FIG. 23.—GOLD LEAP ELECTROSCOPE

Until about the commencement of the present century electroscopes were little used, except for teaching purposes in connection with electrostatics, but the discovery of radio-active materials and their power of discharging a charged body by ionization led M. and Mme. P. Curie to employ the rate of discharge of an electroscope as the best means of detecting the intensity of radio-active bodies, and a large number of new fprms of electroscope have been introduced. That of M. and Mme. Curie is diagrammatically shown in fig. 24. It consists of a small brass case having a block of sulphur SS at its top, from which a metal strip B with a gold leaf L depends. The case is provided with two holes at its sides and a horizontal metal wire carries a charging knob C projecting through one of these holes and a condenser plate P′ at its other end. A second condenser plate P, just below the first, is connected to the case. The instrument is first charged by the knob C until the gold leaf L diverges from the strip B by a convenient amount, after which a cap is fixed over C and the leaf should maintain its position for some time if the insulation is satisfactory. On inserting a small amount of radio-active material between the plates P and P', however, the ionization of the air between the plates causes the charge to leak away, and the rate of fall of the leaf L, which can be observed in a microscope through a window in the case, measures the amount of radio activity of the material.

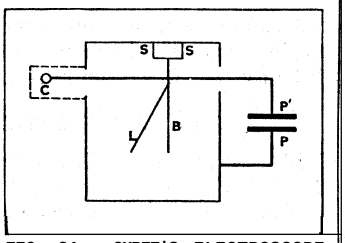

FIG. 24. —CURIE'S ELECTROSCOPE

Somewhat similar forms of electroscopes for radio-active measurements were made by Elster and Geitel, and by C. T. R. Wilson (1901), but in 1903 a great improvement was made by the latter in his tilted electroscope (fig. 25). In this instrument a single gold leaf L is employed which is attracted towards a plate P by connecting a battery of about 200 volts between the plate and the case of the instrument. Any charge of the gold leaf L then causes it to be attracted more or less strongly towards P, and it is found that if the whole case is tilted as shown, a position can be formed at which the instrument is extremely sensitive, and the tip of the gold leaf moves several millimetres when its potential is raised by one volt. The latest improvement in this type of instrument has been made by Wilson and Kaye (fig. 26), and is similar to the above except that the case is permanently tilted through about 45" and the final adjustment of sensitiveness is made by varying the distance of the plate P by turning the micrometer head D. With 200 volts on the plate this electroscope gives a defection of three or four divisions on the scale in the observing microscope for only 0.01 volt on the leaf.

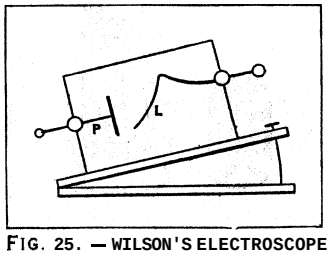

FIG. 25. — WILSON'S ELECTROSCOPE

The electroscope employed for radio-activity investigations, as well as the early electroscope of Henley, are in reality crude forms of electrometers, as they are actually used for approximate measurements. But the term electrometer is generally restricted to instruments intended for accurate measurements of potential differences, and designed to have a more or less definite law. The first instruments of this kind were on the "attracted disc" principle, which seems to have originated in 1746 by Daniel Gralath of Danzig, and to have been termed by him an "electrometer"; but the earliest practical forms were those of A. Volta and Sir Wm. Snow-Harris, in which a flat horizontal disc was suspended from the arm of a balance just over a similar fixed insulated plate. When the latter was electrified it attracted the suspended plate downwards, and balance could be restored by adding weights on a scale pan at the opposite end of the balance arm. Fig. 27 shows one form of Snow-Harris electrometer in which C is the suspended disc above the insulated disc which is shown connected to the knob of a Leyden jar, while the outer coating of the jar is connected to the frame of the electrometer and thus to the suspended plate, so that the P.D. between the plates is the same as that between the coatings of the jar. Snow-Harris found that the weight required to restore balance was proportional to the square of the charge or the P.D. of the jar.

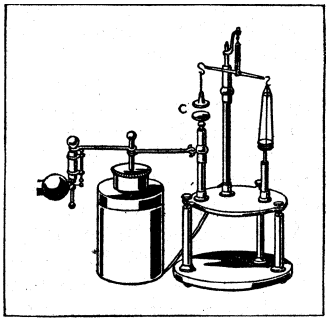

FIG. 27.—SNOW-HARRIS'S DISK ELECTROMETER

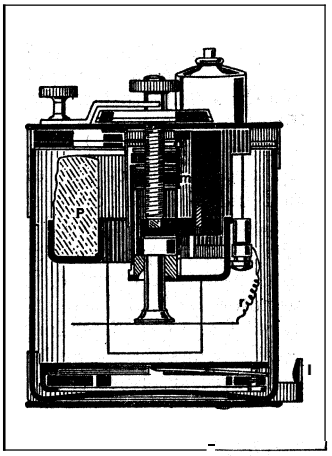
In 1857 Lord Kelvin turned his great mathematical and inventive skill to the subject of electrometers, and produced two forms which have persisted with only detailed improvements to the present day. The first form was derived from the attracted disc electrometer, but had the very important addition of a "guard ring," which made its indications of absolute value. In the simple attracted disc electrometer the electrostatic field between the two plates is not uniform, as the lines of force curve round from the edges of the two discs. But if the fixed disc is made much larger than the suspended one, and the latter is surrounded by a plate which nearly touches it all round, then if the movable plate is exactly in the same plane as the surrounding plate when the measurement is made, the electrostatic field between the suspended and fixed plates mill be practically uniform, and it can be proved theoretically that the force in dynes between them ± will be given by the expression $f = \frac{AV^2}{8\pi d^2}$, where V is the P.D. between-the plates in electrostatic units of 300 volts, A the area of the suspended plate in square centimetres,



BY PERMISSION OF KELVIN, BOTTOMLEY AND BAIRD
FIG. 28.—KELVIN'S PORTABLE ELECTROMETER

and d the distance between the suspended and fixed plates in centimetres, so that $V = d\sqrt{\frac{8\pi gW}{A}}$. d and A are known, therefore, the P.D., V can be determined directly from the force required to balance the attraction.

Lord Kelvin employed this principle in two forms of electrometer, one of them being known as his portable electrometer, fig. 28, the essential parts of which are shown diagrammatically in fig. 29. H.H. is a plain disc of metal fixed inside the bottom of a glass jar, which is coated inside and outside with tinfoil to form a small Leyden jar. In the middle of this disc H.H. a square hole F is cut, and a slightly smaller square plate of aluminium foil provided with an arm at one side is mounted on a horizontal stretched wire so that it will just swing through the hole F like a trap door. The wire is given an initial twist so that the aluminium plate normally rests a little below the upper surface of the disc H.H., and the arm which is provided with a crutch and cross wire is therefore tilted upwards. A circular plate G is fixed on the end of a micrometer screw above the disc H and is connected through the metal cover to the outer coating of the jar. When there is a difference of potential between the two coatings of the jar, and therefore between the two plates, the aluminium plate is attracted upwards and by varying the distance between the plates by the micrometer screw it may be made to come into exact register with the plane of the disc H.H. when the indicating arm will be at zero. As the force required to attract the disc to this position is always the same, the P.D. required to obtain balance is simply proportional to the distance d between the plates which is indicated by the reading on the head of the micrometer screw. The absolute electrometer (fig. 30) is similar in principle but, the guard plate B and aluminium trap door H are near the top of the glass case and the attracting plate A is mounted just below them on the micrometer screw. The trap door is suspended on springs so as normally to be a little above the lower surface of the guard plate, and the force necessary to bring it into exact register can be initially found by placing weights on the disc and observing the position of the latter through the lens L. When this force is known, any P.D. can be measured by connecting it to the two plates and turning the micrometer screw till the aluminium plate is brought to register, the formula being $V = d\sqrt{\frac{8\pi gw}{A}}$, where W is the weight initially required to produce register and g is the attraction of gravity.

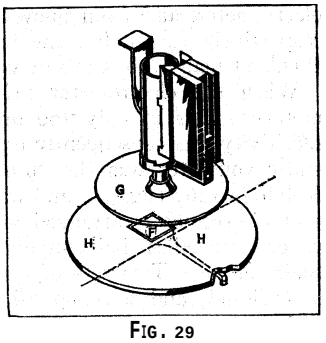


FIG. 29

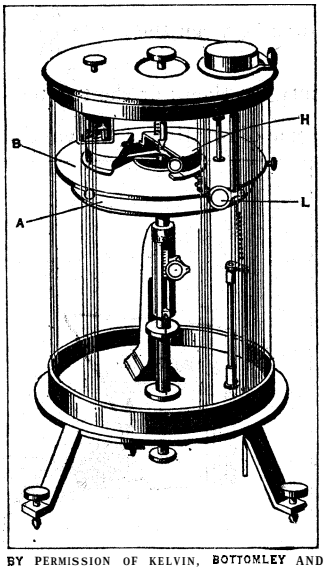

BY PERMISSION OF KELVIN, BOTTOMLEY AND BAIRD
FIG. 30.—KELVIN'S ABSOLUTE ELECTROMETER

The second type of electrometer was developed from the symmetrical electrometer initially devised by T. G. Behrens in 1806 and modified by J. G. von Bohnenberger. In this type a single gold leaf is suspended midway between two vertical metal plates between which a dry pile is connected. If then the leaf is charged it will move towards the plate of opposite polarity. Fechner and Hankel made further improvements; the latter substituting a battery for the dry pile, and adding adjustments to the plates and a scale for measuring the movements of the leaf. Lord Kelvin greatly improved this type of instrument in his quadrant electrometer, the essential features of which are shown in fig. 31. A flat circular metal box is cut into four equal sections or quadrants A, B, C, D, and each section is supported on an insulating pillar and provided with a terminal, the opposite quadrant A and D and B and C being connected together by wires. A light flat paddle shaped aluminium vane U, shown by the dotted lines, is suspended by a bifilar cocoon silk suspension exactly in the centre of the quadrants and normally symmetrically between them as shown. From the centre of this needle hangs a fine platinum wire, which dips into sulphuric acid in the bottom of the glass containing vessel. This acid is conducting and it also serves the quadruple function of forming the inner coating of a Leyden jar, or keeping the interior of the apparatus dry, of establishing contact with the vane or needle, and of damping the movements of the latter. The outer surface of the glass container is partially coated with strips of tinfoil to form the outer coating of the jar. If this jar is charged, the needle can be maintained at a constant high potential by means of a small electrical machine or "replenisher" and a gauge, and if a small P.D. is then applied between the two pairs of quadrants the needle will turn so that a smaller portion of it is between the quadrants of similar potential and a larger portion between those of opposite potential to that of the needle, and its deflection can be observed by attaching a light concave mirror to the stem of the needle, and employing a lamp and scale as in reflecting galvanometers (*q.v.*). If V is the potential of the needle and V_1 and V_2 the potentials of the two pairs of quadrants respectively, theory indicates that the deflection $D = k(v_2 - v_1)\{V - \frac{1}{2}(v_1 + v_2)\}$ where k is a constant of the instrument. Unfortunately, Hopkinson, in 1885, and Ayrton Perry and Sumpner the following year, noticed that this law did nat hold in the Kelvin electrometer, as instead of the deflection for a given P.D. across the quadrants rising proportionally with increase of potential of the needle, it increased up to a certain potential, after which there was little further increase, and in some cases a diminution. The latter investigators traced this action to openings in a guard tube which was employed to screen the platinum wire from external electrical disturbances, and devised an electrometer in which magnetic control was substituted for the bifilar silk suspension, and the quadrants were more exposed and more easily adjustable, thus enabling the theoretical law to be fulfilled, and with increase of sensitiveness. This improvement was of great importance, as it enabled the electrometer to be used as an accurate wattmeter (*q.v.*) for use in alternating current circuits, and this application was independently suggested in 1881 by Professors Ayrton and G. F. Fitzgerald and by M. A. Patier.

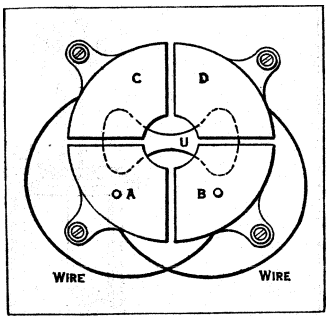

FIG. 31

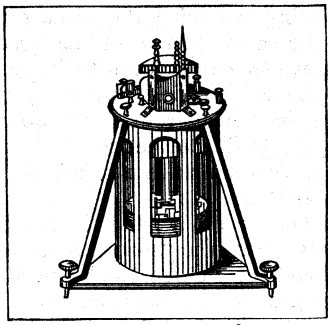
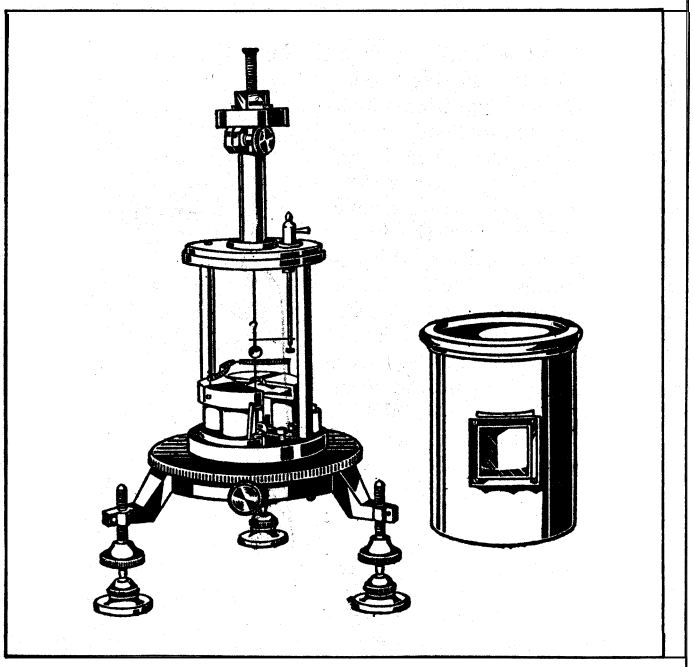


BY PERMISSION OF KELVIN, BOTTOMLEY AND BAIRD
FIG. 32.—KELVIN'S QUADRANT ELECTROMETER

The invention of the quartz fibre by Prof. C. V. Boys has enabled quadrant electrometers to be made of much greater sensitiveness, owing to its extremely small and constant control. Among them that of Dr. F. Dolezalek (fig. 33) has been very successful, because of its high sensitiveness and low electrostatic capacity. The needle and quadrants are made of very small size; the latter being supported on short pillars of amber which give very high insulation, while the needle is of paper thinly coated with silver foil so as to have very small inertia and almost critical damping with the very small control of the quartz fibre, The latter

is rendered sufficiently conducting to charge the needle by dipping it in the first place into a solution of some hygroscopic salt, such as calcium chloride, so that its surface is always moist, or better by gilding it. The whole system is enclosed, like a galvanometer, in a brass case, which shields it from draughts and external electrostatic fields and the deflections are obtained by a small concave mirror on the needle, through a window in the case. A torsion



BY PERMISSION OF J. J. GRIFFIN & SONS

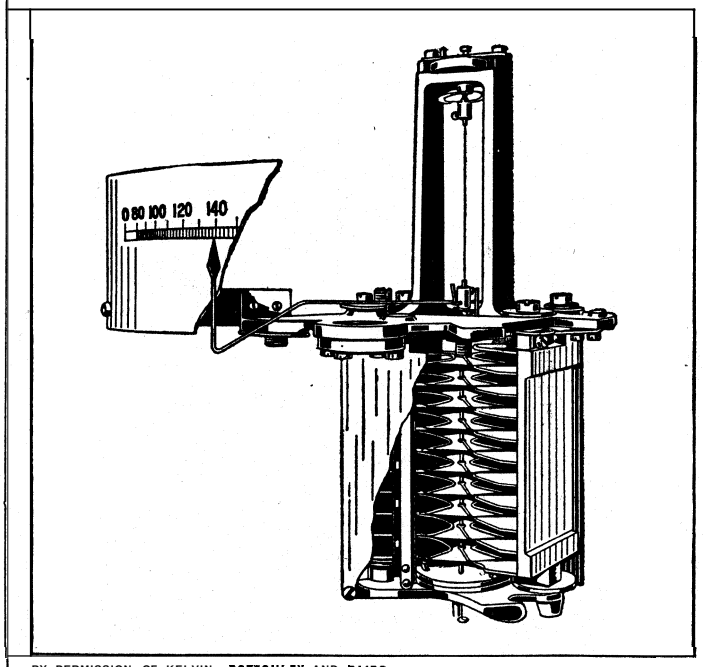
FIG. 33. — DOLEZALEK'S QUADRANT ELECTROMETER

head on the top of the suspension can be employed to adjust the zero of the instrument. With a quartz fibre suspension *60* mm. long and 0·009 mm. diameter and a potential of 110 volts on the needle, its periodic time was *18* sec. and a deflection of 130 mm. on a scale at 2 metres distance was obtained with a P.D. of 0·1 volt between the quadrants. Even greater sensitiveness has recently been secured with this type of instrument by the Cambridge Instrument Co. The latest improvement in the quadrant electrometer has been made by Prof. A. Compton, who has found that by slightly inclining the plane of the needle and giving a vertical adjustment to one of the quadrants, the control can be varied down to zero or even to a negative value. An instrument of this type with a gilded quartz suspension of 0·002 to 0·005 mm. diameter has given from 15 to *140* mm. deflection at a metre with 50 volts on the needle and only 0·01 volt between the quadrants, but the time to reach a steady deflection at the higher sensitivity is about *90* sec.

On the other hand the requirements of radio-activity research has caused the "string electrometer," based on the original instruments of Behrens and von Bonenberger, to be developed into instruments of high sensitivity, low capacity and rapid response by the aid of gilded quartz fibres. In a form of string electrometer made by the Cambridge Instrument company, a single quartz fibre of 0·002 or 0·003 mm. diameter suspended symmetrically between two plates with *25* volts between them, will give a deflection of ·044 mm. or about 5·5 scale divisions on a microscope for *1* volt on the needle with a critically damped period of under 1 second. Prof. Lindemann has produced a deflectional "quadrant" electrometer having a *0.004* vertical gilded quartz fibre under slight tension, and two gilded glass fibres 2 cm. long and 0·02 mm. diameter cemented transversely and symmetrically upon it to serve as a needle. The ends of this needle move between four fixed plates serving as quadrants and the whole system is enclosed in a small sealed metal box with windows above and below, so that it can be placed on the stage of an ordinary microscope. Prof. Lindemann's deflectional "quadrant" electrometer is an instrument which gives ·4 mm. deflection or *136* divisions on the microscope for 0·35 volts between the quadrant plates and 1 volt on the needle.

Electrostatic Voltmeters. — For the measurement of high P.D.'s especially above a few hundred volts, electrostatic voltmeters are largely used as they have the great advantage of only requiring an infinitesimal current and power consumption and of being equally suitable for direct and alternating P.D.'s, in that they are entirely free from inductive errors. There are two main types of such voltmeters derived from Lord Kelvin's quadrant electrometer, and from Snow-Harris' attracted disc electrometer respectively (*q.v.*), but the latter are only used for very high P.D.'s of many thousands of volts.

When the electrometer principle was first applied to voltmeters, P.D.'s of only 100 or 200 volts were in use, and high sensitivity was consequently essential. The first practical electrostatic voltmeter was the "multicellular" form devised by Lord Kelvin in *1867* (fig. *34*) and was equivalent to a number of quadrant electrometers arranged vertically above one another, their vanes or "needles" being mounted on a common stem so as to add their torques. Two sets of quadrant plates only were employed in each set, and were opposite one another and connected together to one pole of the circuit, the vanes being suspended by a fine wire and connected to the other pole. When the system was at zero, the vane system hung so that it was just about to enter between the fixed quadrants at two opposite edges. When a P.D. was applied between the vanes and quadrants the former were drawn further and further in against the torsion of the suspension as the P.D. was increased, and the P.D. could be indicated by a pointer attached to the vertical spindle on a scale as shown. This instrument was very similar to the variable vane condensers now so largely used for broadcasting sets and, in fact, its operation, like that of all electrometers, depends on this variable capacity. The energy stored in a condenser of capacity C and with a P.D. V between its plates is $E=\frac{1}{2}CV^2$, so that the force between them $F=\frac{\partial E}{\partial x}=\frac{1}{2}V^2\frac{\partial C}{\partial x}$, where r is the distance between them; or the torque $T=\frac{\partial E}{\partial \theta}=\frac{1}{2}V^2\frac{\partial C}{\partial \theta}$, where θ is the angle of rotation of the vanes. In the multicellular voltmeter, as



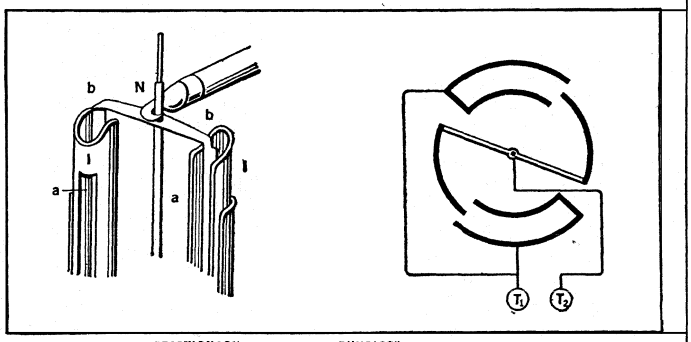
BY PERMISSION OF KELVIN, BOTTOMLEY AND BAIRD

FIG. 34.—KELVIN'S MULTICELLULAR ELECTROSTATIC VOLTMETER

in the vane condenser, the capacity is nearly proportional to the area over which the moving and fixed vanes overlap, *i.e.*, to the angle θ, so that $\frac{\partial C}{\partial \theta}$ is nearly constant. Thus, the torque, and

consequently the deflection θ, is approximately proportional to the square of the P.D. until the moving vanes are drawn nearly completely in, after which the increase of the deflection diminishes. Such voltmeters therefore only commence to have a useful reading at a moderately high fraction of their maximum voltage, but then have a widening scale, closing up again as the maximum is approached. This is a very suitable scale for supply circuits, though less suitable for general measurement.

The multicellular voltmeter came into fairly considerable use



FROM GLAZEBROOK, "DICTIONARY OF APPLIED PHYSICS" (MACMILLAN)

FIG. 35.—ELECTROSTATIC VOLTMETER ("QUARTER CYLINDER" PRINCIPLE)

for circuits up to a few hundred volts, but was very slow in indication owing to the large inertia of its vane system. It was damped by a disc at the bottom of the spindle which turned in a vessel of oil.

For higher voltages Lord Kelvin introduced another form having only two fixed vanes in a vertical plane, with a single vane moving system having a pivoted horizontal axis. Ayrton and Mather devised electrostatic voltmeters for both low and high P.D.'s on what they termed the "quarter cylinder" principle. It may perhaps best be described as a quadrant electrometer in which the moving vanes are bent over so as to form portions of cylinders parallel to the axis, and the quadrants are then also portions of cylinders which are arranged concentrically. This construction has the advantage of reducing the moment of inertia and increasing the rigidity of the system for a given capacity, and therefore of increasing the rapidity of reading. Suspended instruments of this type have been made for P.D.'s down to 80 volts and pivoted horizontal axis switchboard instruments for 3,000 volts or more. These latter instruments are damped by piston air dampers, but Carpentier has adopted the same form, but mounted between the poles of a powerful horseshoe permanent magnet which produces the damping by the eddy currents induced in the moving system. Extra high voltage voltmeters have been made by the Westinghouse company and others on the same lines, but with the system immersed in oil which gives a greater dielectric strength against arcing, a greater torque owing to the increase of capacity, and damping by the viscosity of the oil. Compressed nitrogen has also been employed in electrostatic voltmeters for reducing liability to spark, and the formation of ozone. For very high voltages up to hundreds of thousands of volts, the instruments would become very cumbrous owing to the large distances required to avoid flashing over, but the range of the above instruments may be almost indefinitely extended for A.C. measurement by connecting a condenser in series with the voltmeter as originally proposed by Ayrton and Perry. If the capacity of this condenser is equal to that of the voltmeter, twice the P.D. will be required for the same deflection, or if it is one-ninth of the voltmeter capacity the required P.D. will be multiplied tenfold, and so on, so that an instrument normally reading to 5,000 volts can have its range extended to 50,000 volts or more. This is generally effected by connecting one terminal of the voltmeter to a plate or sphere on an insulating pillar with another plate at an adjustable distance near to it. On the other hand the Snow-Harris attracted disc electrometer (*q.v.*) has been adapted as a high voltage voltmeter by Lord Kelvin in his Volt balance, and by Jona, Siemens and Halske, Grau and others.

INSUBRES, a Celtic people of upper Italy, the most powerful in Gallia Transpadana. Livy states that Bellovesus and his Gauls, having crossed the Alps and defeated the Etruscans near the Ticinus, found themselves in the territory of the Insubres (also the name of a *pagus* of the Aedui). Here they built a city and called it Mediolanum (Milan), after the name of a village in their home in Gallia Transalpina. The name Insubres thus appears applied to the inhabitants (1) of the Aeduan *pagus,* (2) of the territory in Gallia Transpadana occupied by Bellovesus, (3) to the founders of Mediolanum. From 222 to 195 B.C. the Insubres were frequently at war with the Romans. In 222 B.C. they were defeated at Clastidium by M. Claudius Marcellus, who gained the *spolia opima* by slaying with his own hand their king Viridomarus, and in 194 B.C. they were finally subdued by L. Valerius Flaccus.

See H. Nissen, *Italische Landeskunde,* ii. 179 (1902); A. Holder, *Altkeltischer Sprachschatz,* ii. (1904).

INSULATOR, in electricity, is a non-conducting device, or material, used to separate two electrical conductors.

INSULIN. Insulin belongs to the group of substances known as hormones and is secreted into the blood by cells which are situated in or near the pancreas. In the mammalia, in which the pancreas is well defined, the insulin secreting cells lie in scattered groups, called the isles of Langerhans, distributed among the relatively much larger groups, or acini, of pancreatic cells. In certain fishes in which the pancreas does not occur as a definite gland, but is spread out diffusely in the mesentery, e.g., in Lophius and Myoxocephalus, the islet cells form compact encapsulated glands called the principal islets which are often of considerable size and contain no pancreatic (acinar) cells.

Evidence that insulin is present in the pancreas of mammals was originally furnished in 1889 by Mehring and Minkowski. They found that complete extirpation of the gland in dogs immediately caused severe diabetes, and it was not long before the hypothesis was formulated that this must be due to the withdrawal from the body of a hormone having the function of regulating the metabolism of the carbohydrates. The name insulin was suggested (by Sir E. Sharpey Schafer) for this hormone in the belief that it comes from the islets, and many attempts were made to extract it from the pancreas, but with little success. In 1921, however, Banting and Best, working under the direction of J. J. R. Macleod, found that extracts of partially degenerated pancreas contained the hormone. This method was based on the supposition that the powerful digestive ferments of the intact pancreas destroy the insulin during the process of extraction and on the knowledge that the cells which secrete these ferments undergo degeneration more rapidly than those of the islets after the pancreatic ducts have been tied (Schultz and Ssobolew). This observation demonstrated that insulin does exist in the pancreas, and the next step was to devise a method for extracting it in more purified form and in quantity from normal pancreas. Alcohol was found to be a suitable extractive, in that it dissolved the insulin and at the same time inhibited the action of the digestive ferments, and Collip succeeded, in 1922, in sufficiently purifying the alcoholic extracts, by a process of fractional precipitation, so that

they could be injected subcutaneously in man without causing local irritation. Very potent extracts were also prepared from the principal islets of fishes. Further purification of the extracts was effected by precipitating the insulin, either by adjustment of the reaction (isoelectric precipitation) or by means of picric acid followed by treatment with alcoholic hydrochloric acid (insulin hydrochloride). Extracts capable of lowering the blood sugar have also been prepared from other organs than the pancreas, or principal islets, but it is doubtful if their action is really due to insulin. Certain guanidin salts also depress the blood sugar.

The function of insulin is to control those chemical processes of the body which are concerned in the preparation of the foodstuffs for oxidation in the tissues. The material which is immediately oxidized to produce this energy is carbohydrate, a supply of which is always present, as glycogen, in the muscles where it is formed out of the sugar of the blood. This sugar comes from the liver and is derived either from sugar absorbed from the intestine and temporarily stored in this organ as glycogen, or when digestion is not going on, from glycogen which has been manufactured out of protein and fats (gluconeogenesis). Insulin controls the rate of supply of sugar from the liver in proportion to the utilization of glycogen by the muscles.

When insulin is absent from the blood, as after pancreatectomy or when the islets are destroyed by disease (diabetes), sugar production occurs in the liver more rapidly than glycogen formation so that glycogen disappears from this organ, the blood sugar becomes very high (hyperglycaemia) and sugar appears in the urine (glycosuria). At a later stage substances known as the ketone bodies also appear in the blood and urine (ketonuria), being derived from the incomplete oxidation, chiefly of fatty acid but partly also of certain of the amino acids. Death ultimately occurs, either because of starvation caused by the excessive using up of the available foodstuffs of the body, or because of toxic effects for which the ketone bodies are believed to be largely responsible (diabetic coma). Insulin promptly removes all of these symptoms when injected subcutaneously or intravenously, but is inactive when given by mouth, because it is destroyed by the digestive ferments (pepsin) of the stomach. The effect passes off in a few hours, so that the injections must be repeated twice daily. When this is done the symptoms of diabetes remain absent apparently indefinitely, at least two dogs that were depancreatized for over four years were still living in Dec. 1927 and in excellent condition as a result of insulin treatment In diabetes in man, although the islets are more or less diseased they are never completely destroyed, so that when treatment with insulin is continued for some time the damaged islets may possibly become regenerated.

One of the most significant effects of insulin when given to diabetic animals is that it immediately causes glycogen to be again deposited in the liver and a change occurs in the respiratory metabolism. In a normal animal fed on carbohydrates the ratio between the oxygen absorbed and the carbon dioxide expired, the so-called respiratory quotient, is near to unity, whereas in complete diabetes it never rises above 0·7. When insulin is given the diaoetic, the quotient behaves as in the normal animal. Insulin therefore has three fundamental effects in diabetes, it restrains the excessive gluconeogenesis, it stimulates glycogen formation and it raises the respiratory quotient. When insulin is injected into normal animals the blood sugar, which usually stands at about 0·105%, rapidly diminishes and when it reaches a level at between 0.040 and 0·050% curious symptoms supervene. In most laboratory animals these hypoglycaemic symptoms consist at first of nervous hyperexcitability leading to convulsions, and later of coma and fall of temperature. That the symptoms are related to the disappearance of free glucose from the blood is indicated by the fact that they are promptly removed by restoring glucose to the blood, either by giving sugar by mouth or by injecting solutions of glucose subcutaneously or intravenously. Glucose is conspicuously more efficient as an antidote than any other sugar, even than mannose and laevulose which are so closely related to it chemically. The substitution of one hydrogen atom in the glucose molecule by some other radicle such as a methyl (CH_3) group, robs it entirely of its antidoting powers. The mechanism by which excess of insulin causes hypoglycaemia in the normal animal is not clearly understood.

Since insulin can now be prepared in crystalline form (J. J. Abel and Geyling) and a readily dried, solid, compound can be formed with hydrochloric acid — insulin hydrochloride — it may be weighed out for medicinal use, but it is more convenient to use it in liquid form which keeps well in acid reaction. The strength in actual insulin of the liquid is determined by a biological method which depends on the lowering of blood sugar in a normal rabbit. The strength is gauged in units, one unit of insulin being originally defined as that amount which on subcutaneous injection will lower the percentage of blood sugar to the convulsive level, 0·045%, for a period of 5 hours in a fasting rabbit of 2 kg. weight. This original unit was subsequently reduced to one-third. The assay is now carried out by a comparative method in which the hypoglycaemic effect of the solution to be tested is compared with that of a solution containing an accurately weighed amount of insulin hydrochloride. In order to ensure uniformity in the strength of insulin manufactured in different countries the Health Committee of the League of Nations has set aside a sufficient quantity of dried insulin hydrochloride of which 1 mg. contains 8 units. Testing laboratories maintain their own standards, but they can have them checked against the international standard from time to time. By such international uniformity in strength of insulin the diabetic patient is insured against variable dosage and the risk of hypoglycaemic symptoms. **(J. J. R. MacL.)**

INSURANCE, ARTICLES ON. The following deal with insurance in its various branches: ACCIDENT INSURANCE, PERSONAL; AGRICULTURAL INSURANCE; CREDIT, INSOLVENCY OR BAD DEBT INSURANCE; ENGINEERING INSURANCE; FIRE INSURANCE; INDUSTRIAL INSURANCE; INSURANCE: *An* Introduction; INSURANCE, MISCELLANEOUS: Burglary, Drivers' Policies, Fidelity, Guarantee, Plate *Glass, Property* Owners' Indemnity, Third Party, *etc.;* INSURAKCE, POST OFFICE FACILITIES; LIFE INSURANCE; MARINE INSURANCE; MOTOR VEHICLE INSURANCE; BONUS; UNEMPLOYMENT INSURANCE.

Separate articles appear under the headings NATIONAL INSURANCE, HEALTH; NATIONAL INSURANCE, WIDOWS' AND ORPHANS'.

A cognate matter of great importance is the subject of pensions, which will be found under the following headings: INVALIDITY PENSIONS; OLD AGE PENSIONS; PENSIONS, CIVIL SERVICE AND MUNICIPAL; PENSIONS, NAVY, ARMY AKD AIR FORCE; PENSIONS, PERPETUAL; PENSIONS, POLITICAL; PENSIONS: THE UNITED STATES; SUPERANNUATION; WAR PENSIONS.

A special article on ANNUITY is very important as bearing not only upon insurance schemes, but upon house purchase, hire purchase, etc. Finally, EXPECTATION OF LIFE; GUARANTEE; LIFE TABLES; REINSURANCE; TITLE GUARANTEE COMPANIES and WORKMEN'S COMPENSATION are the subjects of special articles under those headings.

INSURANCE, INTRODUCTION TO. Insurance is the practical device by which civilized man protects himself against the contingencies of life. He has for centuries realized the regularity with which the law of average operates when great numbers are involved and has employed his knowledge to provide by insurance against the hazards to which the products of his enterprise and his industry are at all times subject. The principle of insurance was admirably stated by a select committee of the House of Commons who, in reporting (in 1825) on the laws relating to friendly societies, said: "Whenever there is a contingency, the cheapest way of providing against it is by uniting with others, so that each man may subject himself to a small deprivation, in order that no man may be subjected to a great loss. He, upon whom the contingency does not fall, does not get

his money back again, nor does he get for it any visible or tangible benefit; but he obtains security against ruin and consequent peace of mind. He, upon whom the contingency does fall, gets all that those, whom fortune has exempted from it, have lost in hard money, and is thus enabled to sustain an event which would otherwise overwhelm him." It does not detract from the general truth of this pronouncement that a certain part of the premiums paid for insurance is absorbed in the expenses necessarily attendant on the conduct of the business, nor is it a demerit of the system that insurance, since it produces nothing, adds nothing to the wealth of the world. It may, indeed, be claimed to its credit, in this connection, that in practice, with the assessment and modification of premiums with reference to the risks incurred, the system tends, by encouraging the adoption of preventive measures of various kinds, to diminish that waste and loss the fear of which has called it into existence. Due weight being given to the benefits of insurance, both direct and indirect, it must be concluded that its cost to the community, as represented by the maintenance of the great number of persons whose energies it absorbs, and by the profits of those who risk their capital in providing it, is far outweighed by the value of the service which it renders. This, indeed, is as true of insurance on human life, at any rate in its more substantial forms, as it is of insurance against the risk of loss of material things; *e.g.*, by fire or marine disaster.

So far as concerns the trading profits of insurance, which constitute a comparatively minor element in its cost, Great Britain is specially favoured in that the pioneering enterprise of the British insurance companies, and the high reputation which they have long enjoyed, have attracted to them a substantial share in the world's insurance business. The profits on this business cannot readily be computed, but are generally accepted as making a useful contribution to the "invisible surplus" by which the balance of international trade is maintained.

The special position of marine insurance in regard to the commercial prosperity of Great Britain is vividly indicated by Sir Norman Hill in his contribution to *War and Insurance*, one of the series of works on the economic and social history of the World War published on behalf of the Carnegie Endowment for International Peace. Here he sets out shortly the mechanism of the method by which the nation is, in great measure, fed and clothed by supplies from overseas. "By far the greater proportion of the cargoes at any time afloat belong not to the producers, the merchants, or the consumers but to the financial interests who have discounted bills of exchange representing the purchase price of the goods. and who hold as their security the bills of lading and policies of marine insurance. . . . The security against all trading risks is ample because the advance is repaid out of the selling price of the goods on the completion of the voyage, or if the goods be lost, out of the insurance money. Moreover the bills of exchange against which the advances are made afford the most convenient means for the adjustment of international exchange and they therefore pass freely from hand to hand and from country to country in the process of these adjustments. In fact, international finance is in very great measure based on the security afforded by the bill of exchange drawn against goods in transit, and it is to that extent dependent on the security of not only the bill of lading for the goods, but also on adequate insurance against the risks incident to the transit." On a closely related point it may be said that marine insurance has supplied the model for a system of foreign credit insurance which has recently been established at the instance of the Overseas Trade department to stimulate the export trade of the United Kingdom.

Insurance or Assurance.—The terms insurance and assurance are employed somewhat indiscriminately to indicate "the action of insuring or securing the value of property in the event of its being lost, or of securing the payment of a specified sum in the event of a person's death." This quotation is from the *Oxford English dictionary*. Babbage proposed, so long ago as 1826, that the word assurance should be reserved for contracts relating to life, on the ground, in effect, that in this case the event on which the policy depends is a certainty, and that insurance would more appropriately be applied to contracts relating to contingencies. While this convenient distinction has found much favour, it has been challenged in other quarters and is not universally adopted. In the United States the term "insurance" is generally used.

Historical References.— Marine risks mere the subject of the earliest form of insurances. Setting aside the attractive but debatable proposition that insurance was recognizable as an element in the maritime commerce of antiquity, there is ample evidence of its use in the middle ages. A "Chamber of Insurance" established in London under a patent granted by Queen Elizabeth in 1574, the object of which was to register all contracts of insurance negotiated and to record their terms for reference in case of dispute, was a comparatively late-comer, similar bodies having been founded in Barcelona (probably in the 13th century) and in Bruges (1310). The first English statute on "assurance" appeared in 1601 and dealt with marine risks. The earliest known life policy, which followed strictly the form of marine insurance, was effected in 1583.

Scope of Insurance.—Insurance was limited, until recent times, to life, marine and fire risks. Modern developments have added other subjects; *e.g.*, the risk of personal accident, sickness, employers' liability, burglary, motoring, aviation and loss of livestock. Insurance under some of these headings includes the wide range of risks involving liability to civil action in respect of loss of life or damage to property.

While commercial insurance of every class expands continuously, in correspondence with the growth of population and with the enlargement of human necessities and desires, the developments of life insurance recently are of special interest. So far as Great Britain is concerned the growth of the business under "ordinary" policies, providing substantial sums for premiums payable annually, half-yearly or quarterly, has somewhat more than kept pace with the increase of population and the change in the value of money. In North America this class of insurance has advanced remarkably, while in various European States the business has exhibited considerable recuperative power in face of the difficulties created by the depreciation or collapse of currencies. Industrial life assurance has made great progress on both sides of the Atlantic; the number of policies of this type in force in Great Britain and Ireland at the end of 1926 was about 72 millions, an average of nearly two policies for every member of the industrial population. The number of such policies in the United States at the end of 1926 is also reported to have been 72 millions, while nearly four million policies were in force in Canada. Industrial assurance is also practised widely in Australia. The latest development of life insurance for industrial workers originated in the United States under the title of "Group insurance," and has lately reached the British Isles. It is stated that some six millions of American work-people are interested in insurances under this plan, by which the employer effects a year-to-year insurance on the life of each person in his employment through the medium of a single policy covering his whole staff. In certain cases the benefits of the plan have been extended, with the aid of contributions from the assenting employees, to cover sickness and accident and to provide pensions on retirement. There is, perhaps, less scope for such extensions in Great Britain, where the ground is largely covered by friendly societies, by State insurance, and, in growing measure, by superannuation or pension funds connected with particular establishments.

Interesting developments in other directions exemplify the methods by which British insurance is adapted to the requirements of the ordinary citizen. For example, the occupier who owns his dwelling, a rapidly increasing class in present conditions, is able through his building society, or other medium by which his purchase has been financed, to couple with his mortgage a policy of a special type whereby the remaining burden of his debt is lifted from the shoulders of his family in the event of his death before his instalments have been completed. Worthy of mention also is the type of policy—under various names—by which the householder may, by a single contract, insure his personal belongings against such diverse misadventures as fire, gas or boiler explo-

sion, burglary, etc., and may cover his risks as an employer in respect of his domestic staff. Generally, it may be said that while the business of the majority of insurance companies is conducted on fairly conventional lines there is practically no type of contingency for which insurance protection cannot be obtsined from adventurous underwriters at Lloyd's or elsewhere.

State Insurance.—Insurance has taken a prominent place in the modern conceptions of the functions of the State. The compulsory protection of the worker against the contingencies by which his livelihood was most obviously beset originated in Germany where in the years 1884–86 compulsory schemes of insurance against sickness and accident (including medical treatment) for substantially the whole of the wage-earning community were brought into operation. These were supplemented later by schemes relating to invalidity and old age. That these measures took deep root and met the requirements of the people is sufficiently indicated by the fact that they survived the shock of the loss of reserves on the collapse of the mark in 1923. Austria followed the German empire in the adoption of compulsory State insurance and in 1911 it was introduced into Great Britain and Ireland by the National Insurance Act. Although a modest and experimental scheme of unemployment insurance was incorporated in this act, its principal subjects were sickness and disablement (including, with these, the provision of medical treatment and medicine), and over 15 million workers, of whom nearly one-third were women, were brought within its scope. An enlarged scheme of unemployment insurance, applying to about 11 million wage-earners was introduced in 1920, and in 1925 provision was made for pensions and allowances to widows and orphans and for pensions to the insured and their wives on the attainment of the age of 65. A corresponding Act was passed in the same year by the Parliament of Northern Ireland. The scope of this latest scheme is slightly wider than that of the health insurance measure, and while the number of persons who are insured under the scheme in the United Kingdom approaches 17 millions, the number of persons who are interested as actual or potential beneficiaries is about 31½ millions.

Taking the whole of the schemes together, and bearing in mind the provision made by the Workmen's Compensation Act, which is also, in general, safeguarded by insurance (in this case at the cost of the employer alone), it may be said that the industrial workers of Great Britain and Northern Ireland are more fully protected by the action of the State in respect of the more serious contingencies of life than those of any other country. Developments, however, still proceed elsewhere. The General Conference of the International Labour Organization of the League of Nations (10th Session, 1927) has proposed that the member States should be invited to subscribe to conventions relating to sickness insurance for workers in (1) industry and commerce and domestic service and (2) agriculture, and it is understood that the consideration of other risks is to follow. Save, therefore, in North America, where differences of economic conditions are responsible, at present, for differences of outlook, compulsory State insurance, in relation to a comprehensive range of subjects, seems likely to spread to the whole of the civilized world.

Where State insurance invades a field of effort such as that of the British friendly societies, a measure of controversy is, of course, inevitable. Certain distinctive merits must, however, be conceded to compulsory national schemes, even by those who are most reluctant to concur in the new activities of the State. Looking at the matter as it concerns this country it cannot be denied, on the one hand, that the thousands of registered friendly societies made, and continue to make, a substantial provision against sickness and other contingencies in the case of perhaps four millions of those who come within the national scheme; it has also to be recognized that apart from these bodies, whose operations are on a permanent and fairly stable basis, sickness insurance, though on a lower grade of quality, was very widely practised through unregistered bodies. But, on the other hand, there remained several millions of wage-earners, women especially, whom existing agencies had failed to reach, or at any rate to attract National insurance, enforced by public authority, succeeded at the point where voluntary agencies had failed, and brought under a measure of protection, moreover, all who from advancing years or inferior health were ineligible for membership of a friendly society Again, by the scheme for pensions at 65 the State was able to enforce protective measures in regard to which private effort, though exercised untiringly over many years had failed—and that conspicuously—to persuade.

Unemployment insurance as a possible subject of State action presented similar features. Available to many of those engaged in the highly skilled and well organized trades, it made little more than an exceptional appearance in the constitution of the newer trades unions which cater largely for the unskilled classes, while to the millions of unorganized workers it was wholly unattainable. When it is added that where it was practised its finance rested generally on the basis of a single craft, with all the extremes of risk that this implies, it will be realized that the time was ripe for comprehensive action such as the State could certainly take and no other agency had offered to initiate.

Widows' Pensions.—But it is, perhaps, in respect of widows' pensions that compulsion has been of chief value. "Adverse selection" is an element against which insurance on a voluntary basis has constantly to contend, and where the subject is such as pensions to widows and temporary allowances to dependent children this element would operate on a voluntary scheme, dependent on its own resources, with quite paralysing effect. Few with the exception of the married would insure; few, if any. of the insured would keep their policies up when, with the lapse of years, the need of them seemed to disappear. In the result the cost of insurance would be altogether prohibitive. The State, by compulsion applied from early youth to the whole of the wage-earning population, could obviously secure (with or without a subsidy) what private effort dared not attempt. The need for such a scheme, no less than its usefulness in practice, is attested by the fact that in the earliest months of the scheme it relieved the boards of guardians in England and Wales of expenditure at the rate of nearly £2,000,000 a year. This indeed is the lesser relief; the greater is the removal from the ranks of pauperism of scores, if not hundreds, of thousands of fatherless children.

Personnel and Statistics.—The professional interests of the insurance official and the technical education of the junior grades are served by many organizations of which three British bodies may be singled out, both on the ground of seniority and as enjoying the dignity of incorporation under Royal Charter. These are the Institute of Actuaries, the Faculty of Actuaries in Scotland and the Chartered Insurance Institute. The number of those engaged, in all grades, in the practice of insurance at the last census of Great Britain is given as 133,000, of whom one-third were women. Those employees whose remuneration is not more than £250 a year are insurable under the Unemployment Insurance Acts, and in 1927 this class included 86,000 persons.

The statutory returns of the British insurance companies and societies (which do not include the underwriters at Lloyd's) show that in the latest year of account (generally 1926) for which figures are available the total amount received in premiums for business of all kinds was £242,000,000. Of this total £134,000,000 were attributable to insurance contracts other than life, and it is probable that a very substantial part represented business overseas. Claims reached a total of £137,000,000, and reserves of all kinds, of which the funds accumulated under life assurance contracts represented about four-fifths, exceeded the massive aggregate of £1,000,000,000. (A. W. W.)

INSURANCE: MISCELLANEOUS. Under this head are considered various types of insurance which are not dealt with under separate heads (see INSURANCE ARTICLES).

Burglary: Private Dwellings.—Policies are issued to cover the risks of house-breaking and larceny, although larceny is excluded if plural tenancy exists or, in the case of a flat, if it is not self contained. Premiums are based on the full value of the total contents, an excess premium being charged if valuables, *i.e.*, gold and silver articles, jewellery and furs, exceed one-third of the whole. Damage to the building caused by burglars, for which the insured is responsible, is included in the normal policy.

Business Premises.—The cover is more restricted, the larceny risk always being excluded, whilst frequently only theft following "actual violent and forcible entry to the premises" is insured. The rates vary with the nature of the stock to be insured and the means of protection employed. Insurances are generally effected for the full value of the stock at risk and the condition of average (similar to that used in fire business) is freely used.

Cash Insurances.—Cash may be insured whilst in transit in the custody of an employee of the insured (including the integrity risk) and thereafter whilst contained in an approved safe or strongroom until paid away. The premium is calculated on the estimated carryings, subject to adjustment at the end of the period of insurance. The limit of liability for any one occurrence is the maximum amount stated by the insured to be carried at any one time. Cash is also insured whilst deposited in an approved securely locked safe, but loss following the use of the key, unless obtained by threat or violence, is excluded.

"All Risks" Insurances.—Such cover is frequently sought in respect of jewellery, furs, works of art and other items of value, and insurances may include or exclude the fire risk. The cover is usually comprehensive and excludes only losses due to deterioration, vermin, war and kindred risks. The sum set against each item in the policy is generally agreed to be its value as between insurer and insured when the policy is effected and represents the insurers' liability in the event of total loss.

Fidelity Guarantee.—Commercial guarantees are sought for most responsible officials handling money and are provided by insurers after satisfactory enquiries have been made as regards the antecedents of the applicant. The employer's statement to the insurers forms the basis of the contract and discloses the system of check used, which must not be altered without the consent of the insurers. Policies are issued either for individuals or a collective guarantee may be given for an entire staff. In the latter event each employee is mentioned by name and the sum guaranteed on his behalf is stated.

Plate Glass Insurance.—Essentially an insurance against breakage, the risk of fire is excluded from the plate glass policy. Only glass specified in the policy is insured, and wooden framework and lettering, the latter, unless specially insured, is not covered. Premiums are calculated according to the superficial area and type of the glass to be insured. Stained and other valuable glass, lettering and painting are rated on a percentage of value.

Third-party Insurance.—Indemnities in respect of the legal liability of individuals or corporations to pay compensation to third parties for personal injuries or damage to their property caused by negligence on the part of an employer or his employees, or due to defects in the ways, works, machinery or plant used in the employer's business, are almost universally sought. Policies are issued to cover the insured's entire legal liability, excluding, however, liability to a member of his family or to a person in his service, or liability assumed under contract. Within the limits of indemnity selected the insured is relieved of all monetary responsibility, including law costs incurred in defending claims, fraudulent or otherwise. All claims negotiations are conducted by the insurers who may if they wish relieve themselves of all further liability at any time by paying to the insured the maximum sum for which they are liable in respect of any one accident. The limit of indemnity for any one accident mentioned in the policy is defined as meaning "any one accident or series of accidents arising out of one event." Policies suitably modified are issued to almost every trade and may be obtained to cover most contingencies likely to affect third parties.

Property Owners' Indemnity.—Such policies cover the liability of the insured to pay compensation for personal injuries to and damage to the property of third parties caused by defects in buildings. Claims are commonly due to falling slates, tiles and copings, whilst poorer class properties are subject to falling ceilings, defective railings and staircases and many other causes. Such insurances are similar in operation and conditions to third-party policies, and may be extended to include liability which may be incurred in connection with defective stop-cocks and defective sanitary arrangements, (A. G. M. B.)

Hail Insurance.—Hail Insurance is carried mostly to protect growing crops, policies being written for the principal ones. The coverage is limited to a given maximum amount per acre for each type of crop, and the rates vary with the crop and the territory. In general the liability of the Insurance Company applies only after the crop is in a healthy growing condition.

Earthquake Insurance.—Policies for earthquake insurance protect from all direct loss or damage from earthquake or volcanic eruptions and removal from premises endangered by them. A 10% exemption clause and a 70% coinsurance clause are customary. The policies do not assume liability for fire, wind or tidal waves or loss due to neglect of the insured to diligently protect his property.

Tourist Baggage Insurance.—Personal effects can be insured while in transit within defined geographical limits. Usually the protection covers fire, lightning, cyclone, flood, navigation and transportation risks and theft provided the insured promptly notify the local police authorities. Some policies omit theft or limit the liability to a stipulated per cent of the amount of the policy on furs, musical instruments, jewelry, plate, clothes and watches. The amount of premium is dependent on the size of the policy and the length of time it has to run.

Explosion Insurance.—These policies are designed to cover loss or damage from all explosions except those originating within steam boilers, pipes, flywheels, engines and machinery, as these are covered by Engineering Insurance policies (*q.v.*).

Use and Occupancy Insurance.—Use and occupancy insurance is also known as business interruption indemnity insurance. It is needed particularly by manufacturers of advertised and popular goods, merchants, hotels, laundries, theatres, warehouse and public utilities. The policies protect against losses resulting from interruption or suspension of business that follow a fire or some other calamity. Partial payments are provided for partial interruption of business and it is considered advisable for full protection to be insured for an amount equal to one year's estimated net profit and fixed expenses. Shorter terms are available and are often used on similar policies to protect from loss of rent resulting from the same causes.

For Aviation Insurance: See AERIAL LAW; Damage to Machinery Insurance: See ENGINEERING INSURANCE; Drivers' Policies: See MOTOR VEHICLE INSURANCE; Lightning Insurance: See FIRE INSURANCE; Riot and Civil Commotion Insurance: See RIOT AND CIVIL COMMOTION INSURANCE; Soldiers' Insurance: See PENSIONS: THE UNITED STATES; Tornado Insurance: See TORNADO AND WINDSTORM INSURANCE.

INSURANCE: POST OFFICE FACILITIES. The grant of Government life insurances in Great Britain through the agency of the Post Office was inaugurated by the Government Annuities Act, 1864. The avowed object of the scheme was to provide facilities for members of the working classes to insure their lives for moderate sums with the advantages of Government security.

The Act empowered the National Debt Commissioners to make ordinary life insurance contracts with any person between the ages of 16 and 60, but not for a greater sum than £100 or for less than £20, and authorized the Postmaster General to direct his officers to receive premiums and pay claims on behalf of the National Debt Commissioners. The rates of premium were to be calculated on the basis of 3% interest, and in such a manner as to form a fund adequate to meet all claims without entailing any charge, whether for claims or expenses, on the Consolidated Fund.

From the outset the amount of business transacted under the scheme was much smaller than had been anticipated, and in 1882 a Select Committee of the House of Commons was appointed to enquire into its operation. An amended scheme on the lines of the committee's recommendations was prepared, and received statutory sanction in the Government Annuities Act, 1882. Revised rates of premium were introduced and new forms of policies were made available, but the most important alteration was the linking up of the insurance system with the Post Office Savings Bank.

The scheme still failed to achieve the success that had been hoped for, and in 1892 it became the subject of an investigation by a departmental committee. The principal result was the adop-

tion of reduced rates of premiums. The new tables were introduced in 1896, and together with the regulations governing the conduct of the business, which were made at the same time, remain in force to-day (1928). The revised scheme was no more successful than its predecessors, and another departmental committee was set up in 1907. Their report, published in 1908, contained a number of recommendations for increasing the usefulness and popularity of the system, but no action was taken until Jan. 1914, when the stamp premium system was instituted.

Under this scheme the premiums are payable by means of ordinary postage stamps to be affixed weekly by the insured person in a premium book. At the end of each 13 weeks the stamped page containing the premiums for the quarter is withdrawn on presentation of the book at a post office. The scheme is available for persons of either sex between the ages of 14 and 50.

The tables show the amounts which are insured at death by the payment until age 60 of premiums varying from 2d. to 1s. per week, and therefore invite comparison with those of industrial insurance companies which show the sums assured by weekly premiums of one penny or multiples thereof payable throughout life. Owing to the shorter period over which premiums are payable, the sums assured under the Post Office scheme, particularly for the smallest premiums which are the most heavily loaded for expenses, are generally less than those quoted by the companies, and it is not improbable that many prospective insurants obtain the impression that the terms offered by the Post Office are less generous than they are in reality.

Under the ordinary scheme of premiums payable by transfer from the insurant's savings bank account the lives of persons of either sex between 14 and 65 years of age may be insured for any amount from £5 up to £100, the lives of children between 8 and 14 years of age may be insured for £5, but children under 8 years of age are not insured. If the amount of the insurance purchased is less than £100 further insurance may be purchased from time to time until the total sum assured is £100. Insurances not exceeding £25 can be effected with or without medical examination.

Meagre Results.—The extent to which advantage has been taken of the Post Office facilities for insurance is indicated by the following table:—

	No. of policies	Amount insured
		20,040
1916	442	27,258
1921	28j	16,153
1927	397	17,994

The total number of contracts in force at the end of 1927 was 10,171, representing sums assured amounting to £511,552.

These meagre results were in marked contrast with the success which since the inception of the scheme has attended the grant of immediate life annuities by the government, both through the National Debt office and through the savings banks. A substantial portion of the total amount of the life annuity business of the United Kingdom has invariably been transacted by the government.

In 1919 a departmental committee was appointed to enquire into the business carried on by Industrial Insurance Companies and Collecting Societies. The committee presented a unanimous report (1920) in which the Post Office system was criticized. Notwithstanding this criticism the scheme remained substantially unaltered.

The Select Committee on Estimates in a report presented to the House of Commons in July 1928, recommended that the Post Office life insurance business should be discontinued.

Subsequently the National Debt Commissioners announced that after December 31 of that year, no further policies would be issued because the volume of business transacted was infinitesimal when compared with that of the big companies, also the energies of the Post Office officials could be more usefully employed in other services. This ruling was put into force in the beginning of 1929.

The country in which Post Office insurance has attained its highest development is Japan, where the undertaking is in effect a national industrial insurance scheme. It is a government monopoly, but it is not compulsory. Postmen act as canvassers and collectors of premiums. The maximum sum assurable is 450 yen and the minimum 20 yen. The premiums are payable monthly either to a post office collector, or at a post office, or by transfer from a savings account. It was inaugurated in 1916, and within 11 years the number of policies in force was over 10 millions and the sums assured amount to about £130 millions. Surpluses have accrued which are being returned to the assured partly in the form of refunds to the policy-holders and partly in establishing and maintaining health and welfare services. (P. G. B.)

INTAGLIO, a term applied to any recessed carving, in which no part projects beyond the original face of the material. In some cases, as in gem cutting, the entire relief is reversed. In others, as in some Egyptian wall carvings, the outline is sufficiently incised so as to allow normal relief. This type is sometimes known as *cavo* rilievo or sunk relief.

INTEGER: see NUMBER.

INTEGRAL CALCULUS: see CALCULUS.

INTEGRATION, a physiological term, designating the various processes by which the multifarious activities and functions of the organism are knit together to produce a unified individual. The nervous system (*q.v.*) is by far the most important integrative mechanism. By nerve impulses, organs or tissues in one part of the organism are able to exert a co-operative influence on other distant bodily parts. The nerve impulses, in turn, are themselves integrated into harmoniously functioning patterns by action of their common synapses in the central nervous system. Hormones (*q.v.* and see also ENDOCRINOLOGY) are also very important in correlating bodily activities. For integration in mathematics see QUADRATURE.

INTEGUMENT, the external coating or skin of animals. The term is also sometimes applied to the cell membrane. In seed plants the term refers to the envelope enclosing the nucellus of an ovule (see FLOWER) and which later becomes a part of the seed coat (testa).

INTELLECT, the general term for the mind in reference to its capacity for understanding (Lat, intellectus, from *intelligere,* to understand). *See* INTELLIGENCE; INTELLECTUALISM.

INTELLECTUAL CO-OPERATION, INTERNATIONAL INSTITUTE OF. In Sept. 1921 the League of Nations, on the proposal of M. Léon Bourgeois, added to its existing technical committees an International Committee on Intellectual Co-operation, made up of distinguished scholars chosen first from 12, afterwards from 14 different countries. Its membership included, among others, Mme. Curie, Prof. Einstein, Prof. Gilbert Murray, M. Jules Destrée and Dr. Millikan. M. Henri Bergson was elected its first chairman. Prof. Gilbert Murray became president in July 1928.

The task assigned the committee was that of studying the better organization, through united international effort, of literary, artistic and scientific work. The committee soon became convinced that if it were fully to accomplish its task it must have a permanent administrative organ to prepare its programme and carry out its plans. In 1924 the French Government offered to defray for the League the expenses of such an organ, asking only in return that Paris be its seat. The League accepted the offer; and in Nov. 1925 the International Institute of Intellectual Co-operation opened its offices in Paris, at the Palais Royal.

The Institute is divided into specialized sections which are as follows:

University Relations.—This section organizes annual meetings of the directors of national university offices and of representatives of international students' organizations. It acts as an international university information office and as a link between institutions of higher education in all parts of the world. It organizes vacation courses and other facilities for foreign students; provides for equivalence of degrees, exchange of university professors, national institutes abroad and institutes of foreign studies. and international co-ordination of courses in political science and

international affairs.

Two Sections for Scientific Relations.—A. Science; B. Humanities. These sections deal with specific problems of international scientific organization, such as the co-ordination of libraries, scientific bibliographies, reference books of scientific personalities, etc. Steps are being taken to organize an international special service for libraries attached to the institute. It keeps in touch with the important scientific institutions and learned bodies, and aids them to co-ordinate their efforts. It follows closely the activities of international scientific congresses, and publishes their resolutions and other relevant information about their meetings.

Legal.—This service is chiefly engaged on problems concerning intellectual rights (copyright and scientific property) and, moreover, the legal status of international associations not formed for profit, and in liaison with the International Labour Office the economic position of intellectual workers is being examined.

Literary Relations.—This section is specially interested in the question of translation and of authors' rights, and is actively engaged in preparations for establishing an international office of translation.

Artistic Relations.—This section studies the organization, from an international point of view, of the different aspects of artistic activity. It has established an International Museums' Office which organized the successive exhibitions of engravings from national chalcographies, which was held in different European capitals in 1927, and prepared the first International Congress of Popular Arts held in 1928, in Prague.

Information Section.—This section deals with problems concerning the circulation of books, gives communications to the press and to the public, collects intellectual statistics, publishes an annual list of notable books (since 1924) and, from Jan. 1929, a review *L' Information Intellectuelle.*

Year-Books.—A plan has been drawn up to edit a series of specialized year-books, beginning with an international *Who's Who.*

The Institute has extended hospitality in the Palais Royal to various important international associations which are working in close co-operation in the same field of activity, and has offered its reception-rooms and assistance to several large international congresses.

This organ of the League of Nations is strictly international in character. Its officials belong to about 20 different nations: the director is French, the deputy-director English, the head of the section for University Relations German, that of the Scientific Relations section Dutch, that of the Legal section French, that of the Literary Relations section Swiss and of the Artistic Relations Belgian, while an Italian is head of the Information section.

The Institute does not take the initiative, but attempts to encourage, co-ordinate and assist the countless but diffuse intellectual efforts in each country and to improve the conditions of intellectual work. It aspires to be the rallying-point for intellectuals all over the world who can meet and discuss problems of common interest. (J. L.)

INTELLECTUALISM, a term applied, sometimes in a derogatory sense, to the tendency to emphasize or over-emphasize the importance of thought at the expense of feeling or volition, or even of sensation and intuition. In *moral philosophy* intellectualism tends to identify virtue with knowledge, evil with ignorance. In the *theory of knowledge* intellectualism or rationalism attaches more importance to thought than to sensation or intuition. In *ontology* it conceives the ultimate nature of reality to be some kind of intelligence, or at least regards the universe as intelligible through and through. In *psychology* it treats cognition as the primary mental function, as more fundamental than feeling or volition. In *aesthetics* it stresses the importance of the ideas expressed in, or suggested by, the object of aesthetic appreciation. In the sphere of *religion* intellectualism tends to attach supreme importance to theological doctrine or to religious philosophy rather than to religious sentiment or intuition.

INTELLIGENCE or **UNDERSTANDING** is a term that is still used by psychologists with considerable latitude of meaning. Sometimes it is used as a synonym of "cognition," that is to say, it is applied to any of the numerous processes by which knowledge is built up. Sometimes it is restricted to the conceptual processes, as distinct from processes of sense-perception. And sometimes it is used in the still more restricted sense of the process or function of apprehending relations, or even special kinds of relation. In view of the extensive use of so-called "intelligence tests" (*q.v.*) for all sorts of practical purposes, it would seem to be a matter of some urgency to determine as precisely as possible what is meant by intelligence. But that is not the view of many of the investigators in this branch of applied psychology. Some of them frankly admit that they do not know and do not care what this "intelligence" may be which they are measuring, so long as these measurements can be made use of. Others regard it as denoting the average mental ability of an individual in so far as this can be determined by a series of sample tests. Yet others identify it with some "general" ability which the individual possesses, besides certain "special" or "specific" abilities (*see* ABILITIES), and correlate the former with the general stock of "mental energy," and the latter with various "engines," into which this mental energy may be directed alternatively—whatever these physical metaphors may mean. Others again identify intelligence with the apprehension of relations of all kinds, or only with the function of apprehending connections. Lastly, ordinary everyday usage perhaps tends, on the whole, to emphasize the practical character of intelligence as consisting in the ability to employ the right means in order to achieve the various ends pursued.

The view put forward by the present writer is that the terms "intelligence" and "understanding" should be restricted to the mental function of apprehending connections. Such a conception, it is here maintained, is not only most in accord with ordinary usage, but also helps to explain most of the other uses of these terms. In order to make these points clear, it is necessary, first of all, to explain what is meant by *connections.* This term is used in the sense of causal and rational (or logical) relations, or relations of causal and rational (or logical) interdependence. All connections are relations, but not all relations are connections. Such simple relationships between things as, *e.g.,* their similarity or difference are not connections, although they may afford some sort of evidence concerning their connections. Similarly, relations in space and in time are not connections, though these likewise may furnish evidence concerning their connections. The apprehension of these simpler relations seems to call for no other mental functions than those required for ordinary sense-perception. The same processes which render possible, say, the perception of two patches of colour, also render possible our apprehension of their similarity or difference, of their local contiguity or distance, and of their simultaneity or succession. On the other hand, *connections* cannot as a rule be *perceived,* but must be *conceived.* That will explain why most psychologists restrict "intelligence" and "understanding" to conceptual processes. An example or two of our use of these terms will help to elucidate the view here maintained, and will also show its agreement with ordinary usage. By looking at the several parts of a puzzle, or of a lock, one can see their similarities and differences, and their spatial relations, also certain time relations it may be. Everybody with normal sight can perceive that much. But not everybody can grasp, or grasp equally quickly or thoroughly, the *connections* between the various parts of the lock or the puzzle. And ordinary usage would associate the term "intelligence" or "understanding" with an insight into these connections, not with the mere perception of the parts as separate items, or even with the perceptions of relations of similarity or difference, of space and time. Similarly, one would not say that anyone *understands* a proposition in geometry when he has merely learned it by heart, or has just ascertained by measurement that certain properties co-exist in a geometrical figure of a certain kind, but does not apprehend the connection between them. Nor again would anybody be said to understand an historical period or a geographical area if he had merely committed to memory a string of facts without any insight into the causes which produced them. This conception of intelligence will explain

also the common association of the term with the practical application of the right means to achieve one's ends. For it is only when one has an idea of the connections between things, that one knows what methods will produce what results. Similarly with "learning from experience," which is frequently regarded as a test of intelligence. It is only when experience has taught one the connections between things that he has really learned from it; and it is only such learning through insight into connections that is the work of intelligence—the mere formation of habits, even the acquisition of skill through mere repetition need have nothing to do with intelligence.

The apprehension of connections is a distinctive conceptual activity marked by greater spontaneity and originality than are other kinds of cognitive processes, such as sensibility, retention, and even imagination. But it depends upon all these functions for the supply of its raw materials. Similarly, though the apprehension of connections is different from, and superior to, the apprehension of other relations, yet it is usually out of the perception of these other relations (of similarity and difference, of space and time) that there emerges the apprehension of connections. The transition may be illustrated, at the lower level of intelligence, from one of W. Kohler's experiments with a chimpanzee called Sultan (see The Mentality of Apes, Eng. trans. p. 8 *seq.*). A long string was tied to the handle of a small open basket containing bananas, and pulled through a ring in the wire roof of the animal's playground so that the basket was suspended about 2 metres above the ground; the free end of the string, tied into a wide, open loop, was laid over a tree-branch about 3 metres distant from the basket, and about the same height from the ground. Sultan was then let into the playground. The animal first looked at the basket, then made for the tree, and climbed up to the loop. Watching the basket, he pulled the string till the basket bumped against the ring in the roof, and repeated the action until the basket turned over and a banana fell out. Thereupon he got down and took the banana. It looks as if the monkey, perceiving the spatial continuity between the rope and the bananas, had some dim apprehension of their connection, and acted accordingly. But even at the highest level of human intelligence, it is the perception of the other simpler relations that affords the clues to the apprehension of connections. The so-called methods of induction and the other methods of science are mainly based upon such clues.

Intelligence varies enormously in two respects, namely, in degree and in range, or in intensity and in extensity. As regards degree or intensity there must be innumerable grades between the dawning intelligence of a chimpanzee and the ripe intelligence of a great thinker. In the former case the awareness of a connection between certain things is probably too dim and vague to be described as more than a feeling; in the latter case it is clear and explicit. Intimately connected with these differences, perhaps only another aspect of them, are differences in what may be called degrees of analysis or freedom, that is, differences analogous to those between "tied" and "free" images. At the lower levels of intelligence, the connections are not yet distinguished from the terms connected, but are fused with them in one concrete situation. At the higher levels of intelligence, the connections are distinguished from their terms, and different kinds of connection may be tentatively applied to certain objects or events in order to explain them—as happens in all cases of rival hypotheses. Then, again, there are differences in the range of facts which intelligence colligates. A chimpanzee may only be able to deal with a very few facts at a time, and with these only in so far as they constitute one concrete situation. The great thinkers have attempted to colligate the infinite variety of things in one system or cosmos. And there are obviously innumerable intermediate grades possible. Differences in respect of range of intelligence are no doubt intimately connected with differences in degree or intensity, for a higher degree of intelligence stimulates an interest in a wider range of facts.

In the History of Philosophy, as distinguished from psychology, quite a variety of speculations may be said to have originated in reflections connected with the subject of intelligence. The discovery of orderliness in natural phenomena has often been regarded as evidence of the existence of some kind of pervasive intelligence in Nature. In one form or another, such a view was held by Anaxagoras, Heraclitus and the Stoics, among ancient philosophers, and by Maimon and Schelling in modern times. The whole idealistic movement in ancient and modern philosophy has, no doubt, been influenced to some extent by the thought that cosmic order presumes cosmic intelligence. In addition to these ontological speculations concerning the objective subsistence of intelligence in Nature, there are, of course, also speculations affecting the theory of knowledge. It has been argued that since connections are not perceived, but only conceived by the intellect or our intelligence, therefore there is no reason for assuming that there are any real connections among natural phenomena. Science should, therefore, confine itself to mere description, and say nothing about alleged connections. Concectedness or orderliness may be something which the human mind fancifully reads into the phenomena of Nature. Some, indeed, have gone so far as to maintain that the alleged discovery of connection or orderliness among natural phenomena is merely an artistic fancy, a veil of Maya, by means of which the human intellect at once decorates its environment and veils those brutal features which would make life unbearable. Others, again, would admit that the orderliness of Nature is indeed the work of intelligence, and that we consequently know nothing about things in themselves, though we may entertain certain beliefs about them in so far as the moral life of man seems to presume them. Perhaps the most reasonable philosophical conclusion one may draw from the development and survival of human intelligence is that there really are connections in Nature, otherwise our intelligence could hardly be an instrument of life, such as even the agnostics and the sceptics maintain that it is. It seems more reasonable to suppose that human intelligence discovers useful connections than that it invents useful delusions—however limited its powers may be.

Spearman on "The Nature of Intelligence," in *Philosophy* and *Metaphysics* (Aristotelian Society, supplem. vol. v., 1925); C. Spearman, *The* Nature of Intelligence (1924). (A. WO.)

INTELLIGENCE, MILITARY. Military intelligence includes the work of collecting, collating, interpreting and distributing information, in peace and in war, about foreign powers and their armed forces, the countering of foreign powers' efforts to obtain intelligence, and also the organization which performs these duties. Information concerning actual or potential enemies, allies and theatres of war has always been required by governments in the preparation of war plans and by commanders in the field in the preparation and conduct of active operations. Although military intelligence has played a rôle in warfare since the earliest times, its scope and technique have been steadily enlarged and perfected with each new development of human knowledge and means of communication.

Organization.—The intelligence section constitutes one of the co-ordinate sections of the general staff in the war office of most countries. Its accredited agents residing abroad are commonly called military attachés. It not only collects and collates all necessary information, but prepares estimates, maps and other material for issuance to the field forces, and makes plans for the expansion of the intelligence service in event of war and for the training of the additional personnel required. Most countries also provide intelligence sections in the headquarters of major subordinate echelons of command.

Type of Information Required.— The fighting power and possible plans of action of a foreign nation can only be gauged when accurate and detailed information is available on certain factors, the most important of which are the organization, composition, strength and power of expansion, armament, degree of training, tactics, morale and disposition of its land, sea and air forces, the characteristics of its leaders, its defensive works and fortresses, its communications, such as road, railway, waterway, port, aerodrome, cable, telegraph, telephone and wireless telegraph systems, its physical and political geography, climatic

and meteorological conditions, its man power and economic resources and the period of time required to convert them to military use. and its industrial organization, especially munitions and aviation.

Sources of Information. — The main sources from which information is derived in peace time are statistics and economic data obtained from foreign government publications, trade journals and reports, newspapers, technical works and publications, semi-official and official military publications and manuals, articles by military writers and geographical publications. Information from these sources is usually collected by means of accredited agents residing abroad or by legitimate purchase. Some.countries supplement this information by that collected by unaccredited agents who pertain, knowingly or unknowingly, to what might be called the espionage service.

Use to Be Made of Information. — The information collected in time of peace enables the general staff to prepare, and keep up to date, detailed plans for offensive and defensive operations, together with estimates of the strength, composition, armament, and supply of forces required for their execution against any power or combination of powers, with which the particular nation, either alone or in alliance with other powers, might be brought into conflict. Condensed to usable form in accordance with plans, it constitutes the essential information concerning the enemy and allied powers and the theatre of war which is required by the commander of the field forces upon the outbreak of war. It also enables a country to modify its military program, organization, armament and tactics in view of changing world conditions and foreign policy.

INTELLIGENCE IN WAR TIME

Information collected in peace time by the war office forms the basis of the plan of campaign, but must be supplemented with information concerning the enemy's mobilization, concentration and "order of battle." Since the outlaw of war by the Kellogg pact and the development of powerful and destructive armaments capable of immediate use, without a declaration of war, this supplemental information must be available in advance of actual operations. Therefore, in times of political tension the information-gathering agencies must always be on the alert in order to guard against any surprise action by a potential enemy. This entails the instant availability of an adequate aircraft warning service and plans for protection of vital industries and localities of strategic importance, for the control of subversive activities and for a public relations administration or propaganda ministry. The fact that a nation maintains these and other intelligence instruments in time of peace is an indication of its readiness for war.

In war, the greatly increased activities of the intelligence service of the war office are mainly directed to areas outside the theatre, or theatres, of operations. In the latter, the general headquarters and subordinate echelons of command are provided with an intelligence service of their own, which thus become important sources of information for the home office.

Field Organization. — In the field, the intelligence section of the highest headquarters and the intelligence sections of lower echelons within their own spheres of action, collect and collate all information regarding the enemy's forces and capabilities and the terrain, and supply to their respective commanders, staffs and fighting troops information which will assist them in preparing and carrying out plans for the defeat of the enemy. In addition, these sections endeavour to prevent the acquisition by the enemy of similar information. To be of practical value, the information supplied must be relevant, furnished in time to be of use, and in such form as will admit of its immediate use by those concerned. These conditions require the closest co-operation and mutual understanding between the intelligence and operations sections of the staff. New scientific and technical developments have placed at the disposal of the intelligence section many new collecting agencies not formerly available, but the speed of operations in modern warfare. made possible by mechanization, renders some of these practically useless in mobile situations. Intelligence in the field has become a large and intricate organization, the varied and complex nature of whose duties necessitates the employment, as assistants to the general staff proper, of a large number of highly trained specialists. It is absolutely essential that the intelligence service be elastic both in method and in organization in order that it may be quickly adjusted to changes in the character of operations.

Method, accuracy and speed are essential for the collection, transmission and collation of information, but this work is of no value unless timely deductions can be made from the evidence available. The making of deductions, estimates and forecasts both as to the probable action of the enemy and the prospect of successful operations undertaken by its own troops is the most important duty of an intelligence section. Its true function, in fact, is to represent the point of view of the enemy, for broadly speaking, it provides all information concerning the enemy and the terrain under his control, while the operations section provides similar information regarding its own troops.

Scope and Nature of Information. — The scope of the information required by each unit is that concerning the enemy and the terrain which is necessary to prevent surprise and to prepare plans and conduct operations for the defeat of the enemy. The enemy being the principal obstacle to the accomplishment of a commander's mission or task, available information should enable the commander to determine the enemy's capabilities and, if possible, his plan of action. In the past, false deductions as to the latter have frequently led to the downfall of many commanders.

Accurate and timely information concerning the enemy's "order of battle," his movements of men and war material, his tactical method, armament and equipment, the organization of his defences and rear services, his morale and the topography of the theatre of war is of the utmost importance to a commander. The relative value of these different classes of information varies with the character of operations which may change at any moment from open warfare to stabilized warfare, or the reverse.

Information regarding the enemy's "order of battle" is of paramount importance. It includes the organization, composition and strength of hostile formations, the direction of their initial concentration and subsequent movements, their distribution, morale and fighting efficiency, the character of their commanders, methods of recruiting and man power available to replace losses. The identification of units is the foundation of all "order of battle" intelligence. Movements of men, supplies and material on a large scale normally portend some important development or a change of the enemy's plans, but as they must take place along organized lines of communication they are difficult to conceal. Detailed knowledge of the enemy's communications systems and means of transport is therefore essential; the capacity of railways, quality of roads, navigability of waterways at different seasons, system of aerodromes and auxiliary landing fields must be carefully studied if reliable conclusions are to be drawn regarding the size of any movement and the time required for its execution.

Full information regarding the tactics and armament of the enemy at the outbreak of war is usually available by the study of his peace training and organization; but his methods of employing troops and their weapons during the progress of operations must be followed very closely in order to discover new developments and prevent surprise.

In total warfare the entire resources of a nation are available and under the control and direction of the state. The status of the mobilization of industry and the availability or lack of strategic raw materials are known in a general way at the outbreak of hostilities; but the rate of attrition must be studied throughout the campaign in order to gauge the enemy's staying power.

Sources and Means of Collecting Information. — In the theatre of operations the main sources of information are prisoners, deserters, local inhabitants, captured documents and material, ground reconnaissance and observation, intercepted enemy signal communications, air reconnaissance and photography, maps, the enemy and neutral press and broadcasts and agents. The principal agencies for its collection are ground troops and aviation,

the signal intelligence service, artillery observation troops, aircraft warning service and the espionage service. The information, whether positive or negative, acquired by contact with the enemy is that on which every commander mainly relies in making his tactical plan. Hence, to keep the enemy under such close and continuous observation that he can make no movement without being detected is the primary object of all reconnaissance, whether on the ground or from the air.

The examination of prisoners of war, deserters, inhabitants, captured documents and material is usually done in a systematic manner, especially in stabilized situations. It is done not only for the purpose of developing information of immediate tactical importance but for the purpose of determining the enemy's tactical methods, "order of battle," morale, economic conditions and, in the case of material, the improvements in armament and supply.

Ground reconnaissance missions are usually given for the purpose of determining information of the terrain and the enemy. Fast-moving mechanized units and cavalry perform the more distant missions while the infantry provides the close-in patrols, raiding parties and observation from fixed observation points. In stabilized situations visual observation from fixed posts is highly organized for the detection of all enemy activity within its field of view. Trained observers, provided with special equipment and so placed and co-ordinated that the exact location of the enemy activity recorded can be determined by intersection, constitute an integral part of the intelligence sections of the more important headquarters. The artillery maintains a surveillance over the enemy artillery by means of sound and flash ranging. The signal intelligence service maintains a surveillance over its own and the enemy's signal communications.

Information from the air is derived from balloon observation, aeroplane reconnaissance and air photography. The development of air reconnaissance and photography has to a great extent revolutionized military intelligence in the field. Aviation now plays a decisive rôle in long range strategical reconnaissance and a major rôle in tactical reconnaissance. It is most effective when closely co-ordinated with ground reconnaissance and the other information-gathering agencies. The camera has made it possible to obtain, particularly in position warfare, a far more detailed and exact knowledge of the enemy's system of defence, communications and supply than has ever been possible before. It also provides information necessary for the preparation of maps and the correction of existing maps. The principal weaknesses of air reconnaissance are that it is dependent to a certain degree upon weather, is of limited value at night and in areas provided with excellent cover such as woods and dense brush, and is very vulnerable to anti-air activity. Balloons are very vulnerable to attack from the air and must be protected.

The enemy and neutral press and broadcasts are important sources of information. This is especially true in countries which do not impose strict censorship, but to a less extent in those countries which do. Important troop movements and plans are sometimes revealed as are economic and morale conditions in the enemy's homeland. Losses may also be computed from the published casualty lists.

Maps constitute the most important source of information of terrain in the theatre of war. Peace time editions must be corrected and brought up to date as operations progress. Much data for this work are procured by photography.

Agents of the espionage service supply information regarding matters behind the enemy's front arid in his home territory, including strength and location of reserves, rear defences and lines of communication, internal conditions in the enemy's country and the state of his resources in man power and material. Much of a fictional nature has been written of this phase of intelligence work, which has a great appeal for many imaginative individuals. The duties of the espionage service, the procurement of information by illegal means or otherwise, are similar in peace and war. War increases the importance, difficulties and danger of the work. Agents work at an assigned station or on general roving commissions. They penetrate into enemy territory through the ports, in the guise of peaceful neutrals armed with all the necessary papers, or get there by other means, which in mar include penetrating the enemy lines in uniform, landing behind the lines in civilian clothes, or slipping through the frontier from a neutral country. False papers, disguises, secret ink and all the other tricks beloved of the spy novel may form part of their equipment, but in practice, the most dangerous and efficient spy is the least sensational in his methods and the one who can show a legal justification for his presence and reasonable explanation of his activities.

Counter-intelligence.—Counter-intelligence includes all those measures intended to nullify, break up or deceive the enemy's intelligence service. Among others these measures include counter-reconnaissance, ruses, secrecy discipline, concealment by use of protective colouration and natural and artificial cover, signal communication security by means of codes and ciphers, censorship of all communications, the press and radio, counter-propaganda to defeat the enemy's attempt to influence the civil population and the armed forces and counter-espionage.

Ruses have been utilized since the earliest times to deceive and mislead the enemy as to one's intentions, with the object of falling upon him by surprise. The methods employed have varied but the results of success, the destruction of the enemy, have been uniform. According to legend, it was by means of a wooden horse that the Greeks were able to enter and capture the walled city of Troy. In the Palestine campaign of 1918, it was by means of a carefully executed plan of deception that General Allenby was able to lead the Turks to believe their left flank threatened, while, in fact, plans for a penetration of the right and the destruction of their army were being perfected.

The duties of the counter-espionage service are to prevent the leakage of military information, and to destroy the enemy espionage service. The methods employed vary when carried out in home territory, in enemy territory or in allied territory. In the home territory it may be assisted by the police, censorship, port control, hotel registration, and by arbitrary barriers such as prohibited areas, as well as all the other preventive measures developed after years of experience in combating enemy espionage activities. In occupied enemy territory, the intelligence service is assisted by all of these powers, and. in addition, has the arbitrary powers of an occupying army. Its operations are more difficult, however, for the whole population is potentially hostile. In allied territory the difficulties are even greater, as it is the ally who controls in his own territory all the real preventive machinery.

A surveillance is maintained over secrecy discipline within the armed forces with a view to prevent gossip about impending operations, indiscreet conversations, rumours, misuse of code on telephones, telegraph and wireless, the marking of railway cars, trucks and billets with inscriptions giving identification of units, indiscretion in correspondence, careless handling of confidential papers and books, the taking of unauthorized articles into the front lines, on patrol or on reconnaissance, and the wearing of identifying badges or insignia.

(P. M. Rt.)

INTELLIGENCE IN ANIMALS: see Animal Behaviour; Comparative Psychology.

INTELLIGENCE TESTS. An intelligence test or intelligence examination is an instrument to measure the amount of intelligence shown by a human being or a lower animal. The instrument consists of a series of questions to be answered, or directions to be followed, or things to be learned, or intellectual tasks of any sort to be performed. Intelligence or intellect may be defined as the ability to perform intellectual tasks; and an intelligence test is a specially instructive sampling of such tasks.

Sample Tests.—The tasks shown below are representative of those used in standard intelligence tests.

"Show me your nose. Put your finger on your nose." Same with eyes, mouth and hair. Three responses out of four must be correct.

What is the difference between: (a) Laziness and idleness; ***(b)*** Evolution and revolution; (c) Poverty and misery; (d) Character and reputation.

Repeating three digits. After some explanation and practice, the person tested is asked to say 6-4-1, then to say 3-5-2, then to say 8–3–7. The test is passed if one series out of three is repeated without error, after a single hearing.

Repeating six digits reversed. The series used are 4-7-1-9-5-2, 5-8-3-2-9-4 and 7-5-2-6-3-8. The test is passed if one series out of three is repeated without error.

Tom runs faster than Jim. Jack runs slower than Jim. Which is the slowest of the three?

After some explanation and practice, the person tested is asked to "Finish what I say." At night you sleep in . . . Mary has a ring on her . . . You wear gloves on your . . . You wear a . . . on your head.

A person who has been tested in respect of an examination consisting of from 50 to 200 such tasks may be given a score, and so be put in comparison with all others who have been tested with the same collection of tasks.

Intelligence Quotient.— Subject to certain limitations, the score may be expressed in terms of a mental age, that is, the age at which the average child is able to attain it. Thus if John Doe, aged 12.0, scores 118 in the National Intelligence Examination, and if the average child of age 13·1 attains a score of 118 in this examination, John Doe has a mental age of 13·1 years. John Doe's intelligence quotient, or I.Q. is his mental age×100 divided by his chronological age, that is $\frac{13\cdot1\times100}{12\cdot0}$ or 109.

This form of statement is useful for individuals whose scores are not higher than those made by the average child of 14, and whose chronological ages are not over 18. For higher levels and later ages the method is of doubtful value.

The score may also be expressed in terms of the percentage of some defined group who would attain lower scores than it. Thus, if 71% of persons aged 12·0 score lower than 118, and 29% score higher, in the National Intelligence Examination, John Doe may be recorded as in the 71 percentile for his age. This method is especially useful in the case of the higher levels of intelligence and adult ages A more refined measure of this type expresses any individual's score as a plus or minus deviation from the average for some defined group in terms of the variability of that group as a unit.

Systems in Use.—There are 30 or more such intelligence examinations now in use. Some, like the Pintner-Cunningham Primary Tests, are adapted to measure very young children aged two to five years. The National Intelligence Examination is designed to fit the intellects of the level of ordinary children from 9 to 15. The Terman Group Test is especially suited to measure young people from 14 to 20. Some, like the Thorndike Examination for High-School Graduates, are adapted to measure gifted adults. Some, like the Army Group Examination Alpha, require an ability to read and write; some, like the Binet, are given orally; some. like the Army Beta, are largely independent of language. Some, like the Otis Group Intelligence Scale, measure chiefly intellect as it operates with words and numbers and abstract relations; some are more concerned with information about things and persons. In some, the speed of response counts a great deal in determining the score made; in others, it counts very little, the time allowed being sufficient to permit almost everybody to do almost everything of which he is capable.

Historical Development.— Existing instruments for measuring intelligence developed from three roots: the tests of sensory acuity, memory, attention and the like devised in the early history of psychology; the interview, as of physician with patient or employer with candidate for employment; and the school examination. Galton, Cattell and Binet were pioneers in this field of psychology. Sir F. Galton's *Inquiries into Human Faculty* (1883) presented the general problem of the measurement of individual differences; and he soon thereafter set up in the South Kensington Museum in London a laboratory where any person could be measured in a series of physical and mental traits. Under the influence especially of Cattell, many short examinations or "tests" of special mental powers were devised and rather widely used in the United States from 1890 on. Important work was done by Kraepelin and Ebbinghaus in Germany. An eminent French psychologist, Alfred Binet, using the general form of an interview between physician and patient, enriched by suggestions from psychological tests proper, produced in 1905 what may be called a standardized interview, consisting of 30 questions and tasks, many of which were chosen from the tests of special powers now familiar to all psychologists. This "metric scale of intelligence" was further improved and divided into age levels in 1908, and finally revised in 1911. Many variations of it have been used in different countries.

While Binet was developing a scientific interview and record and score, various psychologists in America were testing children in groups by means of printed collections of tests. The next step was the arrangement of such a collection in a standardized unitary examination, after the general plan of written examinations in school subjects. One of the earliest and by far the most influential of such arrangements was the group examination Alpha prepared in 1917 for measuring recruits in the U.S. Army. This examination was taken by nearly 2,000,000 men, large groups (sometimes over 1,000) being sometimes examined at one time and place.

Modes of Use.—Since then, intelligence examinations have increased rapidly in number, have become diversified in nature, and have been much improved in respect of convenience in giving and scoring. They are widely used, especially in the United States, as an aid in the proper grading and classifying and treatment of school children; and in studies of special groups such as defectives, delinquents and dependents. The methods used in conducting intelligence examinations are also being applied to examinations in school subjects, producing the so-called "new-type" examinations and educational achievement tests. At least 1,000,000 such examinations were made in the case of school children alone in the year 1925. Some of the leading American universities require an intelligence examination as a part of the general admission requirement.

In spite of notable improvements during the last 20 years, existing instruments for measuring intelligence suffer from serious deficiencies. An intelligence examination is still a more or less undefined collection of tasks, its score is still a somewhat arbitrary summation of credits, and the correspondence of the scores to the abilities which they purport to measure is still far from perfect. Psychologists are working to supply these deficiences, seeking to replace the undefined collections of tasks by tasks rigorously defined in nature and graded by a true scale of intellectual difficulty, so that the score may mean the precise height of intellectual difficulty which the person in question can master *(see* EXAMINATIONS).

INTENDANT, in certain countries an official title having the same general sense as "superintendent" (from Lat. *intendere,* to apply the mind to, watch over). Thus in Germany it is applied to the head of public institutions, *e* g., State theatres, and in both France and Germany to certain military offices connected with the *intendance militaire* and *Intendantur* respectively, *i.e.* the equivalents of the British quartermaster-general's and financial departments of the War Office.

In France the name was used in early times to designate a functionary invested by the king with an important and durable commission. The most famous of these functionaries, however, the intendants of provinces *(intendants des provinces)* date from the last thirty years of the 16th century. Originally used to restore order after the civil wars, their functions were at first extraordinary and temporary; but a few were retained as permanent state officials, and in time they came to be fairly generally distributed over the kingdom. The existing territorial divisions were kept, each *intendant* being placed over a *généralité,* save where slight modifications were necessary for administrative purposes. In the 13th and 14th centuries the monarchy had organized a species of inspection (*chevauchée*) over the provincial functionaries, which was performed by the *maîtres des requêtes.* In the 16th century this inspectorate was revived and passed to the *intendant,* who became the resident supervisor of the other functionaries in his district; its connection with the old *chevauchée*

is plainly shown by the fact that the intendants were almost always selected from the *maitres des requêtes.* The early intendants had naturally been largely concerned with the troops; eventually special military intendants (the only ones that exist in modem French law) were created, but the *intendants des provinces* retained certain military duties.

The early intendants were called indifferently *intendants de justice* or *intendants de finances.* Their powers were fixed by the commission they received from the king, whose direct general representatives they became in each *généralité,* with authority over the other officials, whom they were empowered to censure, suspend, or sometimes even replace. They were in constant touch with the king's council, with which they were connected by their original rights as *maîtres des requêtes.* In the first half of the 17th century they met with some opposition from the governors of provinces, who had formerly been the direct political representatives of the crown, and also from the parlements, which traditionally intervened in the administration, especially by means of *arrêts de règlement* (decisions, from which there was no appeal, regulating questions of procedure, civil law, or custom). The intendants, however, were energetically supported, and so complete was their triumph that in the 18th century governors of provinces could not enter upon their duties without formal *lettres de rksidence.*

The intendants had wide powers in the drawing by lot of the militia and in the royal *corvées* for the making and repair of the high roads, and were largely concerned with the administration of the *taille,* in which they effected useful reforms. They were the sole administrators of the principal direct and indirect imposts created in the second half of the 17th century and in the 18th century, and had full powers to settle disputes arising out of these taxes. Owing to the vast size of the districts allotted to the intendants (there were no more than 32 intendants in 1788), they were allowed to delegate their powers to *sub-délégués,* who were, however, not royal officials, but merely mandatories of the intendant. Decisions of the intendant could be carried to the king's council, and those of the *sub-délégué* to the intendant.

See Gabriel Hanotaux, *Origines de l'institution des intendants des provinces* (1884); D'Arbois de Jubainville, *L'Administration des intendants d'après les archives de l'Aube* (1880).

INTENT, in law, the purpose or object with which an act is done. The question of intent is important with reference both to civil and criminal responsibility. Briefly, it may be said that in criminal law the constituent element of an offence is the *mens rea* or the guilty intent. The commission of an act without the intent is not, as a general rule, sufficient to constitute a crime, nor, on the other hand, does the existence of a guilty intent without commission of the act amount to the legal conception of a crime (*see* CRIMINAL LAW). In the case of civil wrongs, in general, the opposite holds good. A wrongful act done to the person or property of another carries with it legal liability, irrespective of motive with which act was done (*see* TORT). (W. DE B. H.)

INTER-ALLIED CONTROL IN WAR: *see* WAR CONTROL OF FOOD; WAR CONTROL OF SHIPPING; ALLIED MARITIME TRANSPORT COUNCIL.

INTER-ALLIED DEBTS. An examination of the methods by which the Allies financed the cost of the World War (that is to say, the difference between normal pre-war expenditure and actual expenditure for the period 1914–19 inclusive) can only give approximate results, but it is estimated that of the total war expenditure 6% was met by taxation, 77·2% by home borrowing, 14·5% by loans between the Allied Governments themselves and 2·3% by borrowing in other foreign countries. In general the funds placed by the Allies at each other's disposal were utilized, not for internal expenditure by the borrowing country, but for purchase in the lending country of military stores and supplies and, in certain cases, for exchange stabilization and interest payments on pre-war external loans. At one time or another during the war all the Allies employed this means of obtaining funds abroad, but only three of the Allied and Associated Powers acted to any appreciable extent as lenders, namely Great Britain, the United States of America and France, the advances made by Italy being comparatively unimportant. It is extremely difficult to arrive at any accurate estimate of the total sum of these transactions, as the statements published by the various Governments are computed on different bases. In the cases, however, of Great Britain and the United States all the large debts have been funded, with the exception of those due from Russia, so that it is possible to attempt some survey of the whole question. It was only in 1927 that France began to collect the debts due to her and in many cases the amount of these debts is still in dispute.

I. STATEMENT OF LOANS AND FUNDING AGREEMENTS

Great Britain.—For Great Britain the figures in Table II. are taken from the Financial Statement of the Chancellor of the Exchequer, House of Commons report No. 84 of 1925, but the figures in most cases were altered on final adjustment and are only approximate. The Belgian pre-Armistice debt of £110,000,000 is not given, as, under the Treaty of Versailles, this was a charge on German reparations. The figures do not include loans made to the Dominions for war purposes, but do include advances made to certain new and ex-enemy states as well as to Allies, in the period immediately following the war.

Great Britain's only debt to another Allied Government was that of $4,277,000,000 to the United States. As will be seen from the above, her advances to Allies greatly exceeded the amount borrowed from the United States.

United States.—The United States was a creditor only; and after her entry into the war in April 1917 incurred the main responsibility for financing the Allies, among whom Britain was the principal debtor. After the Armistice large sums were provided by the American Government for relief credits in Central Europe and for purchases of war stores. Table I. shows the total loans to the Allies and other Governments as given in the annual statement of the Secretary of the United States Treasury for 1927.

The majority of these loans have since been the subject of funding agreements, as the following official statement shows: —

TABLE I. *Funding Agreements of Certain Countries with the United States*

Country	Date of funding agreement	Total original indebtedness (principal)	Total debt as funded
		$	$
Armenia	..	11,959,917.49	16,627,153*
Austria	..	24,055,708.02	34,150,106†
Belgium	18 8 25	379,087,200.43	417,780,000
Cuba	..	10,000,000.00	Repaid
Czechoslovakia	13 10 25	91,879,671.03	115,000,000
Estonia	28 10 25	13,999,145.60	13,830,000
Finland	1 5 23	8,281,926.17	9,000,000
France	29 4 26	3,404,818,045.01	4,025,000,000
Great Britain	19 6 23	4,277,000,000.00	4,600,000,000
Greece	..	11,000,000.00	19,659,830*
Hungary	25 4 24	1,685,835.61	1,939,000
Italy	14 11 25	1,648,034,050.00	2,042,000,000
Latvia	24 9 2;	5,132,287.14	5,775,000
Liberia	..	26,000.00	Repaid
Lithuania	22 9 24	4,981,628.03	6,030,000
	..	431,849.14	299,128*
	14 11 24	139,666,972 39	178,560,000
Rumania	4 12 25	37,922,675.42	44,598,000
Russia	..	192,601,207.37	280,197,301*
Yugoslavia	3 5 26	51,758,486.55	62,850,000
Total	..	10,338,323,597.20	11,872,596,524

*Not funded: debt as on Nov. 15, 1927.

†Time of payment of principal and interest extended to June 1, 1943, by authority of Joint Resolution of Congress approved on April 6, 1922. Debt as on Nov. 15, 1927.

France. — The position of France, which, like Great Britain, was both a borrower and a lender, is more obscure. It was only in July 1929 that France ratified the funding agreements made with either Great Britain, from whom she borrowed £446,226,000, or the United States, from whom she received $3,404,000,000. On the other hand, she advanced considerable sums to Russia and the smaller Allies; here, too, no refunding arrangements have been made, and in many cases the exact amount is in dispute.

TABLE II. GREAT BRITAIN: 1. *War Debts*

Country	Original Advances*	Debt as funded† (including interest added to capital)	
	£	£	
1. France	446,266,000	600,000,000	
2. Russia	483,321,000	783,000,000	(Debt on March 31, 1927.)
3. Italy	369,824,000	570,000,000	
4. Yugoslavia	22,383,000	25,591,000	
5. Rumania	16,401,000	18,448,000	
6. Portugal	15,611,000	20,134,000	
7. Greece	16,391,000	21,441,000	
8. Belgium: Pre-Armistice	90,084,000	99,133,000	(Pre-Armistice debt as on May 1, 1921, taken over by Germany.)
do. Post-Armistice	6,799,000	..	(Post-Armistice debt repaid in cash.)
	1,467,040,000	2,137,747,000	
2. *Loans for Reconstruction and Relief*			
	£	£	
1. Belgium	9,000,000	9,000,000	
2. Belgian Congo	3,550,000	3,550,000	
3. Austria	11,578,000	12,727,000	(£2,250,000 repaid in 1923: balance postponed until 1943.)
4. Rumania	1,892,000	2,200,000	
5. Yugoslavia	1,884,000	2,069,000	
6. Poland	3,682,000	4,770,000	
7. Czechoslovakia	461,000	474,000	
8. Estonia	241,000	251,000	
9. Hungary	109,000	109,000	
10. Armenia	88,000	125,000	
11 Lithuania	17,000		(Repaid in cash.)
12. Latvia	20,000		do.
	32,522,000	35,275,000	
3. *Loans for Stores and Repatriation (Post-War)*			
	£	£	
1. France	8,226,000	8,226,000	(£5,976,000 repaid by 1927)
2. Latvia	1,303,000	1,303,000	(Interest waived.)
3. Estonia	917,000	917,000	do.
4. Czechoslovakia	827,000	827,000	do.
5. Lithuania	348,000	150,000	do.
6. Poland	174,000	174,000	do.
7. Greece	108,000	108,000	do.
8. Rumania	36,000	36,000	do.
9. Armenia	747,000	1,001,000	do.
	12,686,000	12,940,000	
Total	1,512,248,000	2,185,764,000	

*See Hansard (House of Commons) July 23, 1925, Col. 2445–6. (The figures were in most cases altered on final adjustment and must be regarded as approximate.)

†See published Funding Agreements: the amounts of the gold deposits (viz., France £53,500,000, Russia £60,000,000 and Italy £22,200,000) are deducted.

The Budget Project for 1928 set forth the debts owing to France by various foreign countries, as of Dec. 31, 1926, as follows:—

	Francs
(1) *Debts in French Currency*	
Russia (Tsarist Govern[illegible])	7,008,928,000
Russia (various local Governments)	416,233,000
Yugoslavia	1,946,042,000
Rumania	1,050,000,000
Greece	812,457,000
Poland	1,047,120,000
Czechoslovakia	474,124,000
Italy	1,145,737,000
Portugal	9,050,000
Lithuania	8,800,000
Hungary	319,000
Austria	379,000
Georgia	200,000
Albania	1,800,000
	fcs. 13,921,189,000

(2) *Debts in Foreign Currencies*		
Russia (various local Governments)	gold roubles	10,533,145
Czechoslovakia	dollars	1,149,000
Italy	lire	16,983,000
do.	£ sterling	18,826
Austria	dollars	16,000,000
do.	lire	35,000,000

Except in the case of the franc debt of Tsarist Russia the figures apparently exclude interest. No account is here taken of counter-claims which are of considerable importance in certain cases.

Italy. — Italy was in the main a borrower, although to some extent she made advances to other Allies. After her entry into the war in May 1915 she borrowed from Britain £369,824,000 and from the United States $1,648,054,050. According to official figures her loans to other Allies were as follows, but certain of the items in the French account are in dispute. Foreign currencies are converted at the rates ruling on April 23, 1926:—

	In thousand lire
Rumania	189,936
France	292,380
Russia	63,000
Yugoslavia	56,000
Greece	5,000
Austria	1,730,000
	2,336,316

Russia. — Russia, on the other hand, was entirely a borrower. Her loans from Allied Governments up to the time of the revolution in 1917 were as follows:—

Great Britain	£483,321,000
United States	$187,729,750
France	fr. 6,023,300,000
Italy	lire 36,045,000

Other Allies.—Belgium was also a borrower, and received considerable sums from the United States, Great Britain and France. As a recognition, however, of the damage done consequent on the violation of the treaty of 1839, Germany undertook in Article 232 of the Treaty of Versailles "to make reimbursement of all sums which Belgium has borrowed from the Allied and Associated Governments up to Nov. 11, 1918, together with interest at the rate of 5% per annum on such sums." At the time of the Peace Conference the representatives of Great Britain, France and the United States agreed, subject to ratification by their Governments, to accept German bonds to the value of the Allied pre-Armistice loans to Belgium thus freeing Belgium from the responsibility of these debts. This was eventually carried out by Great Britain and France. The United States Congress, however, refused to ratify the agreement, and the pre-Armistice debt was the subject of a special arrangement in the subsequent Belgian Debt Funding agreement. For the sake of convenience, the following table gives the advances made by each of the Allies during both periods:—

	Pre-Armistice	*Post-Armistice*
Great Britain	£110,000,000*	£18,500,000
United States of America	$171,780,000	$207,307,200
France	fr. 3,219,474,742*	fr. 241,472,300

*Including interest at 5%.

Of the other Allies, Rumania, Yugoslavia, Greece, Portugal, Armenia, Nicaragua and Liberia were all borrowers, while after the Armistice the new states of Poland, Czechoslovakia, Finland, Lithuania, Latvia and Estonia received advances for various purposes, and Austria and Hungary, of the ex-enemy states, received relief credits. The actual amounts lent can be seen from the preceding tables.

II. HISTORY OF THE LOANS

Any attempt to trace in detail the development of Inter-Allied borrowings, of which the above official figures represent the present position, must be one of great difficulty. For a considerable part no authoritative information has been made available as to the dates at which these various obligations were incurred, and the figures given in the following survey must be taken as mere estimates. For the sake of convenience the history of these loans may be divided into three periods:—

First Period: 1914–17.—Up to the end of 1914 the various Allies were able in the main to finance their own foreign purchases. Russia, however, soon found herself in difficulties. Unlike Great Britain and France, her Government was unable to command large funds abroad, while her incapacity to manufacture munitions on a sufficiently large scale necessitated heavy purchases from her Allies. In addition, considerable sums were required for the payment of interest on the existing external debt. As early as Oct. 1914 she had been forced to apply to the British Government for assistance, and a credit of some £11,500,000 was opened on her account at the Bank of England against a shipment of gold to the value of £8,000,000. At the end of the year a further credit was granted, and in Feb. 1915 at a meeting in Paris the British, French and Russian Finance Ministers agreed to unite their financial resources, to share the advances made to Allied Governments, to issue a joint loan and to co-operate in the purchase of supplies abroad. Actually the second proposal was never carried out, but as a result of this and subsequent conferences large funds were raised for Russia in both France and England by the sale of Russian Treasury Bills on the open market and by the extension of governmental credits against a small proportion of gold from the Russian reserve. It is estimated that Russia, during the period 1914–Sept. 1917, borrowed £483,000,000 from the British Government, against a deposit of gold in London of £60,000,000, and 6,000,000,000 fr. from the French Government. She also obtained advances from the United States Government between the months of April and Sept. 1917. In the United States and Japan, moreover, considerable sums were placed at her disposal by the British Government.

The next country to find difficulty in financing its war requirements abroad was France. In Oct. 1914 she had found it advisable to arrange for the issue of Treasury Bills on the London market. By May 1915 some £10,000,000 worth of these bills had been placed, and by the end of that year the figure of open market borrowings had risen to £33,000,000 and to £80,000,000 in 1917. In May 1915 it was agreed that the British Government should grant France substantial credits against shipments of gold in the proportion of three to one. This system lasted until the end of 1916, when the shipment of gold ceased. During the same period France raised considerable sums on the American market, of which the most important was the joint Anglo-French loan for $500,000,000 in Oct. 1915, repaid in 1920. France, during this period, borrowed altogether nearly £200,000,000 from the British Government and dispatched to London some £53,500,000 in gold. To the other Allies the French Government lent approximately 6,500,000,000 francs.

Great Britain during this period loaned to her Allies over £900,000,000. In addition to the above-mentioned advances to France and Russia, £60,000,000 were advanced to Belgium and £27,000,000 to Rumania, Serbia, Greece and Portugal. Up to Oct. 1915 Great Britain had not had occasion to borrow in the United States, but it was found impossible to maintain the American exchange unless funds were available to cover the greatly increased purchases there of war materials. The joint Anglo-French loan was raised on the market without other security than the credit of the two governments, but all moneys subsequently raised in America during this period took the form of credits or secured notes, collateral being deposited in each case. For this purpose the British and French Governments encouraged their nationals either to sell or lend to the Government their holdings of American securities, which were either sold for dollars or employed as collateral.

Italy did not enter the war until May 1915, and from then until the end of this period confined her borrowing to the United Kingdom (with the exception of a small amount raised in Canada). Credits to the extent of some £153,000,000 were granted to her by the British Government, gold to the value of £22,200,000 being deposited in London as security. On the other hand, she herself advanced about 63,000,000 lire to Russia. Her advances to France during this period are in dispute.

The Second Period.—This dates from April 1917, when the United States entered the war, till the Armistice in Nov. 1918. Towards the end of the previous period the Allies were beginning to grow anxious as to their ability to continue the purchase of supplies in America on the then existing scale for an indefinite period. Accordingly, one of the first acts of the United States Government after the declaration of war was to obtain the consent of Congress to a law (Liberty Loan Act) authorizing the extension of credits to Allied Governments up to a total of $3,000,000,000. This limit was subsequently raised three times up to a total of ten thousand million dollars in July 1918. Such credits were granted without any collateral and they were to bear the same rate of interest and be subject to the same conditions as the corresponding bonds to be issued on the United States market in order to raise the sums required. From that time the American Government assumed the responsibility for Allied purchases in the United States. Market borrowings by the Allies ceased with the exception of certain small amounts required for the purpose of refunding existing market loans, some of which, however, were also paid off with the funds obtained from the new credits.

The total advances by the United States Government to the governments of the Allies amounted during this period to some $7,077,000,000, of which Great Britain received approximately $3,696,000,000, France $1,970,000,000, Italy $1,030,000,000 and Belgium $171,780,000. The Provisional Government of Russia (successors to the Tsarist Government) received $188,000,000 between April and Nov. 1917. Smaller Allies account for the remainder. During the same period the British Government continued to finance the requirements of the Allies in the United Kingdom, and also assisted them by the employment to a certain

extent, of the credits extended to her in America. These credits were principally employed for the purchase there of raw materials required for the manufacture in the United Kingdom of war supplies for the Allies. For, as the needs of the United States army increased, her ability to meet all the Allied requirements decreased to some extent, and Great Britain endeavoured to take her place. In Aug. 1918, however, it was arranged that each Ally should be debited by America with the cost of the necessary raw materials. In addition, during the early part of 1917 Great Britain advanced funds from her American credits to the Russian Government for interest payments due in America. Total loans by Great Britain to her Allies during these years amounted to over £550,000,000, of which France borrowed nearly £250,000,000, Italy £220,000,000 and Belgium £50,000,000. France, on the other hand, in addition to the advances made by Great Britain, borrowed nearly $2,000,000,000 from the United States, and loaned to her other Allies nearly 7,000,000,000 francs. Italy, Russia, Belgium, Serbia and Rumania were all borrowing nations.

Third Period: Nov. 1918–Sept. 1920.—Although the Armistice was signed on Nov. 11, 1918, nearly two years elapsed before it was possible for the lending Governments to cease making advances to the other Allies for the payment of goods already supplied or ordered. They were also required to enable the Allies to purchase war stores left by the lending Governments in their territories. In addition, the impoverished condition of Europe made it essential, if complete economic chaos were to be avoided, for relief credits for the purchase of foodstuffs and for reconstruction to be granted not only to the poorer Allies but also to certain of the new states created by the peace treaties, and even to some of the enemy countries.

In the United States there was some doubt after the Armistice as to the legality of granting further credits under the Liberty Loan Acts. These Acts limited credits to the period of the war, and Congress had refused to approve any prolongation. On the other hand, the presidential proclamation announcing the official termination of the war was not published until July 2, 1921, and the Administration felt themselves justified in continuing to make advances during the intervening period. The balance of $2,500,000,000 authorized under the Acts was, in this way, advanced to the Allies and utilized by them partly to meet existing contracts in America and partly for the purchase of supplies for the relief of Europe. Moreover, special credits were granted with the approval of Congress to the extent of $740,000,000, of which $600,000,000 were utilized for the sale of war stores to Allied Governments, and $140,000,000 for the sale of flour through the United States Grain Corporation. To this must be added a revolving credit of $100,000,000 opened in favour of the American Relief Administration, of which $84,000,000 was expended for relief supplies furnished on credit.

Relief and reconstruction loans by the British Government amounted during this period to £32,522,000, loans for the purchase of war stores to £12,205,200 and for the repatriation of prisoners to £1,450,000. Similar advances by France amounted to some 1,500,000,000 fr. and by Italy to approximately 600,000,000 lire.

III. THE DEBT SETTLEMENTS

Before even the last inter-Ally loans had been made, it was clear that the problem of repayment would assume an importance in international politics second only to the question of reparations. Soon after the Armistice it became known that the British Government favoured a general cancellation of inter-Ally debts, but the United States was not prepared to agree to such a course. In May 1920 the inter-Ally Conference on Reparations at Hythe declared that it was "important to arrive at a settlement which will embrace the whole body of the international liabilities which have been left as a legacy of the war, and which will at the same time ensure a parallel liquidation of the inter-Ally war debts and of the reparation debts of the Central Empires." This was followed, however, a few days later by a statement by the Chancellor of the Exchequer in the House of Commons to the effect that the question of the United Kingdom debt to the United States of America was being dealt with independently of any question of the part of this country's share of indemnity from Germany. By 1922 the different points of view of the various Allied and Associated Powers on this subject became clearly defined. On Feb. 9 of that year the American Foreign Debt Funding Bill was signed, authorizing the refunding of Allied debts to the extent of $11,000,000,000 into securities with a maximum currency of 25 years, carrying interest at a rate of not less than $4\frac{1}{4}\%$, the negotiations to be carried out by a commission of five members (subsequently increased to eight) under the chairmanship of the Secretary to the Treasury. It was, at the same time, made clear that the United States Government would not consider the remission of debts due to them from the Allies but would look for repayment, though it was recognized that immediate payments would not be possible in every case. This action had a determining effect on the attitude of the Powers concerned towards the whole problem of inter-Ally debts.

The Balfour Note.—Great Britain, which had hitherto made no final pronouncement of policy, was now faced with the necessity of funding her debt to America, and consequently compelled to lay down a principle for dealing with her own debtors. Accordingly, on Aug. 1, 1522, a Note was dispatched to the Governments concerned which has since formed the basis of British policy. In this communication, commonly known as the "Balfour Note," it was stated that, while Great Britain would have been willing to forego all claims for reparations and the repayment of inter-Ally debts if this had formed part of an universal settlement, she must now ask for some measure of repayment. She would, however, be content with a total sum from her Allies and Germany sufficient to cover her own payments to the United States, though this was equivalent to only one quarter of the amount due to her. The French reply in Sept. was inconclusive and unsatisfactory, and the policy of that country was definitely revealed in Oct. at a meeting of the Reparations Commission.

At this meeting certain proposals were submitted by the British delegate for the settlement of the reparations problem, provided that the question of inter-Ally debts was settled at the same time. The French delegate rejected this scheme and put forward a counter-proposal which definitely made the payment of inter-Ally debts dependent on receipts from reparations. At the inter-Allied Conference in London in Dec. 1922 Signor Mussolini, on behalf of Italy, proposed the cancellation of part of Germany's reparation liability if Great Britain would agree to the cancellation of the debts due to her from her Allies. Poincaré elaborated this scheme and offered to hand over forthwith part of the French claim on Germany in payment of her debt to Great Britain and to accept similar terms from her own Allied debtors. Both these proposals were rejected by Bonar Law. The discussion was continued at the Paris Conference on Reparations in Jan. 1923. At this conference the French Government reiterated the principle of the dependence of inter-Ally repayments on German reparations.

The British proposal, which was contingent on the acceptance of their plan for the solution of the reparations question, rested on the basis of the remission of all European Allied debts to the United Kingdom except a small percentage which was to be paid in German obligations, while all German payments over a fixed minimum were to be available for the repayment of European debts to the United States. The failure of the Paris Conference, which was followed by the French occupation of the Ruhr, marked the last attempt to reach any common basis of agreement on this question, although the question was dealt with in the British Note of Aug. 11, 1923 addressed to the French and Belgian Governments regarding the occupation of the Ruhr. In this document the British Government offeredas part of a general settlement of the Reparation question to accept in full payment of both reparation and Allied debts a sum equivalent to the amount necessary to cover the funded British debt to the United States, which was estimated on a 5% basis at 14·2 milliards of gold marks. The proposals contained in this Note were not accepted by the Allied Governments concerned.

Anglo-American Funding Agreement.—Meanwhile, the constitution of the United States Funding Commission in Feb. 1922 was immediately followed by preiiminary discussions between

the British and American Governments regarding the debt due from the United Kingdom. It was finally arranged that a British delegation, under Sir Robert Horne (the then Chancellor of the Exchequer), should leave for Washington in Oct. with the object of negotiating a settlement. Owing to the change of Government in Great Britain, its departure was postponed, but a payment of $100,000,000 was made on account—the first Allied payment in respect of interest on war debts. The mission finally sailed early in Jan. 1923 under Mr. Baldwin (the new Chancellor of the Exchequer), and returned to England at the end of the month with a proposed settlement which was accepted by the Cabinet on Jan. 31. Under the terms of this agreement the whole principal sum, which after allowing for interest due to Dec. 15, 1922 at 4¼% per annum and for payments already made, was agreed upon at $4,600,000,000, is to be repaid over a period of 62 years in annual instalments increasing from $23,000,000 in the first year to $175,000,000 in the last. Interest is to be paid at the rate of 3% per annum on unpaid balances for the first 10 years and at 3½% for the remainder of the period. The total annual payments on account of interest and principal vary between $160,000,000 and $187,000,000. Britain may rightfully defer half the interest accruing during the first five years, to anticipate payments and to make payments in U.S. Government bonds issued subsequent to April 1917. As these terms were not in accordance with those which the United States Debt Funding Commission was authorized to accept, it became necessary for Congress to approve the agreement, which was done on Feb. 28. On June 15 the first payment under the scheme was made by Great Britain.

Other Funding Agreements.—While the British negotiations were in progress, the United States administration had made their wish to be repaid known to the other countries concerned. The first country to respond was France, which in July 1923 dispatched a mission under M. Parmentier to Washington. No basis of settlement, however, was reached, and negotiations with the Czechoslovak Government led to the same negative result. In Oct. the Administration, hearing that the Rumanian Government contemplated raising a foreign loan, protested against such action before the American Relief Debt was funded. A Rumanian mission subsequently visited the United States, but failed to come to terms. In May 1923 an agreement was reached with Finland for the funding of its debt of $8,000,000 on the same terms as those accorded to Great Britain. No further settlements were reached until 1924, when an agreement was signed in April with Hungary for the refunding of the Relief credits to the extent of $1,939,000 on similar terms to those accorded to Great Britain and Finland. This was followed by settlements with Lithuania and Poland.

In Dec. 1924 the authority of the Debt Funding Commission was extended for another two years and in the following May a *démarche* was made by the United States Government to induce the governments whose debts were still unfunded to negotiate for repayment on the basis of the capacity to pay of the debtor. Consequently, in the latter part of 1925 the majority of the remaining Allies either came to terms or initiated discussions. Thus in Aug. a Belgian delegation arrived at Washington and an agreement was shortly reached by which the debt was divided into two parts. The pre-Armistice debt of $171,780,000 was treated specially, as by the Treaty of Versailles Germany must pay the Belgian war debt as part of her reparations. Belgium undertook to repay this sum in full over a period of 62 years, but no interest was payable. The post-Armistice debt of $246,000,000 was also to be repaid in full over 62 years, and in addition interest was to be paid at a rate which rose from ⅔ of 1% in the first year to 1% in the tenth year and at the rate of 3½% thereafter.

In Oct. an agreement was reached with the Czechoslovak Government which fixed the debt due at June 1925 as $115,000,000, repayable on terms similar to those reached with Great Britain. Latvia had already signed an agreement in September, and was followed by Estonia in October. In November an Italian delegation signed an agreement which fixed the principal sum due at $2,042 million to be repaid over a period of 62 years. Interest, however, was not to be paid during the first 5 years, and thereafter only at a rate rising by 10-year periods from one-eighth of 1% to 2% per annum, or an average of just under 1% per annum for the whole time. This was followed in December by a settlement with Rumania, on the British model.

The French Debt.—Meanwhile, the French Government, which, since the failure of M. Parmentier's mission in 1922, had made no move with regard to the refunding of its debt to the United States Government, dispatched in Sept. 1925 a mission under M. Caillaux (the then Minister of Finance), but the proposals put forward at that time were unacceptable. Better fortune attended the next attempt. On April 29, 1926, an agreement was signed. France agreed to the total at $4,025,000,000 and undertook to pay a total sum of $6,847,674,104 over a period of 62 years, beginning at $30,000,000 for 1926 and rising to $125,000,000 for the seventeenth and subsequent years. No interest was payable until June 15, 1930, after which one per cent was to be paid to June 15, 1940, 2% to June 15, 1950, 2½% to June 15, 1958, 3% to 1965 and 3½% thereafter. This agreement was not ratified by the French parliament until July 1929, but payments at the rate therein laid down had been regularly made in the interim.

All the remaining debtors, including Yugoslavia, Greece, Estonia and Latvia, later concluded agreements on similar terms, with the exception of Russia, Armenia, Greece and Austria. For the last special arrangements for postponement had been made. If the settlements which had already been made are considered, it will be seen that the terms of the Debt Funding bill with regard to the repayment of capital in full had been carried out in each case, and that, where concessions have been made, they had taken the form of a reduction in the rate of interest. Thus, Great Britain was paying 76% of the 4¼% per annum laid down by the law, while Belgium paid 48% and Italy 253%. These agreements were ratified by Congress early in 1926.

Debts to Great Britain.—Up to the end of 1924 little or no progress had been made with regard to the repayment of debts due to Great Britain from her Allies. In December of that year the Chancellor of the Exchequer (Winston Churchill) made an official statement to the effect that Great Britain would expect any country making a funding agreement with the United States to come to terms, *pari passu,* with his country. As a result, the French Government took advantage of Churchill's presence in Paris in Jan. 1925, at a financial conference on the Ruhr and the Dawes scheme, to state their intention of opening negotiations and to ask for a definition of the British position. An official reply in February adhered to the principle of the Balfour Note, while no longer supporting the proposals contained in Lord Curzon's Note of Aug. 1923 on the ground that they were out of date. It further proposed that France should pay fixed annual amounts from her own resources, together with a further annuity based on the French share of the Dawes annuities. Direct negotiations were resumed in London in July, when Churchill proposed the payment by France for 62 years of an annuity of £20,000,000, subsequently reduced to £16,000,000 and only a small proportion of which was based on payments to France under the Dawes scheme. Caillaux's counter-proposal of £10,000,000 led eventually to a compromise on a basis of an annual payment for 62 years of £12,500,000. This proposal, which reduced the French debt to Great Britain by nearly two-thirds, was referred by Caillaux to the French Government, which, however, resigned before a final decision had been taken. French opinion was subsequently moved towards the hope of obtaining better conditions by the terms of the Italian agreement with Great Britain and in July 1926, M. Caillaux, who was again Minister of Finance, re-opened negotiations. An agreement was eventually reached by which France agreed to pay a sum of £4,000,000 in 1926–7 which would rise by annual increment of £2,000,000 to £10,000,000 in 1929–30. From 1930–31 to 1956–7 she had to pay £12,500,000 annually and from 1957–8 to 1978–9 £14,000,000 annually. She might also postpone half the annual payment for the first three years and by means of a separate letter, reserved to herself the right to ask for a revision of the terms if receipts from Germany did not amount to half the figure laid down in the Dawes scheme. On the other hand, the gold deposit of £53,500,000 was retained by Great Britain (the debt due from France being similarly reduced), until a separate agreement could

be reached. Although the debt agreement was only ratified in France in July 1929, the annual payments had been made.

By an agreement signed on Jan. 27, 1926, the total amount of the Italian debt at that date was calculated at £610,840,000, and it was agreed that Italy should pay 62 annual payments of £4,500,000 with a partial moratorium for the first seven years. In addition, the Italian gold to the extent of £22,200,000 which had been deposited in the Bank of England as part security for certain loans was to be returned to her by instalments over the same period. It will be seen that, while the total amount to be repaid was not so great in proportion as that which the United States would receive, the present value was about the same. Of other debtors Belgium had repaid her post-Armistice debts, and Rumania had reached an agreement on the same basis as that of the offer to France in Aug. 1925, while Yugoslavia, Greece and Portugal had also come to terms. Russia alone had made no move. As for relief credits and credits for stores, Lithuania and Latvia repaid the amount due on Jan. 1, 1925, while funding agreements for the full amount had been concluded with Poland, Czechoslovakia, Estonia, Hungary, Rumania, Yugoslavia and Greece.

Although it was the declared policy of both Great Britain and the United States to treat the problem of inter-Ally debts as entirely separate from that of reparations, the doctrine of repayment according to capacity, enunciated by the United States, had led to results which are not without interest. Great Britain had advanced to her Allies a total sum of £1,423,132,000, and, on the basis of the arrangements already concluded with her debtors, would receive a total sum on account of both principal and interest of £1,147,000,000 in the form of annual payments over a period of 62 years of £18,500,000. On the other hand, she borrowed from the United States approximately £960,000,000, on which she was paying £30,000,000 and would later have to pay £38,000,000 per annum, so that, in effect, although she lent over 50% more than she borrowed, she would receive from her Allies less than half the amount which she must in her turn pay. Even if she received her full share of £20,000,000 per annum of German reparation payments under the Dawes scheme (which was a very optimistic estimate), her total receipts on account of inter-Ally debts and reparations combined would only just cover her payments to America. On the other hand, it is interesting to note that the United States would eventually receive on account of loans to her Allies an annual sum equivalent to 65% of that payable annually by Germany in a standard year under the Dawes scheme.

The Hoover Moratorium. — The various War Debt agreements worked until the world economic crisis in the early summer of 1931, which soon made it impossible for Germany to continue Reparations payments and jeopardized the War Debt payments.

Accordingly, when President Hoover on June 20, 1931, in response to the German appeal, proposed the postponement for one year from July 1, 1931, of all Reparation payments, he also included in his plan all inter-governmental debts. The Moratorium provided that the postponed War Debt instalments were to be refunded in ten equal annual instalments beginning on July 1, 1933, with interest 3% per annum (subsequently 4%). The first instalments affected did not fall due till December 15, and Congress ratified the plan just in time, but rejected the presidential proposal that the Debt Funding Commission should be re-established, and added that it was "against the policy of Congress that any of the indebtedness of foreign countries to the United States should be in any manner cancelled or reduced."

The Lausanne Conference. — The Lausanne Agreement of July 9, 1932, dealt only with Reparations, which it practically abolished. A subsidiary document, however, known as the "Gentlemen's Agreement," provided that the Lausanne Agreement would not be ratified by the Creditor Governments (Belgium, Great Britain, France and Italy) until a satisfactory settlement had been reached between them and their own creditors. If no such settlement could be obtained, a fresh consultation would take place. As a result of declarations by the European Creditor Governments, War Debt payments were suspended until the Lausanne Agreement was ratified. The United States Government was not, of course, committed by any of the documents referred to above.

War Debt Negotiations 1933–1935. — During the three years subsequent to the Lausanne Agreement no settlement was reached between the United States Government and its War Debtors. Consequently, the Lausanne Agreement was not ratified during that period. Reparation payments, however, ceased and the European Creditor Governments did not demand any payment from their debtors. On November 10 and 11, 1932, the British and French Governments sent notes to Washington, asking for an early re-examination of the whole situation and for a suspension of payments meanwhile. From then until the middle of December, a long interchange of notes took place, in which the chief arguments on the British side were the refusal of the United States to accept payment in goods, the increased burden of the debt payments owing to the fall in prices and the diminution in foreign trade, and the destruction of the Lausanne settlement which would follow the resumption of War Debt payments. The American Government argued that the depreciation had also affected the American Nation, that the United States had no responsibility for the Lausanne settlement, that any re-examination of the situation must be conducted with each debtor individually and that payment in December would greatly facilitate an ultimate settlement. Great Britain paid in gold on December 15, but regarded the entire payment as on capital account. The French Government had decided to pay, but was defeated on this question in the Chamber on December 14, and so defaulted. On December 15, 1932, Great Britain, Czechoslovakia, Finland, Italy, Latvia and Lithuania paid the instalments due, while Belgium, Estonia, France, Hungary, Poland and Yugoslavia defaulted. Austria, Greece and Rumania had arranged postponements.

Discussions with regard to the British debt took place in Washington in March 1933, but the American Administration was absorbed in the financial crisis and the devaluation of the dollar and no progress was made. In any case, agreement was unlikely in view of the declaration of British policy contained in the Note of January 25 and two speeches of the Chancellor of the Exchequer. It was then made clear that any settlement must be final and not involve the re-opening of the Reparations question and that the British Government would not consider compensation, since adjustment was as much in the interest of the creditor as of the debtor. The reference to Reparations implied that not more than 10% of the capital would be repaid by Great Britain.

The British Government made token payments of only $10,000,000 in June 1933 and $7,500,000 in December 1933 instead of the $75,950,000 and $117,671,000 due on those occasions respectively. In May 1934 the United States Government asked for payment of the three overdue instalments and the two Moratorium instalments but, owing to recent U.S. legislation, a token payment would then have been regarded as a default. The British Government accordingly made no payment on June 15, 1934, although it still declared its readiness to negotiate a final settlement. Token payments were also made in June and December 1933 by Czechoslovakia, Italy, Latvia, Lithuania and (in June only) Rumania. No debtor country has since made any payment except Finland, which has paid in full throughout. (R. J. S.)

INTER-ALLY COUNCIL OF WAR PURCHASES AND FINANCE. This council (commonly called in British documents the Inter-Allied Council, etc.), was set up by the Allied Governments in the late summer of 1917 with the object of, firstly, making recommendations as to the supplies and finance required by the various Allies in the United States of America, and secondly, of dealing in an advisory capacity with the problems involved by Allied purchases of all kinds in the world at large. Two offices were set up, at Sunderland House in London, and in Paris. Mr. Oscar T. Crosby, the United States delegate in the Council, was its president throughout the period of its activity, and was assisted by Mr. Paul Cravath as advisory counsel. The British members of the council were Mr. (later Sir) Austen Chamberlain, General Smuts, and Lord Buckmaster.

The council's first task was to satisfy public opinion in the United States, and in this it was substantially successful. In relation to the control and co-ordination of the purchase of supplies, the council may be said to have succeeded by failing. The data, upon which it should in principle have set out purchasing programmes of the principal governments, were necessarily out of date by the time they could be adequately examined.

Owing to the entry of the United States into the war, the financing of supplies bought in North America ceased to be a major preoccupation, and shipping became more and more concentrated in the North Atlantic. Shipping considerations therefore, at this stage of the war, exercised a much more effective control over purchasing programmes than the question of finance. Such further control as was possible in reinforcement of Treasury control was provided by the various allied programme committees which were gradually constituted to deal with government demands for certain commodities, and as the circle of government trading was constantly enlarged these commodities came to cover a very large part of the field of Allied expenditure abroad.

(A. McF; X.)

INTERAMNA LIRENAS, an ancient town of Italy in the Volscian territory near the modern Pignataro Interamna, 5 m. S.E. of Aquinum; the additional name distinguishes it from Interamna Praetuttianorum (mod. Teramo) and Interamna Nahartium (mod. Terni). It was founded by the Romans as a Latin colony in 312 B.C. as a military base in the war against Samnium, no fewer than 4,000 colonists being sent thither. The city lay on a hill on the northern bank of the Liris.

INTERBOROUGH RAPID TRANSIT COMPANY was incorporated in 1902 to operate rapid transit lines in the City of New York. Its capitalization consisted of $35,000,000, in common stock. It acquired by assignment the lease of the original so-called subway of the City of New York, which was opened on Oct. 27, 1904, for a distance of twelve miles. On Jan. 1, 1903, it leased (effective April 1, 1903) the elevated railroad lines in the Boroughs of Manhattan and The Bronx, New York, from the Manhattan Railway Company, for a period of 999 years.

The company as of Jan. 1, 1940 operated, under lease from the City of New York, 76·10 route miles of municipally owned rapid transit lines, designated as the Subway division, and 36·03 route miles of privately owned elevated railroad lines, designated as the Manhattan division. During the first full fiscal year of operation the company carried 395,716,386 passengers. During the year ended June 30, 1939, it carried 926,266,154 passengers on the Subway division and 169,414,401 passengers on the Manhattan division. Its present outstanding capital stock, bonds and notes aggregate approximately $246,905,580. It went into receivership Aug. 26, 1932. The Plan of Unification whereby the city of New York takes over and operates the subways and part of the elevated lines of this company was declared operative by the Transit Commission from Nov. 22, 1939. (F. HED.)

INTERCALARY (Lat, *intercalare*, to proclaim), a term applied to a month, day or days inserted between other months or days in order to adjust the reckoning of time, to the revolution of the earth round the sun, the solar year (see CALENDAR). From the meaning, "something placed between," intercalary is used for something which comes between two types. In botany, the term is used of growth between the apex and base of an organ, such as the growth in length of an iris leaf, or of the internode of a grass-haulm.

INTERCOLUMNIATION, in architecture, the distance between the columns of a colonnade; usually defined by the number of times in which the bottom diameter of the column is included in the distance between the two closest points on adjacent columns. Thus the distance between the centre lines of two columns is one diameter more than their intercolumniation. The intercolumniation of classic columns was systematized at an early date and the following standard intercolumniations have been listed by Vitruvius and others: (a) pycnostyle, equal to one and a half diameters; (b) systyle, 2 diameters; (c) eustyle, 2 and a quarter diameters, so-called "well-columned," as the one most generally satisfactory; (d) diastyle, 3 diameters; (e) areostyle, 4 diameters; and (f) areosystyle, a complex form in which the columns are arranged in pairs with the distance between the pairs greater than the distance between the columns of each pair, as in the colonnade of the Louvre, Paris (by Claude Perrault, 1665). No such absolute standardization of intercolumniation as Vitruvius' list would suggest exists in classical work; frequently all the intercolumniations of a single colonnade differed, with the widest in the centre. The list must therefore be considered, like the so-called rules for the orders, merely as a summary of the averages.

INTERDICT, in its technical sense as an ecclesiastical term, is a sentence by a competent ecclesiastical authority forbidding all celebration of public worship, the administration of some sacraments (baptism, confirmation and penance are permitted) and ecclesiastical burial. An interdict is a measure which seeks to punish a population or a religious body (*e.g.*, a chapter) for the fault of some only of its members, who cannot be reached separately. It is a penalty directed against society rather than against individuals. In the Chronicle of Ademar of Limoges (ad ann. 994) it is stated that Bishop Alduin introduced there "a new plan for punishing the wickedness of his people; he ordered the churches and monasteries to cease from divine worship and the people to abstain from divine praise, and this he called excommunication" (see Gieseler, *Kirchengesch.* iii. 342, where also the text is given of a proposal to a similar effect made by Odolric, abbot of St. Martial, at the council of Limoges in 1031). It was not until the 11th century that the use of the interdict obtained a recognized place among the means of discipline at the disposal of the Roman hierarchy, which used it, at times successfully, to bring back the secular authorities to obedience. Important instances of the use of the interdict occur in the cases of Scotland under Pope Alexander III. in 1181, of France under Innocent III. in 1200 and of England under the same pope in 1209.

See Ayrinhac, *Penal Legislation* (1936), *pp. 95 seq.* A. Boudinhon, art. "Interdict" in the *Catholic Encyclopaedia.*

INTERDICTION, in Scots law, a process of restraint applied to prodigals and others who, "from weakness, facility or profusion, are liable to imposition." Its only effect is to prevent the person interdicted from effectively alienating his heritable or real property without the consent of his interdictors. It leaves him competent to dispose of his moveables. Interdiction is either voluntary or judicial. Voluntary interdiction is effected by the prodigal himself, who executes a bond obliging himself to do no deed which may affect his estate without the assent of certain persons called the "interdictors." This may be removed by the court of session, or by the joint act of the interdictors and the interdicted, or by the number of interdictors being reduced below the number constituting a quorum. Judicial interdiction is imposed by order of the court, either moved by an interested party or acting in the exercise of its *nobile officium,* and can only be removed by a similar order. That the interdiction may be effective in questions with third parties it must be published in the appropriate registers.

INTERESSE TERMINI, in law, an executory interest, being the right of entry which the grant of lease confers upon a lessee. Actual entry on the lands by the lessee converts the right into an estate. If the lease, however, has been created by a bargain and sale, which still exist in some colonies, or by any other conveyance under the English Statute of Uses, not requiring an entry, the term vests in the lessee at once. This doctrine

was abolished by the Law of Property Act, 1925, S. 149.

INTERFERENCE is the confusion of radio reception due to stray electrical disturbances, undesired signals or other causes. The name interference is also applied to that which produces the confusion.

INTERFERENCE OF LIGHT: see LIGHT; INTERFEROMETER,

INTERFEROMETER. An instrument which makes use of the interference of light waves (see LIGHT) to measure very small differences in length or very small differences in wave-length. On the one hand, if very homogeneous light (*i.e.*, light which covers an extremely small range of wave-length, often referred to as light of one wave-length) is used, a difference of optical path can be measured by the help of the interference fringes formed: on the other hand, if the light contains two or more separate, but very near, wave-lengths, the component wave lengths can be detected, and their separation measured, by the separation of the fringe systems. (See SPECTROSCOPY.) The interferometer has assumed great importance in modern physics, firstly from its use in attempts to measure a difference of optical path due to motion through a hypothetical ether, in experiments of the type initiated by Michelson and Morley (see ETHER, RELATIVITY), secondly from its use in the determination of the ultimate standard of length, that is, in measuring the length of the standard metre in terms of wave-lengths of a standard light (see SPECTROSCOPY), and thirdly from its use in resolving very close spectral lines, to which reference has just been made.

Separation of Interfering Beams.—The interferometer of Fabry and Perot, in which the interference is produced by repeated reflection of the light between two accurately plane glass plates, is described in the article LIGHT, where reference is also made to another multiple reflection interferometer, the Lummer plate. In both these instruments the reflections lead to what is virtually a large number of sources, with a large path difference, amounting to some tens of thousands of wave lengths, between successive beams. In contrast to such instruments, where the interference is due to the combined effect of a large number of beams produced by the reflections, are instruments in which two beams only, between which interference takes place, are produced from the original beam, the two beams following widely separated paths, so that, for instance, obstacles can be placed in one beam and their retarding effects measured by the consequent displacement of the interference fringes. In the instrument of Jamin the separation is effected by the use of thick plates, the interference from which was first investigated by Brewster. Two similar thick glass plates, with accurately parallel surfaces, are arranged as in fig. 1. The one of the two interfering beams is that which is reflected at the first surface of the first reflector

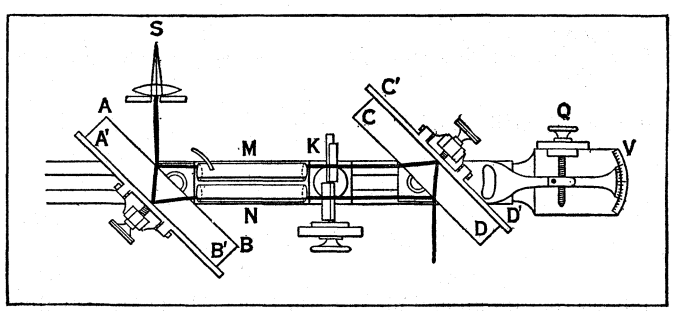

FIG. 1

and at the second surface of the second reflector: the other undergoes reflection at the second surface of the first reflector and at the first surface of the second reflector. If the plates are exactly parallel and exactly equal in thickness the two paths are equal and the two beams should leave the second plate exactly in phase; if there is any lack of parallelism or in homogeneity of the glass interference fringes will be seen. If any substance with a refractive index greater than that of air be introduced in the path of one beam only the retardation produced will cause a shift of the fringes, from which the refractive index can be calculated. To enable the measurements to be made with greater ease a compensator is provided, consisting of two thin glass plates, one in each path, which can be independently tilted to make any desired angle with beam: the greater the inclination the greater the thickness of glass traversed by the beam, so that any desired retardation can be introduced. The instrument has been largely used to'measure the refractive indices of gases, for which pur-

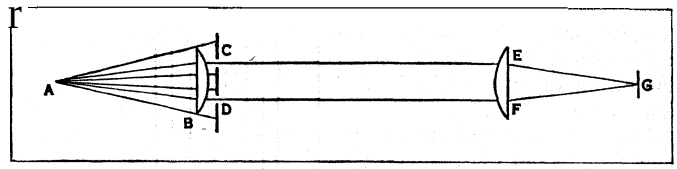

FIG. 2

pose glass-ended tubes are introduced into the path of the beams, one being evacuated, while the gas is slowly introduced into the other, the passage of the fringes being counted. Since the instrument was originally used for this purpose by Jamin it is often known as an interference refractometer. Extensive measurements of gaseous refractive indices have been made with it by C. Cuthbertson.

In the interferometer, also used for the accurate measurement of refractive indices of gases and weak solutions, devised by Lord Rayleigh (3rd Baron), light proceeding from a slit at A, fig. 2, perpendicular to the plane of the paper, falls upon a collimating lens B, which is blocked out by a screen except for two parallel slits at C and D. The parallel beams CE, DF transmitted by these slits are brought to a focus at G by the lens EF, and form interference bands in the focal plane. These bands, which are examined with a high power eye-piece, undergo displacement if any substance which causes relative retardation of the light is introduced into one of the paths. Consider, for example, what happens at the point G itself, which is the image of A. If everything is symmetrical so that the paths ACEG, ABFG are exactly equal, there is brightness, but if, for example, CE be subjected to a relative retardation amounting to half a wave length, we have darkness at G, the band being shifted through half a band interval.

The Michelson Interferometer.— The best known form of interferometer, and the one to which the designation was originally applied, is that devised by Michelson for the Michelson-Morley experiment (see ETHER, RELATIVITY, MICHELSON-MORLEY EXPERIMENT), on the effect of the motion of the luminiferous medium on the velocity of light. In this the interfering beams are not only widely separated hut travel, as is required by the experiment, at right angles to one another for the greater part of their path. Light from the source S, which may be an extended luminous surface (a candle, lamp or a lens with an arc light at the focus) falls at 45° on the surface of a plane-parallel glass plate (fig. 3), the surface of which is covered with a film of silver or platinum, of such thickness that the reflected and transmitted pencils are of approximately equal intensity. The transmitted beam falls normally on the mirror C, the reflected beam on B, both returning to the separating surface **A,** whence they both proceed in the direction AE. Since the beam reflected from C has had to pass three times through the plate A, whereas the beam from B only passes once through A, a compensating plate P' similar to the plate A, is introduced, which is traversed twice by the beam which goes to B. The resulting interference fringes may be projected on a screen or observed by eye, with or without an observing telescope.

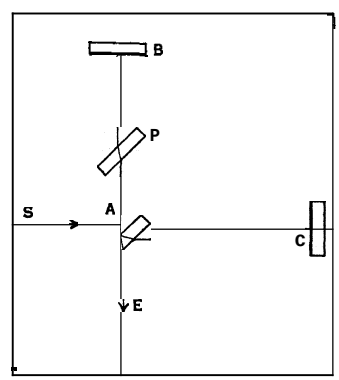

FIG. 3

The construction of the instrument is indicated in fig. 4. A heavy casting serves to support the optical parts, and the car-

riage holding the movable mirror C moves on very accurately ground ways. The motion is communicated by means of a screw provided with a worm wheel and a divided circle so that the motion of the carriage may be accurately measured. The stationary mirror D is provided with screws for adjustments about vertical and horizontal axes. The compensating plate B is held by a vertical steel rod, twisting which produces any required small alteration in the path All of the optical surfaces are very accurately plane, the errors-being of the order of a twentieth of a light wave, or less.

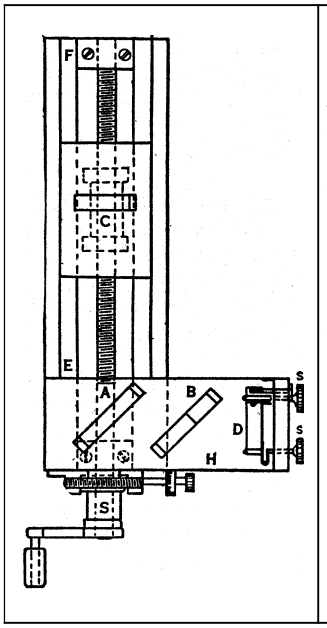

FIG. 4

The adjustment of the instrument is effected as follows. The distances of the mirrors C and B from the half-silvered surface of A are made approximately equal (say, to within a millimeter), and an approximately homogeneous source of light (sodium flame, or better, a Cooper-Hewitt mercury arc) is placed in front of A, as indicated by S. The two images of a needle point placed near S are then brought into coincidence by the adjusting screws of the mirror D, when the interference fringes should appear. They are usually narrow, curved, and not very distinct; but by slowly altering the adjustment of the mirror D they may be given any suitable width, and by diminishing the path difference by turning the screw S the fringes become more distinct. As the path difference approaches zero, the change of inclination of the fringes accompanying a change in position of the eye diminishes; and when this change vanishes, the (coloured) fringes in white light appear, or may be found in a few turns of the worm wheel which gives the slow motion to the screw S. The use of the instrument in the Michelson-Morley experiment is described under RELATIVITY, in measuring the standard metre in terms of lightwaves under SPECTROSCOPY.

THE THEORY OF THE INTERFEROMETER

The arrangement sketched in fig. 5A represents schematically the interferometer in its simplest form. B' represents the image of the mirror B in the mirror M, A and B' being supposed to be not quite coincident: it is evident that to the observer at E the effect of the whole combination is the same as that which would be produced by the surfaces A and B'. The light coming to E may then be considered as having come from two nearly coincident sources, which are the image of the source S in the two mirrors These sources are therefore coherent, but not quite coincident, and the form and visibility of the fringes clearly depend upon the degree of coincidence of the two sources. Exact coincidence would be equivalent to a single source, and consequently there would be no fringes at all in such a case, but exact coincidence is not attained in practice, so that fringes are always visible. When the coincidence is nearly attained the fringes will clearly be broad; when the images are further apart the fringes will be narrow, and usually curved, as mentioned when the adjustment of the instrument was being discussed. The visibility will depend largely upon the aperture, since for good visibility the fringes formed by the two images of one part of the source should be superposed as nearly as possible on those formed by the two images of another part of the source.

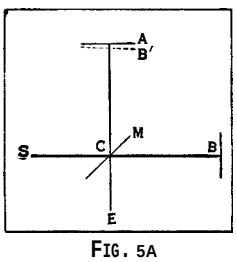

FIG. 5A

As the moving mirror is displaced backwards the two images separate, and the fringes move across the field. Every time the distance between the images increases by a wave length a whole fringe moves past a given fixed point. If the light was perfectly homogeneous the fringes would be visible with any degree of separation of the images, that is, with any difference of path length between the two beams. If, however, the light is not perfectly monochromatic, then clearly with large enough path difference the fringes formed by one component of the light will cancel those formed by a neighbouring component. The fact that even with the most homogeneous source fringes never show with a path length greater than 70 cm. proves that the light consists of trains of about this length.

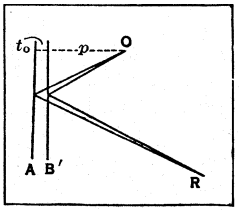

FIG. 5B

Michelson has discussed the formation of the fringes in the following way. In fig. 5B let AB be the two equivalent mirrors shown in fig. 5A, the intersection of their planes being vertical, and consider the effect of the reflection of light from a source R to a point O. Let t be the distance between the mirror surfaces at the point of incidence, ω be the angle of incidence, which may be considered the same for both mirrors, the angle ϕ between them being supposed to be very small (of the order of a second of arc, or less). Further let p be the perpendicular distance from O to the mirrors, t_0 the distance between the mirrors at the foot of this perpendicular, and i the angle between the horizontal projection of the incident ray and the normal. Then the difference in path of the two interfering pencils is seen to be expressed

$$\Delta = 2t\cos\omega$$

and

$$t = t_0 + p\tan i\tan\phi = t_0 + pi\phi$$

since ϕ is very small and so is i, the incidence being very nearly normal.

Hence

$$\Delta = 2(t_0 + pi\phi)\cos\omega$$

The corresponding phase difference is $2\pi\frac{\Delta}{\lambda}$, which with an unlimited aperture may clearly have so large a range of values that all traces of interference vanish. If, however, the cone of rays is limited, either by the pupil of the eye or, in the case of an observing telescope, by a diaphragm, then the range of angles may be small enough to show the phenomenon of interference.

Let us now enquire as to the distance p at which the fringes will be most clearly visible. This must occur when there is no change of Δ with w, the angle of incidence, that is, when

$$\frac{d\Delta}{d\omega} = 0.$$

Now $\frac{d\Delta}{dw} = -2\sin w(t_0 + pi\phi) + 2\cos\omega p\phi\frac{di}{dw} = 0$, or since ω, i and θ are all small, which leads to $\frac{di}{dw} = \frac{\omega}{i}$, we have

$$\omega(t_0 + pi\phi) = p\phi\frac{\omega}{i}$$

or

$$p = \frac{it_0}{\phi}.$$

It follows that for an unlimited beam, when i has various values, the different parts of the interference paths are not simultaneously in focus except, firstly, if $t_0 = 0$, when $p = 0$ and the fringes are localised at the surfaces of the mirrors AB, or, secondly, if $\phi = 0$ or the mirrors are parallel, when $p = \infty$ and the fringes are localised at infinity.

If we call Δ_0 the phase difference for normal incidence, $\omega = 0$ and if $\Delta_0 - \Delta = n\lambda$, then

$$2t_0(1 - \cos\omega) - 2pi\phi\cos\omega = n\lambda$$

or, ω being small,

$$t_0\omega^2 - 2pi\phi = n\lambda.$$

Let θ be the angle between the normal and the projection of the ray on the vertical plane containing the normal, and put

$$\frac{n\lambda}{t_0}=\rho^2, \quad \frac{p\phi}{t_0}=h.$$

Then $$\omega^2=i^2+\theta^2=\rho^2+2hi.$$

This represents a circle whose angular semidiameter is

$$\sqrt{\left(\frac{n\lambda}{t_0}+\frac{p^2}{t_0}\right)}$$

and whose centre is displaced through an angle $h=\frac{p\phi}{t_0}$, and so we see fringes which are circular arcs. If the separation t_0 is small, the equation reduces to

$n\lambda=-2p\phi i=2\phi x$ where $x=-pi$ is the horizontal separation between the fringes, which is constant. Disregarding sign, $x=\frac{n\lambda}{2\phi}$. The fringes are straight, and parallel to the intersection of the mirrors A, B′. The distance between consecutive fringes is clearly

$$b=\frac{x}{n}=\frac{\lambda}{2\phi}.$$

The visibility V of the fringes is defined by Michelson as

$$V=\frac{I_1-I_2}{I_1+I^2}$$

where I_1 and I_2 are the maximum and minimum intensities respectively. Michelson has shown that we can deduce the formula

$$V=\frac{\sin kp\phi(i_2-i_1)}{kp\phi(i_2-i_1)} \qquad \text{where } k=2\pi/\lambda$$

and i_1, i_2 are the limiting values of i for the incident beam. This shows that if $p=0$, which, as we have already seen, involves $t=0$ if all parts of the interference patterns are to be simultaneously in focus, then $V=1$, which is independent of the aperture. For moderate aperture the visibility is independent of the aperture. This is also true if $\phi=0$.

An idea of the order of magnitude of the angular aperture permissible may be obtained in an elementary way as follows. If the differences in phase between the central and marginal rays be λ the discordances will be considerable. In the case where $\phi=0$, and the mirrors are truly parallel, if β is the angular aperture of the objective, then

$$\text{difference in phase}=2t(1-\cos\beta/2)=\lambda$$

whence $\beta^2=\lambda/t$ as a first approximation. Thus if $t=25\lambda$, then $\beta=\frac{1}{5}$, and the angular aperture of the lens should certainly be less than $\frac{1}{5}$.

Comparative Place of Interferometer as an Optical Instrument.—It had been pointed out by Michelson that the interferometer can be regarded as a modification of the ordinary instrument, telescope or microscope, consisting of lenses or mirrors, and that prisms and gratings as well have their analogies in interferometers. We will consider first the case of a converging lens, of supposedly perfect optical construction, that is, for which the optical distance from point to point is equal for all paths. Such a lens, considered as an optical instrument, may be employed to form an accurate image of the object, as in an astronomical observing telescope, but it may also be used for accurate measurement of a displacement, or angle, where a representation of the object is not necessary, so long as there is some recognizable feature of the image on which a setting can be made. It is well known that the image of a luminous point formed by a lens is a diffraction pattern consisting of a bright spot, surrounded by rings, and that the resolving power of the instrument depends upon the extent of the overlapping of the diffraction rings due to two close object-points. (*See* LIGHT, section on Resolving Power.) The size of the diffraction pattern is inversely proportional to the angular aperture of the lens, and the definition and the resolving power both increase as this aperture is increased. With a given aperture, however, the indistinctness of the image becomes more and more pronounced with increasing magnification, since all the imperfections of the image are subject to the same enlargement as the size itself, while the brightness diminishes. The interference fringes of the diffraction pattern, however, are more accurately measurable if the pattern is magnified, since, generally speaking, setting a cross-wire is possible to within a fixed fraction of the fringe width.

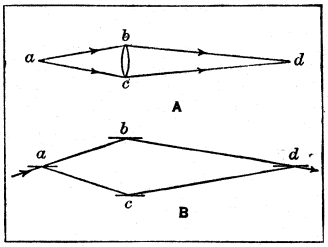

FIG. 6

For the purpose of accurate measurement of position or angle we may therefore block out the central portion of the lens altogether, leaving merely a circular annulus which will produce sharp rings, or, better still, we can merely isolate two small portions of the lens at opposite ends of a diameter. We shall in this way obtain an exceedingly bad image of the luminous object, but we shall have interference fringes which can be increased in size up to practically any limit without affecting the amount of light. The result is exactly the same, as far as measuring position is concerned, as could be obtained with a perfect microscope of infinitely great magnifying power with an infinitely bright source. This device of isolating two small strips of lens at the opposite end of a diameter is, in fact, that adopted in Rayleigh's interferometer, already described. Regarding the lens as an optical instrument we sacrifice resolution and definition, with a gain of accuracy of measurement. We may then say that, since all optical phenomena ultimately depend upon interference in its most general conception, there is no fundamental difference between the interferometer and ordinary lens system. The analogies will now be considered in a little more detail.

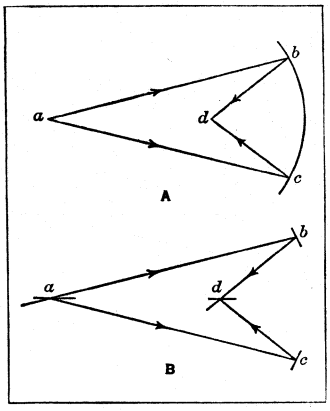

FIG. 7

The Rayleigh interferometer has already been considered. The close analogy between the optically perfect convex lens and an interferometer consisting of four mirrors is illustrated in fig. 6. Thus in fig. 6A the image of a source (a slit A, or a fine line ruled by a diamond on a smooth glass or metal surface) is formed at D (the result of the "combination" of all the rays which fall on the lens BC), where it may be observed, as in the telescope or the microscope, by an eyepiece. In fig. 6B the source is replaced by the surface A, whence two of the pencils (one transmitted and the other reflected) are bent by the prisms (or mirrors) at B and C so that they meet at the surface D, proceeding thence to the eye or the observing telescope. In fig. 7 the same analogy is illustrated when the lens is replaced by a mirror.

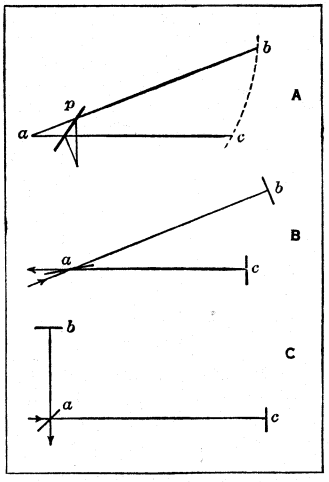

FIG. 8

Thus it appears that the essential difference between lenses or mirrors, on the one hand, and the interferometer, on the other, is that in the former all the rays from the source which fall on the lens unite in the focal plane to form an image; whereas in the interferometer of the type in question there are only two interfering pencils. The advantage of this has already been

pointed out. In the illustrations just given, the microscope or telescope, and the analogous forms of interferometers, may be applied to the measurement of distances or of angles

But prisms and gratings are employed in what seems at first sight to involve different principles, and for a different purpose, namely, the analysis of light into its component constituents The analogy still holds, however, as is shown in fig 8A and B Thus in figure 8A, A represents the slit source of light and *BC* a grating which diffracts the light back to *A* (part being thrown on one side by the plane-parallel plate P for observation or for photography) while in figures 8B and 8C, the interferometer shows a similar light-path, but only for the two limiting pencils of light, 8C being produced from 8B by a slight rearrangement of the mirrors

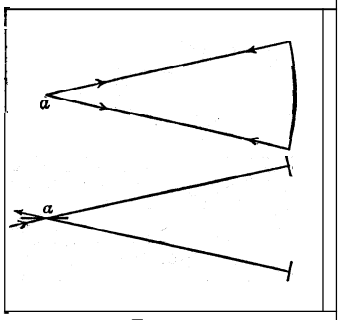

FIG. 9A

If in this arrangement one of the mirrors, say *C*, is movable, and the incident light monochromatic of wave-length and if n is the number of maxima (or minima) corresponding to d, the measured difference in path, then the wave-length is given by $\lambda = d/n$; and, as is described under Spectroscopy, this can be measured with far greater accuracy than is possible by the use of prisms or gratings.

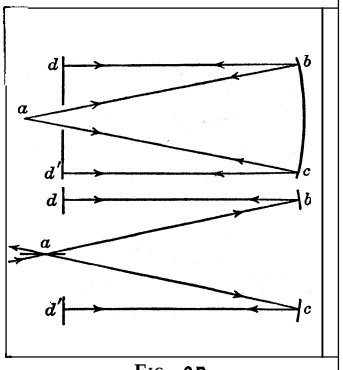

FIG. 9B

Any arrangement of mirrors and lenses has its analogue in a possible interferometer. Fig. 9 shows three different dispositions of optical apparatus and three corresponding interferometers. The diagrams are self-explanatory, A being a concave mirror with the source at the centre of curvature, and hence a single plane mirror in place of the two mirrors of fig 7: C a double convex lens with equidistant object and image, a variation on fig. 6; and B a concave mirror and two plane mirrors with the source at the focus of the mirror. The interferometer diagrammatically represented in Ciii is a slight variation on that of Cii. obtained if the mirrors B and *C* are separated until *AB* and *AC* are at right angles.

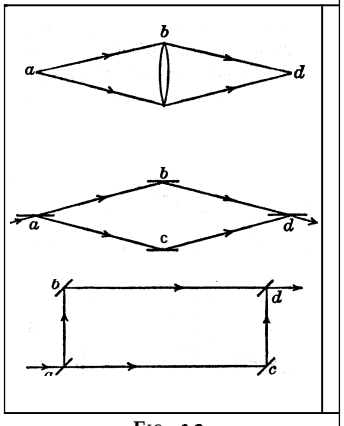

FIG. 9C

Measurement of the Standard Metre in Terms of Light Waves.—The standard metre is defined as the distance between two fine lines on a particular iridio-platinum bar kept at Paris. It is, however, clearly desirable to have some absolute standard of length, not depending upon a particular piece of material, since not only are secular changes possible in the material which will produce minute changes in length, but also, in the remote chance of an accident to the bar, it should be possible to replace it. Long ago two proposals were made to fill this need, the first being to adopt as a standard the length of a pendulum which swings once a second at Paris. It was found on trial that the error of measurement was considerably greater than expected. The second proposal was to use the earth's circumference as a standard, and, in fact, the original metre was intended to be one forty-millionth of this length As a result of several of the very costly investigations of the measurement of a given arc of the meridian it proved, however, that this measurement was too inaccurate to serve. The interferometer with large differences of light paths enables us to measure a length of many centimetres in terms of the wave length of a specified light, and so gives us a standard which can be easily reproduced at any time or place. The International Committee on Weights and Measures decided, in fact, in 1923 on the adoption of such a standard, so that the measurement of the standard metre in terms of a wave length is of the highest importance.

If a wave length is to be a standard length it is, of course, essential that the light should be very homogeneous; among the hundreds of radiations examined none answered the requirements so well as the red line of cadmium vapour. With this light interference fringes are still measurable with a path difference of 22 cm., which distance contains about 350,000 waves, or, say, 700,000 fringes. The optical error of measurement will depend somewhat on the visibility of the fringes, but an estimate of one-tenth of a fringe width is quite conservative, and thus indicates the possibility of making such a measurement to an order of accuracy of one in ten million. The general principle of the method is simply to move the mirror of the interferometer through a distance given by the standard, and to count the number of fringes, but to make sure that the mirror has actually been moved through the standard distance, and to extend the measurements to a length of a metre a number of special devices are necessary.

Since fringes cannot be obtained with a path difference of one metre, and even distances of several centimetres are troublesome, as they involve the counting of some hundred thousand fringes, a standard decimetre and a series of substandards were prepared. The standard decimetre was afterwards compared with the metre in a way which will be described. The intermediate standards, by the help of which the number of fringes was reduced to a countable one, consisted of a 5 cm. one, a 2.5 cm. one, and so on, each successive standard being half the length of the previous one, the ninth and last being .39 mm., which contains only 600 red light waves, or 1,200 fringes in the doubled distance between the parallel surfaces which constitute the standard. This number of fringes can readily be counted without fear of error. The construction of those intermediate standards is made clear by the example shown in fig. 10. It consists of two plane-parallel glasses A, A shown on the front surfaces, and held in contact with three brass pins, which are filed and polished until the two surfacesare as nearly parallel as required. The distance between the planes of the front surfaces of these mirrors, one of which stands, as will be seen, higher than the other, constitutes the standard length.

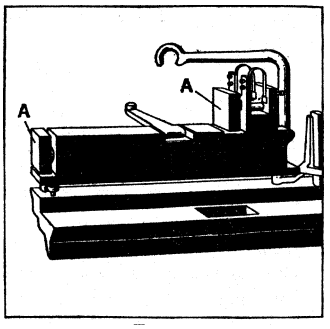

FIG. 10

The first task is to determine the exact number of wave lengths in the smallest standard, which we will call standard I. Fig. 11 represents the interferometer set up for this purpose: d is the moveable mirror, *m m′* are the two mirrors of the standard (the distance between them being exaggerated in the diagram) and *n* is a stationary auxiliary mirror This mirror is used for the purpose of counting the fringes that pass when d is displaced, that is, for measuring the displacement of d in wave lengths. To start, the front surface of *m* is made to fall in line with the image of the reference plane *d*, making, however, a very small horizontal angle with it, so that with white light a series of vertical interference bands is formed, the central band being achromatic and therefore readily distinguishable. The mirror d is now steadily moved back, and the succession of circular fringes formed by the cadmium light on *n* is counted. The

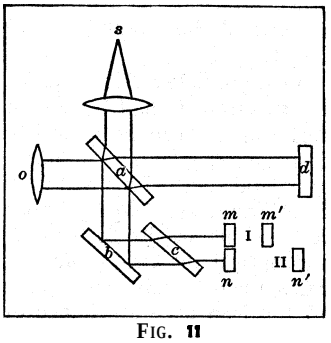

FIG. 11

motion is continued until d coincides with the rear surface m', a coincidence detected once more by the white light fringes, the achromatic band being brought to the same position on m' as it had before on m. The motion of d is thus measured in terms of wave lengths of cadmium light, and the limits of its motion, given by the distance between m and m', determined by the use of white light fringes to establish coincidence.

The next step is to compare standard II. with the one already measured. Now n represents the front mirror of standard II., n' the rear mirror. The two mirrors m and n are brought into the same plane with the help of white light fringes. The mirror d is now moved to coincide with m', and standard I. is moved until fringes reappear on m, so that m' and n' are now very nearly in the same plane. The small distance between m' and n' in this position is determined in fractions of a fringe of cadmium light by moving d, so that the correction to be applied to standard II. is determined. Standard III. is checked against II. in the same way, and so on, until the decimetre is reached.

The tabie gives the results of three independent measurements of the number of light waves in the (doubled) length of standard IX., the decimetre. The fact that these measurements were made. at different times, months apart, and by different individuals, and still give the same result to a few hundredths of a light wave, gives confidence in the accuracy of the result. Besides the red line of cadmium, the green and the blue line were used, as recorded.

Series	Red	Green	Blue
I. . . .	310,678·48	393,307·92	416,735·86
II. . .	310,678·65	393,308·10	416,736·07
III. .	310,678·68	393,308·09	416,736·02

The final operation is the comparison of the decimetre with the standard metre. For this purpose an auxiliary metre X. was provided with two diamond scratches at a distance apart very nearly equal to a metre. An arm extending at right angles from the decimetre has a similar mark which is placed as nearly as possible in coincidence with one of the metre marks. The standard decimetre is then "stepped off" ten times by the help of the interferometer fringes. The resulting error is, however, multiplied by ten, instead of by two as in the comparison of the smaller standards. It is estimated that the error of separate determinations of the metre may be of the order of one-half of a light wave, but the mean of all measurements is doubtless much less. To this error must, however, be added the errors of the micrometric measurements of the "coincidences" at both ends of the metre bar, and finally the error of the comparison of the auxiliary metre with the standard.

The final results are as follows:

Number of Light Waves of the Three Principal Cadmium Radiations in the Standard Metre

Red	1,553,163·5
Green	1,066,249·7
Blue	2,083,372·1

The metre rod is in air at 15° C and 760 mm. of mercury pressure. It is estimated that these results are correct to about one part in two million.

Measurement of Stellar Diameters. — Most of the applications of the interferometer have been mentioned at one part or another of this article. The chief of them are: — the measurement of standard wave length, or, differently put, the measurement of the meter in terms of the light wave; the measurement of the maximum distance over which interference can be produced, or the coherence of a wave train; the measurement of refractive indices of gases and weak solutions; and the resolution of close spectral lines. Reference must also be made to the recent application of interferometric methods for the measurement of stellar diameters. Suppose we consider the whole of the lens of a telescope stopped out, except for two slits at opposite ends of a diameter, as in the Rayleigh interferometer. A single luminous point will produce a pattern of interference fringes. A second close luminous point will likewise produce a pattern of fringes overlapping the first pattern. If we consider the two points as originally coincident, and then gradually separate them, the superposed pattern will give a certain pattern of fluctuating intensities depending upon the separation, but ultimately a separation will be reached such that the darkest parts of one pattern fall exactly upon the brightest parts of the other pattern, and we shall have uniform illumination The argument can be extended to an uniformly illuminated disc, for which it can be proved that the fringes vanish when

$$\alpha = \frac{1{\cdot}22\lambda}{s}$$

where S is the separation of the two slits, λ the wave length of the light used, and a the angle subtended at the telescope by the diameter of the disc.

This principle has been applied by Michelson to the measurement of stellar diameters. It is not feasible to make a lens of large enough diameter to hope for vanishing with the extremely small a provided by a star disc, but Michelson gets over the difficulty by receiving the light from the star on two mirrors set at 45°, from which it passes to two other 45° mirrors which throw the light in two pencils at opposite ends of a diameter of the lens or the mirror of the telescope. The general arrangement of the mirrors on the great reflecting telescope at Mount Wilson is shown in fig. 12. The separation of the first two mirrors, which, with the second two, are mounted on an arm set normally across the telescope at the aperture and, is limited only by mechanical considerations, and, in Michelson's first instrument, was variable and could be made as great as 20 ft. The method of mounting of the mirrors is indicated in fig. 13. With the red star Betelgeuse a vanishing of the fringes was obtained with a separation of about 10 feet (306 cm.), which, taking the effective λ as 5.75×10^{-5} cm., gives the angular diameter a to be ·047 seconds of arc. Using a parallax of ·018 we obtain an estimate of 240 million miles for the linear diameter of this star. The diameters of a few other stars have been measured by this method. In 1928 an interferometer of the pattern in question is under construction at Mount Wilson which will allow a 50 foot separation of the mirrors. (See STAR.)

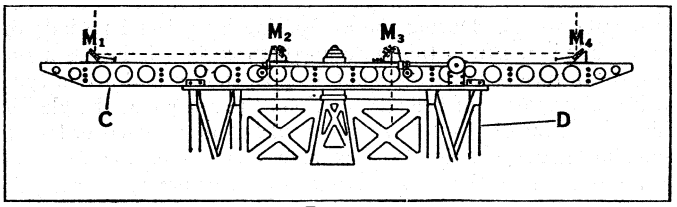

FIG. 13

BIBLIOGRAPHY.—The principles of interferometers are described in the standard text-books on Optics, cited in the bibliography to Light, to which may be added Lummer's volume on Light in Muller-Pouillet's *Handbuch der Physik*. A general account of Michelson's work is given in Michelson's *Light Waves and their Uses* and *Studies in Optics*. The analogy between interferometers and other optical instruments was first pointed out by Michelson in the American Journal of Science 39, 115, 1890. (A. A. M.; E. N. DA C. A.)

INTERGLACIAL STAGES, a series of comparatively warm and mild intervals, each lasting several thousand years, between the equally prolonged times of extreme cold in the Pleistocene glacial period (*q.v.*). For the stages of extreme cold the geologist Albrecht Penck chose names from representative districts in the Alps: Günz, Mindel, Riss and Würm; of these, the Giinz stage is the earliest, the Wiirm stage is the most recent. Penck chose these names because their order in

the alphabet corresponds to the chronological order of the four stages, while space is left between them for additional names, should additional stages of cold be defined.

The same names are conveniently used to indicate the intervening warmer stages. Thus the first mild interglacial stage is called the Günz-Mindel stage; the second, the Mindel-Riss stage; the third, the Riss-Würm. This cyclic alternation of climate through the Pleistocene period is accompanied by alternating Arctic and temperate fauna and flora, while there is a further change, particularly of the fauna, due to the steady evolution of forms throughout the Pleistocene period. Thus in Europe during the colder stages the woolly mammoth and reindeer reached the south of France, while one of the interglacial stages was so warm that the lion and hippopotamus flourished in England.

In North America there was a similar cyclic alternation of climatic conditions throughout the Pleistocene glacial period, but there are difficulties in the way of drawing definite parallels between the Old World and the American stages. It is likely, however, that the earliest glacial stage in North America, which includes the pre-Kansan, Nebraskan and Albertan drifts, and which is called sub-Aftonian by American geologists, coincided with the Gunz of Penck. The earliest, or Aftonian, interglacial stage of North America would thus correspond with Penck's Günz-Mindel interval. In North America, the Aftonian interglacial stage was marked by the presence of mastodons, three species of elephants, six species of horses, and the sabre-toothed tiger.

The second, or Kansan glacial stage in North America, corresponding to the Mindel of Europe, saw the extinction of some American camels and horses. It was followed by the Yarmouth interglacial stage, parallel to Penck's Mindel-Riss, when the fauna included mastodons, mammoths, horses, tapirs, bison, deer and sabre-toothed tigers.

The third, or Illinoian, glacial stage in North America, corresponds to Penck's Riss. It was followed by the Sangamon interglacial stage; this was in its turn fourth, or Iowan, glacial stage, the record of which is not well defined. The fourth, or Peorian, interglacial stage followed; it presents similar difficulties.

The fifth, or Wisconsin, glacial stage appears to correspond to the European Wurm. It was followed by the post-glacial stage, which gradually merges into the present time. Elephants, mastodons, horses and the great sloths disappeared, the exact cause of their disappearance being unknown.

In the earlier or pre-glacial stage, Pleistocene vegetation was characterized by a commingling of warm temperate and cool temperate forms. During the alternating interglacial periods the record of plant life in the more northern regions indicates a succession of forest, barren ground, steppe, tundra and arctic types with each increase of glaciation. Upon the retreat of the glaciers this succession of plant types recurred but in reversed order. In some interglacial periods the climate was milder for the same latitudes than at the present time, so that numerous trees, for example, extended some hundreds of miles north of their present range. In the post-glacial or late Pleistocene stage, which blends into the Recent, plant life assumed substantially the present status and distribution. Many arguments may be advanced supporting the view that the post-glacial and recent constitute a part of an interglacial stage, as the time that has elapsed since the disappearance of the last great ice-sheets from Europe and northeastern North America is less than the duration of some of the former interglacial stages.

The effect of glaciation upon the vegetation of Europe and North America, especially the former, was profound, not only with reference to the present distribution of the flora, but also as regards the extinction of old and the evolution of new types. In Europe the high mountain chains, which extend in an east-and-west direction, together with the Mediterranean, Black and Caspian seas, prevented the migration of the flora southward. In consequence an immense number of plants formerly components of the European flora, particularly that north of the Alps, was obliterated by glaciation. Numerous types of trees now found only in North America and Asia were abundant in Europe in pre-Pleistocene and part of Pleistocene times. Among these were such important trees as the black walnut, butternut, hickory, magnolia, bald cypress and sassafras (*qq.v.*).

In North America the back-and-forth movement of plant life was not impeded, as in Europe, by high mountains and inland seas. The presence of the larch (Larix laricina) in Georgia, of the black spruce (Picea mariana) in Kansas and of the white spruce (Picea *glauca*) in Iowa, all far south of their present range, has been demonstrated. Likewise, the presence during a mild interglacial stage of a fig in fruit in British Columbia, and of the redbud (Cercis), the Osage orange (*Maclura*), the papaw (*Asimina triloba*) and other warm temperate types as far north as Toronto, Ont., has been proved.

INTERIM (Lat. interim, in the meantime), a word specially applied to certain edicts passed by imperial diets during the reformation in Germany with the object of *temporarily* settling controversial points of doctrine and ecclesiastical practice until they could be decided finally by a general council. The interim of Regensburg (Ratisbon) was promulgated in 1541; but the most famous example of such a *modus vivendi* was the interim of Augsburg (1548). This, drawn up at the bidding of Charles V. by Michael Helding, Julius von Pflug and Johannes Agricola, who represented orthodox catholic, Erasmian, and moderate Lutheran opinions respectively, was an ambiguous compromise, accepting on the one hand transubstantiation, the seven sacraments, adoration of the Virgin and saints, and papal headship, but admitting on the other justification by faith, marriage of priests, and lay communion in both kinds. The variation permitted to Maurice of Saxony within his dominions was called the Leipzig interim, and was signed on Dec. 22, 1548.

INTERIOR DECORATION, the art of furnishing and decorating the interior of a building, generally a residence. Furniture, rugs, lamps, wall-coverings, curtains, wall paper, as well as fixtures, bric-a-brac, etc. are the principal materials involved in the art of interior decoration. This article will treat historically styles of furniture, etc., under the main heads: — EUROPEAN; EARLY AMERICAN PERIOD; CHINESE; JAPANESE; MODERN; WOOD FINISHES, PAINTS AND VARNISHES; WAX FINISH AND PAINTING.

EUROPEAN

Early Middle Ages.—In the earliest middle ages domestic life, such as we understand it, can hardly be said to have existed at all. Furniture and equipments had to be of a kind convenient for transport from one place to another. They were solid and strong, and in number they were kept down to the indispensable minimum. Military equipment formed a large part of the travelling baggage. There was no question of a separate furnishing of each temporary abode. Above all, it was necessary for the owner to be able to hold what he had. His habitation was rather a stronghold than a dwelling-house. The principal living apartment was a large hall with bare walls, open-beamed roof, narrow windows (probably unglazed) and floor paved with stone slabs or tiles. It contained very few pieces of furniture, and mostly such as could be brought by the occupants and carried away again when they went elsewhere. Window curtains, if used, were strung on hinged rods swung away from the window in day-time. The doorway might have some similar contrivance. A large hooded chimney maintained a lag fire. Metal braziers on wheels, for local heating, were added during the later middle ages. Warming-pans were probably a still later innovation. A massive table would be fixed to the floor at one end of the hall. Upon it entertainers would mount, to divert the company between or after the courses. Long trestle-tables, easily movable for dancing or displays, were in general use. The seats were mostly plain benches or stools without backs. If a fixed bench ran along one of the walls, there might be panelling at the back against the coldness of the stone behind, and a cushion or two. There were a few folding chairs, generally of metal, light and easily portable, and perhaps a chair of state. Sitting upon the floor, on cushions or rugs, was long customary. The coffer with hinged lid was the chief provision for storage. It served as a packing case during transit, and afterwards as a general repository. It also formed a supplementary bench or table. There was a

EUROPEAN FURNITURE AND INTERIORS OF THE MIDDLE AGES AND RENAISSANCE

1. Room in the Royal Palace, Palermo, Sicily, known as the apartment of King Roger II.; an interior of the Norman period (12th century) showing the influence of the earlier Saracen rulers of the island. The room, though small, has an effect of great suiendour. The walls are lined with marble, with animals, birds and trees above in gold and coloured mosaics
2. "King René seated at table," from an illuminated manuscript at Chantiiiy, showing a French interior of the first half of the 15th century. The wall is decorated with tapestry, ard rush matting coversthe floor. A screen of rushes is placed between the kina's seat and the fireplace behind it
3. German oak cupboard with Gothic tracery, iron locks and hinges, 15th century
4. Spanish sideboard carved with Gothic tracery, 15th century
5. Bedroom with walls and ceiling of wood, from the Landesfurstliche Burg at Meran, South Tirol. A Tirolese interior of the 15th centurv
6. Room from the Speisshof, Switzerland, about 1580, re-erected in the Historical Museum at Basle
7. Room from the "House of the Cardinal," 1540, re-erected in the Historical Museum at Basie. A chandelier hangs from the rafters and on the left is a table with the hinged top ouen, revealing the space used for storing writing implements or toilet articles
8. Room with wood floor and carved and panelled walls and ceilino. from a house in Flims, Switzerland, 17th century
9. Courtyard entrance of the castle of Issogne, Val d'Aosta, north Italy: wall bench, linen-fold panelling, and frescoes below the vaulting 15th century
10. Kitchen of the Castle of Issogne, Val d'Aosta; the floor is paved with stone, and the ceiling is vaulted

EUROPEAN INTERIOR DECORATION OF THE RENAISSANCE

1. "St. Ursula's dream," by Vittore Carpaccio (c. 1465–c. 1522). In the Academy, Venice, showing an Italian interior of the late 15th century. The bed is uncurtained; the windows have leaded glass lunettes
2. Fireplace in the large hall of Weikersheim Castle, Germany. Early 18th century
3. The Hall of Exchange in the Collegio del Cambio (Bankers' Guild), Perugia, panelled and frescoed after the Italian manner of the 15th century. In the right foreground is a desk of carved and inlaid walnut. The frescoes are by Perugino (1446–1523)
4. A room in the Borgia apartments of the Vatican, known as "Sala del Credo." In the lunettes are paintings of the Apostles, with clauses of the creed. The walls are painted, and benches of coloured marble fiil the window embrasures. 15th century
5. Fireplace by Benedetto da Rovezzano (1474–1552), Italian. Now in the National Museum, Florence
6. A room in the Davanzati Palace, Florence. The lower section of the walls is painted in imitation of hangings. The furniture dates from the 15th and 16th centuries
7. Bedroom from the Palazzo Sagredo, Venice, c. 1718. Now in the Metropolitan Museum of Art, New York. The bedstead is carved and gilded. The ceiling is attributed to Gasparo Diziani
8. Mantel-piece in the castle of Fontainebleau. Period of Francis I. (1494–1547)
9. The "Golden Hall" in the Town Hall of Augsburg, built 1616–20 by Elias Holl. It is 113 feet long, 59 feet broad and 53 feet high. it is decorated with paintings and is profusely gilded

EUROPEAN FURNITURE AND INTERIORS OF THE 17TH TO THE 19TH CENTURY

1. Venetian chair of carved walnut upholstered in velvet. 17th century.
2. Dutch ebony cabinet on ebony stand. The doors and drawer fronts are carved with mythological and other subjects and edged with wavy mouldings. The architectural ornament of the interior is inlaid ivory and coloured woods. Middle of the 17th century
3. French ebony cabinet with marquetry of tortoise shell and brass, marble top and gilt bronze mounting. Probably after a design by Berain. Late 17th or 18th century
4. "Bureau du Roi" made for Louis XV. of France by Oeben and Riesener between 1760 and 1769. It is made of marquetry of various woods and adorned with mouldings, statuettes, vases and gilt bronze plaques
5. French writing table in sycamore wood with gilt bronze mounts, marble top and inlay of plaques of Sèvres porcelain. Period of Louis XV.
6. Bedstead of carved and gilt wood with coverings of blue silk damask. French. Period of Louis XVI.
7. Panelled room of painted and gilded oak erected between 1682 and 1694 by Alexandre Sevin in the Château de la Tournerie near Alençon
8. Salle du Conseil at Fontainebleau, built under Charles IX. and decorated under Louis XIV. and Louis XV. The walls and ceilings are painted by F. Boucher and the settees and chairs covered with Beauvais tapestry
9. Boudoir (re-erected) constructed for Madame de Sérilly, lady-of-honour to Queen Marie Antoinette. Late 18th century
10. Commode with marquetry of coloured woods, marble top and gilt bronze mounts by J. Caffieri. From the room of Louis XV., Versailles
11. interior of Herrenchiemsee castle, a magnificent building in Louis XIV. style erected on the Chiemsee, Bavaria, by Louis II., 1878–85

simple form of dresser, for the preparation of food, with shelves above for utensils.

One or more spaces in the hall were curtained off by movable hangings, suspended from the rafters or from iron rods projecting from the walls. Separate apartments were thus temporarily provided. Low movable beds were placed within, covered with blankets or skins. Mattresses and pillows were stuffed with pea-pods or straw; feathers did not come into general use before the 15th century. The wealthy also had travelling beds, of palanquin form, borne behind and before by horses or men. If recesses in the hall were curtained off, a nearer approach to separate sleeping-rooms was provided. The cabinets or bowers for women's work and recreation were formed in this way.

The kitchen was a low apartment with a depression in the middle of the floor for the fire, provided with a great iron grid, which was slid over for cooking upon. In some cases there were one or two private rooms, perhaps on an upper floor. Guests were accommodated in the large hall, where movable beds could be set up in case of need. Sometimes strangers had separate apartments, with an entrance from outside. In the greater houses there was a chapel, where daily prayers were read.

Later Middle Ages.—Such conditions, varied according to local circumstance, were generally prevalent in western Europe down to the close of the 12th century. Where Eastern habits of life had already penetrated, as in Sicily or Spain, magnificent buildings were erected. A room in the palace at Palermo, Sicily, is still known as that of the Norman king, Roger II. The walls are lined with marble, and the lunettes and ceiling above are encrusted with elaborate mosaics. Changes were gradual and progressive, but a definite step forward was made about the 12th century. Most of the military leaders in France (and many in neighbouring lands) had by then taken part in the Crusades, and they had learned something of a more luxurious mode of living. The accumulation of possessions now began, and women took a more prominent share in the regulation of the household and the provision of daily needs. Curtains brought from the East would be of thinner texture, and they were drawn back in folds rather than swung away from the windows. The better store of hangings enabled the bareness of the walls to be relieved. The wooden ceilings were coffered, and sometimes painted in bright colours and gold. Where folding shutters were provided for the windows, the need of glazing would be obviated. The high table was placed across the end of the hall, where the floor was raised. Long massive tables at right angles accommodated the household and retainers. Tables of horse-shoe form might still be used, as in early times, for convenience in serving. Tables for the dishes were at the lower end of the hall. A small "credence" table, for tasting wine and liquors, was set against a side wall. Wooden cradles for infants were made to rock on the floor, or to swing between end-supports. Seats with upright wood backs, and, perhaps, a carved hood above, would replace the plainer benches for the chief personages. The coffer, or chest with hinged lid—that perennial and indispensable article of furniture—had its drawbacks. Everything set upon it had to be removed before it could be opened. Hinged doors were therefore set in front, perhaps with a nest of drawers behind, and a long drawer below. From this the armoire and the varieties of presses and cupboards would take shape. Beds became fixtures, though not yet relegated to separate sleeping-rooms. They were of panelled wood, sometimes taking the form of a huge cupboard with open front. The mattress raised above the floor was often of ample dimensions, affording space for a whole family in case of need. It was generally set in the corner of the room, and at the free angle the curtain was looped up during the daytime in a kind of rolled bundle, still exemplified in Dutch pictures as late as the 17th century. Sometimes there was a narrow space between the bed and the wall for dressing and undressing. This was screened off by the bed-curtains.

In the later middle ages the wardrobe was a separate room, with deep presses lining the walls, having cupboards above and lockers below. Here mere stored the hangings, floor-coverings, curtains, tapestries and linen of the establishment, besides the garments and materials for a large household. With the lack of shops this was the place to replenish supplies. It was also the workroom of the establishment, with tables and other provision for tailors, repairers and needlewomen.

As the middle ages went forward, the hall continued to serve many purposes; but gradually the dwelling became divided into ante-chamber, hall and withdrawing-chamber. There might be also a state bedroom, where guests could be received. A lit de parade was sometimes provided solely for this purpose. The "bed of justice," of which we hear from mediaeval times onwards, was at first a couch or low seat for reclining upon, where the French sovereign met his parliament.

The kitchen was now provided with vast low arched recesses in the walls, where the fire could be better regulated than in the middle of the floor. Rotating spits, in stages, for roasting, had dripping pans below, and there were hooks for suspending cooking-pots over the fire.

The floor (of stone or earthenware tiles in large houses, of the bare earth in others) was covered with sawdust, as it is even to-day in great kitchens. In course of rime it became usuai to spread the floor with rushes and fragrant herbs. It was not till the later middle ages that the rushes were plaited into mats. Plain woollen cloth or furs were sometimes laid down. For ceremonial, rich stuffs were spread before the royal throne. Oriental pile carpets were not used before the 15th century, and they were rare in western Europe before the 17th century.

Torches at first provided the principal lighting, and the fire served to give light as well as heat. There might be a few sconces fixed to the walls, with prickets for candles. A small hanging iamp with floating wick was more convenient than the candle for the light, which was usually kept burning all night within the bed-curtains, as much to scare away spirits as corporeal beings. Standing candelabra of iron for many candles came into use, as well as small portable pricket candlesticks, and occasionally chandeliers or "lustres" hung from the rafters.

As the women of the household took more and more to the management of domestic affairs, furniture tended to accumulate. The use of ornaments and various articles of luxury grew during the times of the Crusades, increasing as commercial relations with the Near East became closer in subsequent centuries. Indoor provision for washing and bathing must also be included among luxuries. A long trough with a row of taps in a courtyard served for most of the household. At times there was a tank or cistern with water continually running. A metal bowl, flat-sided, was sometimes fixed to the wall of a living room, with a swinging ewer or a small cistern with tap over it, and a towel upon a hinged rod near by. Provision for reading was made by a portable lectern with sloping top. The top might revolve to facilitate reference to different books, or it would work up and down for convenience. Sometimes it had a recess for the storage of books. A sloping board for writing upon could be adjusted to the arms of a seat, or it could rest on a table.

Sometimes a shallow box, with inkhole, was set on the writer's knees.

Small convex mirrors were hung on the walls as early as the 15th century, but hand mirrors of polished metal or glass were the only mirrors in general use before that time.

An illustration in the celebrated manuscript in the Museum at Chantilly, the "très riches Heures du Duc de Berri," represents King René seated at table. Behind him is a fire in a hooded chimney. He is protected from its heat by a circular screen of plaited rushes.

The wall is covered by a tapestry hung upon hooks. Rush matting is on the floor.

The table is covered with a white cloth, and courtiers and servants are busy around. It forms a striking picture of seigniorial life in the first half of the 15th century.

The amount of mediaeval domestic furniture which has come do n to the present day is relatively small, but the general characteristics need to be borne in mind, for the middle ages were the cradle of later times, and much that came afterwards is explained by reference to them. Indeed, in backward countries, or in remote districts little affected by change of fashion, the

mediaeval tradition has been carried down to our own times. Besides eastern Europe, parts of Switzerland and Scandinavia may be cited as examples. The wooden chair (see WOODCARVING), from Tyldalen church, in Oesterdalen, Norway, is attributed to the 10th century.

Alpine Lands.—The mediaeval furniture of the lowlands was principally of oak and hard woods, but in mountainous districts, such as Switzerland, the Tyrol and south Germany, the use of fir, pine and the softer woods at hand determined the form and ornamentation of the furniture made from them. Such woods were often the only available building materials as well, and floor, walls and ceiling alike would be entirely of wood, as they often are today. A bedroom from the Landesfiirstliche Burg at Meran, South Tyrol is a remarkably complete and well-preserved example of an interior in a house of some standing in the latter half of the 15th century. The old Swiss furnished interiors exhibited at the Historical museum in Basle, though only in one case dating back to the mediaeval period, illustrate much that has been said about earlier times. They were carefully removed from old houses, chiefly in the town.

There are others in the museums of Berne and Zurich, covering the period from the 15th to the 17th century. Floors are of wood, walls and ceilings are moulded and panelled. Sometimes there is inlay or veneering of harder and more ornamental woods. The mouldings are bold, but any carving is usually in slight relief, owing to the nature of the wood, and the inlay is generally simple and geometrical. Tables have legs of trestle form, and the tops are hinged so as to lift up and reveal a spacious receptacle for writing implements or articles of the toilet. Chairs are primitive, with solid wooden seats and splayed legs. Benches are fitted along the wall. Panelled beds of ample size are in the living-room: Coffers tend to be high, with a wider base containing one or two drawers. The walls being of wood, the construction of corner cupboards is simple. Flat carving may be in a style recalling fretwork. Bands bf foliage and other ornament following the Gothic tradition, and suited to the coarse grain and softness of the wood, are very effective. These decorative parts were painted in bright colours, and entire pieces of furniture were sometimes painted over with figure-ornament or other motives.

Italy.—The Castello d'Issogne, in the Val d'Aosta, in northern Italy, is remarkable among surviving examples of the adaptation of the mediaeval domestic interior to the mild climate south of the Alps. It was built about the year 1490 by a member of the Challant family, who held the post of governor of the Val d'Aosta. Though mediaeval in structure and appearance, it is not a stronghold, but a summer retreat. It is built in a square with a tower at each corner. There is an inner courtyard, along one side of which is a kind of vaulted portico supported by pillars and open to the courtyard. This is used as a hall, with wooden linen-fold panelling and a fixed bench running along the wall. The lunettes above the panelling are filled with fresco paintings of scenes in daily life—the shops of a provision merchant, an apothecary, and a tailor and draper, an outdoor market, and soldiers in a guard-room. There is also a dining-room with credence, tables and stools, an armoury, a kitchen, servants' hall and chapel. The coffered ceilings are carved and painted.

During the middle ages furniture in Italy differed but little from that of neighbouring countries. Any deviation was likely to be due to the use of walnut, a more tractable wood than oak, and to the outdoor life which rendered an accumulation of furniture superfluous. The Gothic style never took firm hold in Italy, though occasionally Gothic tracery is found in the furniture of Venice and Tuscany.

RENAISSANCE

The Renaissance, which originated in Italy in the early years of the 15th century, gradually brought about a complete change in the domestic furniture of that country and of Europe. The classical tradition had never been entirely lost in Italy. Traces of Roman greatness were to be seen in many places, though excavation was only undertaken with the aim of obtaining building materials from the ancient ruins. When a deliberate return to old models was made, furniture gained an importance that it had not known hitherto. Columns, capitals, entablatures, pediments and other architectural features provided the skeleton of the structure, and the purpose of the cabinet or table, or whatever it might be. was subordinated to its form. The joiner borrowed from the architect.

The furniture of the early Italian renaissance is often very restrained and beautiful. For the more elaborate kind of work, sculpture in low relief and stucco modelled in intricate patterns were much used. The stucco was usually gilt all over and picked out in colours. Such pieces became elaborate and costly works of art, though it must be admitted that they mere a by-product of the furniture-maker's craft. Carpaccio's painting of St. Ursula's dream, in the Academy at Venice, gives a most attractive idea, though in some measure fanciful and exaggerated, of an Italian interior in the last of the 15th century. The bed is of a form allied to the great panelled bed of northern Europe, but the heavy curtains are not required in a room flooded by the light and warmth of the early morning sun. There is a bench along one wall, an arm-chair, a stool and a low table. A cupboard is let into the wall, and a smaller cupboard holds books and other articles.

The ceiling is panelled and the windows are shuttered, with leaded glass lunettes above.

There was no class of furniture on which the wood-carver's and stucco-modeller's skill was more exercised than on the cassone or marriage-coffer, provided and filled for the bride. In addition to the elaborate relief-work and gilding, these coffers were often painted on the front and sides, and occasionally inside the lid as well, with appropriate scenes executed by some of the chief artists of the day.

At times these chests imitate the forms of the ancient Roman stone sarcophagi. Walnut, a common wood in Italy, was an admirable material for delicate carving. The panelling of rooms was sometimes finely carved and inlaid. The Hall of Exchange at Perugia shows the panelling, with pilasters and cornice, and a fixed bench along the wall. **A** large writing desk is built out into the hall. Italy did not need the heavy draperies of colder regions, and the dry climate rendered fresco-painting durable on the walls.

The fixed writing desk is the forerunner of the writing bureau, which became an indispensable article of furniture as the practice of writing became general.

A type of chair much favoured in Italy, and often richly carved and gilded, was evolved out of a simple joiner's contrivance of mediaeval times. The seat was a small wooden slab, generally octagonal. It was supported at front and back by two solid boards cut into an ornamental shape.

Another piece of wood, in the shape of a half-opened fan, formed the back. The tables were generally oblong, supported by columns, consoles or terminal figures, with a long stretcher running from end to end.

In Italy the domestic arts were not relegated to a place inferior to those which it has been customary, since the 18th century, to designate as the "fine arts." The amazing versatility of the great artists of Italy is largely accounted for by this circumstance. The influence of the Italian furniture of the renaissance soon spread into neighbouring countries, revolutionizing the furniture-making of Europe.

Austria and Germany.—Italian models were followed in the Austrian provinces to the north. The cabinet makers of Augsburg and south Germany evolved an elaborate type of work based on the example of Italy. Cabinets had doors in front, which revealed an arrangement of drawers and compartments inside. They were covered with veneering and inlay of tinted woods, and details were delicately carved.

Rooms were panelled in harmony with the furniture. The inlaid writing desk of Christoff Miiller, of Augsburg, made in 1555, now in the Berlin museum, is shaped at the end like the facade of a mansion of the Renaissance.

France.—The French monarch of the 16th century invited Italian artists to the court. They were employed in extensive

undertakings, and the forms they introduced were generally followed. Italian models in furniture were closely imitated. The carved walnut furniture of France in the 16th century is remarkable for gracefulness and delicacy. Sometimes it is relieved with inlay of small plaques of figured marbles and semi-precious stones. Elaborately-carved oblong tables were supported by consoles or fluted columns, connected by a stretcher surmounted by an arched colonnade.

Cabinets and chairs followed Italian shapes. As in other countries where a tradition has been imported from outside, the influence was largely restricted to the capital and to districts under the influence of the court. Older local traditions lingered in the remoter regions.

In France, for example, the distinctive furniture of Brittany and Normandy has retained its local characteristics down to the present day.

Spain.—In Spain the alien influence came at an earlier time and from remoter parts. With the invasion and occupation of the south by Arabs and Korth Africans, in the 8th century, the greater part of the peninsula became virtually an oriental country, and so it remained fur seven centuries. After the expulsion of the last Arab ruler, at the end of the 15th century, many "Moriscos" still remained in the country, and the intelligent and industrious craftsmen among them still worked for the Christian rulers of the land in their own traditional styles. The vaulted, coffered ceiling in pine wood from the palace at Torrijos, near Toledo, elaborately carved and painted, was built at the end of the 15th century for Gutierraz de Cardenas and his wife.

Several types of these oriental panelled or coffered wood ceilings are found in Spain. A type of cabinet known as the vargueño is typically a Spanish production—a medley of European and oriental elements. The upper part is a chest, generally elaborately mounted in wrought iron, with a massive iron lock to the drop-front. When the front is lowered, an elaborate arrangement of drawers and recesses is revealed, often with ivory inlay, gilding and brilliant colouring.

Sometimes the base is another chest with cupboards. Later examples have supports with baluster legs and arcading elaborated from French or Italian models. The chest itself is sometimes decorated under the same influence. Mediaeval Spanish furniture has various foreign elements. The buffet already referred to recalls French work. The iron-mounted coffer, originally painted all over and bearing shields of arms, is a Spanish adaptation of the Italian cassone. Folding chairs of X-shape, with mosaic inlay of ivory and coloured woods, were much in use in the 16th century.

There is a tendency for Italian models to be followed in the furniture of the 16th and 17th centuries. In a country so renowned for its iron-workers, it is not surprising to see that bracing-irons of fanciful workmanship are often attached for strength to tables and benches.

Low Countries.—Perhaps the Italian renaissance found its most characteristic expression outside Italy in the Low Countries. The Gothic furniture of earlier times was solid and strong, with linen-fold pattern and intricate tracery. Its use is exemplified in the work of the contemporary oil painters, whose work gives so convincing a picture of the prosperous and comfortable domestic life of those industrious provinces in the middle ages. Rooms were lofty and spacious. The walls were wainscoted in oak or covered with embossed and painted leather. Windows were partly enclosed by glass panes, often embellished with heraldic and figure ornament, and partly by inside shutters of oak, studded with nails. When the shutters were thrown back, light and air were provided at the same time, for numerous Dutch pictures show that in many cases there was no glass behind them. Chimney pieces, with overmantels carried up to the ceiling, were embellished with marble columns and elaborate carving, and similar architectural ornament flanked the doorways. Heavy oak tables (sometimes "draw tables," which could be extended to twice the length) had massive bulbous legs and solid stretchers. The beds in the corners of the living rooms were heavily draped. Folding wooden chairs and low stools with more or less elaborate turnery, were still used, besides a new type with baluster formed or twisted legs, arms, and straight backs heightening as the 17th century went forward. The leather upholstery of seat and back were replaced by caning in the latter half of the century, when the high back had a narrow panel flanked by balusters or columns resembling the legs.

Low chairs with back, arms and ears in one solid piece, were stuffed and padded, and upholstered with tapestry, embroidery, velvet or other material, showing that the limit of domestic comfort had by that time been reached. Large folding screens with leather panels, or others of lacquer-work imported from the east, kept out the draught.

Lacquered furniture was also imported from China and Japan, and travellers learned the secret of this specifically oriental craft, so that imitations were made in Holland, as well as in France, north Italy and elsewhere.

The great tapestries for which the Netherlands had long been famous afforded additional protection from the cold air, and oriental pile carpets mere used as table-cloths, for it was not yet customary to spread them on the floor, where they would have accorded ill with the habits of domestic life.

Scandinavia.—In Scandinavian countries much domestic architecture continued to be of wood, and the furniture remained simple and primitive.

Relief was afforded by painted linen hangings, sometimes representing Biblical scenes, with the figures in contemporary peasant costume, and by brightly-coloured cushions in embroidery or tapestry.

Houses of the well-to-do contained furniture from north Germany or the Low Countries, providing models which the local carpenters might copy.

The Baroque.—During the 17th century the baroque (see BAROQUE), had a drastic effect upon furniture design. Large wardrobes and cupboards had twisted columns, broken pediments and heavy mouldings.

The baroque style owed much to the oriental influence which swept over Europe in the 17th century, when several of the European maritime countries established regular trading relations by sea with India and the far east. Besides the furniture and domestic goods imported from the east, the oriental craftsmen worked, for export, in a pseudo-European style, from designs supplied by the traders.

Heavy tropical woods were also brought to Europe, and from these furniture was made which borrowed much from the prevailing taste for oriental elaboration. Ebony cabinets with waved mouldings, intricate carvings in low relief, and profuse inlay in tinted ivory and coloured woods, were made in Italy, Germany and the Low Countries.

The ébéniste then acquired his name.

Later French.—In France, the Italian influence of the 16th century was gradually assimilated, and a national style of furnishing was evolved which soon spread its influence into neighbouring countries. The "styles" of Louis XIV, the Regency, Louis XV, Louis XVI, the Empire and so forth, have passed into the phraseology of Europe generally, and their influence has operated wherever the terms have been used.

The reign of Louis XIII, covering most of the first half of the 17th century, was a time of transition. The fame of his son and successor, Louis XIV, the great monarch. might suggest that the outlook of a great nation was then modified and enlarged by the force of a single personality, but it was the national spirit which created Louis XIV, and his times. Expansion in Asia and America, and the growth in the national wealth, were the causes which led to the building of Versailles and the Galerie *d'Apollon* of the Louvre.

The great "Salon" now came into being, and the number of separate apartments was multiplied. A suite would comprise a vestibule, ante-chamber, dining-room, salon, state bedroom, study and gallery. Stately and spacious staircases were provided. The interior economy of the modern house dates back to this time.

The Gobelins factory, which still remains a national establishment, was founded under Louis XIV for the production of *meu-*

bles de *luxe* and furnishings for the royal palaces and the national buildings.

Charles Le Brun was appointed the first director of the Gobelins. Furniture was veneered with tortoiseshell or foreign woods, inlaid with brass and ivory, or heavily gilt all over. At times it was even completely overlaid with silver. The name of André Charles Boulle (*q.v.*) is particularly associated with this tendency. His cabinets and tables were completely covered by sheets of tortoiseshell and brass cut into intricate patterns so as to fit into one another, the tortoiseshell alternately forming the pattern and the ground. (See INLAYING.)

The light fanciful "grotesques" of Bérain were much used for this work. Heavy gilt bronze mounts protected the corners and other parts from friction and rough handling. In ancient times, folding chairs might be of iron or bronze, and iron hinges and mountings have, of course, been used at all times where strength was required.

The massiveness and elaboration of the furniture under Louis XIV was followed by the rococo style of the regency in the first half of the 18th century. This style owes more to the influence of Chinese art than any other. The famous writing-table of Louis XV, exhibited in the Louvre, was the work of the celebrated furniture makers, Riesener and Oeben. It is said to have taken nine years to make. Furniture under Louis XVI showed some return to classical models. Curved surfaces were replaced by severer design, and straight, tapering legs succeeded the cabriole. A limit of elegance unknown before was reached.

Plaques of the delicate porcelain of Sèvres, with ornament painted in brilliant colours on a dazzling white ground, were freely employed upon tables and cabinets. The graceful tapestries of the Gobelins and Beauvais replaced the heavy velvets of the 17th and early 18th centuries for upholstering chairs and settees and for window hangings. The French furniture of the 18th century set the standard of elegance and refinement for the whole of Europe.

Rooms were rebuilt or remodelled in accordance with the taste of the day. Elaborate parquet flooring was introduced before the close of the 17th century. Walls were enriched with relief work and gilding.

Tall glass mirrors, reaching from floor to cornice, were set between the windows and protected by console tables. Ceilings were painted by some of the chief masters of the time. Later, when more restrained types of furniture were made, walls were painted white, with mouldings picked out in gold. The plain white-washed ceiling did not come into favour before the 18th century was well advanced.

A panelled room from the Château de la Tournerie, near Alençon (in the Victoria and Albert museum), is of oak, painted and gilt, and embellished with embossed leather panels enriched with painting and gilding.

The château dates mainly from the 16th century, but the panelling was erected between the years 1682 and 1694 by Alexandre Sévin. It bears his crest and initials with those of his wife. A boudoir in the museum, from a house in the rue Vieille du Temple, in Paris, is said to have been erected under the personal supervision of Queen Marie Antoinette and Madame de Sérilly, her friend and lady of honour.

Later Styles.—Towards the end of the 18th century the influence of the discoveries that had been going on at Pompeii penetrated into Germany and Austria, and interiors were decorated in the light and fanciful style exemplified in the wall-frescoes of the Pompeian houses.

About this time a vogue arose for draping interiors into the resemblance of a tent. The draperies completely covering the walls were sometimes pleated, and if the ceiling was high enough it would be concealed by a kind of sloping velarium. A bed would be enclosed by festoons of drapery.

The influence of the well known cabinet-makers of England in the second half of the 18th century, was reflected in the work of the furniture-makers of north Germany and Denmark.

The Napoleonic régime hastened the changes then in progress in European furniture-making. The example of Roman majesty was continually in the emperor's mind, and the "Empire" style aped the hninspired decorative formalities of Roman imperial times.

Furniture with outcurving legs was copied from representations in Roman reliefs. Griffins and sphinxes were freely used as decorative motives or supports.

Beds with rolled ends and stuffed backs, sometimes with drapery above like a gable roof, were the forerunners of the sofa of the later years of the century.

The rest of Europe adopted the "Empire" style, of which the chief merit was a return to more sober models after the exaggerated fancifulness of previous styles.

Towards 1825 the reaction came. Earlier fashions were again reverted to, for a time, in a half-hearted manner. The new wealth of industrial and trading communities gave rise to new ideas of material well-being.

The comfortable "Biedermeier" style arose in Germany. Furniture was luxuriously cushioned and padded. Thick curtains, festooned draperies, table-covers, antimacassars, tassels and fringes were seen everywhere.

The subsequent tendency to revert to imitations of the furniture of the 17th and 18th centuries is not altogether praiseworthy. It is easier to stifle originality than to revive it when the inevitable need arises.

Moreover, there were contributory causes for most of the changes which have been here briefly reviewed, and to copy a type of chair or table when the circumstances which originally gave rise to it are no longer operative is not in harmony with the soundest principles.

(See also the various short articles on pieces of furniture, such as BED, CHAIR, CHEST, TABLE, etc.; also the different styles and periods, such as ROCOCO, BAROQUE, etc.).

ENGLISH

Henry III.—A notable early specialist in house decoration in England was Henry III, who rebuilt Westminster Abbey. The Liberate Rolls of his reign preserve all the orders he gave for the adornment of his various castles and his manor houses. Larger windows, and, especially, rose windows were built in halls, their painted glass adding to the rich colour decoration that the king loved and obtained at other times by painting "histories" on his walls, as in his Great Chamber at Westminster. His queen had a figure of winter painted over her fire-place there, and spring-like flowers painted on the white-wash of her room at the Tower. Walls were frescoed with histories, including scenes both Biblical and classic, and below them often was wainscoting with painted and decorated boarding. Wrought roofs or painted ceilings completed a rich domestic treatment, which was very rare in 13th century England, when walls were bare and hangings were the usual means of decoration resorted to by nobles or rich burghers.

Flanders tapestries, known by the generic name of "arras," were then the most favoured material. Solidly woven, they resisted the wear and tear of the movings of great men who had various estates but little gear. Tapestries were hung curtain-wise from wood-quartering set with tenterhooks, and such have been renovated at Tattershall castle, where, except for such hangings, the brick structure of the walls was visible, as is seen also in a picture from an illuminated manuscript produced in Flanders for Edward IV (c. 1475) of Richard II feasting. There is no arras, but the king sits under a rich textile canopy, similar mate-

ENGLISH INTERIORS OF THE 15TH AND 16TH CENTURIES

1. "Richard II. Feasting," from *Les Chroniques d'Angleterre*, an illuminated manuscript of about 1475; showing architectural treatments and decoration of the period
2. Marble chimney piece in the gallery at Cobham, executed by Giles de Whitt of the Low Countries, 1599
3. Hall screen of single storey height at Cuckfield, Sussex. Early Renaissance style. Dated 1581
4. Gallery door at the Vyne, Hampshire; carved in Gothic linen fold with various heraldic devices. About 1515
5. A room (restored) in Tattershall Castle, Lincolnshire, built about 1438 by Baron Cromwell, Lord High Treasurer to Henry VI.; with tapestries, Gothic chests and table of the late 16th century

INTERIOR DECORATION

ELIZABETHAN AND JACOBEAN INTERIORS

1. The hall at Plas Mawr, Conway, Carnarvonshire, an admirable example of an Elizabethan interior. The patterned ceiling is a product of the school of plasterwork that flourished during the last quarter of the 16th century; the upper part of the chimney piece is also plaster
2. Ceiling in the great chamber at Herringston, Dorchester, dating from about 1615. It is barrel-shaped and worked with an elaborate pattern of floral scrolls, heraldry, beasts and birds. The pendentals are a feature of the period
3. Stone hall screen at Wollaton Hall, Nottinghamshire, a residence erected in 1580 by Sir Francis Willoughby. Elizabethan
4. The large or north drawing room at Levens Hall, Westmorland, showing 3 decker chimney piece, plaster work ceiling, and north window with roundels of painted glass. The family heraldry is carved in the compartment above the fire arch; Queen Elizabeth's arms in the centre panel of the top compartment, and the date 1595 in that to the right. The family heraldry also provides the motifs of the six painted window ovals

ENGLISH INTERIORS— SYON HOUSE AND CHATSWORTH

1. View of the great dining room at Syon House, Middlesex, looking east, showing the niche system (introduced to add to the sense of width), the columned apse and the enriched ceiling. The chimney piece is of white marble, and the room is painted yellow with gilded enrichments. Designed about 1762 by Robert Adam

2. The great chamber at Chatsworth, Derbyshire. Late Stuart style. It is wainscoted from floor to ceiling, and the more important panels decorated with carvings in Grinling Gibbon's manner by Lobb, Davis and Watson in 1692–3. The ceiling was painted by Verrio, the famous contemporary Italian artist

EARLY GEORGIAN INTERIORS

1. South side of the stone hall at Houghton, Norfolk. *c.* 1725. The room, surrounded on three sides by a gallery, is of white Whitby stone, with stucco ceiling and mahogany windows and doors

2. Chimney piece of dark veined marble with frieze and sculptured ornament of Carrara marble, at Godmersham Park, Kent. *c.* 1732. Design of the picture frame resembles that of the other wall panels and the window cases

rial also hanging in front of the musicians' stand. It was not as yet customary to have walls lined with oak, but it was used, and used richly, by the highly expert carpenters of the day for such structural purposes as hall screens and room partitions.

They had not, however, taken in hand the chimney-piece, which remained in the domain of the mason who in the 15th century bestowed pains upon its adornment, as we see in the great heraldically carved chimney-pieces at Tattershall, dating from about 1438.

The Development of Panels. — It was not, however, until the days of Elizabeth that this feature became monumental, often reaching from floor to ceiling by the use of superposed classic columns.

By that time framed wood linings had become usual, and to them gradually became applied the word "wainscote," which had originally merely meant foreign oak.

Such panelling, although only common under Elizabeth, occurred under Henry VIII, the finest and amplest surviving example being probably that in the Gallery of the Vyne, in Hampshire, where the linenfold carving is enriched by various heraldic badges that enable us to date it from between 1515, when Wolsey was made a cardinal, and 1530, when Catherine of Aragon fell into disfavour.

The same treatment, extending also to ceiling beams and panels, we may still see in such Essex houses as Paycocke's, in Coggeshall, the Granby inn at Colchester or the manor house at Tolleshunt Darcy.

Frescoing walls still continued, but most of it has perished. Some late 15th century representations of Bible scenes have been found under whitewash at Cothay, in Somerset, while of Elizabeth's reign a very good example has come to light at the White Swan inn at Stratford-on-Avon, depicting scenes from the story of Tobit.

Hangings, however, still held the premier place as wall coverings. In the early part of the 16th century, the number of sets belonging to kings and great men was almost countless, and a Vyne inventory of 1541 gives sets in almost every room of the house, including the chambers of dependents.

A somewhat similar effect was reached by cheaper means, and there was a great output of tempera — painted or "stained" cloths, using the same subjects as tapestry — histories from Biblical or classic sources, verdure of woods and fields with beasts and birds and decorative subjects passing from Gothic to Renaissance *motifs*.

Nearly all this "counterfeit arras" has perished, but a set displaying the Acts of the Apostles survives at Hardwick hall in Derbyshire.

Leather, embossed, painted and gilt, was less used in England than on the continent, but such woven fabrics as velvets and damasks for the wealthy, and "sayes and bayes" for modest folk, found a place on the walls as well as for bed and window hangings.

The Elizabethan joiner, when his employer's purse permitted, enriched his wainscotings with carvings and inlay and completed the circuit of the room with elaborate oak door-cases and chimney-pieces, using for them classic orders and Renaissance *motifs*. For the most part their work shows an uncultured vivacity rather than a trained head and hand, a knowledge of the anatomy of the human form being very rarely displayed. Typical of the English craftsmen of the day is the great drawing-room at Levens in Westmorland.

The chimney-piece, dated 1595, is of three stories, Doric, Ionic and Corinthian orders being piled one upon the other. Elaborately framed wainscotings, enriched doorcases, plaster-work ceiling and roundels of painted glass in the windows complete the picture.

Screens continued to be used in halls even when they were of single-story height, as at Cuckfield in Sussex, dated 1581. The vast majority were of oak, but in important houses, stone was sometimes used, as at Wollaston and Montacute. Stone and even marble were used for chimney-pieces, especially in James I's reign when Max. Colt, "carver in wood and stone of all his majesty's works." provided three marble chimney-pieces for Hatfield; and we find similar ones at Knole and Bramshill. One example, however, there is of the previous reign; a noble chimney-piece in the Gallery at Cobham, wrought in 1599 by Giles de Whitt.

Plaster Ceilings. — Although wainscotings became the normal wall treatment under Elizabeth and her immediate successors, yet there was still scope for tapestry, and also for enriched plaster ceilings consisting of narrow interlaced ribs forming geometrical patterns. There are interesting examples at Plas Mawr in Conway, where the same material forms the upper part of chimney-pieces, the royal arms indicating a date in Elizabeth's reign. Such treatment of ceilings was often very elaborate in those distinctive Elizabethan rooms, the long gallery and the great chamber, which were often upstairs; and greater height was obtained by using the roof space and forming a barrel-shaped ceiling. They exhibited not only the narrow ribbing of Elizabeth's time, but also the broad bands with enriched soffits that came in under James I, one of the finest examples of which is at Herringston, near Dorchester, dating from about 1615.

The Staircase also reached its final development in this reign. In mediaeval times, the winding newel form, sometimes of wood but more often of stone and never very wide or easy in gradient, had prevailed. But under Elizabeth it had begun to be placed round an ampler open space, and its decorative possibilities being recognized, enriched newel posts, balusters and strings were given to it. The idea was developed under her successor, and one of the finest, both in planning and execution, is the great stair at Hatfield, dating from 1610. The newel posts are richly carved and surmounted with figures so skilfully sculptured in wood that they may well be the work of Colt himself. Here, and at Audley End, the halls, which still rise to the roof, are fitted with great screens embodying all that is best and finest of the native design and workmanship of the time.

Jones and Webb. — A feeling for classic reserve was now spreading and the Late Renaissance period might well have begun under Charles I but for the political difficulties that checked the zest for fine building. Returning from Italy in 1615. Inigo Jones introduced the new style in the Whitehall banqueting house and the Queen's house at Greenwich, and, despite English conservatism at first and the Civil War and the Commonwealth afterwards, we find his hand and that of his kinsman and associate, John Webb, at Wilton, Forde abbey and Thorpe, all houses altered or built by men on the winning, or Parliamentary, side. Also built under the Commonwealth is Coleshill, the earliest and one of the best of English country seats where classic form and Italian tendencies prevail.

Wood was less used than stone and stucco by the Italians for wall linings, and Inigo Jones favoured their materials as well as their manner. Webb, however, and other Englishmen were more northern in taste and native in training, so that wood held its own in England till the end of the century. But it had to conform to the new taste. Wainscotings must no longer be framed sheets of small panels in the nature of movable linings, but must simulate wall structure. They become architecture, not furniture. Vast panels thrust forward from their stiles by bolection mouldings are made up of two or more boards skilfully chosen and worked to hide the joint, even where they are left unpainted, as by Grinling Gibbons, the amazing delicacy of whose carving in lime is obscured by paint but stands out excellently against an oak background.

The Age **of** Wren is characterized by an architectural treatment as of stone but with the natural surface showing, as exemplified by the admirably designed and executed joinery not only in churches and public buildings, but in houses, such as Belton and Chatsworth. The passage from the early to the late Renaissance period is a change not only of style but of spirit.

During the former period, the craftsmen retained much of the independence of action of mediaeval times, and the work was free and forceful but not fine. But perfection, reached through discipline, is the essence of the classic spirit. The design becomes more learned and includes detail which it was the business of the executant to follow obediently but skilfully. The field of individuality was closing for the craftsman, but that of dex-

terity was opening wide. Thus mastery of technique is a distinguishing feature of men like Gibbons and Hopson, Strong and Tijou,—natives and foreigners who combined to give finish to the decorative output of the later Stuarts.

The Georges.—Even during the last years of that dynasty, and still more under the Georges, the wood-workers found their domain contracting. Italy exerted more and more influence, stone and stucco became more used. Vanbrugh began and the Burlingtonian school continued the stucco, stone or marble halls of the new Whig palaces, such as Castle Howard and Blenheim under Anne, Houghton and Holkham under George II., Syon and Heveningham under George III. Stone treads and iron balustrading, moreover, were introduced for staircases, although in this feature the joiner long retained the lead. Under Charles II. the work is solid with massive balusters or open panels elaborately carved under a broad hand-rail, as at Wolseley or Sudbury. But with the 18th century it becomes lighter and more delicate, although equally finished and rich, as at Beningbrough in Yorkshire where, in 1716, we find the joiner still supreme, and are enchanted with the quality and quantity of the wood-work as it appears there and in so many doorways and chimney-pieces, shutterings and framings in George II houses, like Godmersham in Kent.

Elsewhere, however, it is the Italian stuccoist who holds sway and riots in the exuberant ornament that was so wonderfully reached by experts in *il* stuc, and of which we find some outstanding examples at Mereworth and Houghton, Moor Park and Clandon.

Textiles.—But it was not only stone and plaster that was driving the joiner from walls of rooms. Textiles became increasingly popular. For them as for wood the late Renaissance demanded a more architectural handling and they were no longer hung but stretched on frames fixed above a dado. Not only tapestry but cut velvets and damasks were favoured, and a single order for these given by the duchess of Marlborough in 1707 was for over 3,000 yards. Indian calicos and other lighter and less expensive textiles mere also fashionable, but the most serious, because still cheaper, competitor to wainscoting was paper, which, from being a 17th century rarity became a prevalent feature as the 18th century progressed. During George III.'s reign we notice an increasing lapse from classic restraint and Palladian purity. French rococo joined Italian baroque and was sprinkled with vagaries that passed for Chinese and Gothic. Ceilings, chimney-pieces, door-cases were apt to be so treated, the most astonishing being perhaps those at Clayden in Buckinghamshire.

Adam.—Reserve rather-than excess, however, was the English characteristic, so that baroque and rococo gave way to the choice delicacy and clean lines that were the basis of the style of Robert Adam, who commenced his London practice in 1759. With him the despotism of the architect over the craftsman was complete. No detail of decoration or furnishing escaped him: his rapid and precise draughtsmanship covered the whole ground. The executant must not depart one hairbreadth from the drawing supplied, but he must have reached exquisiteness of technique. This spirit, joined to that of severity and restraint in design, makes the perfection reached during the last decade of the 18th century a little chilling and inanimate, implying a ceremonious rather than a domestic life.

Adam's clients, however, were for the most part the Italy-loving leaders of an aristocratic and artificial age, who affected a palatial and ultra-architectural treatment of interiors, as shown by the painted wall surfaces broken by pedimented door-cases, the columned apses and the scooped-out niches that we find in the hall at Kedleston, the dining-room at Syon and the saloon at Heveningham. In smaller and more domestic rooms, if the materials differed, the same practice obtained. Even carpets were made to reflect the ceiling design. Wood was never left unpainted, and although the joinery is still admirable, the enrichment is often in composition or in pewter. We find specially designed temple-fronted bookcases, and specially painted pictures set in specially designed frames fixed and painted to form an integral part of the wall structure.

"Gothi@."—So much logical completeness, such wholly unemotional perfection, was bound to stir up opposition, especially at a time when a new romantic school was forming and the cult of the picturesque was gathering strength. Although architecture and decoration—indeed, life itself—were treated much as playthings by Horace Walpole, and Strawberry Hill was a mere confectioner's romance, yet his influence was large and helped to turn James Wyatt from the classic manner, which he had practised as successfully as Adam, to pseudo-Gothic. For decoration it was a singularly unfortunate introduction. What in the mediaeval interior was not movable was truly structural, and not imitative of it; so that not only did flimsy wood, plaster and paper decorations entirely miss the Gothic spirit, but they were introduced as the trappings of houses designed to meet entirely different habits of life. Thus, when the 19th century was reached, a plan that, in the disposition of parts, the shape of rooms, the height of ceilings, suited the habits and views of the day, might be decked out by the architect in what he was pleased to think was Gothic or Tudor, Roman or Greek, French or Italian, Egyptian or Indian.

In the last quarter of the 19th century there began a struggle to get free from this welter of confused aims and misunderstood styles, but with all this there was too great a reliance on the past, on the halcyon days of the Renaissance styles, early and late. The best craftsmen were employed on mere copying, on the production of "Period rooms."

ENGLISH FURNITURE

English furniture has developed in the course of many years from a few primitive types to highly specialized varieties; it has evolved gradually with the progress of civilization. So little survives from mediaeval times that information must be sought in contemporary references, supplemented by representations in illuminated manuscripts. Most of these miniatures are of foreign origin; but they are reliable evidence, for the governing classes were Continental in their habits and the equipment of their homes. The furniture made for them was strongly influenced in form and detail by Gothic architecture, and was freely embellished with colour and gilding. English oak was the chief material, but softer woods were also used.

The furniture usually found in important houses consisted of beds, chests, cupboards, tables and stools. These objects are the basic types from which the whole evolution can be traced. Wills and inventories prove that draped bedsteads were treasured possessions of mediaeval householders, prized not for the rough framework but for their magnificent woven and embroidered hangings. These draperies consisted of a celure (back), tester (canopy), curtains and valances, and on them were worked scenes from the chase and many fanciful devices. Such beds were placed in the principal living rooms, and served as couches in the daytime. Chests were almost the only receptacles for valuables. They survive in large numbers, many 13th century examples being preserved in churches. The fronts, formed of stout planks, are pegged into wide uprights, plain, or carved with grotesque monsters. Later specimens are sometimes carved with arcades of Gothic tracery, scriptural incidents or mythological subjects. Large travelling chests, called "standards," were bound with iron and covered with leather. At the ends were iron handles through which ropes could be passed to facilitate transport. The guild of cofferers already existed in Edward III.'s reign, but could not prevent the

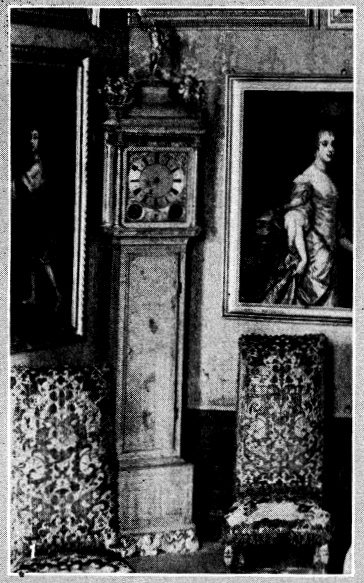
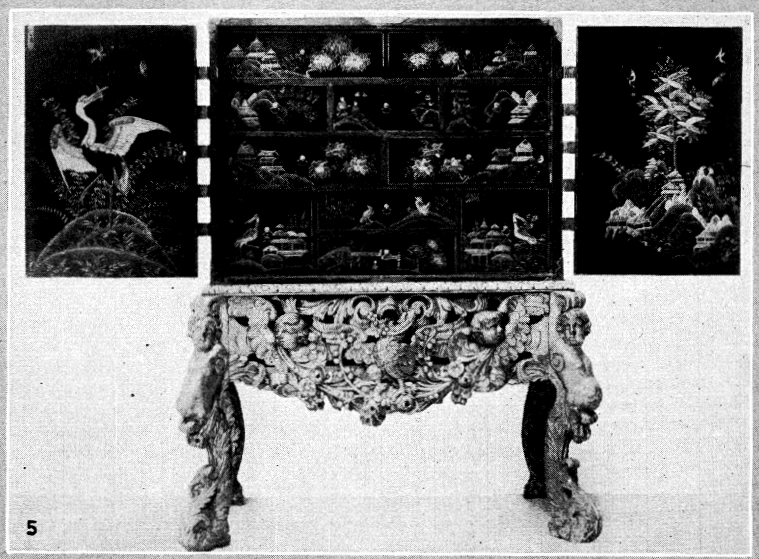
ENGLISH FURNITURE OF THE 14TH, 16TH, AND 17TH CENTURIES

1. Armchair of carved walnut; about 1680. 2. Gate-leg table of turned oak, the legs having wooden hinges, 2 ft. 4½ in. in height; about 1660. From Capt. N. R. Colville. 3. Armchair of oak inlaid with various woods; about 1600. 4. Carved oak chest of the late 14th century; (from Sir Edward Barry). 5. Draw-table of oak, with inlaid frieze and carved legs; about 1600. 6. Court cupboard of carved and inlaid oak; dated 1610. 7. Bedstead of carved walnut with inlaid frieze; 1593





(1, 3) BY GRACIOUS PERMISSION OF HIS MAJESTY THE KING, COPR., WALTER BOURKE; BY COURTESY OF (2, 4, 5) THE DIRECTOTOR OF THE VICTORIA AND ALBERT MUSEUM, (6, 7) P. D. GRIFFITHS

ENGLISH FURNITURE OF THE 17TH, 18TH AND 19TH CENTURIES

1. Long-case clock, the case veneered with walnut. Enrichments of chased and gilded brass. Movement by Daniel Quare, about 1705
2. Cabinet design by J. P. Seddon and painted by Sir Edward Burne-Jones, Dante Gabriel Rossetti and other artists, mounted on a turned stand; about 1860
3. State bed with hangings of rose damask, made for George, Prince of Wales, in 1715
4. Mahogany armchair, one of a set, in the style of Chippendale; 1755
5. Cabinet lacquered in gold and colours, on a black ground, the stand carved and silvered; about 1675
6. The seat of the chair seen in fig. 7, showing detail of *petit-point* needlework
7. Hoopback chair veneered with burr walnut and finely carved; about 1720

ENGLISH FURNITURE OF THE 18TH CENTURY

1. Commode veneered with satin wood and decorated with marquetry. About **1770**

2. Bookcase of carved mahogany. About **1745.** From Mr. **J.** Thursby Pelham

3. Commode chest of drawers. Carved mahogany. About **1760**

4. Bureau bookcase veneered with burr walnut, gilt carved. About 1730

5. Mirror in frame of wood, carved and gilt in the rococo style. Probably by Chippendale. About **1755**

6. Cabinet on stand; walnut decorated with floral marquetry. About **1685**

7. Side table with marble top, carved and gilt. In centre is figure of a child seated on a shell. Designed by William Kent. About **1730.** Houghton Hall

8. Armchair of carved walnut, upholstered in **red velvet.** About **1720**

9. Side table with classic decoration; carved and gilt. Designed by Robert Adam about **1770.** From **20,** St. James's Square, London

EARLY AMERICAN INTERIORS AND FURNISHINGS

1. Reproduction of the Capen house kitchen, Topsfield, Mass., 1683, an example of the earliest type of American architecture. The fireplace opening, with a round brick oven at one end, extends over half the length of one wall. The clock near the chest is of the 17th century type and is run with weights. The chair seats are covered with coloured linen. 2. Kitchen from Millbach house, Lebanon county, Pennsylvania. 1752. 3. Armchair of Governor John Carver, and early spinning wheel, Plymouth. 4. A "Connecticut chest" with carved tulip decoration. The drawers are of oak, and the top, bottom and back of pine. 1675–1700. 5. "Hadley chest" with incised carving. Upper Connecticut valley

importation of Danzig chests and others of overseas work. On a dresser in the hall flagons and cups were displayed. It was an open framework of shelves with a projecting lower portion, sometimes enclosed by doors. Side-tables, used for serving meals, were in the form of a chest mounted on legs, the panels pierced with Gothic tracery. What are now termed cupboards were known as ambries. Existing specimens are of massive construction with cross divisions and foliated iron hinges. Until the close of the middle ages chairs were lofty, throne-like structures, few in number and regarded as symbols of authority. The ordinary seats were chests and stools with benches sometimes fixed to the walls. Mediaeval dining tables were of trestle construction, boards of oak or elm resting on a series of central supports. They had removable tops and could be stored away after meals. Two examples still remain at Penshurst Place, the tops, nearly 30ft. long, being supported on carved trestles with cruciform feet. Towards the end of the 15th century panelled framing, or joinery with mortice and tenon, replaced the primitive method of construction in which planks split or sawn from the log were roughly put togetlier with pegs. At this period panels were often carved with the linen-fold pattern, so called from its resemblance to linen arrsnged in upright folds.

Tudor.—In the Tudor period the character of domestic furniture was gradually transformed by Renaissance influence, carved profile heads, dolphins and foliated scrolls appearing on structures which at first remained Gothic in design. Henry VIII. employed Italian craftsmen for the equipment of his new palaces, and their works were imitated by native craftsmen with less delicacy and finish. Walnut, more readily carved than oak, was extensively used, and, though much of this furniture was imported, there are undoubted English examples. Under Elizabeth inlay consisting of arabesque or chequer patterns in coloured woods came into vogue as decoration. There was a notable increase in domestic comfort. Harrison about 1587 reported that costly furniture had descended "even unto the inferior artificers and manie farmers." By this time the style had emerged from foreign tutelage and assumed a character distinctively English. It is coarse and vigorous, prodigal of material and floridly enriched. The round arch figures prominently with corbels and grotesque terminals; foliated strap-work fills the decorative areas, while nothing is more characteristic of Elizabethan furniture than vase and melon-shaped supports of prodigious girth profusely carved. In the matter of new types there was little innovation, but capacious presses were provided for clothes and mirrors of glass in highly decorated frames were becoming known at court. Chairs were more abundant. They had panelled backs and joined frames and could be readily moved; in some the woodwork was hidden by rich fabrics. Beds were now constructed of wood throughout, a panelled back and posts supporting a ponderous tester. Joined tables with "draw," or extending, tops ousted the trestle variety; while court cupboards and buffets laden with plate adorned every well-appointed hall.

The Stuart Period.—This increase in domestic comfort continued until the outbreak of the Civil War. From James I.'s reign padded and upholstered seats survive, and at Knole may be seen chairs of X pattern covered with silks and embroidered velvets. A very remarkable specimen, in which Charles I. is said to have sat during his trial, has lately been acquired by the Victoria and Albert museum. Such chairs show Continental influence, but the main output was insular and traditional. The style gradually lost its rude vigour. Structural members dwindle in scale, and fanciful carving degenerates into stock patterns, eked out with applied bosses and spindles. The furniture of the Protectorate is, for the most part, severe and angular.

After the Restoration there was a striking change. The exiled court on its return introduced French fashions, and austerity gave place to lavish display. Furniture became lighter, more highly finished, and better adapted to varying needs. Walnut was the favourite material. Joinery developed into accomplished craftsmanshipand new processes appeared, notably veneering wide surfaces with thin sheets of wood into which floral patterns in marquetry could be inserted. The passion for colour found an even better outlet in lacquer decoration The importation of works of art from the East had begun in Tudor times, but was of small account until after the Restoration. Then the taste became widespread, Evelyn and other observers reporting their friends' houses to be furnished with Indian screens or panelled in the finest Japan—descriptions implying oriental lacquer. Such things came from China and were soon imitated in England, the art of covering furniture with successive coats of coloured varnish being known as "Japanning." New forms of decoration coincided with a multiplication of types. Day-beds, a form of couch with an adjustable end, and winged arm-chairs served for repose. A little later, sofas with back and arms carried comfort a stage further, patterned velvets mainly of Venetian origin and damasks woven at Spitalfields being the usual coverings. Bureaux with an enclosed desk were produced towards the end of the century, and chests of drawers came into general use. Mirrors were no longer rarities after the duke of Buckingham had established his famous glass-works at Vauxhall, the frames being carved, lacquered or inlaid. Charles, says Evelyn, "brought in a politer way of living which passed to luxury and intolerable expense." An example of this extravagance is afforded by the tables, mirrors and stahds covered with embossed silver with which the king's mistresses furnished their apartments. Fashions succeeded each other with great rapidity. Chairs show these changes most clearly. developing in a brief period from mere seats into movable decoration. They had floridly carved crestings and stretchers, while for the structural members many varieties of turning were employed. Scrolled legs were general under Charles II., being succeeded by taper and baluster forms a few years after his death. In beds of this period, the tester, back and posts are covered with material pasted on to the wood and matching the hangings. They were of enormous height with elaborately moulded cornices, and had ostrich plumes or vase-shaped finials at the corners of the tester. The ornate stands and side tables of this age demand special notice, for, profusely carved and often gilt, they are among its most striking productions.

The 18th Century.—At the beginning of the 18th century a new style arose. It was simple and dignified, based upon curved lines and entirely admirable in its insistence upon form. The cabriole-shaped support with claw-and-ball or paw feet was a salient feature, and early in the development stretchers were eliminated. This style depended largely upon finely figured walnut veneers, and made but a sparing use of carved ornament. Chairs changed their character completely. They had hooped uprights and vase or fiddle-shaped splats curved to support the back, beauty and comfort being combined in the design. Tallboys, or double chests of drawers, cabinets fitted with shelves, and bureaux in two stages met the demand for greater convenience, while the types already known were much improved. About 1720 mahogany began to supersede walnut as the fashionable material, its consumption increasing with the repeal of the heavy import duties. The furniture which had prevailed during Anne's reign no longer satisfied the governing class, whose taste inclined to ostentatious magnificence. They demanded something grandiose and cumbrous, suited to the great Palladian houses for which it was destined. Inspired by the contents of French and Italian palaces, such furniture was largely the production of architects. William Kent, the most celebrated, having travelled in Italy before starting practice. The basis of design was classical, the manner baroque. Columns, architraves and entablatures are prominent with terminal figures and heavy scrolled supports, masks and acanthus scrolls being favourite ornaments. The carving was bold and often masterly, gilding, freely used, enhancing the effect. At Houghton, Holkham, Rousham and elsewhere, Kent's furniture may be seen in its proper environment, gilt mirrors and side tables with sets of chairs and settees covered with patterned velvets recalling the vanished splendours of that opulent age.

About the middle of the century a fresh wave of French fashions produced an Anglicized version of the rococo style. It was romantic in conception, fantastic and capricious in the manner of its working out. It banished the straight line and made asymmetry a cult, while it sought its ornament in conventionalized

renderings of natural forms — shells, foliage and flowers. With it flourished the Gothic and Chinese "tastes," the one a travesty of a forgotten art, the other an attempt to exploit the furniture of an unknown land. Architects with a hold upon tradition were now challenged by cabinet-makers who produced their own designs. Chippendale, Ince and Mayhew, Johnson, Manwaring and many others published illustrated trade catalogues to advertise their wares. Of these works Thomas Chippendale's *Director* is the most important. It affords an apt summary of contemporary tendencies, and is at once eclectic and original. Chippendale borrowed his rococo from Meissonier, but depended much on his own fancy for what he deemed Gothic or Chinese. It was an age of specialization, and many varieties of furniture are represented, ranging from extravagant side-tables for saloons to ingeniously contrived little objects for bedrooms. In the explanatory notes mahogany is generally recommended, but many of the designs are to be japanned or finished in burnished gold. The contents of such houses as Nostell and Harewood (where the original bills are preserved) show Chippendale to have been a craftsman of genius; though he had many rivals scarcely less gifted. His name affords a convenient label for furniture of the middle of the 18th century — mostly the work of other hands. The classical reaction, which set in shortly after 1760, swept away tortuous forms and terminated licence in design. Robert Adam, whose name is inseparably associated with this movement, had, like earlier architects, studied in Italy. His fastidious taste rejected the art of the later Renaissance, and sought inspiration in the remains of antiquity. When he was given a free hand, furniture and decoration were included in his architectural schemes. What he could achieve when "the subject was great and the expense unlimited" Syon and Nostell remain to show. They are brilliant essays in the "antique style" with the contents carefully thought out in relation to their surroundings. This furniture makes a learned use of classical ornament, but paterae, husks, rams' heads and urns are less eloquent of the change than the symmetrical structural lines. At this time commodes and other objects intended for display were often of satinwood with marquetry or painted decoration, the latter copied from designs by leading artists. The style as Adam conceived it was too severe and scholarly to be widely appreciated. It was modified by contemporary cabinet-makers, and may be seen translated into popular terms in Hepplewhite's *Guide* (1788). In the process the furniture has lost its ceremonial character, and become simple, homely and graceful. It retains, for the most part, symmetry of form and excellence of proportion. Heart and shield-shaped backs on chairs and settees with tapered and fluted supports are noticeable features, while feathers, wheat ears and shells are prominent in the painted or inlaid decoration. The movement was towards lightness and elegance, and furniture of a distinctly feminine kind is found represented in Sheraton's *Drawing* Book (1791). This period saw the highest technical accomplishments, and a degree of specialization hitherto unapproached. Sheraton's designs for fitted washing-stands, dressing- and work-tables are triumphs of ingenuity and eminently practical.

At the end of the century a strange archaeological revival, based upon a closer study of Greek, Roman and Egyptian remains produced the Empire style and that modified version of it which became current in England. The chief English exponent was Thomas Hope, an amateur designer with some antiquarian knowledge; but when the fashion was taken up by cabinet-makers the results were often woefully incongruous. They essayed the production of Roman bookcases and sideboards undeterred by the lack of classical precedents, and to what depths of incongruity they descended may be seen in Sheraton's later publications and in George Smith's *Household Furniture*. Rosewood was used with bronzed or gilt ornament and metal inlay, sphinxes and animal terminals being favoured as supports. With the last phase of this style, prolonged into the reign of George IV. and growing ever more grotesque, the making of furniture ceased to be an art. The introduction of machinery ended the craftsman's direct responsibility and robbed him of pride in his work The old tradition of sound craftsmanship lingered, and may be detected even in the cumbrous productions of the Victorian age, devoid though they be of any aesthetic interest. It may confidently be said that the domestic arts were never at lower ebb than during this period.

The Pre-Raphaelites and Modern Movements. — Early in the '60s the complacent acceptance of mass embellished with ungainly ornament was challenged by the movement inaugurated by William Morris and a group of pre-Raphaelite artists. They sought to rehabilitate craftsmanship, and with this end in view their sympathies were naturally drawn to the middle ages when craftsmanship was in its prime. Their work is distinguished from the earlier Gothic revival by greater understanding and a regard for modern needs. That it can wholly escape the charge of being "sham mediaeval" cannot be maintained, but it was sincere in intention and provocative of thought. Morris realized part of his ambition, for he trained a company of enthusiastic and highly skilled craftsmen. The propaganda spread in spite of the prevailing Philistinism, and a marked improvement in taste was the result. For an appreciative few Morris furniture continued to be made, and, among the inheritors of his traditions, Ernest Gimson deserves honourable mention. The movement was, however, too typical of a time when the arts had become disastrously divorced from life. It found its chief supporters among a cultured minority with exclusive standards and a somewhat superior attitude; in consequence there was more than a hint of the "precious" and artificial about the furniture made for them. A notable result of pre-Raphaelite activities was to direct attention to the striking merits of furniture which had been banished by the Victorians. It was rescued from obscurity and the collecting habit spread, rapidly producing a huge crop of "fakes" and reproductions. This habit has undoubtedly determined the character of English furniture for nearly 50 years. It has stifled originality and degenerated too often into an unintelligent craze, while it must be held responsible for the cheap and horrible travesties of historic styles, which under the label "period" have done so much to degrade public taste. In the last decade there have been unmistakable signs of a renaissance, and something of the Continental enthusiasm for modern furniture has spread to England. In the productions of this new school fitness for purpose is again considered and great attention is bestowed on the material, many beautiful, exotic woods being used with striking effect. Ornament is unobtrusive (excepting in the more fantastic examples), and even mouldings are kept in subordination. The forms are often eccentric, reflecting the latest aberrations of fashion; attempts to produce jazz or cubist furniture are not unknown. At the present day the opportunities are quite severely limited by the inevitably high cost and also by lack of patronage. The outlook is promising, both on account of the genuine originality sometimes displayed by designers with a firm hold upon tradition, and because fine craftsmanship is again highly prized for its own sake. The Twentieth century will possess a distinctive style of its own when a few really gifted designers emerge to consolidate the gains which have already been won.

LATE TRENDS IN U.S. HOME FURNISHINGS

1. Beginning about 1930, metal was widely adapted to the design of U.S. furnishings, as in this dining room set. About 1935–37 there began a classical trend in U.S. modern design which signalized a departure from European influence
2. After the departure from European models, U.S. furniture and its accompanying furnishings became sturdier and more practicable. Typical of the trend was this living room
3. A further refinement of design and the development of flexibility through built-in units
4. An interior of Swedish modern, which was introduced in the United States about 1937 and became increasingly popular thereafter
5. Characteristic of U.S. furniture in the early 1940s was the further development of built-in units and the use of oriental accessories with contemporary designs

Swedish at first on the Hudson and the Delaware and German as well as British in Pennsylvania. Even among the leaders ftw represented courtly fashion. Hence, the earliest household decoration and furnishing, after the period of primitive makeshifts, reflected rather the character of the common houses of the small towns and rural districts abroad. In these the fundamental element deep into the 17th century, in Germany even into the 18th, was a survival of the art of the middle ages, with its structural emphasis, its simple forms derived from materials, tools and use.

Thus in New England in the 17th century we find the clay-filled walls, the timber houses roughly plastered and whitewashed, or perhaps wainscoted with wide moulded boards, which, standing vertically, served as the partitions. The joists of the ceiling were exposed, supported on heavy moulded summer-beams; the great fireplace was likewise spanned with a huge beam, and was devoid at first of any moulded frame. The effect was one of homely solidity, achieved by the frank revelation and elaboration of every element of the construction.

Into such houses in New England and Virginia went furniture of Jacobean oak, a few pieces doubtless brought over by the leaders, but the vast majority made in America after remembered models, from the abundant supply of native woods, chiefly American oak and pine. They included chests, court and press cupboards, trestled tables and forms and, at first, but a few chairs of the turned or wainscot types. One variety of armchair with turned spindles has acquired in America the name of Carver chair from the familiar example belonging to John Carver, still preserved at Plymouth. Other characteristically American types are two forms of chests found in the Connecticut valley: the "Connecticut chest" of the lower valley, with Jacobean spindles and the panels carved with a tulip decoration; the "Hadley chest" further up the valley, of which the frame likewise has incised carving. In the English colonies the furniture, as well as the woodwork, was generally left without paint or other finish. Inventories of the better 17th-century houses reveal that they contained much in the way of hangings, including tapestries and needlework, as well as treasures of plate made by the American silversmiths of the time, and pewter by local pewterers.

Similar in their generally mediaeval character were the interiors of the Pennsylvania-German houses, where, however, there was a rich colour, in the painted decoration of the chests with motives of birds, tulips and other traditional elements, the illuminated texts, birth and marriage certificates which hung upon the walls. It was the German colonists also who first made any high development of pottery, as in the Pennsylvania slip ware, with similar decorations, and in glass-making, as in the wares of Stiegel and Wistar. The familiar hand-woven coverlets, chiefly of blue and white, were likewise derived from patterns brought in by the German weavers.

Following the evolution of style in England, under the Commonwealth and the Restoration, there appeared in America chairs of the Cromwellian and Carolean types, with spiral turnings and baroque scrolls, with seats and backs upholstered in needlework or with panels of cane. The chest with a drawer or drawers then made its appearance. The founding of Philadelphia by William Penn in 1682 brought to America for the first time the decoration of the period of Wren, which had appeared in London after the great fire and had been developed by Wren and Daniel Marot in the reign of William and Mary. Its influence only became wide in the colonies with the opening of the 18th century. The construction disappeared beneath a formal interior finish. Panelling took the place of sheathing, the fireplace was surrounded by classic mouldings, at first boldly projecting, to produce the chimney-piece. The doors and windows, too, were surrounded by classic frames, and the wall might even be divided, in the finest houses, by pilasters. In the staircase the open string, with carved brackets at the end of the steps, was adopted; the balusters and newels, more slender, were richly turned, often in varied spirals.

Walnut became the favourite wood in furniture, until superseded by mahogany in the middle of the century. The style of William and Mary, with its trumpet turnings in legs of chairs, dressing tables and chests of drawers (now elevated on frames to constitute "highboys"), its high curved chair-backs; and that of Queen Anne, with its cabriole legs, succeeded one another some score of years after the advent of these monarchs in England. To this time we may refer the first creation of the American types of Windsor chairs, many of them so different from the English Windsors and owing more to the roundabout chairs. In hickory the Americans found an admirable wood for the bows and spindles. The early Georgian style was adopted in America simultaneously with the use of mahogany, so that mahogany pieces are to be found in the colonies of types which in England were disused before the advent of this wood. Certain types were also created in America, most notably the "block front" secretaries and dressing tables made by John Goddard of Newport about 1763, with alternate projections and recesses crowned by carved shells.

The heyday of the colonial style came in the fifteen years before the Revolution and coincided broadly with the Chippendale influence. Chiefly with the publications of Abraham Swan the forms of the French *rocaille*, with its characteristic pierced shell work, reached America and were used in the adornment of the great mansions of Annapolis and Philadelphia, and such fine houses as that of Jeremiah Lee in Marblehead and Miles Brewton in Charleston, or the Philipse Manor in Yonkers. The delicate carving of the overmantels, with their scroll tops, was matched in the airy relief work of the plaster ceilings. This was the period of the great Philadelphia cabinet and chair makers, such as William Savery, whose earlier work is of a simpler character, Benjamin Randolph, James Gillingham and Jonathan Gostelowe, whose workmanship compares with that of the London craftsmen. The most characteristic pieces, distinctively American, are the high-boys and lowboys of mahogany, their tops and skirtings carved with delicate shell ornament. The trade of the upholsterer now also flourished; the craft of the silversmith in the hands of such men as Philip Syng and Revere the elder excelled in adaptations of fine Georgian models.

On the eve of the Revolutionary War the influence of the Adam style began to be seen, as in the garlanded ceilings at Kenmore and those executed for Washington after the outbreak of hostilities. The war postponed any widespread effect until after the resumption of relations in 1783. In the following year John Penn, of London, in building his little box, Solitude, on the banks of the Schuylkill, gave the first complete example, and others were furnished in the great Philadelphia mansion of the Binghams and the country seat of William Hamilton, the Woodlands, near-by. The style was introduced in New England by Charles Bulfinch who found an apt follower in the Salem carver, Samuel McIntire. Mantels and doorways were adorned with delicate composition ornaments, at first imported from London, later made also by American craftsmen like Robert Wellford of Philadelphia. Ingenious adaptations of the Adam motives, made with gouge and auger, were widely employed about 1800. Owing to war but little characteristic Adam furniture was made in America, but the developments of Heppelwhite and Sheraton were early and eagerly adopted. The later Georgian models also gave inspiration to silversmiths like the patriot Paul Revere, in Boston, and Joseph Richardson in Philadelphia. Through the new relations with France not a little fine French furniture of the Louis XVI. style was imported to America, as, for instance, by Washington and by such residents in Paris as Jefferson, when American minister, and James Swan of Boston. Both Sheraton and Directoire models were adapted by the gifted cabinet-maker in New York, Duncan Phyfe, whose lyre tables and sofas are among the most refined of American furniture designs. Of this general character must have been the original furnishings of the White House under Jefferson, destroyed by the British in 1814. In the refurnishing of the White House under Monroe, about 1817, it was furniture of the French empire and Restoration which was imported. The heavy mahogany of this classic style with its gilt mountings filled the high, chaste interiors of the American houses of the Greek revival and persisted until the advent of Victorianism.

CHINESE

The Chinese mode of living is quite different from that of the Japanese, though in art and culture the two peoples have many points in common. The difference in the diet and the difference in the style of their dress, manifest themselves in their houses and in their mode of living. Unlike the Japanese, the Chinese house interior is profusely decorated and furnished with chairs, tables, beds, stands, cabinets, screens, etc.

In an ordinary Chinese house the guest room, which opens to the courtyard, has a bare tiled floor, and is furnished with tables and usually 8 chairs. The place of honour in the room is marked by the long table, *kew tai* (bridge table) placed at tlie middle against the back wall where hangs a painting or a pair of hanging scrolls bearing quotations from the Classics or both. Upon the long table are placed vases of flowers and objects of art. Directly in front of it one invariably finds a square table named, for good luck, *Pa Hsien Tai* (table for the eight Taoist immortals). On either side of it is placed a square stool or an arm chair for the honoured guests. The back wall is often formed of a screen partition, *bing mun*, behind which there generally is another room with a sacred shelf, *sun low*, where deities and the spirit of the ancestors are enshrined high up near the ceiling; and below on the floor a place is provided for the god of the earth, *te chu sun*. In homes of the common people, the sacred shelf constitutes the main feature of decoration in the house, usually occupying the most prominent place above the bridge table in the guest room. In the houses of the upper class, there is more than one guest room or parlour. There is an entrance room, through which the guests pass into the courtyard and into the *cha tai*, a small room where the visitors may change their street attire into a proper dress before appearing in one of the guest halls, *ka dong*.

By removing the *chang chou* (the long windows), the latticed panels between the pillars, the guest hall is thrown open to the courtyard for the entire length. Some homes are provided with another guest hall, *kwa tai* (flower parlour), which may be used for the banquet as well. Whenever possible, the screen partitions (not sliding screens like the Japanese ones) are employed so that two or more rooms may be used as one big room when a large party is entertained. The main wall, as well as the side ones, are generally covered with many paintings or scrolls mounted as the Japanese *kakemono*, which are changed periodically so as to keep them in harmony with the season. In some houses tapestries take their places. The parlour generally has a tiled floor and the bedroom a wooden floor, rugs or carpets being very seldom in evidence even in the wealthy homes, though the country has long been famous for the production of splendid rugs.

The cabinet, tall and dignified, with shelves and chest of drawers inside the swinging doors, occupies an important position in the living rooms of the Chinese house. No less significant is the bedstead, which is often a work of art in its design and embellishment with carvings and paintings. The bedstead usually combines a small compartment to contain a chair and a table. Sometimes the bed is enclosed in a large portable structure with a ceiling, the wooden parts being decorated with beautiful carvings, generally lacquered over. The curtains for the bed, during winter, are of double satin, and in summer either of white taffeta or of very fine gauze, both of which are open enough to permit the air to pass through and close enough to keep out mosquitoes and other insects. The structure is a room in itself, being provided with a door and generally so large that it is fitted with shelves and contains, not only the bed of ample size, but a table, chairs and a cupboard. The usual furniture is in the dark, heavy, precious hardwood, *tzu-tan*. The chairs with seats of the same material, and backs with an inset of *tai-lee-sek*, marble from Yunnang province which has natural pictorial marking like the paintings after the "southern school," have their simple dignity. Little square stands used for serving tea are often topped with *wan-sek*, the ordinary marble.

Both tables and chairs are often inlaid with mother-of-pearl in floral and bird designs, but the best wood is preferred to be admired in its natural state. Some pieces are lacquered in various colours, while others are lacquered and carved or incised, many of them presenting impelling dignity by their shape, size and tasteful decoration; some of the best examples may be seen at the Victoria and Albert museum. With the massive furniture, heavy carved beams on the wooden ceiling, and panels of latticework that shut off the glare of the courtyard, the room is restful. Superb workmanship in decorative art, with inlay of ivory, coloured horns, mother-of-pearl, etc., on a lacquered ground is shown on the tall folding screens used as partitions in the room. A single-panelled screen, *ping-mun*, also called a devil screen, is placed at the entrance to the house to act as a buffer. While it prevents a view of the interior from outside, it serves to deflect, or ward off, according to the Chinese superstition, the evil spirit.

JAPANESE

The refinement of simplicity, which finds its aesthetic ideal in the natural beauty of materials and is compatible with the austerity of architectural form, is a keynote of a Japanese house-interior.

The Walls.—Rooms of various sizes are made by the use of walls and *fusuma* (sliding partitions of wood covered with patterned or painted paper or silk), running in grooves, which usually measure some 6 ft. in height and $2\frac{1}{4}$ to 43 ft. in width. *Shōji*, the equivalent of windows, censist of light lattice-work to which is pasted white translucent paper, and also slide in grooves. The grooves run between squared wooden posts, and allow the screens to pass one another, rendering hinged doors unnecessary, and permit of the screens being lifted out altogether, thus throwing a series of rooms into one great apartment. The "filling" (varying in height from 2 to $4\frac{1}{2}$ ft.) between the beam over the screens and the ceiling, is generally, in good class houses, of latticed wood or bamboo or of pierced woodwork called *ramma*. The carving of the *ramma*, often elaborate in palaces and mansions, should be in harmony with the character of the room. Those in certain palaces and temples in Kyoto are exquisitely carved, some having intricate designs in pierced work carved from a single piece of wood, showing flowers and birds on one side and trees and animals on the other, and, in one instance, a flight of wild geese over swaying pampas grass so carved that a painting of the silver moon on the upper wall of the next room may be seen through the openings in the carved *ramma*, beyond the dark silhouette of the carved flying birds.

The Floors.—The floor boards are completely overlaid by *tatami*, straw mats some 2 in. thick and measuring about 3 by 6 ft., each one covered by finely woven grass matting. The size of the room is computed in mats, according to whether it needs 43, 6, 8, 10, 12 or $12\frac{1}{2}$ mats to cover the floor. In ordinary dwelling houses a room is seldom larger than 1j mats. The spotless matting of closely-woven fresh reeds, bound on the long sides of each mat with a narrow strip of dark linen, together with their pale green colour neutralized by light filtering through the paper screens, and their fresh fragrance, appeal strongly to natives or Japan, and those who can afford it continue to preserve this freshness by reversing and changing the top matting from time to time.

The Ceiling.—The ceiling is equally simple. In an ordinary dwelling house it is about 9 ft. from the floor and formed of thin, slightly overlapping panels of unpainted wood about 12 to 18 in.

MODERN HOME INTERIORS

1. Modern combination of oriental and occidental. The chairs are leather, the coffee table mahogany, and the accessories Chinese
2. A corner in the Paris home of Robert Mallet-Stevens, modernist architect. The walls are white stucco and the floor is tiled in a geometric pattern in black, brown and grey. Aluminium is used in finishing the bases of the easy chairs, and in the end tables. The furniture is upholstered in Hélène Henry fabric
3. A modern adaptation of an early 19th century English dining room done in the style of Thomas Hope. The furniture, designed by William Pahlmann, is in white with gilt trimming, top of table in royal blue lapis lazuli. The rug is white and the drapery wine colour
4. Room with circular library

wide, whose monotony is broken by parallel strips some 18 in. apart running across the ceiling, and invisibly nailed from above. Since the grain of the wood forms part of the decorative scheme in the interior, the boards are cut from a single tree to insure uniformity. The panels, 6 ft. in length, must be so laid as to suggest continuity of the grain across the room, and must be carefully planed by the carpenter, for they are to be admired in their natural state and no flaw in human handicraft must be allowed to spoil their intrinsic beauty. All the woodwork of the interior must in the same way be left virgin, unspoiled by colour-stain or paint, with occasional exception of the narrow framework of the fusuma, and the tokobuchi — a piece of wood several inches in width and thickness running along in front of the *tokonoma* (see below) to its full extent — both of which may be lacquered in harmony with *tatami* borders or the *tokonoma* post. This is often made from a tree having some special tint or texture, or else made to conform to its natural curve of growth. A portion of its bark or the worm-eaten marks beneath it, or the stump of a branch or some other witness of nature, is preserved, thus focussing on the *tokonoma*—the most important feature of a Japanese interior — the significance of the design of the room

The **Tokonoma.**—This slightly raised recess or alcove, usually built into the wall at right angles to the verandah, is commonly from 2 to 3 ft. deep and $4\frac{1}{2}$, 6 or 9 ft. wide proportionately to the size of the room. In it are displayed the only independent decorations in the room. A painting or a set of two or three kakemono (hanging-paintings mounted on rollers) occupy the back wall of the alcove, and a vase holding the *ike-bana* or flower arrangement (*q.v.*), an incense burner or a wood-carving, or some other art object, is placed on its floor. They must each be in harmony with the season or with any special occasion which may befall, and are chosen with a view to give pleasure to an expected guest. There may be many *kakemono* put away, especially in old families, but only one is shown in the tokonoma, selected to do honour to the guest. If he is likely to enter other rooms having a *tokonoma,* a distinctive atmosphere must be created in each, while emphasizing some central harmonizing idea. The flower arrangement and other decorative art objects must be complementary to the painting. Thus a kakemono of the moon may be accompanied by a few sprays of autumn flowers, artistically arranged in a bamboo basket, and a small bronze censor in the shape of a cottage, thus suggesting a fishing hamlet on a tranquil evening of autumn. Or a painting of a waterfall may hang in the tokononta, while on its floor is placed a rectangular bronze vessel well filled with water and with a few water-lilies appropriately arranged in it. In a small room the same atmosphere may be achieved by showing a narrow kakemono of a waterfall in a roughly-executed black monochromatic style and placing on the floor a single white blossom of Hibiscus *mutabilis,* half-concealed among its freshly moistened leaves, displayed in a slender bronze vase with very cold water so that the moisture collects outside and trails down over the beautiful patina, creating the suggestion of a miniature pool on the round flat lacquered board of liquid black upon which the vase stands.

Thus the guest is brought to feel the very spray from the waterfall, transforming the confined room into a fitting place in which to entertain visitors on the hottest of summer days. An alternative to the painting is a couple of lines of poetry on which the guest may meditate on his entrance into the room. His attention may next be led to a bon-seki (*q.v.*), a tiny landscape contrived with natural stones and sand, on a black lacquered tray at the foot of the kakemono. It may call to mind some familiar scene — a rocky promontory with an island near by, and beyond the moonlit sea the dim contours of undulating hills. The poem on the kakemono (for calligraphy is also treated as a pictorial art) thus quickens with new meaning for him and he can share the poet's inspiration.

Other Decorations. — In a companion recess adjoining the tokonoma are chigai-dana — shelves arranged stepwise — for additional art objects and there is usually a small cupboard with appropriately decorated sliding doors either above or below the shelves. There may also be a low writing-place built at the side from which the light comes, in front of the tokonoma, where lacquered boxes for paper and other writing paraphernalia can be placed, further decorating the room. What articles, and how and where they are to be arranged in these places to conform to the general scheme and to afford the maximum of decorative value and aesthetic pleasure, has been an aesthetic study for centuries. In the time of the Shōgun Yoshimasa (1436–90) a set of systematic rules of decoration had already been formulated, and is still followed by some of the "tea-men" There may also be placed by the low writing-table in the master's room, a portable lacquered set of shelves or a cabinet carrying a few objects of art for his delectation in moments of leisure.

Thus simplicity of display is fully compatible with wealth of possessions. The same object is rarely seen twice in a dozen visits. Hundreds of beautiful things may be stored in the treasure-house. Guided by his knowledge of the character and temperament of his guest, his recollection of the impression made by the things on view on former occasions, a Japanese host will select from his store, always aiming at giving pleasure and a delightful surprise to his guest.

Sometimes a skirting of strong white or grey paper about a foot high as a protection against the broom is seen on a Japanese wall, but it is never papered or covered up by paintings, although a gaku, consisting of a painting or a few written characters expressing or suggesting a poetical sentiment or a truth may be framed above the *fusuma.* Plastered earth and sand, variously coloured, and mixed with boiled *funori* (*Gliopeltis furcata*) to give solidity, is used for the interior surfaces of the lath and plaster walls, and the pounded shell of little fresh-water bivalves or iron filings is sometimes mixed with the sand for their decorative value. Plaster in tint of smoke, mist or cloud, often has a hard and resistant surface.

Furniture. — In the Japanese house the furniture is conspicuous by its absence. There is neither table nor chairs such as are used in China or in the West. Everybody removes his or her shoes, sandals or clogs upon entering the house, and even slippers or house sandals are left outside in the wooden corridor. People sit, or rather kneel and sit back on their heels, on the tatami on flat square cushions. Each person is provided with a tabako-bon (smoking set) in summer and a *hibachi* (charcoal brazier) in winter. In some houses to-day gas or electric stoves are fitted, but the brazier is the characteristic means of warming a Japanese interior. It may be of bronze, porcelain or wood decorated with lacquer, and is furnished with a pair of small tastefully designed and ornamented fire-irons like chopsticks. Braziers are usually small and portable.

Beds may be arranged on the floor in any room at night by piling up wadded quilts, which are folded and packed away in the closet, after airing in the sun, in the morning, leaving the room clear for other uses during the day. A *tansu,* a chest-of-drawers in plain paulownia wood, may betray the sleeping apartment, but this, too, is often placed in the closet, shut off by *fusuma,* so as not to be seen. A clothes-horse is as a rule also placed out of sight behind a screen. *Byobu,* ornamental folding screens of 2, 4 or 6 panels decorated with writing or painting, or carried out in plain gold, serve many a convenient purpose, warding off draughts or hiding an undesired view. A single-panelled screen called tsuitate is usually placed in the entrance-room, to allow of the front *shōji* being pushed open without exhibiting the interior of the house to a caller. Even the dining-room is without any sign of its use, a collapsible low table being brought in for family use at mealtime, or food being carried in and served to each individual on small low lacquer tables called *o-zen*, kept in the kitchen cupboard when not in use.

In the summer heat the ordinary *fusuma* and *shōji* are frequently removed and replaced by others specially made of rushes or split bamboo to permit the passage of any breath of mind that may happen to stray into the house. The floor, too, may be covered over with rattan matting, to impart coolness; and *misu* or blinds made of split bamboo or rushes, may be suspended from the eaves to give shade and privacy.

Simplicity the Keynote. — Japanese rooms are thus extremely

simple, though neither barren nor cheerless, since every detail of form and colour is studied and harmoniously combined, even the joinery being so perfect that not a trace of a nail can be seen anywhere, with the result that, at least for beauty, the empty room is sufficient in itself. There is a sense of relief in this absence of furniture. These neat and airy rooms, so restful and so spacious, may be opened at will for their entire width onto a tiny landscape over which the eyes delight to wander. Or they may be closed up completely, leaving the occupant alone with an iron kettle (an object of art in itself) gently boiling on the charcoal fire, overlooked from no window, but companioned by the silhouettes of bamboo or pine branch in the garden forming countless attractive patterns on the creamy paper of the *shōji*. In such a room may be admired an ancient tree of stately form, growing in a pot placed in the *tokonoma*, and still retaining its dignity in its miniature form. Freed from the distraction of furniture, the men and women in the room recapture their dignity and significance. In the simple form in which the exigencies of construction determine the refined and reserved quality of the decoration, and the furnishings are reduced to the essentials, while the subtly blended colouring and the constant variety of the view on which it can be made to open build up a composition of delicate lines and graceful forms, the Japanese interior well fulfils its main and consciously recognized functions: it supplies an appropriate setting for clean and simple living. (See JAPANESE ARCHITECTURE; JAPANESE SCULPTURE; WOOD CARVING: *Far Eastern;* BON-SEKI; BON-SAI.)

MODERN

Any consideration of the principles of interior decoration as determined by modern needs should contain a comparison between the work of past periods and that of our own. Sound development does not lie in a mere production of novelties; the whole circumstances of the age must lead in a natural line to the new form. We know that the mentality of our ancestors up to the beginning of the 19th century was unblushingly feudal and that comfort itself was sacrificed to the ideal of magnificence. Anybody with any pretensions had to be magnificently dressed, and his personal status was indicated by a suitable uniform, with abundance of gold, long tassels and richly-chased arms. Obviously the rooms in which these men lived had to be equally magnificent. Tradition, assured culture and discipline, combined with great naivety, made this possible. We can still imagine to-day that the craftsman found salvation only in producing work of the best possible quality; but unfortunately we have no conception left of how it was possible to make him so happy that he produced one new form after another, with amazing power, and how he was able, without any serious friction, to carry all his contemporaries with him and, lacking all the enormous modern facilities, yet to spread his ideas throughout the whole civilized world. The age which followed gave the bourgeois its chance, and simplified everything; the form aimed at was more severe, but despite this limitation there was an increase of refinement, and a great and sometimes fantastic, but suggestive multiplicity of design appeared. This phase ended in Europe about the middle of the 19th century, and was succeeded by a dreary, generally mistaken imitation of earlier styles, intolerant of all else, and fatal to all genuine tradition; corrupting work and making it superficial, and leading at the best to falsification. Although the modern man is changing completely in externals, concentrating increasingly on practical matters, and would certainly not dream of appearing in the street dressed up as a knight, in the decoration of his home he thinks it necessary to copy some form of decoration belonging to the past: In this way he loses all feeling for real development and, through his art studies which are generally superficial, loses all touch with living art. Work is mostly performed by machinery. The engineer is preoccupied with his constructive, calculating methods; nothing is sacred to him; he can make anything to order; and the products inflicted on us, the cast-iron stoves, benches and furniture, the first motor-cars, the pots and pans and small artistic products with a superfluity of decoration in every style, the Gothic not excepted, have accustomed the great, ever uncritical majority to buy the most hideous objects with indifference, and to lose all sense of natural beauty and of individual form. This process has been carried so far that business men have made serious good work impossible through their so-called "cheap goods." People with taste draw back from all this and collect antiques and generally end by forgetting that it is their duty as it was formerly the duty of the court, the nobles, the Church, and later, of the educated classes, to foster a high standard of art and craftsmanship. The modern movement has begun by realizing this and by searching for a way out. Ruskin and Morris both sought to awaken humanity to the beauty of good craftsmanship and genuine material, and gradually introduced old techniques and methods of work. As a result of their teaching wonderful works in metal, leather, ceramics and textiles were produced, but were often created in bygone styles, although freely adapted. Ashbie, in 1885, went farther, and produced in the Guild of Handcraft excellent modern silver work—although again in antique form; the development of the art of the Scot Mackintosh into a wholly new, original style is amazing. His rooms in pale grey wood and violet strutts and embroidery adorned with rose-red flowers, his original lighting and glass, his heating apparatus, indeed every detail, were remarkable and full of promise. Innumerable forces bestirred themselves, seeking to evoke, in England first, then in Holland, Germany, Austria, France and the Scandinavian countries, a great, genuine and creative artistic movement, to help the world to reach again a unity of culture. At first there was no radical transformation. The business inter-ests were alarmed, disconcerted, and, without established precedents to guide them, were quite bewildered. The public also was wholly bewildered, in part enthusiastic, in part misunderstanding and prone to severe criticism.

Yet the movement, which ended with the beginning of the war in 1914, succeeded in making itself felt everywhere. To-day we are confronted by a movement which is even stronger and obviously more radical than before, which has learnt in the hard school of war and poverty which followed it many a lesson which the great public needed and was bound to receive.

In modern interior decoration, now that it is recognized that decoration alone, even new forms of decoration, admittedly does not create style, the great need is to have a complete apprehension of the task in all its essentials. We no longer think in terms of pillars, window-frames and decorations of one type or another; we create the room to be the environment of some particular human occupation, adapted for that purpose, simple and concise in form, and constructed in the best and most suitable materials. Manifold needs give birth to equally manifold expressions and we are beginning to construct with comparative certainty, without the risk of committing blunders. A city of to-day looks quite different from the city of a hundred years ago. With the help of new technical contrivances we can achieve quite unprecedented effects, because our first care is to apply all the methods of sanitation, to preserve correct proportions in design and to consider the needs of every class of society. In a modern house bacilli lead a sorry existence; light and air flow through every corner and cranny. Glass, manufactured in every possible way, set in metal, to economize space on the frames, is replacing white walls. We attach the chief importance not to the lighting apparatus but to the light, and similarly we care more for the heat than for the heating apparatus

First consider the living rooms. The size and height must partly depend on circumstances; the height must not be less than 7 ft. 6 in. to 8 ft. 6 in. One wall—facing east, south or west should be glass from ceiling to floor; many rooms, such as the breakfast-room, winter garden, living rooms and day nurseries may have two or even three sides of glass. Double glass, reaching to the floor and lined with water-tight material, may provide a space for flowers, plants and perhaps statuary. Besides having a door in the inner glass wall there could be a second door in the outer glass leading on to a balcony or a terrace. There should be no pernickity curtains, blinds, etc., but some suitable means of protection against excessive sun. In first class work the actual wall surfaces are sometimes left without further treatment with fine effect. In rooms already built and wall surfaces already treated, it is

necessary to treat the wall aright, making it either washable or porous, according to how the room is to be used. As room space is usually scanty, we cannot have walls which will be too easily damaged or stained during occupancy. The whole wall treatment, up to the ceiling, should be uniform. Above all, there should be no wainscots. Wood panelling is highly effective—choice woods, beautifully grained, the doors not unnecessarily large, and unframed, and simply cut out of the wood. In small rooms the ceiling also may be executed simply in wood, a treatment which gives a good, severe, solid effect. Parquet floors, covered with self-coloured linoleum or with loose carpets are often desirable; carpets are needed where the occupants are likely to spend long hours comfortably seated at ease. The carpets might be self-coloured and of good material; if they have broad or narrow stripes of dark colour marking the border, they look well and will certainly never be thought tasteless. Whatever cupboards are required in such a room should be built into the wall, and writing-tables, etc., should be made to tilt up and disappear into the wall. Collectors will perhaps add glass cases, reaching to the ceiling, to these walls, and may even keep pictures in this way; for to use valuable pictures or statues as wall decorations is dangerous to occupants and the safety of the pictures or objects.

Heating and Lighting.— The approved method of heating to-day is by hot-water pipes, which give a fairly certain and regular warmth. As they require large radiating surfaces, on account of the not excessive warmth they impart, they might also be built into the lower parts of the wall—suitably isolated, of course. Light is best admitted through the window, hence this should be well lit up in the evenings also—perhaps by ceiling lights between the double glazing. This form of illumination will usually suffice, but a number of contact points at carefully chosen places, including some in the floor for standing lamps, etc., of the most varied types, will prove serviceable. The age of pompous lamps and chandeliers, etc., hung from the ceiling, is past; they break up the space and blind the eye. It is important to note that candle-light burns upwards, and does not dazzle if the brilliance is not excessive. It was natural and necessary, in an age of magnificence, to assemble countless candles in a cluster; the flickering light, surrounded with polished crystals of glass, was capable of producing great effects. The form of illumination produced by imitation candles of frosted glass and electric lamps in the shape of flames—a lifeless copy—is one of the most incredible blunders in taste. Gaslight, as an open flame, or better, with mantle, also burns upward. Its characteristic mark is the supply of the fuel by means of pipes. The pipes must therefore be given special prominence. Electric light is used in incandescent wires; its characteristic note is that it hangs downward, and on a cable. This is the proper position of an incandescent lamp, and it is an abuse to place it sticking upward, for the sake of some favourite lamp. The modern age of incandescent lamps offers the most varied and original combinations and will prove particularly serviceable in public localities and large apartments. The candle continues and will continue to be employed as a table illumination at meal-times, on account of its comfortable, and at the same time decorative effect. *(See* LIGHTING AND ARTIFICIAL ILLUMINATION.)

Colour Treatment of Walls, etc.—In deciding on the wall treatment of a room the governing factor is always its purpose or use, which should determine its form. In many rooms which are only meant to be occupied for short periods, and are made of masonry, the colour of the paint, in particular, can work wonders. A beautiful bright cinnabar red, pale yellow or green have a cheerful effect. A deep red will certainly have a solemnizing, pale blue and grey a tranquillizing, effect. Very light brown, pink or pale violet are generally suitable for ladies' rooms. Blue is a very good colour for resting rooms and bedrooms. A white wall, as such, in a beautiful, natural material, will always remain in favour, and will invariably prove a good convenient background for furniture and stuffs. In considering any other colour, the chief point is whether a warm tone (yellow, brown, red) or a cold one is required. This is where most mistakes are made; a very strong sense of colour is necessary if the whole effect is not to be spoiled by woods and stuffs which do not harmonize in colour. A new idea, which conforms with our feeling for space, is to put slashes of the colour of wall and ceiling on to the window wall. If we put in any exceptional piece of furniture, part of the wall, against which it stands, can be coloured to suit. It will sometimes be admirable to cover walls and ceiling altogether with stuff, giving an effect of warmth. It is preferable to do this first with stuffs in a single colour.

Disposition of Furniture.— We shall, then, need less and less furniture in our living-rooms, since everything put there merely for show, or, worse still, for symmetry, must vanish. The fireplace, burning wood or coal, should be retained on account of the ventilation which it affords, of the beauty of the open flames, and of its warmth in autumn and spring. The inmates of the house will love to gather round it of an evening, or in chilly weather, and this is the chief place in which seating accommodation, of varying size and shapes, is to be placed. A low occasional table, always placed beside a chair, never in front of it, and electric lamp, and perhaps a small moveable stand for books, newspapers, and possibly light refreshments, will meet all needs. As most, if possible, all articles of furniture should be fitted into the walls, we hardly need any more furniture in the living-rooms beyond chairs and tables, except perhaps a flower-pot for a beautiful, large indoor plant. The latter should preferably be a lime or an oak, rather than a palm or anything else alien to native flora. Cut flowers in a beautiful glass or a good piece of pottery, set in the right place, give great pleasure. The first law of the decorative artist is to make life cheerful and full of joy by the simplest possible means. The time is gone when human beings were supposed to find pleasure in dark, cellar-like rooms with heavy carpets and festal plush curtains, innumerable ugly knick-knacks such as balustrades, candelabra without lights, flowers with artificial dust to imitate the genuine, wardrobes and chests of drawers.

Bedrooms and Bathrooms.— The bedroom must be light, again with one wall all windows, the beds on simple steads of wood or metal, not unnecessarily large. The light must be behind the head, so that one can read easily, lying on either side. A roomy easy chair with a small table beside it, a footstool, small, light tables on either side of the bed on which to place books, medicines or a glass of water, will be sufficient furniture, if we have made arrangements for everything else in the bathroom and dressing-room.

The bathroom has become increasingly important. It is impossible to do without it, and for various reasons it is desirable to allow it ample space. It is used, not only for washing and bathing, but for gymnastics and massage and all sorts of exercises. It must allow of quick and thorough cleansing; both walls, floor and ceiling should therefore be tiled. Furniture, if any, should be of enamelled metal glazes, as in the operation room of a hospital. The walls and ceiling may, of course, also consist of enamelled metal glazes, and the colour, besides white, a very pale grey, or, for a lady, even a pale pink shade. The dressing-room may have cupboards for all purposes around three walls, with one wall wholly mirror, in front of which should be a small table for toilet articles and the like and a low, wide chair, painted in dull oil or varnished. The lighting should be built into the mirror wall on either side, the floor covered with heavy mats or carpets, as it will often be trodden by bare feet. It should be possible to see that the floor of the bathroom is warm, not ice-cold, without employing bath-mats. In small houses, however poor, at least a sheltered table-nook must be arranged.

Attics, Kitchen and Pantry.— The attics, kitchen and pantry, the latter next to the dining-room, should also be clean, easy to wash, and in every way practical in their arrangements. No machines or implements whose shapes are in any way decorative or ornate should be used. The stands for kitchen utensils should be open, the lighting from the ceiling, which, like the walls, should be covered with simple white, undecorated tiles. The floor should be paved with plain slabs, preferably in pale grey or black. Pans, jam pots, etc., are better put away in a separate niche than in a refrigerator.

Assistants must be trained to look on themselves not as servants but as colleagues. They must be lodged in a nice. cheerful room

and have their own recreation and dining rooms, to avoid any feeling of inferiority. It is advantageous, if only on practical grounds, to have each of these rooms in a different colour. Obviously there must be ample facilities for bathing and washing.

To turn to the nursery, it is well to separate the day from the night nursery. Where there are many children, a sickroom with all modern comforts would be very desirable. In the day nursery everything which might cause injury, such as sharp curves and angles, must be avoided. Special regard must be paid to the childish habit of crawling about. Tables should be round and the edges of the surface and the feet rounded off. Toys may be kept in cupboards which can be opened easily and without danger. Walls and ceiling must be in bright colours, perhaps each with a different colour, red, yellow, green, white, the ceiling light blue and the whole decorated with small stars. A convenient low chair for the mother or governess is an absolute necessity: the cover should be bright stripes, of washable material; the lighting again from the window wall and with convenient contact points for a portable lamp. Contacts for a wireless and cinematograph also must not be forgotten. A small darkroom for photographic purposes is desirable. In large houses a small workshop might be fitted out for the boys, to arouse their instinct to use their hands at an early age, and have a place where small repairs can be carried out.

Furniture and Craftsmanship.— The furniture in the living-rooms should be chiefly of walnut and oak, and in countries with colonies, also of foreign woods such as mahogany, etc. Dyeing and staining is out of date, but inlay work, carefully prepared and used in dry rooms, has proved its value. Deal is very suitable for bent wood furniture, which is made in the following way: the wood is cut into strips, which are put into metal frames, through which steam is forced at very high pressure. In this state the wood grows so soft that it can be bent into any desired shape. This kind of furniture is often employed in offices, cafés and similar establishments for which its extraordinary cheapness, which can yet be combined with excellence of shape, fits it. Naturally, wherever possible, any other kind of wood may be employed if obtainable and suitable for this purpose. Nowadays metal is also often used, both bare and enamelled or painted. Abstinence from the use of machinery in making furniture, as required by Ford Madox Brown in 1881, is no longer practicable. The machine should be used simply as a tool; and under no circumstances must it imitate handwork; it should be used only on work of the type which demands no artistic impulse; *e.g.*, the pressing and filing for inlay work under steam pressure, the trimming and preparation of the material, etc., operations which will not distort the craftsman's work; the machine is there to save time and labour. Any unintelligent work can be replaced by the proper appliances. The shape produced by machine work must be quite distinctive, to allow a proper appreciation of its peculiarities. It is certainly wrong to make use of machinery to produce large quantities of ugly objects, with its accompanying waste of material. It is not absolutely necessary for us to produce everything by handwork, nor is that the sole criterion of value, but it is absolutely necessary that machine productions should be well thought out—high-minded, in fact, but not deformed and obscured by unsuitable decoration. An inventive brain and good planning and design will always re-discover beautiful form. Detection of servile imitations will always allow real talent to accomplish work of value. This point is of the greatest value even from the economic point of view, when we consider that even to-day in many countries, valuable material is rendered valueless by bad workmanship, whereas right treatment could only enhance its value and so make life more precious and sanctified. Only beauty, beauty everywhere, can further exalt our modern life and make us happy. There ought to be a movement, similar to that of the Church, to follow these ends and declare war on all bad methods of work. The great talents many of which live and perish to-day unnoticed would suddenly awake to life and create works of undreamed-of grandeur, as of yore. It is this spirit, together with a universality of understanding and co-operation, that is the great lesson of the past; not bad imitation, which inhibits and destroys fresh ideas. The fact is that to-day we in Europe no longer have any conception of the mysterious rorces of the old workshops, which yet produced work that was always good—sometimes outstandingly good. What was the social position of those men in comparison with the organised world of to-day? Our chief interest lies in the men who lived and worked in the period between the great migrations and the mid 18th century. How could that extraordinary unity arise between palaces, castles, churches, city halls, even whole cities and whole villages—a unity complete down to the smallest detail, and crystallising into clearly defined styles? Art follows no law. It can only spring from deep spiritual movements, and the greatness of it is the mirror of the greatness of an age. It penetrates into the smallest mountain hut, whose simple, unsophisticated shapes are equally a reflection of the spirit of the age. To-day we are learning to appreciate increasingly the unsophisticated work of these simple men; it is a revelation to us, as is the work of the modern child. The essential in old times lay in the wonderful work fashioned by master craftsmen in excellent workshops. It may have been the year long community in work and creation. The blossoming of childhood in good surroundings. The complete mastery of the handicraft and the joy of producing something ever new, ever more fully perfect. The only external impulse in those days came from strange pieces of booty brought home by knights from the wars, and through the co-operation of masters who had been carried off in captivity. These masterpieces blend in natural wise with the native works, and new, mysterious creations issue. In those days there were no workmen, only masters and apprentices. The work, design and execution, sprang from one force and was therefore created with a love unknown to-day. Based on a great tradition swayed and inspired by universal sympathy, men were ever inventing something new, either in form or in better work, striving towards the highest perfection. The clumsy apprentice was mocked and cast out, the skilful admired and encouraged. To watch the life of his fellows from childhood in the workshop was for the layman the best education, to train him to become a true and appreciative connoisseur.

There may still be workshops of this sort to-day; the tailor's workroom, perhaps, comes nearest to it. Let us consider a moment where their true value lies. Something is sewn, for example, with a machine invented on the grand scale, superior to handwork chiefly in accuracy and regularity. Superior except in one point, the feeling for material. Once set in motion, the machine can only work on mechanically, and so must fail wherever attentive hand-work, inspired by mind and feeling, takes account of every difference, however small, and thus gives even greater steadiness, being therefore better in quality and so also creating greater value.

Complete recognition of the task and unshrinking performance of it must lead to a new style. While the first necessity is the simple, unadorned form, we need have no fear of genuine talented enrichment. Talent will always find the right way by instinct, and need not shun the most complicated shape. Finally let it be said that where for any reason a richer shape is preferred the forms created must always be new and natural. Repetition of old forms, old styles that have already had their day, is simply ruinous. It is equivalent to a confession of poverty of ideas and destroys all natural understanding and enjoyment. At the Congress of modern bridge building in Vienna, Sept. 1928, the president, Dr. Otto Linton, of Stockholm, treated this question at length, declaring that the architect was now a back number, and had been replaced by the engineer. He sees in the architect, the decorator who sticks pointless rosettes into purposeful building—a misrepresentation of the artist's real rôle, which consists in giving expression to the requirement-plan, and order to the purpose-form. He will always find aim and purpose for his work in satisfying fully the needs put forward by the builder, think in good proportions and rightly chosen material and express himself through these, and not through ornaments stuck on at random.

Style cannot, as Linton says, be dictated by the brain of the mathematician or the blue pencil; it springs from the character of a nation. The determining factor is whether that character is natural or corrupt, crude or refined, and whether it has advanced to the stage of seeing and preferring the better. It will never

ENGLISH AND FRENCH WALL-PAPERS, 16TH–19TH CENTURY

1. English wail-paper, 16th century; Elizabethan era (1558–1603). Wood-block print in black and white. 2. English wall-paper, 18th century, with Chinese design of birds and foliage, a favourite motif up to 1750. 3. Domino wall-paper, France, late 18th century. This example (1795–1800) clearly shows the *Directoire* style in the medallions containing furniture and pottery. The colours are red-brown, green-grey and tan. Domino papers were printed with designs in compartments, geometrical figures, or grotesques. 4. French wall-paper, early 19th century. in sepia, black and white. These scenic papers were very popular in France and America. 5. Overdoor wall-paper by J. B. Reveillon, France, 2d half of 18th century. Reveillon manufactured paper panels deslgned by artists; this one was in the room with the Cietti paper shown in fig. 6. 6. Wall-paper designed by Cietti, Italy, and printed by J. B. Reveillon between 1780 and 1789. Cietti here uses a Pompeiian design and colours, precursors of the less delicate Pompeiian styles popular during the Directory (1795–99). 7. French wall-paper, 18th century panel designed by Prieur, manufactured by J. B. Reveillon; now in the Musée des Arts Decoratifs, Paris. 8. "Renaud and Armide," printed by Leroy, France, 1828. Here Renaud, the Crusader, is shown with the enchantress, Armide, in her pleasure-gardens. (See Plate II., fig. 7.) 9 and 10. Classic wall-paper, "La Galerie Mythologique" (1814), by Joseph Dufour, Paris. This paper, in *grisaille* and green, represented all the gods and goddesses

be possible to make exact caiculations regarding colour, and yet colour is one of the most important factors in modern building and decoration. It would be equally foolish to say that artistic painting is a back number to-day, varnishing and distemper alone required. The only true measure is to appreciate the value of modern painting, feel its quality and estimate that alone. The essential is not even the individual species within modern painting — although this, too, certainly needs to be considered, but solely the significant side and special quality within a capability. We see this best in photography, which can be splendid or absolutely uninteresting, according to the amateur who handles the camera. The main point is therefore to re-educate ourselves so far that we can choose the right forces in every field and allow only great capacities to influence us. The more true forces assert themselves, the higher will be the cultural level of a people. The work of the engineer is much less cramped than that of the architect, hence his untiring development, particularly in all creative fields. Respect for the achievement is still intact, and the success is consequently greater.

Business Premises. — In fixing our business localities, consideration must be paid both to absolutely economic and purposeful arrangement and also to advertising effect. The principal problem is again that of material, colour and lighting; but the wares on sale must also be good.

As for the cinematograph, the first requisites are good, comfortable seating accommodation and easy entry and exit. Tip-up seats covered with good leather, a good carpet on the floor (if possible of the same colour as the leather); the walls preferably hung with stuff, and similarly all curtains, partitions, etc. made of the same material, will give a good effect. An efficient system of ventilation and perfect lighting (*q.v.*) (preferably by means of soffits), for the intervals, is required. Particular attention must be paid to the vestibule, as this is very much used. Marble or inlaid wood are both suitable materials. If the till and the buffets are made automatic, great simplification in running will result. If the rooms are given convenient shapes, the staff can be reduced. In cinematographs and the like special attention must also be paid to securing the electric cables. They are best laid in the walls; but it is advantageous for the purpose of repairs, to have them easily accessible. The cables must therefore either be laid in grooves in the walls, or stretched free, absolutely taut; for the frequent, untidy crooked laying and fastening is dangerous as well as ugly. Absolutely perfect fixing is the first duty. The last word on this point has not yet been said. It is best if the cables can be fastened without visible screws, for screws are always a makeshift. Otto Wagner declares permanence to be the first law of all architectural expression. This calls for good material and excellent work well planned and designed. To achieve this, requires constant practice and the possession of a natural capacity of identifying oneself with one's task. For example, in decorating and fitting a butcher's shop. Our immediate thought is to cover walls, ceiling and floor with a material which will keep cool and can be washed, therefore tiles are used. In old days we should have wanted to adapt it to Roman precedents; to-day we invent good fittings, avoid all ornamentation, but put the signs in the right place, and in perfect lettering. The lettering, which is usually a disturbing element, has assumed particular importance to-day.

There have always been certain objects which accurately reflect our age, and a later age will find it easy to recognize in these the forms in which we express ourselves. This is especially relevant to the coach-work of motors and modern carriages, rolling-stock, aeroplanes, etc., and many machines, if designed solely to express their purpose and not marred by antique decoration. The armchair, too, has been altered and adapted to suit modern requirements, solely on practical grounds. The interior fitments of many theatres, hotels, restaurants, cafés, cabarets and bars must be described as quite new and successful. The equipment of ocean liners, especially in the working parts, is also modern, even though here, as with the American sky-scrapers, an absolutely modern construction is often spoiled by incomprehensible, antiquated decorations.

Materials and Ornaments. — We must emphasize the value of the material itself. We should never think of decorating a pearl; similarly we should consider carefully to what purpose we should apply materials. Under no circumstances whatever is imitation permissible. The use of linoleum, for example, is an admirable thing when it can be obtained in self-colour or in a pattern which suits the material. As soon as it begins to imitate veining, it becomes unusable. When linoleum is used it is best to employ a light, grey, even tint, Everything is an appliance for the use of the modern man, and must consequently, logically, be made to fit modern clothes.

In 1843 Rossetti founded the pre-Raphaelite Society in London; in 1881 Morris and Co. was founded. New stuffs, carpets, books, book-bindings and furniture were related. In 1881 the workshops were removed to Morton Abbey in the South of London.

In 1883 the Art Workers' Guild was formed, which began to hold the Arts and Crafts Exhibitions in 1888. In 1885 Ashbee in England founded the Guild of Handicrafts with Baillie Scott in Essex House. On the continent the chief experimenter in a new style of building was Berlage in Holland. His Bourse is a milestone on this road. He was principally interested in building with raw brick, with concrete facings. J. B van Loghem, J. P. Oud and Jan Wils, architects chiefly concerned with utility buildings, were the leaders in this field. Van de Velde in 1914 built the tripartite theatre at the Cologne Theatrical Exhibition. Sweden produced, among other buildings, the fine concert hall of Tengborn. In 1898 Olbrich built the "Secession" in Vienna, in 1904 Otto Wagner constructed the Post Office Savings Bank. In 1903 the Wiener Werkstatte were founded, and in 1905 the Stoclet Palace in Brussels built. In the German countries the "Werkbund" movement arose, and schools were founded everywhere in the many large towns which spread like the new intentions. Peter Behrens erected the offices to the Allgemaine Elektrizitatsgesellschaft in Neubabelsberg, near Berlin, in 1917, and a turbine factory for the same company. Still earlier, in 1910, Hans Pölzig had built a factory in Luban, near Posen.

The intention is to do justice to the construction and accommodation, to avoid all statistic forms and simply let the construction speak for itself, the chief stress being laid on well-chosen proportions. Fahrenkamp in Dusseldorf, Pfeffer and Mendelssohn in Berlin go further, and prefer a richer style for internal accommodation. Bruno Paul and Arnold Nechansky have also created rich and original interiors in Charlottenburg. After the war, the whole trend was towards greater simplicity. Walter Gropius in Dresden built solely in concrete and glass. He constructed the Stadttheater in Jena in 1922, the Bauhaus in Dessau in 1925. W. M. Dudok, of Hilvershum, Holland, built the school at Boschrift on three lines in 1922. To the same school belong also the designs and buildings of Corbusier and Pierre Jeanneret in Paris, Mies van der Roho, Bruno and Max Taut in Berlin, and the works of Freysinnet, Mallet-Stevens and Chaneau in Paris. The arrangements of the Stuttgart settlement in 1927 give a good indication of the new projects. The chief authors here, besides Gropius, are Corbusica and the Viennese Josef Frank. The most grandiose achievement is the Stuttgart railway station, together with the festival buildings in Salzburg by Behrens and Holzmeister. The buildings and decorations of the exhibition on the "Pressa" in Cologne in 1920 and the Dusseldorf Art Exhibition give a true picture of the whole development. In America the leader is Frank Lloyd Wright, who has been following the same path for 20 years. Many utility buildings, such as the imposing granaries in Montreal, and others in South America, are completely satisfying. The sky-scrapers are unluckily marred by unharmonious architecture; on the other hand, a granary of the Washburn-Crosby Company, built in Minneapolis in 1920, is an absolute model.

The collections of stuffs and wall-papers in the Wiener Werkstätte and the Deutsche Werkstatte show patterns which are original and usually successful. Good and successful work in lace, embroidery, carpets and tapestries can also be found everywhere. The treatment of metal has also made extraordinary advances. Angela Stodthen's room, of pure beaten copper, in the Austrian pavilion at the International Arts and Crafts Exhibition of 1925

in Paris, is an example of this type of work. Similarly, ceramics has developed greatly, and plays an important part in fireplaces, wall-decoration and above all in frescoes. The free painting of walls, particularly in restaurants, cafés and similar localities is also much in use, but fresco-painting is also often successfully employed. *(See* also RUGS AND CARPETS; LIGHTING AND ARTIFICIAL ILLUMINATION.) WALL-PAPER

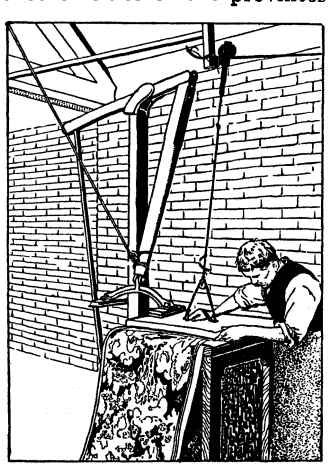
Paper wall-hangings were first invented as inexpensive substitutes for the costly and sumptuous hangings of brocade, brocatelle, tapestry, stamped leather and Genoese velvet, used in the palaces and the great houses of Europe in the 16th and 17th centuries.

The earliest beginnings of this art are still in some obscurity. It is evident, however, that printed wall-papers were not made until after the discovery that type could be cut on wood-blocks and printed. Apparently some of the earliest paper wall-coverings were produced by the letter-press printers themselves. This fact is substantiated by a discovery made in 1911, during restorations to the entrance hall of Christ's college, Cambridge. On the original beams of the ceiling, in the entrance hall and dining room, was found the oldest block-printed wall-paper known to be in existence. The design is in black and white, done on the reverse of the proclamation of the accession of Henry VIII. Scarcity of good stock evidently led to this economic use of both sides of the paper. The pattern is that of a contemporary velvet or brocade. It is signed with "a great H and a goose," the mark or rebus of the master-printer, Hugo Goes, who was living and working in Steengate, York, in 1509.

Domino Papers.—But the real development of the wall-paper idea is due to the *dominotiers* of France, a group of men working in the 16th century in Rouen and other cities of the provinces to make domino papers and marbled papers, which were eagerly bought by the peasants as a decoration for their fireplaces. Undoubtedly this inspiration came from the decorative Italian papers used to line boxes and books. The Frenchmen, however, were the first to put such papers to general use as wall-hangings.



BY COURTESY OF JOHN LINE & SONS
AN EXPERT AT WORK ON THE PRODUCTION OF A HAND-MADE DESIGN

Domino papers were printed with little geometrical figures, designs in compartments, or grotesques. Marbled papers required no printing, but were made by floating off the colours from the surface of water, after "combing" them into various marble designs. Both domino papers and marbled papers were also used in France for end-covers of books, and for covering or lining boxes. Special marbled papers in black and white were made for funeral prayer-books and other mortuary requirements.

By permission of the king, the *dominotiers* merged with certain wood-engravers in 1586, and formed a corporation or guild of *"dominotiers, tapissiers et imagiers."*

Small sheets of paper like those used for the *Images d'Épinal* (c. 12×16 in.) were employed for these paper-hangings, which were sold by the quire or by the ream. The outline of the design, engraved on wood-blocks, was printed by mrans of a simple press. The design was then coloured by hand, by means of stencils, using distemper colours mixed with glue. The French name of *papier peint* for wall-paper is a descriptive relic of this early process. No attempt was made in these earliest wall-papers to arrange designs in such a fashion that they would match when the small sheets were put together on the wall. It was not until the master *dominotier*, Jean Papillon (1661–1723), invented continuous matching designs about 1688, that people were relieved of the casual effects created up to that time whenever wall-paper was used.

Jacques Chauvau, who was a pupil of Papillon, improved on his master's ideas by printing all the colours from successively applied wood-blocks instead of stencilling them by hand. He had great success from his initiative; his method was quickly taken up by Boulard in Paris; and papers of the same sort were soon printed in Chartres and in Orléans. During Papillon's time the popularity of wall-paper increased. Savage opened a factory in Reims; Le Tourmy and Rabier-Boulard had wall-paper factories in Orleans; Isnard of Strasbourg, Descouteaux of Chaumont, Vautrain of Nancy, and Roche of Lyons became well-known for their work in engraving and printing paper-hangings. The new technique of printing in colour was not universally substituted for 'the old. Until the end of the 18th century, there were still small ateliers that remained faithful to "illuminated" papers. Nevertheless the process was widely used.

Both paper-printers and paper-hangers had been greatly handicapped up to this time by the fact that they were obliged to work with small-sized sheets of paper. In 1760 Fournier, a merchant on the rue Carré St. Martin, Paris, made the first attempt to produce paper in long strips by pasting the small sheets together before printing, thus forming a roll. An edict of Louis XVI. in 1778 decreed that each such "roll" should contain 24 sheets of paper, pasted end to end, making the length about 34 feet. The name and address of the maker was obligatory on the two end sheets. This was the standard size for a roll of wall-paper until the metric system was adopted.

Flock Papers.—The discovery was made in 1620 that chopped wool could be used to produce wall-paper which resembled velvet and tapestry so closely as to deceive both the eye and the fingers. This new invention, especially suited to contemporary fashions in house-decoration, was launched by Le François of Rouen. His process was very simple. Instead of the ink or distemper colours used by the *dominotiers* for printing their wood-blocks, he employed a mordant or greasy varnish. Before it dried he shook or blew over it, by means of small bellows, very finely chopped wool in different colours. This substance adhered to the varnish and covered the design. The superfluous wool was then shaken off, and a perfect imitation of brocaded velvet was obtained.

The cost of flock papers was small, in comparison with the sumptuous stuffs imitated, and their effect was so impressive that they attracted great attention and made the name of Le François famous in all the countries of Europe. Jerome Lanyer, of England, was inspired to attempt the same process under a grant made by Charles I. in 1634, giving him the exclusive right to manufacture flock hangings which he called "Londriniana." For this privilege he paid the sum of £10 a year to the crown. Lanyer's flocks were made, however, on "linnen, cloath, silke. cotton, leather and other substances," probably because there was not at the time any English-made paper strong enough to use for the purpose.

Fifty years later Dunbar of Aldermanbury was advertising an amazingly large assortment of flock papers, "some after the manner of real tapestry, others in imitation of Irish stitch, flowered damasks, sprigs and branches; others yard wide in imitation of marble and other coloured wainscots, others in yard wide embossed work, and a curious sort of flock work in imitation of Cassaws and other hangings of curious figures and colours."

In France the first generation of flock papers died out before they were in genera1 use, to be succeeded by the illuminated papers of the school of Papillon. In England, on the contrary, flock papers took root and flourished. The process was perfected

and improved in this country, and in 1750 England suddenly began to ship flock papers back to France. The greatest success was the brocaded paper done on blue or gold grounds, which quickly became the rage in Paris. Madame de Pompadour commanded it to be hung in her dressing room at Versailles and in her bathroom at the Chbteau des Champs. Ladies of the court sent their Gobelin tapestries to storage, in order to put "English blue paper" in their place. The charming designs of Papillon were forgotten or depreciated in devotion to this new fashion.

An English paper-stainer named Lancake went so far as to get permission to establish a factory at Carribres, near Paris, for the production of flock papers, and French manufacturers were driven to defend themselves against the English invasion. They knew the secret process and had no difficulty in adapting themselves to the taste of the day. To prove their superiority they used chopped silk instead of chopped wool, imitating the finest silks that came from the looms of Lyons.

It is interesting to observe how these papers were applied to the wall Early papers in England were nailed on with fiat-headed nails. Later papers, both in France and England, were applied with paste — but flock papers were treated with as much courtesy as if they had been the actual stuffs of which they were imitations. They were mounted on a chassis, or stretcher, which was first nailed to the wall and covered with stout linen, tightly stretched. Over this brown paper was pasted as a lining paper; the flock paper was applied when this was dry.

Paper Imitating Painted Panels. — The second half of the 18th century was marked by a new development in paper hangings, due largely to the genius of Réveillon, a Paris manufacturer, who took his inspiration from painted room-decorations executed by the artists of the day. Réveillon determined to make paper panels of such a character that they might be used in wood-panelled rooms in place of decorations painted on canvas or on wood, and to employ the best artists as his designers. The panels created for him by Huet, Cietti, J. B. Fay, Prieur and Lavallée-Poussin, executed with Réveillon's amazing knowledge of technique, are undoubtedly the most beautiful wall-papers that have ever been made. (Several panels by Prieur will be found in the Musée des Arts Décoratifs in Paris.)

In Réveillon's opinion, no paper stock existed that was fine enough to be worthy of these designs. He reports in his Mémoires that he saw a piece of vellum paper brought to France by Benjamin Franklin — paper that mas used in England by Baskerville in printing fine books — and that he greatly desired to reproduce it. In 1770 he purchased a paper-mill at Courtalin-en-Brie, and began there the fabrication of the paper for which in 1786 he was awarded the Prize for the Encouragement of Useful Arts.

His wall-paper factory in Paris employed about 300 workmen. It received from Louis XVI. in 1784 the title of "royal manufactory," which gave Réveillon among other privileges the right to add to his sign the crown and the three fleurs-de-lys. The establishment met disaster in the riot of April 28, 1789, at the beginning of the French Revolution. Incited by jealous competitors, and roused by the rumour that their wages were to be cut, his band of employees pillaged the factory, leaving destruction and ruin in their wake. Unable to find and murder Réveillon himself, they burned him in effigy. The guards, ordered out to quell the disturbance, fired on the mob. Many persons were killed and several were sent to prison.

Réveillon fled to refuge, and from his retreat sent a despairing letter to Necker; in reply he was offered by the king a sum of 30,000 francs to offset his loss and was assured of protection and continuance of royal favour if he would resume his work. Discouraged and broken in health and spirit, however, he emigrated to England where he died a few years later, leaving his factory in the hands of Jacqueniart and Bénard, who proved to be worthy successors. Although chiefly noted for panel-decorations designed by eminent artists. Réveillon also made all the various sorts of papers that expressed the taste of his day; to these he gave a distinction of design and colouring that endowed them with a special sense of refinement and grace.

Similar developments in the printing of paper panels occurred in England around 1754 under the direction of John Baptist Jackson, who is the most interesting and prominent character in the history of English wall-paper. Jackson published a book on the "Invention of Engraving and Printing in Chiaro obscuro . . . and the application of it to the Making of Paper Hangings of Taste, Duration and Elegance." The book is written largely about himself, styled "Author of that Paper Manufactory now carrying on at Battersea." It was here that Jackson produced the famous series of Venetian prints ordered by Horace Walpole for Strawberry Hill, and also the large landscape-panels and medallions which are a curious mixture of Pillement and Piranesi.

Jackson's papers were printed in oil on a rolling press of his own invention. He guaranteed that "the colour will never fly off — no water or damp can have the least effect on it." Engravings made by him in Rome and in Venice, copies of Canaletto, Rembrandt, Titian and other old masters, were used as subjects of these panels. He also reproduced statues like the Belvedere Apollo, the Dying Gladiator, and the Venus de' Medici, so that "the person who cannot purchase the statues themselves may have these prints in their places." The latter part of the 18th century in England was also notable for the work of Francis Frederick and George Eckhardt, who established a factory in Chelsea in 1786 and executed some remarkable papers with needlework designs, and others with printing in silver-leaf.

In 1712, under Queen Anne, a tax of one penny a square yard was assessed on English paper-hangings. In 1714 this tax was increased one-half. No change in duty was made thereafter for nearly a century. Wall-paper was exempted from duty in 1825, the same year in which prohibition of importation of this manufactured article was removed.

Paper in continuous rolls was invented by Nicholas Louis Robert, of Essônes in 1799, and the English patents, "to make paper without seam or join," were obtained in London in 1801 by John Gamble and Didot St. Leger. The use of paper of continuous lengths was not, however, permitted in England before 1830, because of the important revenue derived from the tax stamps on the small sheets. France, meanwhile, made use of the new invention after 1810.

Scenic Papers. — The attempts made by Reveillon and Jackson to produce paper which represented paintings in panels had a natural development in wall-paper history. They were followed by the epoch of scenic papers — panoramas that covered the entire room with a landscape or a story without repetition.

Late in the 18th century, after the papers of the Revolution with their liberty caps and tricolor cockades and fasces, their pyramids and palms, had come and gone, the makers of wall-paper took up this new idea and carried it out with infinite detail. Robert, whose partner, Arthur, died on the guillotine, produced a Directoire paper with designs of Bosio. Jacquemart and Bénard printed the "Hunt" at Compiègne, of which there is a set in the Metropolitan Museum of Art in New York and also in the Victoria and Albert Museum, London. But the two specially prominent names in the realm of scenic papers are those of Zuber and Dufour.

Zuber's factory, founded in 1790 and still in operation, is at Rixheim in Alsace. In 1804 this paper factory issued the "Vues de Suisse," which, although crude in colour and style, roused great interest because of their decorative possibilities. In 1825 appeared "Paysage des Lointains," and in 1830, "Paysage de Brezil," designed by Rugendas. In 1831 Zuber printed the Paysage à Chasse. "Scenic America" was first edited in 1834, designed by Zipelius and Ehrmann. With its colourful views of West Point, Niagara Falls, New York Bay, Boston Harbour, the Natural Bridge in Virginia, and the Dance of the Winnebago Indians, it has proved to be one of the most popular of all the scenic papers, and new editions are still being issued each year.

In 1838 came the "Courses des Chevaux" in grisaille, with chariot racing in Rome, obstacle racing in France and flat racing at Newmarket. In the same year, Zuber issued "The War of Independence," which was printed with the background of Scenic America, but with Continental soldiers, Washington's triumphal entry into Boston, and the surrender of Cornwallis at Yorktown in

place of the figures in the foreground. This paper, of which no editions were printed for more than 60 years, has recently been re-edited. "Isola Belle" was brought out by Zuber in 1843, and "Eldorado" appeared in 1848. Zuber was the only manufacturer in the provinces who rivalled the scenic papers produced by the Parisian makers, and is the only one, except Desfossé, whose papers are still published today, using the old blocks. The Zuber factory printed the first continuous rolls in colour in 1829, and obtained from Manchester in 1850 the first cylinder colour-press to come into France.

At the head of the distinguished Parisian group making fine scenic papers in the early 19th century, stood Joseph Dufour, who made his reputation with the Captain Cook wall-paper printed in Mâcon in 1804–1805 (anno XIII.). This picture-paper represented a number of scenes from Captain Cook's voyages in the islands of the Pacific ocean; it is very rich in colouring, and tapestry-like.

It was the usual custom to publish a descriptive booklet with each scenic 'paper, giving careful instructions for matching and putting the strips together, whenever a new design appeared. Many of these papers were sent to America, wrapped in tin-foil tubes to protect them against dampness. They were put on the walls with the aid of a numbered chart, after the fashion of children's picture-puzzles. Their success in France and America was not repeated in England, where they were little known.

In 1808, Dufour presented to his public twelve panels representing the Twelve Months of the Year, designed by Fragonard fils; and in 1814, a classic paper in grisaille, with all the gods and goddesses, known as the "Galerie Mythologique." But his masterpiece was the "Cupid and Psyche" paper, which appeared in 1816. The designs for this paper were made by Louis Lafitte, who exhibited them in the Salon in 1817. Two of Dufour's papers, especially popular in America, were "The Bay of Naples" and "The Monuments of Paris" (1815). They may still be found in many old New England houses. Other notable scenic papers from Dufour's ateliers were "Paul and Virginia" (1820, designed by Brock); "Olympic Fêtes" (1824, designed by Mader père); "The Voyages of Antenor"; "The French in Egypt" (1814); "Telemachus in the Island of Calypso" (1825); "The Banks of the Bosphorus" (1816); "Views of Hindustan," and "Views of Turkey." Other famous makers of scenic papers were Jourdan-Villars, who issued the "Battle of Austerlitz" in 1806; Delicourt, producer of "The Great Hunt" in 1851; and Cler and Margéridon, who edited the "Fêtes Louis XIII."

The operations of making scenic papers were common to all fabricants. Small sheets were first glued together to form a "roll," the paper was then sized, and spread out to its full length on long tables, where it received the background colour, put on by a workman with a brush in each hand. After the rolls had been hung up to dry, they were polished on the back. They were then ready for the printer and his wood-blocks. Tempera colours, mixed with hot glue, were used for printing, and a different block was used for each colour, which necessitated as many blocks as there were colours or shades in the design. One colour was printed at a time throughout each roll, and left to dry before proceeding with another. The printing of such papers in this fashion to-day is not a commercial possibility, because of lack of workmeh sufficiently skilled in the art, the high cost of labour, and the length of time required to complete a set.

Scenic papers of a date later than the discovery of continuous paper were still printed on small sheets, the economical manufacturers having a supply of the old paper in stock, and finding that it was of better quality than machine-made paper. It may be noted that the 19th century scenic papers still in existence owe their long life to the durability of the material of which they were made. Panoramic decorations of wall-paper commenced to fall into disfavor about the middle of the century. The advent of the printing machine in 1849 discouraged any further attempts of this magnitude, and, since then, the old order of hand-printers has almost passed away.

Early American Wall-papem — The first wall-papers used in America were naturally imported from England or from France. They were sold by book-sellers and stationers in quires and reams, as they were sold abroad. For the convenience of housewives, they were also peddled about from door to door. "Painted paper" is found in the inventory of Michael Perry in Boston in 1700; Daniel Henchman of the same city records the sales of quires of painted paper between 1712 and 1714. "Stampt paper in rolls for to paper rooms" is first advertised by John Phillips in the New England Journal in 1730.

Plunket Fleeson of Philadelphia founded the first American manufactory in 1739, and sold his papers in the shop with his other wares, which included "bedticks, live geese feathers, blankets and sacking bottoms." In 1769 he advertised "American paper-hangings, made in Philadelphia, of all kinds and colors, not inferior to those generally imported, and as low in price." He suggested also that "every one among us who wishes prosperity to America will give preference to our own manufacture, especially on the above proposition, if equally good and-cheap."

Wall-paper was not yet important enough to induce merchants to devote their whole time to it; so it was often sold by the upholsterers and undertakers, as well as by the ironmongers and those who furnished army equipment. James White, arriving from London in 1754, announced "paper-hangings, put up so as not to be affected by the hottest weather, also funerals furnished and shrouds, either pinked in London or plain and pleated, and sheets."

Between the years of 1740 and the outbreak of the Revolution, there were constant importations of paper-hangings, arriving from London and Paris by every ship. It is to be supposed that American manufacturers kept pace as best they could with foreign fashions. In Philadelphia, Ryves and Fletcher, Joseph Dickinson, Burrill and Edward Carnes, and William Poyntell were importers and manufacturers. In Boston, Jerathmeel Pierce, John Welsh, Jr., Moses Grant, Joseph Hovey, and Prentiss and May made paper-hangings "equal to any on the continent." In New York State were John Rugar and John Howell and Son. In Springfield, New Jersey, was the important firm of Mackay and Dixey. An event in the history of American wall-paper was the printing of the "Washington Memorial" paper in 1800 by Ebenezer Clough of Boston.

Brissot de Warville reported to France in 1795 that paper-hangings were "universal in the United States. No other decoration is known there; almost all houses are neat and decent." The rage for scenic papers possessed New England by 1817. Many of them were brought across the ocean as wedding gifts, or birthday or anniversary presents, in special charge of the sea-captains. Wall-paper establishments soon followed the new fashion, and imported many sets of these "varieties of views." In 1844 John Howell brought from England the first colour-printing machine, and wall-paper entered on a great era of development which continued until the close of the Victorian age.

Chinese Wall-papers. — With the founding of the Dutch East India Company in 1597, the English East India Company in 1600, and the French Company in 1660, Europe was inundated with a flood of Oriental stuffs, and objets *d'art*. In the ships with these goods came wall-papers that were different from anything the Occident had yet seen. They were painted by hand with birds and flowers, forming delightful backgrounds for the lacquer and Oriental porcelains that were fashionable. The first of these papers to arrive in the western world were presented by the great Hongs, or merchants, to their important customers to take home as gifts after the consummation of some important sale.

Such giits were the objects of great admiration and curiosity, and many friends desired similar sets. Orders for them went back on the next ship and soon a regular commerce in Chinese papers was established. Shipments were made with the tea-boxes; Minting lane in London became the centre for their distribution. To avoid the long delay caused by ordering paper specially painted in China, attempts were made to imitate them, both in France and in England, thus creating what are known as Anglo-Chinese and Franco-Chinese wall-papers. As such designs were looked on favourably by Badminton and Versailles, both the original Chinese papers and their imitations were stamped with royal approval

Interesting examples of some Anglo-Chinese designs exist in the Victoria and Albert Museum, London. The average height of Chinese papers was 12 feet. The favourite designs up to the middle of the 18th century were birds and flowers; after 1750 these were largely superseded by landscapes with figures.

Occasionally Anglo-Chinese papers were ordered for American homes, as for example the one executed in London for Thomas Hancock in 1793 in accordance with his command to make "a great variety of different Sorts of Birds, Peacocks, Macoys, Squirril, Monkys, Fruit and Flowers."

The English Gothic Revival.— Notable in the last half of the 19th century in England was the Gothic revival in paper-hangings. In 1843 Augustus Welby Pugin made for the new Parliament Buildings the papers in Gothic patterns that are an admirable expression of the spirit of the architecture. The Daisy pattern of William Morris, the first of a long series, including the Trellis, the Pomegranate and the Acanthus, was published in 1862. All of these papers were an attempt in colour and pattern to revive something from the old Gothic tapestries. They gave inspiration in their turn to Owen Jones and later Gothicists. Since then, no great achievements are to be noted in the history of English paper-hangings.

Wall-paper in Modern Decoration.— The reaction against the over-decorated Victorian era, and the lack of good designs in machine-made wall-papers resulted after 1900 in a temporary disuse of this practical wall-decoration, which had filled a need for three centuries. In its place for twenty years or so have been monotonous putty-coloured walls, panelled with picture mouldings.

Wall-paper, however, has recently come back into its own. A definite attempt to revive the old designs of the 18th century and the old processes of printing has resulted in great benefit to this humble art. With this revival of old designs, much study has been made of the fashions of hanging wall-papers a century ago. In many early houses only three walls of a room were covered with design; the fourth, usually the fireplace wall, was panelled with wood. This idea is being repeated in many country houses to-day.

Modern lovers of wall-paper have also discovered that a partially-papered wall is sometimes more successful than a wholly-papered wall. Hence the use of wall-paper in panels, outlined either with wood mouldings or with paper borders such as were used in olden times to complete a room. These panels are carefully designed to fit the architecture of the room, and the painting of intervening wall-spaces and door and window-trims is carefully studied to complement the colours of the paper.

An enthusiastic revival of the use of scenic papers may also be noted, which has resulted in the pillaging of many houses that contain original examples of Dufour's and Zuber's work. Such papers as the "Bay of Naples," the "Monuments of Paris," and "Captain Cook" are eagerly sought for use in entrance halls and dining-rooms, where there are few high pieces of furniture to hide the pancrama. To protect these papers, and assure the possibility of their safe removal, it is customary to line the walls with canvas before the paper is applied. Canvas and paper may be removed with great facility. The decorated bathroom is a new development of the day, and here again wall-paper has lent its aid. Gay designs, given a coat of waterproof varnish, make bathrooms into places of colour and beauty, and provide a durable decoration.

In rooms where plain walls are a requirement, a wall-paper cornice is sometimes used, with a border above the chair-rail, in a fashion that recalls the old stencilled rooms of early days, where each member of the family took part in stencilling a frieze. Paper panels are again being set into wood rooms, as Reveillon desired, making a pleasant contrast between the panel-decorations and the natural colour of the wood.

Modern manufacturers are producing many good "background papers" for those who have pictures to hang on their walls, and also many papers that are an adequate decoration in themselves. There are glazed papers for the kitchen, marbled papers for the hall, and an imitation of wood-graining that gives the effect of pine.

Papers that represent stuffs, such as toile de Jouy, chintzes and damasks; papers that represent paintings; and papers that are good imitations of the Chinese are relied on to give decorative effects and variety in modern homes.

Present-day schemes of modernist decoration include, beside the textures of wood and glass and metal, many gold and silver wall-papers, and others done in brilliant colours and daring designs. These are used by the modernists in a curious fashion, four or five different papers being combined in the same room—a frieze of one color and pattern at the ceiling line, another paper on the dado, and two or more different papers with their borders on the field of the wall. Many examples of this type of room were seen in the 1926 Paris exhibition of Arts decoratifs.

Wall-paper has also been found useful for enlivening the small decorative objects of the household. Wall-paper screens give a note of colour and interest to a room, and have become practical since the discovery of a method of making them puncture-proof. Wall-paper desk-boxes, blotters, and scrap-baskets, with a coat of shellac, are quite as decorative as leather. Wall-paper lamp-shades in bedrooms and country houses are amusing and gay. Wall-paper sheif-borders decorate a closet at small expense, while bandboxes and dress-boxes of wall-paper on the shelves make uniform and colourful dust-protectors.

WOOD FINISHES, PAINTS AND VARNISHES

Wood, which is both the most available and the most easily workable of structural materials in the majority of the habitable regions of the globe, has from the earliest times been extensively utilized. When, in the course of cultural development, the sense for beauty was awakened, the art of wood finishing had its beginning. In ancient Egypt the embellishment of wood structures by painting and gilding reached a comparatively high state of development, and it was diffused thence, slowly, eastward and westward throughout the settled regions of the world. Each country receiving the tradition, modified and adapted it in conformity with the nature of the native woods, the materials available and the cultural genius of its people.

In the Far East, and especially in China, a highly specialized art developed under the early dynasties, and was carried thence to Japan where it reached its highest state of development. The treatment familiar on Chinese and Japanese articles of vertu and known as lacquer is based on the sap of a tree extensively cultivated in both countries solely for this use, the *Rkus vernicifera,* which is closely related to the *Rhus toxicodendron* of the West, and similarly poisonous. Various grades of lacquer or varnish are made by treatment and selection of its sap or juice, and the lacquer, coloured with selected dyes or pigments is applied in successive coats (in the finer pieces as many as 16) each laboriously ground down with emery flour or other abrasives and as laboriously polished with different substances, the final polish being given with pulverized deer's horn. Each coat must be dried in the dark and in a moist atmosphere. Inlay work and other decorative materials are applied to the lacquer while it is still moist and imbedded therein by the application of subsequent coats.

In Europe during the middle ages and later, besides gilding and similar processes, the decoration of wood consisted principally in staining with a vegetable dye, such as a decoction of log wood, or a chemical agent, such as tannic acid, and the subsequent application of a drying oil or a spirit varnish, consisting of a gum resin (*sandarach elemi,* damar, etc.) dissolved in a volatile solvent, or East Indian lac dissolved in alcohol. Wax was also a favourite material for finishing such work.

The French artisans early developed a finishing process of unique quality which is still popular under the name "French Polish." The process is simple though somewhat tedious. After

the surface has been properly prepared a very dilute solution of shellac in alcohol is applied with a pad made of stocking material. As soon as this coat is dry another is applied over it. This is repeated until the required lustre is obtained. Then, using the same pad, the surface is polished with a very little linseed oil, and after standing over night the polishing with oil is repeated. The soft sheen obtained in this way cannot be duplicated.

The varieties of woods used in construction at the present time differ widely in physical characteristics as well as in their chemical reactions. As a consequence different methods of initial treatment or preparation are required. Wood finishers classify them as "soft" or "hard," connoting generally their relative absorbent properties; "open" or "close" grain, indicating the relative solidity of the surface offered for finishing; resinous or non-resinous, the former class including woods such as cypress, which contain juices that are not really resins; and "plain" or "figured," these terms connoting the visual prominence of the wood structure.

All open grain woods require "filling" as a preliminary to the decorative treatment. This so-called grain consists of the sap-ducts which have been laid open in cutting the lumber, and becomes apparent in those woods having large sap-ducts. These are chiefly the woods classified also as "hard woods." The principal types encountered are butternut, walnut and the juglans family in general; oak, of all varieties; ash, elm, mahogany, rosewood, and chestnut. The following, classified as close grain woods, are, with the exception of maple, birch, cherry, gum and yellow pine, also classified as soft: bass, beech, birch, cedar, cherry, cotton wood, cypress, fir, gum, hemlock, holly, maple, the pines. poplar, redwood, spruce, sycamore and tulip. The preliminary treatment in all cases includes stopping of cracks and nail holes with putty coloured to match the finish to be applied, sandpapering with fine sandpaper to a smooth surface, removal of blemishes if the finish is to be transparent, and thorough dusting off.

Transparent Finish in the Natural Colour.—The woods suited to this treatment are those possessed of natural beauty due to their colour or configuration of grain. Those ordinarily selected for this treatment are the hard woods in general, sometimes including close grained woods like the hard pines, the maples, some of the cedars, cherry, cypress and some types of birch. The natural beauty of certain of these woods, especially oak, is often enhanced by "quarter sawing" in which the boards are cut diagonally across the log.

The more open grain woods are "filled" with paste wood-filler, of which the best grades consist of finely powdered quartz ground to a rather stiff paste in a special varnish. The filler may be coloured or uncoloured. In the latter case, being transparent, it merely provides a smooth surface for varnishing. In the former, the grain is more clearly defined and very beautiful effects may be obtained by the addition of colour, aluminium bronze or white pigment. The paste filler is applied across the grain with a stiff brush, and after it has "set," but before it becomes hard, the surplus is wiped off, again across the grain, with excelsior, burlap or similar material. After the remaining filler has become completely hard, the entire surface is sandpapered with fine sandpaper and carefully dusted off. The first coat of varnish is then applied, using a flat varnish brush. The grade of varnish used depends upon the finish desired. If the work is to be rubbed or polished, the varnish selected is a rubbing and polishing grade; if not, a softer and more elastic grade of interior varnish is usually preferred. In either case three or more successive coats are applied if a good finish is desired. Sufficient time is allowed for the complete drying of each coat—from 24 to 48 hours, depending upon the character of the varnish. However, quick drying varnishes made from synthetic resins, in which the drying time has been reduced to a few hours, have recently been introduced.

If the more beautiful finish produced by rubbing is desired, each coat of varnish after thorough drying, is rubbed with powdered pumice stone and water or pumice stone and oil to produce a perfectly smooth surface. If a dull or low lustre finish is desired, the final coat is rubbed only. If a lustrous finish is required the rubbing of the final coat is followed by polishing with rottenstone and oil. For both rubbing and polishing a pad made by fastening felt to a flat block is most serviceable, and for sandpapering a similar pad is serviceable, the sandpaper being laid over the felt.

Staining.—The modern tendency in wood finishing is to colour the wood before applying the finish. In fact, it has long been the practice to stain many of the choicer woods, such as mahogany, walnut, rosewood, oak, etc. The natural colour of mahogany is a very pale yellow, but staining of this wood has been so long in vogue that the very name suggests red, though in recent years brown has become the more popular colour. Certain woods are also stained to imitate rarer varieties, as, for instance, birch and maple to simulate mahogany, or birch in imitation of cherry.

The older craftsmen employed a variety of vegetable dyes and various chemicals to produce the effects they required, but with the invention of coal-tar dyes, in their great variety and beauty, the older art has largely fallen into disuse. Many of these so-called "aniline dyes" are now sold as powders under the names of the woods on which they are supposed to be used, as, for example, mahogany brown, mahogany red, walnut brown, oak stain, etc. Most of the stains used in ordinary finishing, however, are purchased ready for use from the manufacturers, who furnish them in endless variety.

Stains are of five types, selected according to the woods on which they are to be used—water stains, oil stains, spirit stains, acid stains, and penetrating stains, the last including alkaline stains. The water stains are usually prepared by the user by dissolving the dye in water, though they can be purchased in solution; the rest are obtained ready for use from the manufacturer. The oil stains are generally preferable to the water stains, since they do not "raise the grain" of the wood like the latter, which necessitate sand-papering. The water stains nevertheless are preferred for the light coloured soft, absorbent woods, because oil has a tendency to darken these. Where lacquer is the finishing material, water stains are usually preferred, because of the better adhesion of the finish after their use. Many stains are also made with the same insoluble pigments that are used in the manufacture of paint; and finally, varnish stains are procurable for first coating in which the stain and the first coat of varnish are applied in one operation. Acetic acid is usually added to some stains to increase the solubility of the dyes not readily soluble in water; and oil or spirit—usually turpentine or an alcohol—is substituted for water in other stains for similar reasons.

With water or spirit stain the procedure is to apply the stain with a soft brush. Skill is required here to obtain evenness of distribution. A coat of dilute shellac varnish is then applied. This serves to stiffen the wood fibres that have been "raised" by the stain, so that they may be easily cut. The surface is then lightly sand-papered with fine sand-paper. The transparent wood-filler is next applied if required, followed by a second application of stain, if required, and a second light sand-papering. The varnishing follows—two, three, or more coats, either rubbed or unrubbed, according to the finish desired.

The term enamel, originally applied to fused vitreous coatings on metals, is now also used for opaque pigmented varnish coatings. Such finishes were formerly produced with spirit varnishes (principally dammar) but are now commonly produced with prepared enamels. As found in the market, the better grades of these consist of zinc oxide or the best quality of lithopone ground in a special rubbing varnish.

In producing the finish the wood is first filled, if necessary. One or two coats of flat drying oil paint are then applied, followed by two or more coats of the enamel, according to the quality of finish desired. These coats may be rubbed, as in clear varnish finishing, and the final coat polished; or they may be applied successively without further treatment.

Graining.—This type of finish, once universal, is now rarely used, except where necessary to match old work. Its purpose is to imitate with cheaper woods the colour and figuration of more expensive woods. Expert grainers of the old school can so closely simulate rare and costly woods that it is almost impossible for the eye alone to distinguish between them. Woods usually selected for the purpose are the common soft close grained woods, such as

FRENCH WALL-PAPERS, 18TH AND 19TH CENTURIES

1. Wall-paper, France, *Directoire* period (1795–99), issued by Nicholas Louis Robert, of Essones. The colours are blue, green and *grisaille*
2. "The French in Egypt" (1814), a notable paper with scenic representation of Napoleon's Egyptian Campaign, by Joseph Dufour, Paris
3 and 4. Wall-paper in grey and sepia, printed by Jean Zuber of Rixheim, Aisace, c. 1830, representing scenes from Scott's "Lady of the Lake"

Fig. 3 (Part I): "Each boatman, bending to his oar,
With measured sweep the burthen bore"

Fig. 4 (Part II): "Then like a sunbeam, swift and bright,
She darted to her shallop light"

5. "The Bay of Naples" paper, printed by Joseph Dufour, Paris, between 1815 and 1820. The views show the Bay of Naples, ships, Vesuvius in eruption, Tivoli, Amalfi. This paper was very popular in America
6. "Cupid ana Psyche" ("Les Amours de Psyche") paper (1816), Joseph Dufour's masterpiece designed by Louis Laffitte, designer to the king. The scene here shows Psyche at the bath. The set has 26 strips, in *grisaille* and sepia
7. "Renaud and Armide," printed by Leroy, France, 1828. In this scene Renaud, the Christian knight and Crusader, vanquishes the demons of the enchantress, Armide, with his magic sword. (See Plate XX, fig. 8)

WALL-PAPERS, 18TH AND 19TH CENTURIES

1. "The Banks of the Bosphorus" ("Les Rives du Bosphore") paper, printed by Joseph Dufour, Paris, 1816. The complete set, consisting of 26 strips in colour, represents landscapes with river and *caïques*
2. Hall of Hamilton House, South Berwick, Maine; paper with repeated arches
3. "Views of Hindustan" ("Paysage Indien") paper, printed by Joseph Dufour, Paris, 1815. The set consists of 20 strips in colour. A set still exists in the Putnam-Hanson house, 94 Boston St., Salem, Mass.
4. Blue wall-paper, one of three panels, from designs by Boilly (1761–1845), France
5. "Paul and Virginia" paper, illustrating the story by Bernardin de Saint-Pierre, designed by Brock (1820), printed by Joseph Dufour, Paris
6. Old Canton wall-paper, 18th century, showing *The* Making *of* Porcelain, now at Beauport, Gloucester, Mass. This fine Chinese paper, treating also the subjects *The* Cultivation *of* Tea and *The* Raising *of* Rice, was imported to America shortly after 1770, by Robert Morris. The complete set consists of 40 strips, each 12 ft. x 4 ft. To-day half of the paper is in Mr. Henry D. Sleeper's house, Gloucester, the remainder at Providence, R.I. (see fig. 8)
7. Mrs. Henry Rea's hall, with painted paper panels, formerly belonging to George Sand
8. Old Canton wall-paper, 18th century, now in the ball-room of Mrs. E. Bruce Merriman, Providence, R.I. (see fig. 6)

BY COURTESY OF G. A. LA VALLEE OF THE MARIETTA PAINT AND COLOR COMPANY AND THE MURPHY VARNISH COMPANY

PANELS SHOWING PROGRESSIVE STEPS IN WOOD FINISHING

1. Southern pine. Cherry stain (one coat); one binding coat; special varnish (two coats)
2. Gum. Mahogany stain (one coat); one binding coat; gloss varnish (two coats)
3. Birds-eye maple. Silver gray acid stain (one coat); color developer (one coat); gloss varnish (two coats)
4. California redwood. Black acid stain (one coat); filler (one coat); color developer (one coat); dull varnish (one coat)
5. Birch. Mahogany stain (one coat); one binding coat; gloss varnish (two coats)
6. Quartered oak. Combination oak filler (one coat); gloss varnish (two coats)
7. Walnut. Circassian walnut stain (one coat); walnut filler (one coat); gloss varnish (two coats)
8. Mahogany. Mahogany stain (one coat); mahogany filler (one coat); one binding coat; gloss varnish (two coats)

pine, poplar, soft maple, etc. A "ground colour" closely resembling the prevailing colour of the wood to be imitated is first applied, two or more coats being necessary. These colours may be bought ready for use. Specially prepared graining colours to match the deeper shades of the wood to be imitated are then applied evenly with a soft flat brush. This process is called "rubbing in," from the fact that paste colours formerly used, necessitated rubbing to spread them. A comb of steel or hard rubber is then passed over the portions of the work that are to be left plain. For imitating the less open grain hard woods, such as walnut, cypress, yellow pine, cherry, etc., the steel comb is covered with a rag. Rags are also used for wiping out "heart-grains." Then by the use of combs and wiping rags the expert grainer can closely imitate the grain pattern of any wood. The finishing touch is added by "overgraining," to soften and blend the work, with water colour, to which a little beer or vinegar has been added. For commercial work machines, stencils and transfers are available which fairly imitate the grains of various woods. The chief objection to them is that the pattern is monotonously duplicated. The most successful of these is perhaps the "graining wheel," consisting essentially of a printer' ink roller hearing the grain pattern in relief. A more recent invention consists of a steel roller which stamps the grain pattern into the substance of the wood, which is then filled, stained and treated exactly like the wood imitated. The completed work is preserved by varnishing.

WAX FINISH AND PAINTING

Instead of varnish, wax is oiten used for finishing natural or stained wood surfaces. This is one of the oldest methods of wood finishing. The material used was formerly beeswax dissolved, with the aid of heat, in turpentine, or simply the plain powdered wax, spread with the aid of weighted brushes. Both methods are still used, especially in the finishing of hardwood floors, but the commoner modern practice is to use prepared waxes, consisting of several kinds of wax with a small proportion of a volatile solvent. This treatment produces a dull finish, which becomes lustrous with rubbing. The usual undercoat for wax is shellac varnish. No special skill is required to produce this finish, vigorous rubbing being the chief essential. The same effect is produced in more permanent form by the so-called "hard wax finishes," containing carnauba or other hard waxes.

While not usually classified as a method of wood-finishing, painting is more commonly practised than any other method. In the methods just considered the purpose is to enhance the natural beauty of the wood itself, whereas paint is applied for the purpose of concealing the wood. Other types of finishing require that the wood shall be uniform in colour and free from defects and blemishes, but as paint (like enamel, already considered) permanently hides the surface, no selection is necessary.

Preparation for painting is essentially the same as for the types of finishing already discussed. The surface is sandpapered; open grain woods are filled with paste filler coloured with the paint to be used; nail holes, cracks, etc., are stopped with putty similarly coloured; the surface is again sandpapered; and finally all resinous spots and knots are coated with a shellac varnish. The first or "priming" coat is then applied. This coat usually contains somewhat more oil and more volatile "thinner" (turpentine or mineral spirit) than the succeeding coats, to facilitate penetration and assure firm adhesion. The second coat contains less oil and less volatile "thinner" than the priming coat; and the third, which is usually the finishing coat, less "thinner" than the second coat.

The methods of decoration with paint are of infinite variety, depending upon the taste, skill and ingenuity of the craftsman, since the hues, tints and shades at his disposal are practically unlimited and the possible combinations countless.

Lacquer and Other Special Finishes. — The oriental lacquer produced from the *Rhus* vernicifera has already been described. Another type of finish, long used in the West for preserving the lustre of polished metal surfaces and called by the same name, consists simply of spirit varnish — resins dissolved in alcohol or other volatile solvent. This type was largely superseded for the purpose by another form of "lacquer" consisting of nitrated cellulose dissolved in amyl acetate or other volatile solvent with the addition of various "plasticizers," such as castor oil. These were similar in general composition to collodion (nitro-cellulose dissolved in sulphuric ether) or celluloid, in which the plasticizer is camphor. The technical study of nitro-cellulose, stimulated by its importance in explosives, photography, moving pictures, the manufacture of artificial silk and of celluloid products, naturally led to a consideration of its possibilities as a decorative and protective coating. Research and experiment quickly led to the production of a nitro-cellulose, or "pyroxylin," which contained less nitrogen and was therefore more stable than the earlier types, and at the present time many industrial products requiring a finish are coated with pyroxylin lacquer.

Various chemicals which in reacting with the chemical components of the various woods produce colour changes of greater or less intensity are occasionally used by wood finishers, though to a less extent than formerly. The most popular of these is the treatment known as "fuming." It consisted formerly of prolonged exposure of the wood — chiefly oak or mahogany — to the fumes evolved from strong ammonia. It is now commonly brushed on the surface, but the older process yields more uniform effects. Other chemical stains with which varied effects may be produced on different woods are tannic, pyrogallic, chromic, picric, acetic, nitric, hydrochloric and sulphuric acids, the alkalis, potassium bichromate, potassium permanganate, copper sulphate (blue vitriol), ferrous sulphate (green vitriol), ferric chloride, chrome alum and manganese sulphate. These chemical agents all have the advantage of producing permanent coloration, in contradistinction to many of the commonly used dyes. Wood treated in this way is finished as with ordinary stains.

Various effects are produced by first applying ground coats of flat paint or enamel, and after this foundation is dry applying a coat of transparent glaze of a different colour and while still wet stippling, wiping with a rag in various patterns, imitating graining with brushes and a whisk broom, etc. The effect known as "antiquing" is produced in a similar manner, by applying over the flat ground coats a semi-transparent glaze coat of somewhat darker tone. Raw umber or a mixture of raw and burnt umber is commonly used. While the glaze is still wet it is wiped off with a soft rag. Sufficient colour remains to give the "antique" effect desired. The "old ivory" effect is produced by adding to white paint a little raw sienna and burnt umber for the ground coats and after these are dry glazing with a thin mixture of the raw sienna and burnt umber. Ebony is simulated by painting first with vermilion (Japan colour) and finishing with two or three coats of black tinted with Chinese blue. All these special finishes should be protected with one or two coats of varnish.

Spray Machine Finishing. — The spray painting machine was used to an unimportant extent from 1870 to 1923, but it was only with the introduction of pyroxylin lacquer into the furniture and automobile finishing field, in 1923, that it found extensive application. Since that date the improvement of the device has progressed rapidly and its adaptation to other fields has steadily spread. But for this machine the industrial lacquers, which dry too rapidly for application by brushing, could not have been utilized. With slight modifications it was found equally serviceable for the application of paint and varnish, and its use with these has rapidly expanded. With it many decorative effects, such as mottling, spatter finishes in one or several colours, glazing, colour misting, etc., can be produced rapidly and at comparatively slight expense. Modern pyroxylin lacquers are of three types: (1) clear, quick-drying, unpigmented lacquers, applied by the spray-gun; (2) quick-drying pigmented lacquers also applied by the spray-gun; (3) slower drying pigmented lacquers applied with a brush.

The first type, used to replace varnish in the finishing of furniture and similar industrial products, is applied to surfaces already stained, filled and otherwise prepared in practically the same way as for finishing with varnish. The lacquer coating hardens within a few minutes. Two or three coats are usually applied, the final coat being rubbed as in finishing with varnish. Pigmented spraying lacquers are most largely used for finishing automobiles, railway coaches and similar products. The rate of drying is somewhat

slower than that of the clear lacquer, but still quite rapid. Two or more coats are applied, with or without rubbing according to the finish desired.

Brushing lacquers were devised for domestic use. They are pigmented, like the coloured spraying lacquers, but the speed of drying has been retarded so as to permit application with a brush. They are, nevertheless, completely hard within about 30 minutes. They are "flowed" from the brush and cannot be worked over like varnish. The technique is different, but easy to acquire, and the results are novel and both beautiful and enduring

Still more recently, to meet the competition of lacquer and to overcome some of its disadvantages, the quick-drying oil varnishes known as "four hour varnishes" have been developed They are, to all intents and purposes, oil varnishes in which certain synthetic resins have been substituted for the fossil resins commonly employed.

INTERIOR, DEPARTMENT OF: *see* GOVERNMENT DEPARTMENTS.

INTERLACED ARCHES. Arches which span twice the width of the space between the piers of an arcade, so that each arch crosses two others. In some cases the arches interlace, their mouldings crossing alternately over and under those of the other arches; in some cases the whole is on one plane and the arches merely intersect. Interlacing arches are common in Romanesque work *(see* BYZANTINE AND ROMANESQUE ARCHITECTURE), especially Norman, and also in English Gothic *(see* GOTHIC ARCHITECTURE), and are also occasionally used in Moorish work, as in the great mosque at Córdova (8th century). For illustrations *see* ARCADE.

INTERLAKEN, a Swiss town (1,864 ft.) in the canton of Berne, situated on the flat plain *(Bodeli)* between the lakes of Brienz (E.) and of Thun (W.), and connected by steamer, as well as by railway (17½ m) with the town of Thun. It is built on the left bank of the Aar, and grew up around the religious house of Austin Canons, founded about 1130 and suppressed in 1528. In the surviving buildings of the convent religious services (Anglican, Scottish Presbyterian and French Protestant) are now held, while the more modern castle is occupied by offices of the Cantonal Government. The fine and well-shaded avenue called the *Holzeweg* runs through the main portion of the town, and is lined on the north side by a succession of huge hotels and the large Kursaal. Interlaken is much frequented in summer, partly because of the glorious view of the Jungfrau (13,669 ft) which it commands to the south, and partly because it is the best starting-point for many excursions, as to Schynige Platte, Lauterbrunnen, Grindelwald, Mürren and Jungfraujoch. The lines serving these places all start from the eastern railway station (that from Thun reaches the western or main railway station), whence steamers depart for the Giessbach Falls, Brienz and Meiringen, on the may to Lucerne or to the Grimsel Pass. In 1930 the population of Interlaken was 3,703 (mainly Protestant and German-speaking). Opposite Interlaken, and on the right bank of the Aar is Unterseen (population 3,119), which was built in 1280 by Berthold von Eschenbach.

See *Fontes rerum Bernensium* (original documents up to 1366) (8 vols., Berne, 1883–1903); *Die Regesten des Klosters zu Interlaken* (Coire, 1849); E. Tatarinoff, *Die Entwickelung der Probstei Interlaken im XIII. Jahrhundert* (Schaffhausen, 1892).

INTERLOPER, one who interferes in affairs in which he has no concern. This word, with the verbal form "to interlope," first appears at the end of the 16th and beginning of the 17th century in connection with the interference of unauthorized persons in the trade monopoly of the Russia Company and later of the East India Company. The *New English Dictionary* quotes from H. Lane (1590), *Hakluyt's Voyages,* "From those parts the Muscovites were furnished out of Dutchland by enterlopers with all arts and artificers and had few or none by us," and also from the *Minutes of the Court of the East India Company,* 22nd of February 1615, "to examine all suspected personnes that intend interlopinge into the East Indies or Muscovy." Edward Philips *(New World of Words,* 1658) defines interlopers at common law as those "that without legal authority intercept the trade of a company, as it were Interleapers." The word appears to be of English origin, for the Dutch *enterlooper,* smuggler, often given as the source, was taken from English, as was the French *interlope.* The word is a compound of *inter,* between, and *lope,* a dialectal variant of "leap." A common word for a vagrant, or "straggler," as it is defined, was till 1580 "landloper," and the combination of "straggler" and "interloper" is found in *Horsey's Travels* (Hakluyt Soc.), 1603–1627, "all interlopers and straglyng Englishmene lyving in that country."

INTERMEZZO. An interlude or entr'acte of a light and pleasing character serving as a contrast between the acts of a more serious drama or tragedy, and, in its developed form, continuing as an independent piece in this manner throughout the whole work, two entirely independent works, one serious and one light, being thus presented in alternate instalments. Pergolesi's famous La *serva Padrona* was such an intermezzo as originally produced. Nowadays the term is more generally applied to a short piece introduced between the larger movements of a symphony or sonata or to an independent short composition.

INTERNAL COMBUSTION ENGINES. An internal combustion engine is one in which energy is directly translated into mechanical power by causing an explosion to take place behind a piston. Professor Andrade has epigrammatically described this as "putting the furnace into the cylinder."

An explosion is an event of so sudden and violent a character that it might well seem impossible for man effectively to bring under his complete control so destructive and apparently unruly an agent; yet many billions of perfectly regulated gaseous explosions now minister daily to our needs in internal combustion engines of all kinds throughout the world.

Genghis Khan, in China, is recorded as having first used gunpowder in cannon about A.D. 1234 and King Edward III. in western Europe about A.D. 1327; the earliest proposal to utilize explosions (of gunpowder) to obtain *continuous* motive power was probably made by Christiaan Huygens in 1680, and Papin and the Abbé Hautefeuille later endeavoured to develop his proposal, but without success; it has now long been agreed that gunpowder is an entirely unsuitable substance for employment in any internal combustion engine.

R. Street, in 1794, proposed an engine driven by a flame-ignited explosive mixture of vapourized spirits of turpentine and air, and Sir Dugald Clerk regards this as the first real gas engine described in Britain. In 1820 W. Cecil at Cambridge described to the Cambridge Philosophical Society his engine operated by the explosions of a hydrogen-air mixture used to create a partial vacuum below a piston, the atmospheric pressure then producing the working stroke, much as in the earliest steam engines; he describes such an engine and states that at 60 revolutions per minute the explosions were perfectly regular; this is considered to have been the first actually working gas engine in the world.

With this brief introduction, we pass to the consideration of the various forms in which the internal combustion engine is used. These may be divided as follows:

I. Gas Engines
II. Heavy Oil Engines
III. Light Oil (or Petrol) Engines
IV. Special Engines

Separate articles are devoted to DIESEL ENGINE and AERO-ENGINE.

GAS ENGINES

The commercial career of the gas engine began with Samuel Brown (1823 onwards), whose design operated on the atmospheric-vacuum principle; actual Brown "gas-vacuum" engines were made and sold, and in 1832 were in regular service at Croydon, Soham, and Old Brompton; Brown engines were also fitted in a road

vehicle in 1826, and in a 36-foot boat in 1827.

Progress after this became more rapid: Wright in 1833 described an engine working with an inflammable mixture of gas and air much as in a normal double-acting high-pressure steam engine; followed William Barnett (1838) to whom the gas engine owes important advances, as he first realized the importance of compressing the explosive charge before ignition; he invented also the well known Barnett igniting cock which remained in general use up to as late as 1892. The next noteworthy advance was due to Barsanti and Matteucci who in 1859 produced a singular design known as the "free-piston" engine, subsequently improved in practical details by Otto & Langen; these inventors, at the 1867 Paris exhibition, first showed an actual example of their later well-known and widely used "free-piston" engine. In this the cylinder was vertical, of considerable height, and open at the top; it contained a heavy piston, below which, when in its lowest position, the explosive charge of gas and air was fired electrically; the piston was quite free in its ascent, and was fired upwards by the explosion, like a projectile; its ascent continued until the pressure below fell sufficiently for the atmospheric pressure and its friction, to bring it momentarily to rest; immedirtely thereafter the atmospheric pressure, its weight and the partial vacuum beneath it caused its rapid descent, during which a rack attached to the piston engaged with, and drove, a pinion, thus turning a shaft carrying a heavy fly-wheel; near the end of its descent the burnt gases were allowed to escape into the atmosphere. The engine was excessively noisy in operation and mechanically an outrage, but it possessed three advantages:

(1) The exploded mixture was very rapidly expanded.
(2) The expansion ratio obtained was considerable—often as much as 6:1.
(3) The partial vacuum produced below the piston was utilized in its operation.

Hence, for the period, its gas consumption was quite economical, amounting to only about 44 cu.ft. per B.H.P. hour; to this comparative economy much of its commercial success was due.

Lenoir, in 1860, had commenced building his gas engines which were worked exactly like, and closely resembled in appearance, a double-acting steam engine of normal horizontal pattern; he introduced an uncompressed mixture of gas and air into his cylinder during the first part of the stroke; cut off and ignition then simultaneously took place, and the remaining (*i.e.*, the working) portion of the stroke was then performed by the pressure and expansion of the exploded charge. A great many Lenoir engines were built, and worked with great regularity, smoothness and quietness; but they were very wasteful, the gas consumption being commonly roundly 100 cu.ft. per B.H.P. hour; mainly on this account the Lenoir engine was in due course entirely superseded by the mechanically much inferior Otto and Langen "free piston" engine above described.

By 1860 the necessity of pre-compressing the working charge before ignition was clearly recognised by several investigators; as early as 1799 Lebon, in France, had referred to compression, but the real originator of the practice was Barnett; in 1861 G. Schmidt stated definitely to the Society of German Engineers that explosion engines would work more economically, if the mixture were compressed to three atmospheres before ignition as in this way "a great expansion and heat transformation is possible."

The Beau de **Rochas** Cycle.—But it was in 1862 that the essential requirements, and the means of satisfying them, were first explicitly stated by Beau de Rochas in Paris, who then laid down the following four essential conditions for the greatest economy in working: (1) A maximum cylinder volume with a minimum cooling surface. (2) A maximum rapidity of expansion (3) A maximum ratio of expansion. (4) A maximum initial pressure of the ignited charge.

And he stated further that these conditions can be practically realized by the adoption of the following sequence of operations: (1) Suction during the first out-stroke of the piston. (2) Compression of the mixture during the following instroke. (3) Ignition of the compressed charge at the dead point, and subsequent expansion of the exploded gases during the next out-stroke; this is the "working stroke." (4) Expulsion of the burnt and expanded gases during the next in-stroke.

This is the celebrated Beau de Rochas cycle now universally employed in all "four-stroke" cycle internal combustion engines.

The Otto Gas Engine.—Another 14 years elapsed, however, before de Rochas' suggestions were embodied in an actual engine; but in 1876 Otto produced the world-famous "Otto silent gas engine," in which the "de Rochas" or "four-stroke" or "Otto" cycle, as it is variously termed, was strictly followed; and the Otto silent gas engine at last launched the internal combustion engine upon its amazing commercial career.

A single-acting four-stroke internal combustion engine of the simplest possible type is shown diagrammatically in fig. 1. A cylinder, open at one end, is fitted with a closely fitting piston which drives a crankshaft through the medium of the connecting rod indicated; when the piston is in its uppermost position there is still a portion of the cylinder volume above it, and this is termed the "combustion chamber"; forming part of this chamber is the valve-pocket containing an inlet valve A (here shown as of the simplest "automatic" type—as used in early engines), and an exhaust valve B which is operated by means of a cam C and "tappet-rod" D. The cam C is borne on a shaft gear-driven at half-speed from the crankshaft as indicated by the dotted circles; this is termed the "cam-shaft" or "half-time shaft" or "timing shaft." The action is as follows:—Suppose that by some means the engine has been set in motion. On the first down-stroke of the piston the partial vacuum produced above it causes the automatic inlet valve A to open, and a mixture of gas and air to rush in, filling the combustion chamber and volume swept out by the piston; this is the *suction* stroke. On the succeeding up-stroke the automatic inlet valve at once closes, and the charge of gas and air is compressed by the ascending piston into the combustion chamber; this is the compression stroke. At the upper dead point the compressed charge is

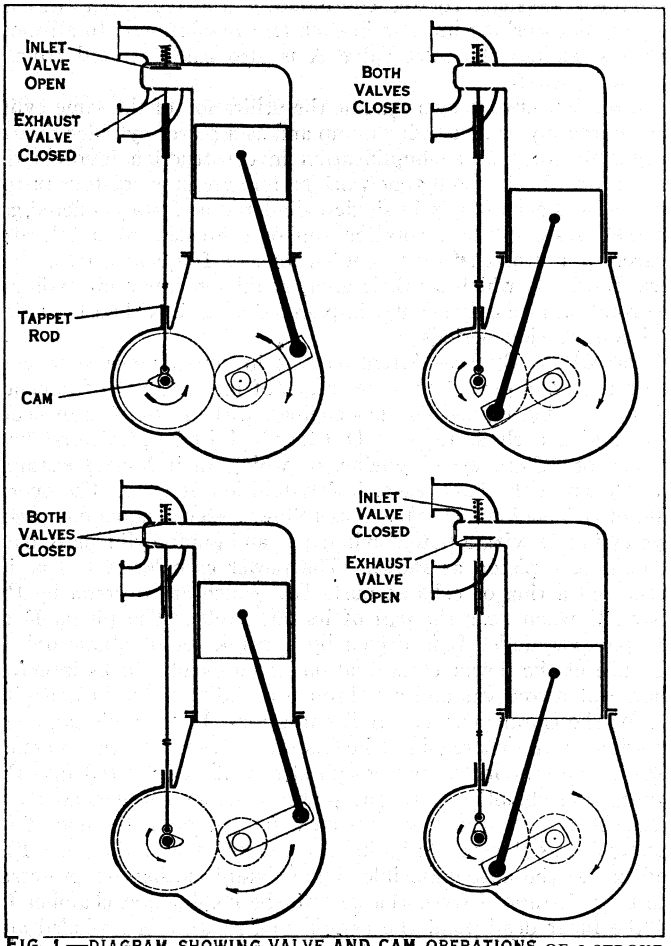

FIG. 1.—DIAGRAM SHOWING VALVE AND CAM OPERATIONS OF 1-STROKE CYCLE INTERNAL COMBUSTION ENGINE

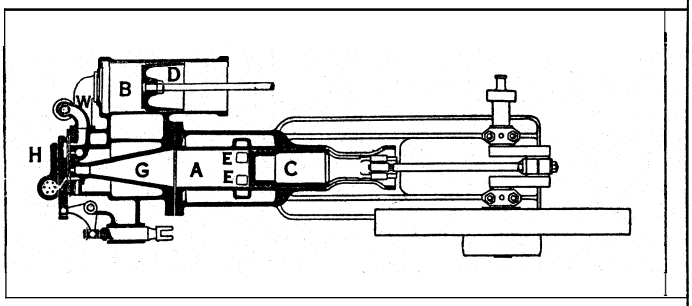
ignited by some suitable means, explosion instantly takes place, a great rise of pressure occurs, and the piston is driven forcibly downwards by the inflamed mixture whose pressure and temperature rapidly fall during the expansion; this is the *working stroke.* At the end of this stroke the exhaust valve B is lifted by its cam and held open throughout the succeeding up-stroke, causing the expanded and burned gases to be discharged into the atmosphere;



FROM GIBSON AND CHORLTON, "MODERN MECHANICAL ENGINEERING" (BLACKIE & SONS)

FIG. 2.—CLERK 2-STROKE CYCLE INTERNAL COMBUSTION ENGINE

this is the *exhaust stroke.* This cycle is now repeated indefinitely and the crankshaft rotates continuously, the crank-pin thus receiving *one* working impulse in each *two* revolutions. In all modern gas engines the inlet valve A is also cam-operated from a half-speed shaft.

In the four-stroke cycle engine the utilization of the same cylinder alternately as a charging pump and as a power cylinder though very convenient as a simplification in construction involves the serious drawback of only one working impulse in every four piston strokes, and accordingly in single-cylindered or few-cylindered gas engines the crankshaft rotation can only be kept at a tolerable degree of uniformity by providing one, or frequently two, massive fly-wheels which by their great angular momentum maintain the rotation rate only slightly impaired during the exhaust, suction and compression periods.

The Clerk Cycle.—Attention was in consequence soon concentrated upon providing some means of increasing the frequency of the working impulses in gas engines, without sacrifice of economy, and as early as 1878 Sir D. Clerk had produced his first *two*-stroke, or "Clerk cycle" engine, of which an improved example was shown at the Paris Electrical Exhibition of 1881. The operation of this engine (fig. 2) was as follows:—The engine comprises two cylinders, viz., a power cylinder A and pump cylinder B, each containing a piston as shown. The power cylinder **A** has at its outer end a ring of exhaust ports EE' which are overrun by the piston C when near the end of its out-stroke. The piston D of the pump cylinder B is driven by a crank set of about 90° in advance of the power crank and on its out-stroke sucks into B a charge of mixed gas and air through a sliding valve H and pipe W. At the commencement of D's in-stroke, H being closed, compression of the charge in B begins, and as soon as the pressure rises above that in the power cylinder A, it is delivered into the combustion chamber G of the power cylinder through an automatic inlet valve, the power piston C being then at the end of its out-stroke, as shown. On its in-stroke C first masks the ports EE' and next,—the automatic inlet immediately closing,—compresses the thus entrapped fresh charge into the combustion chamber G. At the inner dead point the compressed mixture is exploded and the piston is driven forcibly downwards, thus performing the working stroke; the expanded and burnt gases rush out into the atmosphere immediately the piston uncovers the ring of ports EE'. It is clear, then, that in this engine every out-stroke of C is a working stroke, and thus the design provides one impulse in every revolution, and so has double the impulse-frequency of the four-stroke cycle

An ideal two-stroke, or Clerk, cycle engine accordingly should develop twice as much power as a four-stroke engine of the same size and speed. In practice, however, the two-stroke cycle possesses certain features which prevent the ideal performance being attained; these are:—(I) In the four-stroke engine the inlet valve is opened just before the end of the piston in-stroke and remains open throughout the whole of the suction stroke and usually for a short period thereafter, so that cylinder-charging continues during about 220° of crank-shaft revolution. But in the two-stroke cycle engine the charging period is only the short interval elapsing between the un-covering and re-covering of the ports EE' by the piston, which usually occurs during some 80° of crank shaft revolution. Hence in the two-stroke engine it is in general impossible to get so large a charge as in the four-stroke.

(2) In the four-stroke engine, discharge continues throughout the whole of the exhaust stroke (and in practice even longer), and thus the residual burnt gases are definitely expelled by the piston during its exhaust in-stroke so that, finally, only the combustion chamber remains filled with residual burnt gas, and this often at somewhat less than atmospheric pressure. But in the two-stroke engine the whole cylinder remains filled with hot residual exhaust gases which, while assisted in their exit by the incoming cool fresh charge, *heat* this fresh charge, so expanding it and thus reducing its density and so further diminishing the "volumetric efficiency" of the engine.

(3) Loss of fresh charge frequently occurs by "short circuiting" through the exhaust ports, and many small two-stroke cycle engines suffer some loss of unburned gas from this cause. Clerk cycle engines have been practically superseded in small sizes by the Day engine next described, though a modern example of a small Clerk cycle design appears in the "Dolphin" petrol engine, an account of which is given in *The Gas, Petrol & Oil Engine,* vol. ii. But in the largest types of two-stroke gas engines the Clerk cycle prevails, with some modifications, as in the well-known Koerting and Oechelhauser designs referred to later.

The **Day** Engine.—A valuable simplification of the Clerk cycle engine was made in 1891 by Day who ingeniously dispensed altogether with the charging pump B (fig. 2) by adapting the crank chamber to perform its service; the Day engine is illustrated in fig. **3** in two forms, that on the left showing the "two-port" type as used in the well-known "Bolinders" marine oil engine, while that on the right illustrates the "three-port" type as universally employed in the small high-speed two-stroke engines of motor bicycles, launches, etc.

In each of these the crank-chamber is completely enclosed so as to be air-tight. In the two-port type the ascending piston creates a partial vacuum in the crank-chamber and the charge of fresh mixture at once enters through an automatic valve as indicated. On the down-stroke this valve at once closes and the mixture is compressed in the crank-chamber to a few lb. per sqin. pressure; when near the bottom of its stroke the piston first over-runs the exhaust port (on right), the expanded and burnt gases above it at once rushing out through the exhaust, and immediately afterwards over-runs an inlet port (on left) communicating with the crank-chamber, thus permitting a charge of fresh mixture to enter the cylinder. **A** "hump" on the piston deflects the stream of entering fresh mixture upwards and so minimizes loss by short-circuiting through the exhaust port. The piston, rising, first cuts off the inlet and exhaust ports and next compresses the entrapped charge into the combustion chamber where it is fired, and the working stroke next follows as usual. The two-port engine thus requires one valve, but the three-port engine is valveless, and is the simplest form of internal combustion engine possible, the only moving parts being the piston, connecting-rod and crankshaft. Referring to the right-hand diagram of fig. **3,** the third port is shown below the exhaust port. When the piston rises the inlet port is closed, and, as before, a partial vacuum is created in the crank chamber; when near the top of its stroke the *lower* edge of the piston over-runs the third port and fresh charge immediately rushes into the crank-chamber. The subsequent descent of the piston first cuts off the charging port and next compresses the fresh charge in the crank-chamber; the remainder of the cycle is as in the two-port type.

These two-stroke engines will obviously run equally well in whichever direction the crankshaft may be started; this property renders their reversal easy—a valuable feature in marine applications.

Simple Theory.—The working substance is usually, for sim-

plicity, regarded as air, conforming strictly to the equation:—

$$pv = cT \qquad (1)$$

where p is pressure, estimated in lb./sq.ft.; v is the volume of 1 lb. in c.ft.; c is a constant, having the value of about 53·3; and T is "absolute temperature" in °F and is equal to the ordinary °F plus 460. The action is further imagined as taking place with the same mass of air always within the cylinder, and the

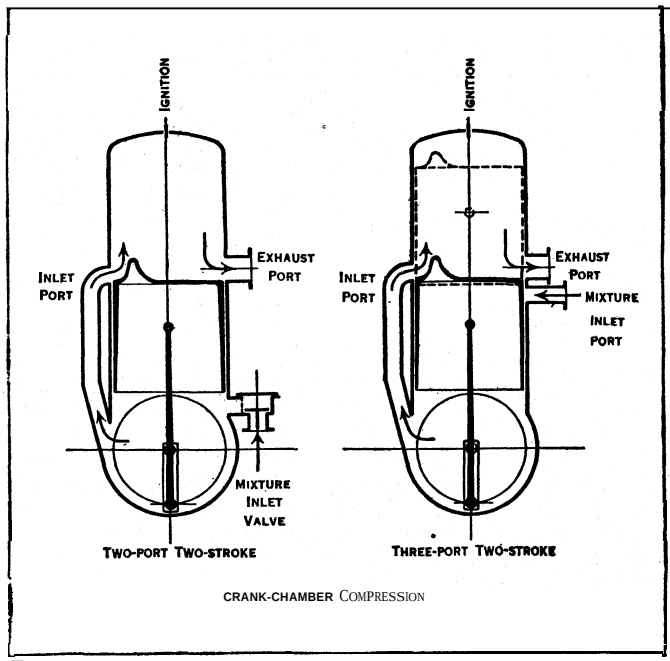


FIG. 3.—DIAGRAMS SHOWING 2-PORT AND 3-PORT 2-STROKE INTERNAL COMBUSTION ENGINES WITH CRANK-CHAMBER COMPRESSION

compression and expansion are regarded as "adiabatic," *i.e.,* no gain or loss of heat to the cylinder walls is contemplated. Fig. 4 exhibits the ideal indicator diagram of a four-stroke cycle engine with these simplifying assumptions.

Imagine the piston as at the top of its stroke with the combustion chamber volume filled with air; this is represented by the point O on the diagram, the combustion chamber volume being v_0 and the atmospheric pressure p_0. The piston next performs the suction stroke and the corresponding line O1 is traced on the diagram; at 1 the whole cylinder volume, v_1, is filled with air at atmospheric pressure (p_1). The return of the piston next compresses the air into the combustion chamber, the rise of pressure with diminution of volume being represented by the (adiabatic) compression curve 1–2. At the end of the compression in-stroke the mixture is exploded and an instantaneous rise of pressure occurs from T_2 to T_3; next follows the working out-stroke and the exploded gases expand (again adiabatically) as indicated by 3–4. At the end of the working stroke the exhaust opens suddenly and the burnt charge rushes out, the pressure falling instantly to that of the atmosphere, as indicated by 4–1. Then during the return exhaust in-stroke of the piston the line 10 is traced. This cycle is then repeated indefinitely.

In theory the working air is regarded as receiving a sudden accession of heat at 2 which causes its temperature (absolute) to rise from T_2 to T_3, and a sudden withdrawal of heat at 4, whereby its temperature is reduced from T_4 to T_1. During the periods of adiabatic compression and expansion no loss or gain of heat is considered to occur. Thus the only heat *given* to the working air per cycle is during the explosion 2–3, and the only heat *subtracted* is that during the "exhaust drop" 4–1. The difference between the heat given and the heat subtracted, or "rejected," is the (heat equivalent) of the mechanical work done by the piston per cycle. Accordingly as both heat exchanges take place at constant volume, if K_v denote the specific heat of the working air at constant volume we have:—

Heat given per cycle $= H = K_v(T_3 - T_2)$. B.Th.U.
Heat rejected . do. $= R = K_v(T_4 - T_1)$. B.Th.U.

Work done per cycle $= H - R = K_v(T_3 - T_2) - K_v(T_4 - T_1)$. (B.Th.U. = British Thermal Unit, the heat required to raise 1 lb. of water 1°F.) and thus:— (2)

The Thermodynamic Efficiency $= \dfrac{H - R}{H} = 1 - \dfrac{R}{H} = 1 - \dfrac{T_4 - T_1}{T_3 - T_2}$.

This equation expresses the efficiency in terms of the absolute temperatures at the four corners of the diagram; it is much simplified in the following manner:— The ratio $\dfrac{v_1}{v_2}$, termed the adiabatic compression ratio, is always known, and is denoted by r; then $r = \dfrac{v_1}{v_2}$, and it will also be observed that in the four-stroke engine r is also equal to $\dfrac{v_4}{v_3}$,—the ratio of adiabatic expansion. Now it is easily shown in thermodynamics that along an adiabatic curve of a perfect gas the product $Tv^{\gamma-1}$ is constant where γ is the ratio of the specific heat of the gas at constant pressure to the specific heat at constant volume. So that, from fig. 4 in this case: —

$$T_2 v_2^{\gamma-1} = T_1 v_1^{\gamma-1}. \quad \therefore \quad T_2 = T_1 \left(\frac{v_1}{v_2}\right)^{\gamma-1} = T_1 r^{\gamma-1}.$$

$$T_3 v_3^{\gamma-1} = T_4 v_4^{\gamma-1}. \quad \therefore \quad T_3 = T_4 \left(\frac{v_4}{v_3}\right)^{\gamma-1} = T_4 r^{\gamma-1}.$$

Substituting these values for T_2 and T_3 in (2) gives:—

$$\text{Thermodynamic Efficiency } 1 - \frac{T_4 - T_1}{T_4 r^{\gamma-1} - T_1 r^{\gamma-1}} = 1 - \left(\frac{1}{r}\right)^{\gamma-1}.$$

and accordingly the expression takes the very simple form:—

$$\text{Thermodynamic Air Efficiency} = 1 - \left(\frac{1}{r}\right)^{0\cdot4} \qquad (3)$$

as for air $\gamma = 1{\cdot}4$ roundly, in the simple theory here set out.

A committee of the British Institute of Civil Engineers in 1905 recommended the adoption of this expression to indicate the ideal maximum thermodynamic efficiency of the four-stroke engine; it is known as the 1905 Air Standard, and has been very extensively

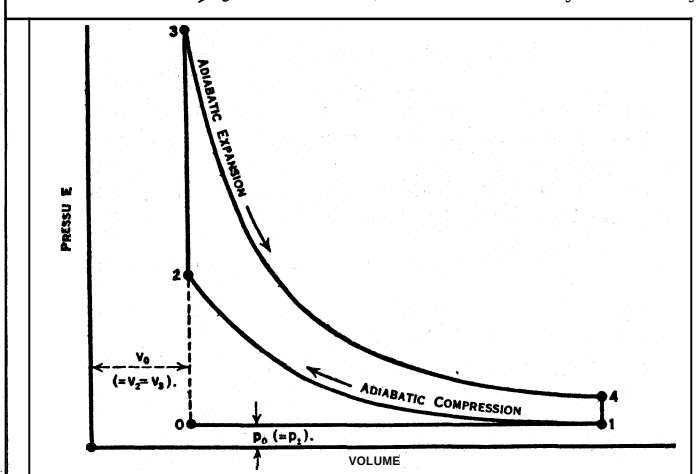

FIG. 4—IDEAL "OTTO" OR 4-STROKE CYCLE DIAGRAM

employed. It makes the ideal maximum efficiency increase with the compression ratio, as is shown by the following figures:—

For r =	4	6	8	10	12	14
The air std. =	·426	·512	·565	·602	·630	·652

In spite of the simplifying assumptions involved it has very well served its purpose; thus, after very extended experience Ricardo, *The Automobile Engineer*, 1928, observed, "As we raise the compression ratio of an engine we improve both the power output and the efficiency very nearly in proportion to the increase in the Air cycle efficiency."

Estimation of Horse-power.— The smaller-powered quicker

running classes of gas engine are usually tested for power by some form of brake dynamometer by which the "brake" or "effective" horse power is directly determined. With larger engines indicator diagrams (see fig. 4) may be taken from the working cylinder; the average height of the figure 1234, measured by the scale of pressures of the diagram, gives the mean effective pressure on the piston in lb./sq.in. during the working stroke; this is usually denoted by p.

Now let d denote the piston diameter in inches, s its stroke in inches, and n the number of revolutions of the crankshaft per minute. Then the piston area is $\cdot 7854\ d^2$ square inches, and therefore the mean effective piston load during the working stroke is $\cdot 7854\ d^2 p$ lb. weight.

This load works through $\frac{s}{12}$ feet; and accordingly the "indicated work" performed per working stroke is $\cdot 7854 d^2 p \times \frac{s}{12}$ foot-lb. In one hour $60 \times \frac{n}{2}$ working strokes are made and, assuming them all exactly alike, the total indicated work per hour is thus $\cdot 7854\ d^2 p \times \frac{s}{12} \times 60 \times \frac{n}{2}$ foot-lb.

But a horse-power is, by definition, a rate of working of 33,000 foot-lb. per minute, or $60 \times 33{,}000$ foot-lb. per hour; finally, therefore the indicated horsepower of a single-cylindered single-acting four-stroke cycle internal combustion engine is expressed by: $\frac{\cdot 7854\ d^2 psn \times 60}{12 \times 2 \times 60 \times 33{,}000}$; and this reduces by ordinary arithmetic to:—

$$\text{Indicated H.P.} = 992\ d^2 psn \times 10^{-9}. \qquad (4)$$

If the engine have N cylinders, the total I.H.P. is obviously N times as great as (4).

Suppose that by test both the I.H.P. and B.H.P. of an engine have been ascertained. Then their difference, viz., I.H.P. − B.H.P. is the horse-power absorbed in engine friction and in doing any other work incidental to the performance of the cycle of the engine. Their ratio, viz., $\frac{\text{B.H.P.}}{\text{I.H.P.}}$ is termed the "mechanical efficiency" of the engine and is usually denoted by η; thus:—

$$\text{Mechanical Efficiency} = \eta = \frac{\text{B.H.P.}}{\text{I.H.P.}}. \qquad (5)$$

The product ηp, *i.e.*, mechanical efficiency multiplied by indicated mean effective pressure, is termed the "brake mean effective pressure."

The mechanical equivalent of one B.Th.U. is 778 ft.-lb. of work; and accordingly the heat equivalent of one horse-power-hour is $\frac{33{,}000 \times 60}{778} = 2{,}545$ B.Th.U. Suppose, for example, trial of a gas engine to show that 15 cu. ft. of coal gas was consumed per I.H.P. hour, the gas having a heat value of 500 B.Th.U. per cu. ft. Then $15 \times 500 = 7{,}500$ B.Th.U. of heat are expended in obtaining 2,545 B.Th.U. of indicated work; and thus the absolute indicated thermal efficiency $= \frac{2{,}545}{7{,}500} \times 100 = 33{\cdot}9\%$.

If the mechanical efficiency of the engine has been found to be 85%, so that $\eta = 0{\cdot}85$, then the brake thermal efficiency would be $33{\cdot}9 \times 0{\cdot}85 = 28{\cdot}8\%$. If the ratio of compression, r, of the engine were 6, the corresponding ideal air standard efficiency would be 51·2%. And accordingly the relative indicated thermal efficiency $= \frac{33'9}{51{\cdot}2} \times 100 = 66{\cdot}2\%$. Similarly the relative brake thermal efficiency $= \frac{28.8}{51{\cdot}2} \times 100 = 56{\cdot}25\%$. These figures are from actual test results from a well-designed 100 B.H.P. gas engine in 1923. The small gas engine is rarely as efficient as the large one, contrary to the steam engine.

GAS ENGINE PROGRESS

Fuels Used by Gas Engines. — The principal are: — (1) Town's gas; often styled "coal gas." (2) Producer gas. (3) Coke oven gas. (4) Blast furnace gas. (5) Natural gas.

For a description of these, see FUEL; GAS MANUFACTURE; NATURAL GAS.

The table following gives some average values of these fuels and data relating to their employment for power purposes in gas engines: —

TABLE I. Gas Engine Fuels: average heat values

Fuel	Heat value in B.Th.U. per c.ft. at 1 Atm and 60° F.	Minimum vol. of air, c.ft. required per c.ft. of fuel	Maximum heat evolved on combustion of 1 c.ft. of mixture B.Th.U.
Town's gas	500	5·5	77
Coke-oven gas	400	4·0	80
Producer gas (from anthracite or coke)	130	1·0	65
Blast-furnace gas	100	0·75	57
Natural gas	950	9·5	90

To avoid overheating the engine it is in practice found necessary to provide a considerable excess of air in order to reduce the heat evolved per cu.ft. of mixture used to form 50 B.Th.U. in the smaller types to 35 B.Th.U. in the largest. This practical limitation prevents advantage being taken of the high heat-evolution per cu.ft. of Town's gas, coke-oven gas and natural gas, and furnishes the reason for the suitability of so poor a gaseous fuel as blast-furnace gas.

Ignition. — The ignition of the charge in gas engines with certainty and regularity proved for long a difficult problem first successfully solved by the Barnett (flame) igniting cock (1838), already mentioned, which continued in use up to about 1892. A method very widely used up to about 1923, particularly in small-powered gas engines, was that known as "hot-tube" ignition; it was first employed in the Stockport gas engine in 1883 and in its simplest form it consisted merely of a metal tube, usually of iron or nickel, a few inches long, closed at its outer end, screwed into the end of the engine cylinder, its open inner end being in constant communication with the contents of the combustion chamber ("open-tube" ignition). The tube was continuously heated during working by an external Bunsen-flame lamp, and explosion of the engine charge occurred as soon as the compressed fresh mixture reached its red-hot portion. Tube ignition proved quite satisfactory for engines of up to about 20 horse-power.

Modern gas engines are almost universally fitted with electrical

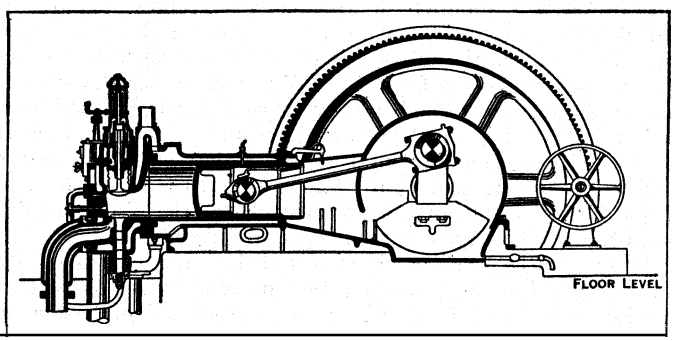

FIG. 5. — CROSSLEY HORIZONTAL GAS ENGINE: SECTIONAL VIEW

ignition, commonly of the low tension magneto type wherein a magneto with a rocking armature provides current to a low-tension make-and-break ignition plug fitted to the combustion chamber of the cylinder. High tension magneto ignition, substantially as used in all petrol engines, — though of robuster type, — is also becoming more general; thus in 1922 the gas engines of, inter *alia*, the National, Campbell, and Browett-Lindley companies were fitted with H.T. ignition.

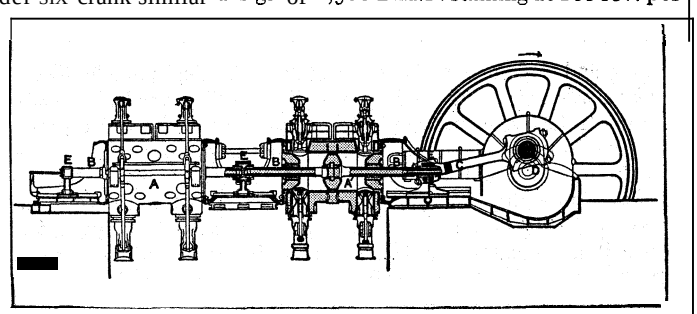
Starting of Gas Engines. — For engines of less than about 30 H.P. no special starting apparatus is usually needed; having

retarded the ignition, and turned on the gas supply, the fly-wheel is turned by hand as quickly as possible and the engine thus started.

Many gas engines of 30–200 H.P. are started by aid of a small pump fitted to the engine by which an initial charge of gas and air is delivered by hand-power into the combustion chamber, and ignited by "flicking over" the L.T. magneto by hand; many flywheels are furnished with a ring of holes round the rim for insertion of a crow-bar, by which the engine may be "barred" round so as to get the crank-pin in a favourable position for starting, *i.e.*, about 20° beyond the inner dead centre on the firing stroke. Large gas engines are started by compressed air stored in cylindrical steel reservoirs at a pressure of 100–300 lb. sq in. The air compressor is sometimes belt-driven from the engine, but in very large engines is a separate unit driven by a small auxiliary engine. A special air-starting valve is fitted to the combustion chamber of the cylinder, and on admission of the compressed air through this the engine commences to turn, and takes up its working cycle after a few revolutions.

Modern Gas Engines. — In gas engines of less than about 400 H.P. but little essential change has occurred since 1910; there is a steady output by many builders of repute of a nearly standard type of horizontal four-stroke cycle single-acting one- or two-cylindered engine using Town's gas or producer gas as fuel. A normal engine of this type, by Crossley Bros. is shown in fig. 5, comprising a water-jacketed cast iron cylinder fitted with a gas-tight cast-iron piston driving a crankshaft in the usual manner by means of a connecting rod. The very massive flywheel will be noted; in this case it is formed with an internally-toothed ring and by means of the hand-wheel and enmeshed pinion shown "barring" round before starting is effected. At the closed end or "breech end" of the cylinder is the combustion chamber containing at the top the mixture inlet valve and at the bottom the exhaust valve both, of course, cam-operated from the half-speed shaft. Ignition is by low-tension (L.T.) magneto. The engine speed is regulated by a governor which varies the lift of the inlet valve.

Vertical Gas Engines.—The considerable bulk and weight of the horizontal slow-running larger gas engine has caused attention to be given to faster-running multiple-cylindered inverted-vertical designs, occupying much less floor area, and of diminished size and weight. Prominent among British builders of this type is the National Gas Engine Co. whose designs range from a four-cylinder, two-crank, single acting four-stroke inverted vertical tandem engine of 300 B.H.P. at 300 rev. per minute, to a 12-cylinder six-crank similar design of 1,500 B.H.P. running at 200 rev. per



FROM GLAZEBROOK, "DICTIONARY OF APPLIED PHYSICS" (MACMILLAN & CO.)

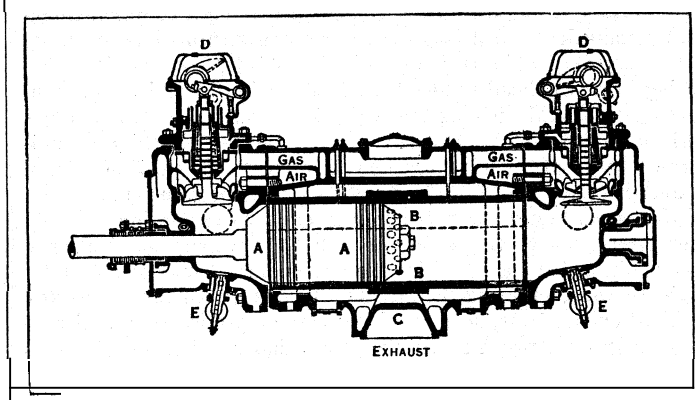
FIG. 6.—LARGE HORIZONTAL GAS ENGINE. A 2-CYLINDER, DOUBLE-ACTING. 4-STROKE, SINGLE-CRANK NUREMBERG ENGINE

minute. One "National" installation of this type aggregates 11,500 horse power.

Large Gas Engines. — From about 1910 improvement in the largest types of gas engine have been mainly in matters of detail as, *e.g.*, in the more extended use of refuse material as fuel for the gas producers: in the employment of high tension electrical ignition: and in better cooling and governing arrangements.

The large horizontal slow-speed engine is typified by the four-stroke double-acting tandem design as developed by the Nuremberg (M.A.N.), Ehrhardt, Deutz, and Haniel companies in Europe, and built also in Great Britain by the Lilleshall Co., Vickers and Galloways.

The *tandem* double-acting four-stroke engine possesses the important advantage that every stroke is a working stroke. A view of a 2,500 Horse-power M.A.N. engine, in part section, is shown in fig. 6. The two liberally water-cooled cylinders A,A′, are in line with their water-cooled pistons mounted on a common piston-rod (also water-cooled), to one end of which is attached the connecting-rod C driving a single-throw crankshaft D. The



FROM GIBSON AND CHORLTON, "MODERN MECHANICAL ENGINEERING" (BLACKIE & SONS)

FIG. 7.—SECTION OF 600 B.H.P. KOERTING ENGINE CYLINDER

three crossheads EEE are adjusted to carry the weight of the piston rod and also of the two heavy pistons, so that these "float" in the cylinders, thus greatly reducing engine friction and consequent wear. The inlet valves will be noted at the top, and the exhausts at the bottom, of each cylinder. To illustrate performance:—Eight engines of this type by Vickers had each a cylinder bore of 43·3 in., a stroke of 47·3 in. and, using blast furnace gas, developed roundly 1,800 B.H.P. at a speed of 100 rev. per minute. One of the largest installations of M.A.N. engines is a 65,000 horse-power plant at Bruckhausen. The type is very reliable and economical; a 2,000 H.P. engine using blast furnace gas has run, day and night, during 19 months. In 13,870 consecutive hours the engine actually ran during 13,687 hours, *i.e.*, 98·6% of the whole time possible; and the stoppages were due to the blast furnace, and not to the engine.

Large Two-stroke Gas Engines.—The large two-stroke Clerk cycle engine has proved very successful, particularly in the horizontal designs of Koerting & Oechelhauser.

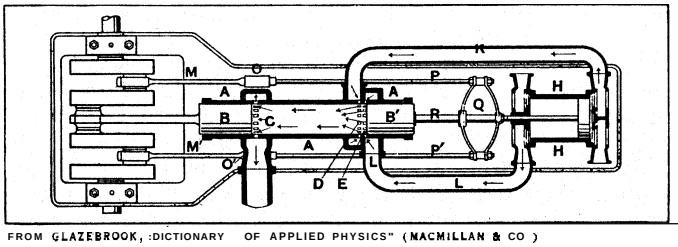
The Koerting is a single-cylindered double-acting horizontal two-stroke engine, and the piston thus receives a working impulse in every stroke. A sectional view of a Koerting cylinder appears in fig. 7. The engine is characterized by the long water-cooled piston AA,—of length fully half that of the cylinder; in its extreme right and left positions the piston over-runs a central belt of exhaust ports BB, and so permits the escape of the burnt gases into the exhaust branch C. At each end of the cylinder is a mechanically operated inlet valve D, D^1. The illustration shows the contents of the right-hand end of the cylinder exhausting through BB; simultaneously the inlet D^1 is opened admitting firstly air only, and immediately afterwards the working charge of mixed gas and air. The preliminary air is a scavenging charge; the working charge is delivered to the inlet valve boxes by separate double-acting pumps driven by the engine and no mixture of gas and air occurs until they jointly enter the working cylinder; this is an important point in relation to large gas engines. The piston now moving towards the right first cuts off the exhaust ports BB and next compresses the mixture into the combustion chamber where it is fired (by L.T. magneto) as usual, the resulting explosion driving the piston towards the left. The same cycle of operations is performed in the left-hand end of the cylinder, and thus every stroke of the piston is a working stroke. Starting is effected by compressed air stored at 150–300 lb./sq.in.; the air starting valves are shown at EE in fig. 7.

The Siegener Co. have built Koerting engines giving 2,000 horse-power from a single cylinder of 42 in. bore and 55 in. stroke, running normally at 80–90 revs. per minute. The inlet valves of these very large engines were 19·7 in in diameter. with a lift of 3·14 in. The American de la Vergne Co. have installed at Buffalo

Koerting-type engines aggregating 40,000 B.H.P. Upwards of 250,000 B.H.P. of Koerting engines had been constructed in 1923.

The Oechelhauser Engine.--This successful large two-stroke gas engine works on a modified Clerk cycle; a diagrammatic view appears in fig. 8. The engine is of the horizontal single-acting type having a cylinder AA open at both ends, containing two pistons BB^1 working in opposite directions, and driving a common three-throw crankshaft. B drives the central crank through an ordinary connecting rod, while B^1 is fitted with a short piston rod R terminating in a crosshead Q fitted with side rods PP^1 and return connecting rods MM^1 driving the two side cranks. The combined gas and air pump H H is also driven from the crosshead Q as indicated. Just before it reaches its extreme "out" position piston B over-runs the ring of exhaust ports C; at the same time piston B^1 over-runs firstly the ring of air inlet ports D and immediately thereafter a second ring of gas ports E. The exhaust gases at once escape through C, assisted by the scavenging charge of air under slight pressure entering through D. This fresh air also cools any residual exhaust gas, so minimizing risk of pre-ignition, and preventing loss of fresh fuel through the exhaust when the gas ports E open. The pistons next approach one another and compress the entrapped fresh charge between them; at the end of the "in," *i.e.*, compression stroke, the mixture is fired electrically and the working out-stroke then follows. The engine thus furnishes one impulse per revolution. The double-acting pump H is an air-pump on one side of its piston and a gas-pump on the other; gas and air are pumped separately into the reservoirs L and K respectively, in which a pressure of 5–6 lb./sq.in. is maintained. It will be noted that the gas and air are only mingled actually within the working cylinder. Oechelhauser engines to Messrs. Beardmore's designs range from 400 horse power at 130 rev. per min., with cylinder 24 in. bore and stroke of go in., to 2,500 horse power at 80 rev. per min., with cylinder bore of 48 in., and stroke of 60 in.

The *Fullagar* Engine.—A valuable advance in the double-piston Oechelhauser type of engine was made by H. F. Fullagar about 1912. By associating together two open-ended cylinders he dispensed with the somewhat cumbrous side-rods and return connecting-rods of the Oechelhauser design, and also was able to use a normal flat two-throw crankshaft. In this way weight and cost were saved and a very compact engine, giving two impulses per revolution, resulted. The essential feature of the Fullagar power unit is a pair of side-by-side open-ended cylinders with their pistons connected across by special diagonal tension rods; the obliquity of these rods is not great, and the side-thrusts arising therefrom are borne by crossheads and (water-cooled) guides. The compressed power charge between, say, pistons A and B being fired, B is driven downwards thus actuating the left-hand crank, while A is driven upwards, thus simultaneously actuating the right hand crank through a tension rod; hence as the result



FROM GLAZEBROOK, :DICTIONARY OF APPLIED PHYSICS" (MACMILLAN & CO)

FIG. 8.—DIAGRAM OF THE 2-STROKE DOUBLE-PISTON OECHELHAUSER ENGINE

of each working impulse the crankshaft experiences a nearly simple "torque"; moreover, the cylinders being open-ended, no stresses are set up in the engine-framing during running; thus the Fullagar engine may be built somewhat light for its power output. As described here, the charges of gas and air are as if supplied by pumps formed by boxing in the top crossheads; the charge is delivered at a pressure of about 3 lb./sq.in. As with other two-stroke cycle engines, the Fullagar may be run in either direction by giving it the necessary initial motion, and suitably timing the ignition.

An early experimental engine of 550 B.H.P. by Allen of Bedford comprised two Fullagar units with cylinders of 12 in. bore, and each piston with a stroke of 18 in.; normal speed 250 rev. per min. A go-hour trial of this engine showed an absolute thermal indicated efficiency of 37.6%; the weight of the engine was only 87.j lb. per B.H.P. which is small for a stationary design. A 2,000 horse-power engine by Belliss and Morcom in 1918 comprised three Fullagar units, with 18 in. cylinders and 27 in. stroke, running at 170 rev. per minute. This engine used as fuel coke-oven gas having a net calorific value of 440 B.Th.U. per c.ft. and tests showed a full-load consumption of roundly $22\frac{1}{4}$ c.ft. of gas per B.H.P. hour, corresponding to an absolute brake thermal efficiency of 26%. The Fullagar engine also uses oil fuel in the Diesel manner, and marine Fullagar-Diesel engines are constructed by Cammell Laird and others in sets of 3,000 B.H.P. and over.

HEAVY OIL ENGINES

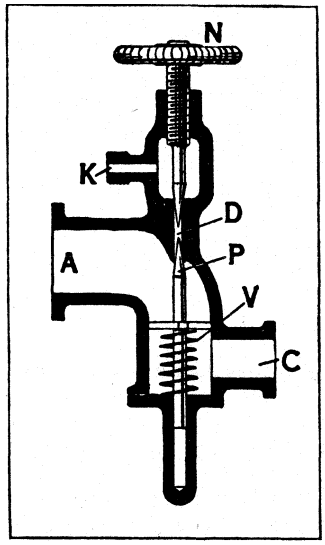
The success of the Otto and Langen engine, described above, and the final establishment of internal combustion engines on a commercial basis by the Otto silent gas engine of 1876, directed the close attention of many engineers to improving further such engines particularly in relation to the fuels employable. Town's gas was an expensive fuel, and available only in large centres of population. The increasingly wide distribution of petroleum oils, particularly the paraffin oils, lamp-oils, or kerosenes, no doubt suggested that if such oils could be rendered available as fuel a much wider area of usefulness would be opened to the internal combustion engine. The earliest of such engines to achieve a considerable measure of success was the Priestman Oil engine introduced in 1885.

Heavy Oils.—This is a general name for inflammable liquid hydrocarbons, particularly petroleums. of flash point exceeding about 75" F and ranging in specific gravity from 0.78 to 1·0; with such liquids a considerable preliminary heating is necessary to obtain an explosive mixture of their vapour with air, and the earliest heavy oil engines were accordingly of the vapourizing class, and used as fuel American and Russian kerosenes, Scotch paraffin and shale oils. and even crude and residual petroleum oils.

The Early Priestman *Oil* Engine.—This engine was built (1885) in four-stroke cycle single-cylindered types up to 11 horse power, and gave best results when using as fuel kerosenes of 0·8 sp gr. and flash point about 100° F. The oil fuel was delivered by air pressure through a minute orifice, in the form of a very fine spray or mist, into an exhaust-heated vessel or "vapourizer." where it immediately became gaseous; in this condition, during the suction stroke of the engine, it entered the cylinder together with a correct proportion of air drawn in through an automatic valve; this mixture was then compressed and fired and the working stroke followed as usual. To start the engine the vapourizer received a preliminary heating from a blow-lamp; a small hand-pump then furnished air for the initial spraying of the fuel into the vapourizer; the flywheel next being turned by hand, the engine started running. As soon as all was well warmed up, the blow-lamp was extinguished, the engine exhaust thereafter maintaining the vapourizer at its necessary high temperature. A test of a 4·5 horse-power, 8·5 in. bore × 12 in. stroke × 180 rev. per min , Priestman engine in 1890, using as fuel Broxburn lighthouse oil of ·81 sp.gr. and flash point 152° F, showed a consumption of 1·243 lb. of oil per B.H.P. hour. In later tests (1892) of an engine of the same size, running at 204 rev. per minute, and using as fuel Royal Daylight oil of ·79 spgr. and flash point

77° F, the consumption was reduced to 0.842 lb. per B.H.P. hour. The pressure of compression in these tests was 35 lb./sq.in., and of explosion, 151·4 lb./sq.in. above atmosphere; and the total heat value of the Royal Daylight oil was stated to be 21,490 B.Th.U. per lb.

Gardner *Paraffin* Engine.—Priestman was quickly followed by other inventors, as Griffin, Samuelson, Thornycroft, etc., who used exhaust-heated vapourizers, and by Gardner, Howard, Smith-Dudbridge, Crossley, etc., who used lamp-heated vapourizers. In the earlier Gardner paraffin engines, for example, the paraffin was supplied, either by gravity or under pressure, to the "mixer" diagrammatically shown in fig. 9. The paraffin, entering through K, passed into the small duct D through a hand-regulated needle-valve N. The air entered through the branch A. The spring-supported disc, V, borne on a spindle terminating upwards in a needle valve P automatically closed the fuel supply when the engine ceased running. The branch C communicated with the lamp-heated vapourizer.



FROM CLERK AND BURLS, "GAS, PETROL AND OIL ENGINE" (LONGMANS, GREEN & CO.)

FIG. 9.—EARLY GARDNER PARAFFIN "MIXER"

During each suction stroke of the engine, air drawn in through A depressed the disc V, so permitting delivery of a sprayed charge of fuel through D. The mixture of the air and fuel-spray next passed via C into the vapourizing vessel which was continuously heated by an external Bunsen-flame oil lamp. As fuel it was found practicable to use kerosenes of ·825 sp.gr. and up to zoo° F flash (by close test). Four-stroke vapourizing engines of this type were built having from 1 to 8 cylinders, and developing from 5 to zoo horse-power.

In the vapourizer, heavy oil fuels were rendered gaseous, mixed with a suitable volume of air, admitted to the cylinder and then exploded exactly as in an ordinary gas engine. Simple though this would be were heavy oils hydrocarbons of one definite chemical composition, it has proved practically troublesome with actual heavy oils, which are in general composed of a mixture of many different liquid hydrocarbons, boiling at temperatures ranging from zoo° F to 600° F; thus completely to vapourize such fuel its temperature must be raised at least to 600° F. But at this high temperature the lighter constituents of the fuel are liable to be "cracked," *i.e.,* decomposed into free hydrogen and carbon; the carbon deposits in the vapourizer, in time choking it up. In practice a fuel temperature in the vapourizer of about 500° F was found to be the best to use. This necessary pre-heating of the fuel involved three serious disadvantages:—(1) The fresh charge of air and vapour being heated before entering the cylinder, had expanded thus reducing the mass of the charge, and hence the power output of the engine. (2) The fresh charge being heated, only a low compression ratio, usually 3·0 to 3.5, could be employed in order to avoid detonation and pre-ignition troubles. (3) The use of a low compression ratio kept the thermodynamic efficiency of such engines low.

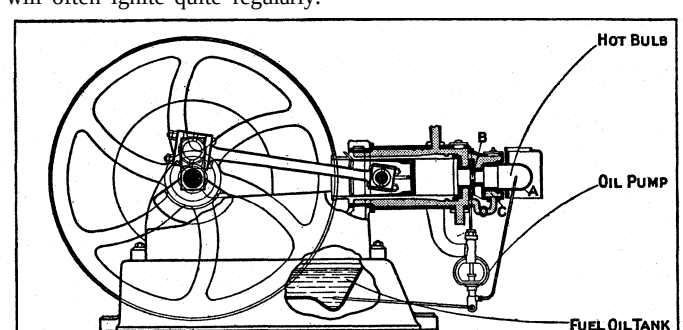
Accordingly although the heat value of kerosene usually somewhat exceeds that of petrol, vapourizing oil engines designed to use either fuel usually give only some 85% of their maximum power output with paraffin, and show a reduced economy.

In small powers (5 H.P. or so), vapourizing engines are still used to a small extent for domestic lighting and light agricultural work, but are rapidly being replaced (a) by the much more cleanly and convenient small petrol engine, and (b) by more modern and simple heavy oil engines as described later herein.

The Hornsby-Akroyd Oil Engine.—An important simplification in the working of heavy oil engines was effected by Akroyd Stuart (1886–90) who succeeded in dispensing both with a separate vapourizer and also with all ignition apparatus. The famous Hornsby-Akroyd oil engine was the first to utilize successfully the heated wall of a special portion of the combustion chamber to effect both vapourization of the fuel and the automatic ignition at the correct instant of the working charge. A sectional view illustrating this engine appears in fig. 10 which shows an ordinary single-acting horizontal four-stroke cycle internal combustion engine but with an extension **A,** termed the "hot bulb" attached to the end of the combustion chamber, communication between them being by a relatively small passage B.

The action is as follows:— The hot bulb receives a preliminary heating from an external blow-lamp; the engine flywheel being next turned by hand, the piston during the suction stroke draws a charge of air directly into the cylinder through an air inlet valve; at the same time the charge of oil is delivered by the small force-pump into the hot bulb where it vapourizes and the vapour, mixed with residual exhaust gas from the previous cycle thus fills the bulb, the cylinder containing air alone. On the compression stroke of the piston the air passes through the narrow passage B into the bulb and then mixes with the oil vapour: the mixture is at first too rich to ignite, but the engine is so adjusted that just as the compression is completed a correct mixture is attained; the heat of the hot bulb then causes automatic ignition, and the resulting pressure drives the piston outwards, thus performing the working stroke. The bulb temperature is maintained by heat derived from successive explosions during running. After prolonged heavy-load running the bulb tends to become too hot, which causes pre-ignition of the charge, and also "cracking" of the oil, with resulting deposit of "coke"; on the other hand if the engine be run light for some time the bulb tends to become too cool to ignite the charge. A suitable bulb temperature is maintained by varying the supply of cooling water to the jacketed forward end of the bulb by means of the hand-controlled valve C. With reference to the automatic ignition of the charge, Sir D. Clerk observes (The Gas, Petrol and *Oil* Engine, vol. ii.):

"It is a peculiar fact that oil vapour mixed with air will explode by contact with a metal surface at a comparatively low temperature, and this accounts for the explosion of the compressed mixture in the hot bulb A, which is never really raised to a red heat. It had long been known to engineers conversant with gas engines that in certain conditions of the internal surface a gas engine will run and ignite with great regularity without any special form of ignitor, if only some portion of the interior surface of the cylinder or combustion chamber be so arranged that its temperature is moderately raised. Although that temperature may be too low to ignite the mixture at atmospheric pressure, yet when compression is complete the mixture will often ignite quite regularly."



FROM CLERK AND BURLS. 'GAS, PETROL AND OIL ENGINE' (LONGMANS, GREEN & CO.)

FIG. 10.—EARLY HORNSBY-AKROYD OIL ENGINE

In an old early two-stroke cycle engine (circa 1880) Clark screwed a bolt into the end of the piston, the bolt being long enough to project well into the explosive charge. After running the engine for about 15 minutes in the usual way he found that if the flame-igniting device were put of action the engine still continued to run regularly, the mixture being fired by the heated end of the bolt which caused ignition just as the mixture became fully compressed; in this case, however, the bolt attained a high red heat. Later, "hot-bolt" ignition was for a time used in some oil engines by, *e.g.,* Clayton and Shuttleworth and Crossley.

Test of a single-cylindered 32. B.H.P. Hornsby-Akroyd engine in 1908 gave results as follows:—

Compression pressure, 85 lb./sq.in.

Explosion pressure, 260 lb./sq.in.

Lbs. of fuel used per B.H.P. per hour (full load), 0·613.

The fuel used was "Russolene" oil having a sp. gr. of ·82, a flash point of 88° F (close test), and a heat value of 18,450

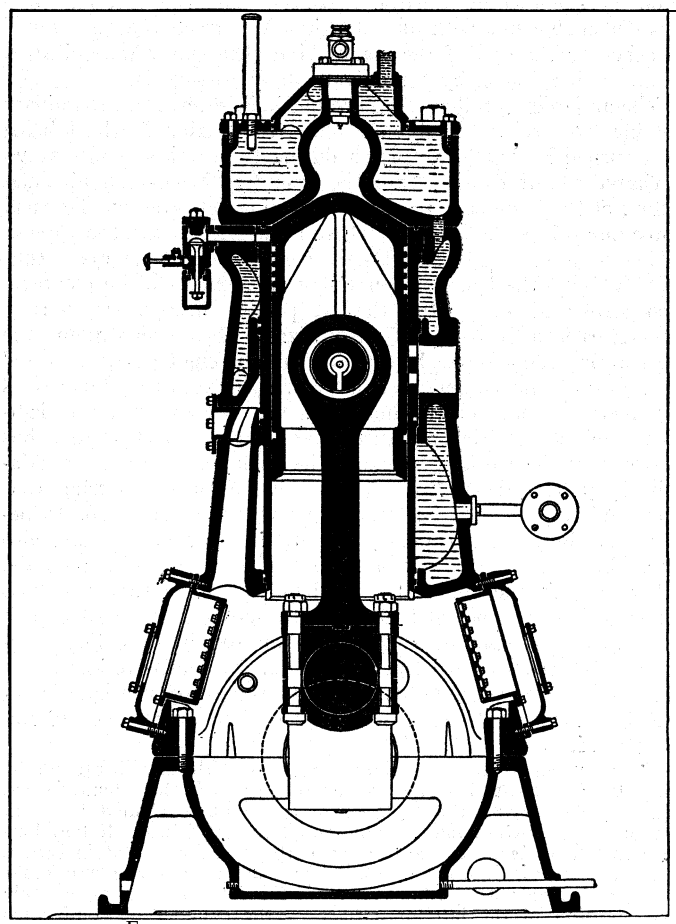


FIG. 11.—PETTER "C" TYPE HEAVY OIL ENGINE

B.Th.U. per lb.: the Brake Thermal Efficiency was therefore $\frac{2545}{·613\times18450}\times100=25·5\%$. The engine ran at 230 rev. per minute.

Many other "hot bulb" engines soon appeared, *e.g.*, the Blackstone, Crossley, National, Robey, Petter, Ruston, etc. Thus, in the Crossley Lampless oil engine, the oil is vapourized by injection into a hot bulb forming a prolongation of the combustion chamber; ignition is, however, here effected automatically by a hot tube which projects into the bulb and is maintained at the high temperature necessary to cause ignition by heat derived from the successive explosions; many early hot-bulb engines were similarly fitted. During prolonged running at heavy load a small spray of water could be injected into the exploded mixture through the "water sprayer"; the practice of water injection was at one time somewhat extensively adopted, but it is preferable to avoid it if possible.

Numerous hot-bulb engines have appeared since about 1886 varying only in the details of vapourization of the fuel, their mode of operation being, in general, not essentially different from that of Akroyd Stuarts' engine.

SEMI-DIESELS

Appearance of the Diesel engine (*q.v.*) in 1895, with its remarkably low fuel consumption and high efficiency of performance, attracted engineers to the problem of obtaining this low fuel consumption without being compelled to have recourse to the extremely high compression and high-pressure injection-air-blast of the Diesel, which involve a heavy and costly engine, necessitating great refinement in design and manufacturing processes to ensure satisfactory continuous running.

This problem has been very well solved by combining the hot bulb engine with a moderate compression and airless or "solid injection of the fuel at or about the instant of maximum compression in a large class of engines of both four-stroke and two-stroke cycle, now termed semi-Diesels.

The accepted definition of a semi-Diesel engine is as follows:—

"A semi-Diesel engine is a prime mover actuated by the gases resulting from the combustion of a hydrocarbon oil. A charge of oil is injected in the form of spray into a combustion space open to the cylinder of the engine at or about the time of maximum compression in the cylinder. The heat derived from an uncooled portion of the combustion chamber, together with the heat generated by the compression of air to a moderate temperature, ignites the charge. The combustion of the charge takes place at, or approximately at, constant volume."

By 1928 the great majority of hot bulb semi-Diesel engines operated on the two-stroke cycle, with or without crank chamber compression (see above); among the few examples of four-stroke cycle hot bulb semi-Diesels the Ruston and Hornsby "Class M" engine may be noted. These, built in single-cylindered horizontal type from 6 to 40 B.H.P., are run on crude, standard Diesel, or refined oils, and show a consumption from ·48 to ·6 lb. per B.H.P. hour. The hot bulb receives a preliminary heating by lamp, and the oil fuel is injected by a small force-pump as usual. Starting is effected by hand, or compressed air if preferred. Four-stroke hot bulb semi-Diesels were also then built by Fielding and Platt, and by Tangye; the four-stroke type though more costly to build, is somewhat more economical in fuel consumption than the two-stroke, and requires also in general considerably less oil for lubrication.

The great simplicity, low production cost, and considerable fuel economy of this type caused it to grow rapidly in favour with power users, and among prominent builders in 1928 may be mentioned:—Allen, Babcock, Beardmore, Bolinders, Campbell, Gardner, Marshall, Mirrlees, Petter and Robey.

A typical two-port, two-stroke, hot-bulb, semi-Diesel heavy oil engine with crank-chamber compression (see above) is the (Swedish) Bolinders engine as largely used for marine purposes in motor trawlers, etc., which is built in robust four-cylindered designs up to 500 brake horse power. In this engine air enters an enclosed crank-chamber during the up-stroke of the piston through automatic valves, and near the end of the down-stroke, under slight pressure, rushes into, and charges, the cylinder through an inlet port, and assists also in the expulsion of the burnt gases through an exhaust port on the other side. On the succeeding up-stroke the air is compressed to 125–150 lb./sq.in. into the combustion chamber and hot bulb and at the end of compression the fuel pump sprays the charge of oil into the bulb, the explosion automatically following. The hot bulb receives a preliminary heating by lamp, and the engines are started by compressed air.

To reverse the marine Bolinders engine it is slowed nearly to the stopping point, when a special device sprays a charge of oil into the bulb before the piston has quite completed its up-stroke; a premature explosion follows, and reversal of motion takes place, the engine thereafter running equally well in the new direction.

Vickers-Petter Heavy Oil Engines.—These engines are also solid-injection, two-port, two-stroke cycle semi-Diesels with crank-chamber compression, but with the bulb water-jacketed, as shown in fig. 11. By extended tests the makers are enabled to obtain automatic ignition of the charge using only a moderate compression pressure, and thus eliminate the *hot*-bulb. These engines are built of single-cylindered 25 B.H.P. type running at 375 rev. per min. to six-cylindered 600 B.H.P. running at 270 revs. per minute, and use as fuel refined, crude and even low-grade residual petroleum oils; the consumption is as low as 0·43 lb. of fuel per B.H.P. hour. Starting from cold is effected by compressed air in about one minute.

Though there is no "uncooled portion of the combustion chamber" in this and the following type, they are still usually classed

by engineers as "semi-Diesels" as the combustion of the fuel is, in general, of the "constant volume" type.

"Cold Starting" Heavy Oil Engines.—Lastly is to be noticed a large modern class of heavy oil engine mostly of four-stroke type in which the bulb is entirely eliminated. The type depends for ignition solely upon the high temperature attained by the air on compression; it employs compression pressures higher

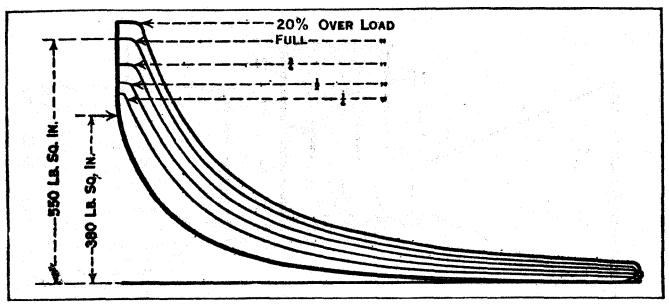

FIG. 12.— INDICATOR DIAGRAMS FROM BLACKSTONE "COLD STARTING" SEMI-DIESEL ENGINE

than those used in the hot bulb class, yet lower than those in the true Diesels; the fuel is sprayed by airless or "solid" injection into the combustion space at, or near, the instant of maximum compression, the resulting combustion being, in general, partly at constant volume and partly at constant pressure. Such are styled "cold starting" engines and are usually included among "semi-Diesels," as in a true Diesel engine the combustion pressure should not rise above the maximum pressure of compression.

This is very well illustrated by fig. 12, which is a reproduction of diagrams taken from a 150 B.H.P. Blackstone cold starting heavy oil engine. It will be observed that the maximum compression pressure was 380 lb./sq.in., while the maximum explosion pressure was 550 lb./sq.in. at full load, and that combustion continued constant at this maximum explosion pressure for a short portion of the working stroke.

Four-stroke cold-starting engines were built in 1928 by, among others, the following prominent British makers:— Blackstone, Campbell, Crossby, National, Premier, Robey, Ruston & Tangye; these were built in units of from 6 to over 300 B.H.P.

The table below shows roughly the progressive increase in fuel economy in heavy oil engines from the introduction of the early Priestman vapourizing paraffin engine of 1885 to the Scott-Still combined Diesel-steam type of 1928:—

TABLE II. *Illustrating progressive fuel economy in Heavy Oil Engines*

Type	Average fuel consumption in lb. per B.H.P. hour
Early Priestman Vapourizing "Paraffin" engine	1·24 to 0·84
Early Hornsby-Akroyd hot bulb	0·61
Later improved hot bulb engines	0·48 to 0·6
Water-cooled bulb engines	0·43
"Cold Starting" engines	0·41
True Diesel engines	0·39
Still-Diesel-steamengine	0·35

BIBLIOGRAPHY.—?.he subject of heavy oil engines is a large one, and only a somewhat superficial account can be presented in a short article; readers who wish to proceed further may refer with advantage to some of the following works:—

Pollock, *Hot-bulb Oil Engines* (1919); L. H. Morrison, *Oil Engines* (1919); A. H. Goldingham, *The Design of Oil Engines* (1922); A. W. and Z. W. Daw, *Oil and Gas Power* (1923); A. H. Bird, *Oil Engines* (1923); A. P. Chalkley, *The Diesel Engine*, 6th ed. (1927). *See* the various engineering and marine journals.

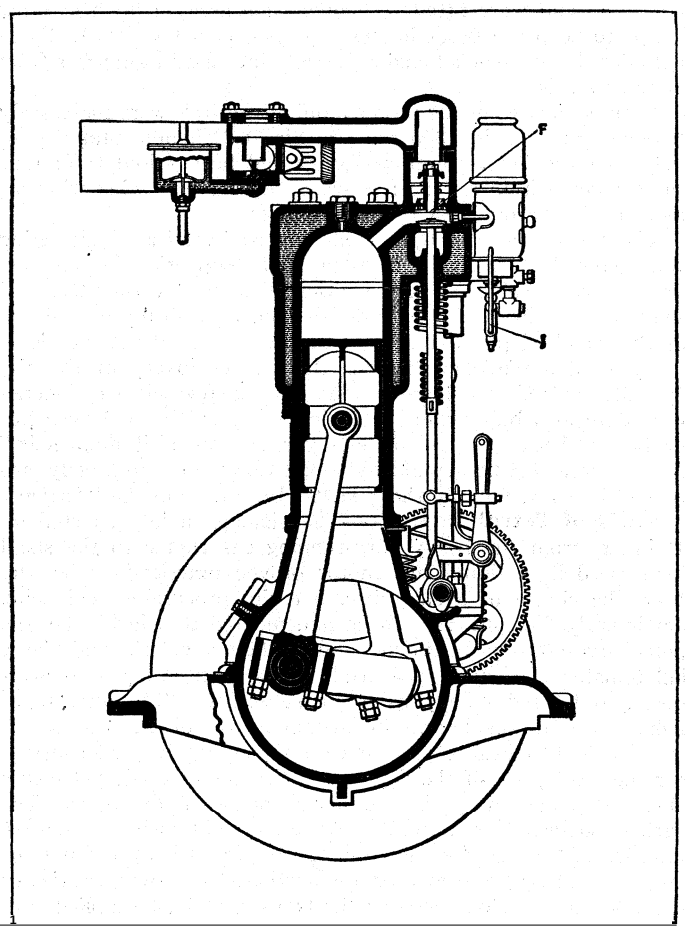
LIGHT OIL (OR PETROL) ENGINES

Few inventions in the short space of a single generation have effected such profound changes in human life as the small high-speed light oil internal combustion engine, more familiarly known as the "petrol motor." Not only has it completely revolutionized land transport, but it has also rendered popular flight by heavier-than-air machines, and in marine, submarine, industrial, agricultural, and even in domestic life has wrought important and far-reaching changes.

Daimler's Engines.— The principal credit of the invention of this all-important type of internal combustion engine is due to Gottlieb Daimler (1834–1900). Up to about 1883 even the smallest internal combustion engines were extremely heavy weighing as much as 1,100 lb. per horse-power, and running at not more than 200 rev. per min.; Daimler's 1886 engine ran at fully 800 rev. per min., and weighed only 88 lb. per horse-power. An early design by him is illustrated in fig. 13; it is of the normal four-stroke inverted-vertical type with enclosed crank-chamber and "splash" lubrication. Daimler first used the starting handle. The valves will be noted in a pocket on the right of the cylinder, the (automatic) inlet being placed above the cam-operated exhaust; between them is to be seen the platinum open-tube igniter, heated by an external petrol-burning lamp *l*.

In fig. 13 a simple type of float-feed carburetter is indicated, but in the earlier Daimler motors a surface carburetter was used in which warmed air was drawn through a constant thickness of petrol during the suction stroke of the engine.

Thus Daimler's great achievements were (1) The successful



FROM GLAZEBROOK, "DICTIONARY OF APPLIED PHYSICS" (MACMILLAN & CO.)

FIG. 13.— DIAGRAM OF EARLY DAIMLER ENGINE

employment of high revolution speeds enabling bulk and weight to be greatly lessened and power increased, and (2) The successful and safe employment of mixtures of volatile liquid hydrocarbons or "petrols" as fuel. The first Daimler motor-bicycle ran in 1886, and the first Daimler-engined car in 1887. It is curious at the present day to learn that he did not regard favourably the application of his little engine to road vehicles, and that he devoted his attention later to their use in propelling launches and canal boats, in which services they were largely used from 1887 onwards.

But in 1889 Panhard and Levassor arranged for the manufacture of Daimler's engines in France, and progress in automobilism quickly became apparent. Contemporaneously with Daimler, Benz of Mannheim had devoted much attention to the production of a small I.C. engine for road vehicles, and achieved considerable success; as early as 1878 Charles Benz fitted a tricycle with a $\frac{3}{4}$ horse-power motor, and obtained a speed of 7 miles per hour. The early Benz cars, belt-driven by a horizontal four-stroke single- or double-cylindered rather slow-running engine located in the rear of the vehicle, for some years enjoyed a deservedly high reputation; at the 1889 Paris exhibition a Benz car was the sole representative of automobilism!

Among the early pioneers must also be mentioned de Dion Bouton, who effected substantial advances in motor-car engines from 1895 onwards; these little engines—fitted even then with high tension ignition with non-trembling coil and dry battery—ran very fast and had a notably high power output. The early de Dion $1\frac{3}{4}$ and $2\frac{3}{4}$ horse-power motor tricycles were widely used for several years. Their original engine was air-cooled with the now long familiar finned cylinder and aluminium crank-case, splash lubrication, automatic inlet valve, high tension electric ignition, and ran at 1,500–1,800 rev. per min. The early heavier type cars of Daimler and Panhard were usually driven by two-cylindered engines of about $3\frac{1}{2}$ in. bore $\times$ 5 in. stroke $\times$ 700 rev. per min., and were fitted with open-tube ignition, with external lamps to keep the tubes hot (see p. 500, GAS ENGINES). Four-cylindered water-cooled engines largely increased in number from 1902 onwards.

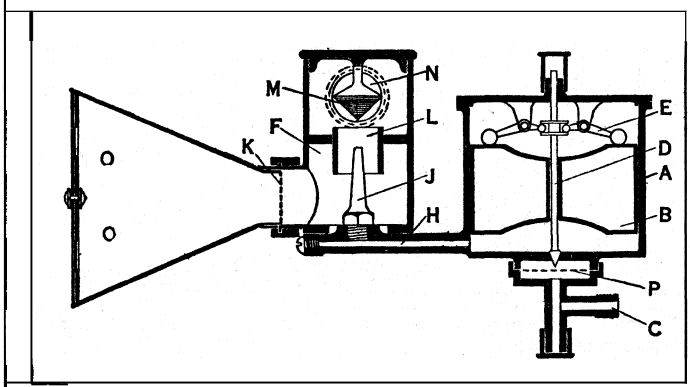
Early estimates of the power required for cars were ludicrously inadequate; even in 1896 the late Sir D. Salomons stated publicly that the horse-power necessary had been raised from four to six; yet, within a very few years cars were running with engines of 60, 80 and even 100 horse-power.

The four-cylindered four-stroke inverted-vertical single-acting water-cooled engine with cam-operated "poppet" inlet and exhaust valves, H.T. magneto ignition, float-feed carburetter and semi-forced lubrication has now for long been firmly established as the standard petrol motor of the average road automobile.

By 1928 a tendency towards the greater luxury of the six-cylinder-engined car became manifest; a few eight-cylindered cars were also built; and the Daimler Motor Co. had even put on the market a twelve-cylindered car, the "30 H.P. double-six." A few successful two-cylindered small cars were also largely employed in 1928, notably the 7 H.P. "Jowett," and the "Trojan."

Fuels of Petrol Engines.—The change, mainly effected by Daimler, from the heavy slow-running gas engine to the small high-speed light liquid fuel motor proved practically a lengthy task, the choice of a suitable and easily procurable fuel being particularly difficult. It is to be remembered that in his day the petroleum industry was young, and the lighter volatile and highly inflammable constituents of crude oil were regarded as dangerous, and treated mainly as waste substances. The mixture of light hydrocarbons known in Britain as petrol, in America as gasoline and in France as essence, now so largely used consists, for the most part, of the lighter constituents of crude petroleum oils, and ranges in specific gravity from about ·68 to ·78. The earliest engines "carburetted" their air, *i.e.*, obtained an explosive mixture of air and vapour from the liquid fuel, by passing the air drawn in by the engine on the suction stroke over a series of trays fitted in a closed vessel; the trays were kept supplied with a thin layer of the liquid fuel by a small pump. The air thus became saturated with vapour, and correct proportions of the mixture were obtained before reaching the engine by regulated admission of an additional quantity of fresh air. This was the general principle of the surface carburetter, which survived in a few cases (as, *e.g.*, the Lanchester) even as late as 1910. The insuperable objections to the type were (1) The difficulty of obtaining a correct mixture at varying speeds and temperatures, (2) The lighter constituents of the fuel usually evaporated first, leaving a heavier and relatively non-volatile residuum which was wasted. Hence arose a great demand for a practically homogeneous petrol of about ·68 sp.gr., but the rapid growth in the world consumption soon exhausted available supplies of this very light spirit.

Maybach's famous "float-feed" carburetter, invented in 1893, was, however, found to supply a completely satisfactory practical solution of the problem of using successfully much heavier grades of petrol, and this, in numerous improved forms, is in universal use at the present time. A diagrammatic illustration of this cele-



FROM CLERK AND BURLS. "GAS, PETROL AND OIL ENGINES" (LONGMANS, GREEN & CO.)

FIG. 14.—DIAGRAM OF EARLY "MAYBACH" CARBURETTER

brated device is given in fig. 14. Within the chamber A is a light brass or copper cylindrical float B which maintains at a constant level the petrol supplied through C by its action on the central needle valve D through the weighted levers E. A small duct H maintains constant communication between the float chamber and the spray chamber F which contains the spray nozzle J within which the petrol rises nearly to the top when the engine is at rest. During the suction stroke air is drawn through the funnel-shaped intake OO and gauze screen K, and passes up the Vena *contracta* or choke tube L surrounding the spray nozzle; in the choke tube the air velocity is great and its pressure in consequence small; the petrol accordingly issues from the nozzle in a very fine stream and, mingling with the air, is broken up into spray. This "atomization" and the subsequent vapourizing are assisted by impact upon a corrugated cone M, above the jet; the mixture then passes on to the engine along an inlet pipe N, being usually adjusted on its way by admission of a regulated further quantity of fresh air. It is clear that by use of the spray nozzle all the fuel is used, and no selection of the more volatile constituents is possible.

The specific gravity of commercial "petrols" has risen steadily from ·68 to ·78, the usual range being however from about ·72 to ·76. Increasingly large supplies are obtained by the "cracking" of heavier petroleum oils. (See PETROLEUM; LOW TEMPERATURE CARBONIZATION; GASOLENE; ALCOHOL: *In Industry*.)

Two essentials of a motor spirit for every-day use are:—(I) Easy starting, and (2) "Anti-knock" properties. Some heavier petrols do not vapourize at (British) winter temperatures and recourse must be had to carburetter warming to enable a start from cold to be effected. The possession of "anti-knocking" properties is of the greatest value in the fuel; detonation is an almost instantaneous automatic explosion of the mixture as a whole, and is evidenced by the "pinking" or "knocking" of the engine; it causes an immediate reduction in power and rapid overheating which sets up pre-ignition of the mixture. Moreover an easily detonating fuel restricts the compression ratio that may be used in the engine, and so reduces its thermal efficiency. (See p. 500 under GAS ENGINES.)

Certain substances, as the liquid hydrocarbon toluene (C_7H_8), the coal tar product benzol, ethyl alcohol, lead tetra-ethyl, etc., when added to ordinary "petrols" in suitable proportions possess the property of reducing the tendency of the fuel to detonate, and are accordingly often termed "anti-knock dopes." Modern petrols are carefully prepared mixtures designed to possess reasonable anti-knock and easy-starting qualities. Exhaustive investigations relating to the various liquid fuels for motors were carried out by the Empire Motor Fuels Committee, whose Report 1923–4 is of great value.

RATING AND PERFORMANCE

It is shown above that the brake horse power of a single-acting four-stroke petrol engine with N cylinders is expressed by:—

$$\text{B.H.P.} = 992 \cdot d^2 \cdot \eta p \cdot snN \times 10^{-9}. \quad (1)$$

For rating purposes in car and motor-boat competitions it was found necessary at an early date to have some formula which should give simply, and in terms of some easily ascertainable dimensions of the engine, the maximum practicable horse-power, to a reasonable degree of approximation.

An examination by Sir D. Clerk, of the performance of about 100 engines in 1905–6 showed at that time a prevailing piston speed $\left(=\frac{n \times 2s}{12}\right)$ of roundly 1000 feet per minute, with a brake mean effective pressure, ηp, averaging 70 lb./sq.in. If, in (1) above, 6000 be substituted for sn and 70 for ηp, the equation will be found to reduce-by common arithmetic to:—

$$\text{B.H.P.} = 0{\cdot}417 d^2 N \quad (2)$$

In 1906, the Royal Automobile Club decided to take 0.4 as the coefficient instead of 0·417, and thus was obtained the famous R.A.C. Rating Rule for petrol engines, viz.:—

$$\text{R.A.C. Rating} = 0{\cdot}4 d^2 N \quad (3)$$

where d is the cylinder bore in inches. This simple formula was also adopted by the British Treasury for taxing purposes, and has continued in operation up to the present time.

In passing, it may be noted here that at the end of 1927 there were running on the 178,361 miles of roads in Great Britain, a total of 1,694,000 licensed motors, as compared with 270,000 in 1919. The amount received by the British Treasury for motor licences for the year ending Nov. 30, 1927, totalled £23,456,378

The R.A.C. and Treasury rating formula, depending only upon the number and the square of the bore of the cylinders, immediately caused petrol engine designers to concentrate on the problem of obtaining a maximum output from the minimum cylinder.

In this direction extraordinary success has been achieved, particularly by British designers; even by 1912 tests of normal engines at Brooklands showed a power output averaging nearly 50% greater than that given by the R.A.C. formula, individual cases showing an excess of even 100%. Much of the improvement has resulted from recognition of the necessity of designing an engine not only as a prime mover, but also as a highly efficient pump; the increased pumping, *i.e.*, volumetric efficiency, coupled with increased revolution speeds, has enabled remarkable results to be achieved; a notable early instance is furnished by a Vauxhall four-cylinder 3.54 in.×5·12 in. racing engine, with a Treasury rating of, roundly, 20 H.P., which developed 90 B.H.P.—or 43 times its rating—when running at 3,600 rev. per min.

After the outbreak of war in 1914 it soon became manifest that the high-speed petrol engine was of fundamental importance in connection with road transport, aircraft, and later "tanks," and all available engineering skill was for some years again concentrated upon effecting still further improvements. There have resulted very high-speed motors, both small and large, of extraordinarily high power output in relation to their size and weight, rivalling in efficiency the largest slow-running stationary types. Many examples can be cited from the tiny four-cylinder, seven H.P. and eight H.P. Austin and Singer designs respectively to the six-cylinder 35/120 horse-power Daimler engine, the lower figure representing the R.A.C. rating.

Even more striking is the astonishing success achieved with the petrol engine as applied to racing aircraft; thus the 1928 12-cylindered "broad-arrow" water-cooled four-stroke single-acting Napier "lion" racing aero-engine with a bore of 5·5 in. and stroke of 5·125 in., using a compression ratio of 10:1, and a fuel composed of 75% petrol, 25% benzol, and a small "dope" of lead tetra-ethyl, and weighing 835 lb., had a power output of 875 B H.P. at 3,300 rev. per minute, or 1 B.H.P. for each 0·954 lb. of weight. (See AERO-ENGINE.)

In Table III. some figures are given for a few typical modern engines; the values in the extreme right-hand column depend on the nature of the service demanded from the engine; thus petrol engines for marine work, or for driving heavy road lorries are called upon for a much heavier continuous power output than are the engines of normal motor-cars, and are accordingly more robustly built and are in general run at somewhat slower speeds. At the extreme top of the range of output performance is the racing aero-engine from which all that is demanded is an absolutely maximum output during a very short period of time.

Capacity Rating.—A mode of petrol engine rating much employed for classifying purposes is that obtained by taking the total volume swept out by the pistons in one stroke of the engine, and this is termed the "capacity" rating. It is evidently expressed by piston area X stroke × number of cylinders, or, in symbols:—

$$\text{Capacity Rating} = 0{\cdot}7854 \, d^2 sN \quad (4)$$

If d and s be in inches, the value is expressed in cu.in. It is, however, more usually expressed in cubic centimetres; so that d and s, denoting the bore and stroke in *millimetres*, and N being the number of single-acting four-stroke cylinders, we have:—

$$\text{Capacity Rating} = 7854 d^2 sN \times 10^{-7} \cdot \text{c.c.} \quad (5)$$

or, in litres, $$= 7854 d^2 sN \times 10^{-10} \quad (6)$$

A useful expression of performance is to state the B.H.P. per litre of capacity; this is given in the extreme right-hand column of Table III., and is of course at once obtained by dividing the B.H.P. by the capacity. If the general formulae for B.H.P. (Eq. 1) and for capacity (Eq. 4) be employed we get the useful relation:—

$$\text{B H.P. per litre} = 771 \cdot \eta p \quad n \times 10^{-7} \quad (7)$$

TABLE 111.—Some data *relating to a few typical engines of recent years*

Engine	No. of cyl.	Bore		Stroke		Rating		Normal full speed r.p.m.	B.H.P. at normal full speed	B.H.P. per litre of capacity at normal full speed
		inches	mm.	Ins.	mm.	R.A.C.	Capacity in c.c.			
Thomycroft 4-ton lorry engine, M/4	4	4·5	114·3	6	152·4	32·4	6,245	1,200	37	5·92
14/28 Morris-Oxford normal motor-car engine	4	2·95	75	4·02	102	13·93	1,802	1,700	24·3	13·5
35/120 Daimler sleeve-valve large car engine	6	3·85	97	5·13	130	35·5	5,764	1,600 (at a car-speed of 45 m.p.h.)	76	13·2
7 H.P. Austin; the very-small-car-type engine	4	2·2	56	3·0	76	7·74	748	2,400	10·5	14·0
8 H.P. Singer; a small bur-seater car-type engine	4	2·2	56	3·38	86	7·74	848	2,000	12·4	14·6
Napier "Lion" racing aero-engine	12	5·5	139·7	5·125	130	145·2	23,907	3,300	875	36·6
Bristol Mercury Mk I. racing aero-engine	9	5·75	146	6·5	165	119	24,854	2,500	800	32·2

wherein ηp is the brake mean efficient pressure in lb./sq.in., and n is the number of revolutions per minute.

Small Motor-car Engines.—A recent 15·9 Morris engine, a typical engine of the average motor car, is a four-cylindered, four-stroke vertical unit of 3·15″ (80 mm.) bore, and 4·92″ (125 mm) stroke, and accordingly has a Treasury rating of $0{\cdot}4\times3{\cdot}15^2\times4=15{\cdot}9$, and a capacity of $7854\times80^2\times125\times4\times10^{-10}=2{\cdot}513$ litres.

The four cylinders are cast en bloc with side-by-side inlet and exhaust valves cam-driven through adjustable tappet rods; the valves are all of the same size, and their springs and stems are enclosed by a readily removable cover-plate to exclude dust and retain oil The cylinder heads are detachable, facilitating greatly decarbonisation and access to the valves.

The power output by bench tests is as follows:—

At rev. per min.	1,000	1,500	2,000	2,500
B.H.P.	14 0	21·5	27·5	31·2

The off-set hollow crankshaft is borne in three bearings which are housed in the lower part of the cylinder block, thus giving great rigidity to the engine. The connecting rods are of duralumin, and all main and big-end bearings are of white metal in bronze shells Aluminium-alloy pistons are used. Lubrication is forced,—by a drowned plunger pump driven by an eccentric on the camshaft,—to the three main crankshaft bearings, the four big ends (via the hollow crankshaft), and also to the camshaft bearings. The pump in-take is through a gauze fitter easily removable for cleaning; a gauge on the dashboard of the car indicates the oil pressure in the circulating system while running. Ignition is by the usual H.T. (high-tension) magneto.

The "Baby Austin" Engine.—The performance of the modern tiny motors typified by recent Austin and Singer designs is so remarkable as to merit special notice. A section of a seven H.P. Austin small-car engine is given in fig. 15. The four en *bloc* cylinders of 2·2 in bore and 3·0 in. stroke (see table) are fitted

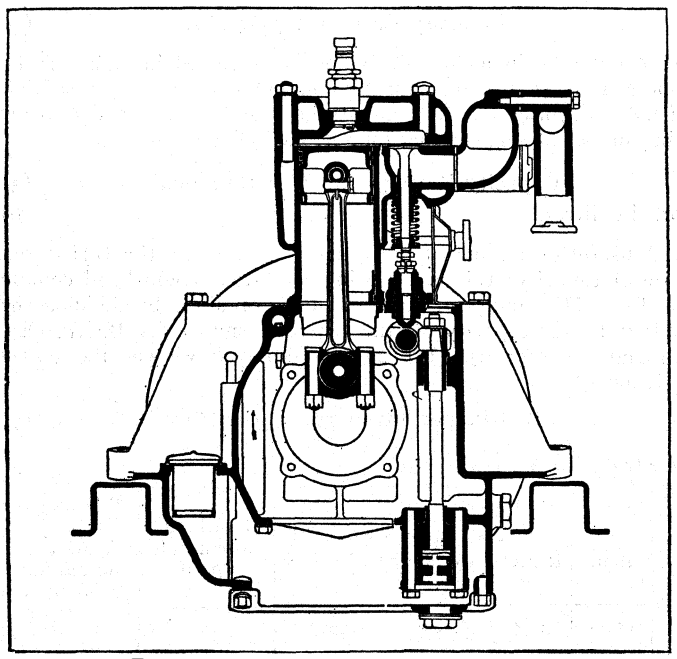


FIG. 15 — SECTION OF 7 H.P. AUSTIN ENGINE

with a detachable head. The pistons are of aluminium alloy. The side-by-side valves are cam-operated in the usual manner. Lubrication is by a drowned oil-pump driven from the camshaft as indicated, and ignition is by H.T. magneto. Thermosyphon cooling with a "film" radiator and fan. The four-throw crankshaft is borne in two roller bearings. The mixture is supplied by a Zenith carburetter. The power output is:—

At rev. per min.	1,000	1,500	2,000	2,500	2,800
B.H.P.	3·8	6.2	8·7	11·0	12·0 (max.)

This miniature engine propels its car containing three or four adults with ease at 35 miles per hour on an ordinary good road-surface, with a petrol consumption of 40–50 miles per gallon.

The Eight H.P. Singer "Junior."—A recent design of this car has an engine of the same bore as the seven H P. Austin, but with the larger stroke of 3.38 in. (see table). The cylinders and crankcase form a single casting and an aluminium casing houses

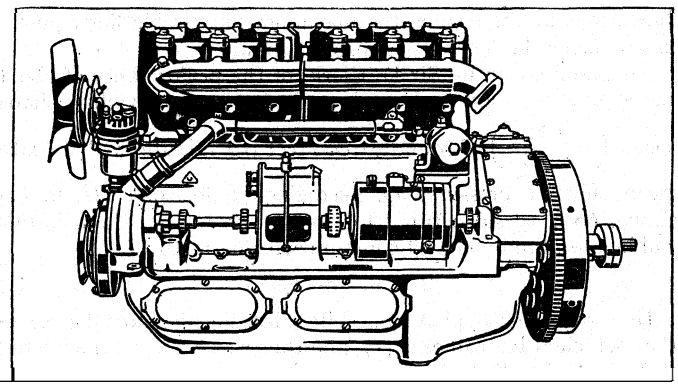

FIG 16 — THE 35/120 H.P. 6-CYLINDER DAIMLER SLEEVE-VALVE ENGINE

the timing gear and forms the front support of the engine. The short stiff crankshaft is borne in two solid white-metalled bearings. The pistons are of cast iron with three spring rings, the lowest ring securing the gudgeon pin. The connecting-rod big end bearings are of white metal in bronze shells. The valves in this engine are overhead and inclined and are operated by rockers; the overhead camshait, oil-pump, magneto, and starting and lighting dynamo are all driven from an intermediate shaft placed above the front end of the crankshaft and driven by it through helical gearing; the drive from the intermediate shaft to the overhead camshaft is by double roller chain fitted with an automatic tensioning device. The detachable cylinder head is a single casting carrying the camshaft in three bearings, and is fitted with renewable valve guides. Lubrication is by pump and troughs; the pump intake draws the oil through an easily removable gauze filter, and delivers into four troughs into which the connecting rods dip, and also up to the overhead camshaft and valve rocker bearings. The oil pressure is indicated by a gauge on the dashboard. Cooling is on the "convection" or "thermo-syphon" system. Ignition is by H.T. magneto. A Solex horizontal carburetter is used. The engine is enclosed, dust-excludingand oil-retaining. The power output is:—

At rev. per min.	1,000	1,500	2,000	2,500	3,000	3,250
B.H.P.	6·2	9·3	12·4	14·9	16·2	16·4 (max.)

and in the autumn of 1927 a car fitted with one of these very small engines accomplished a run from London to Edinburgh, and back in 24¾ consecutive hours, corresponding to an average speed throughout of about 33 miles per hour.

Sleeve Valve Engines.—In these the poppet valves are replaced by ported sliding sleeves which, in the single-sleeved engine is the working barrel of the cylinder and has a motion partly reciprocating and partly angular, while in the double-sleeved engine both the ported working barrel and the second ported sleeve enveloping it have a simple axial reciprocating motion.

Space permits but a brief reference to the single-sleeved type, but the Burt-McCollum design has been successfully employed for some years in the engines of Barr and Stroud, Caledon, Argyll, and Karrier; an exhaustive account of this type is given by Ensor in the Proc. *Inst. Auto.* Engrs. (1927–8).

The Daimler-Knight Double-sleeve Engine.—Used with great success since 1908, the smooth running "Silent Knight" engine is deservedly famous. The four-stroke, single-acting, six-cylindered, 35/120 h.p. design, illustrated in fig. 16, has a bore of 3·85 in. a stroke of 5·13 in., and consequently a Treasury rating of 35·5. Bench tests show that at a speed of 3,000 rev. per min. the engine develops roundly 120 b.h.r. At a car speed of 60 miles per hour the engine runs at 2,140 rev. per minute. The manner in which

the ported light steel sleeves regulate the inlet and exhaust periods is clearly shown in fig. 17.

The inlet port opening and the exhaust port closing at the beginning of the suction stroke is shown in A. The inner sleeve is rising and the outer sleeve is descending. The exhaust is shown closed and the inlet closing at the beginning of the compression stroke in B. The ports in the inner sleeve are passing

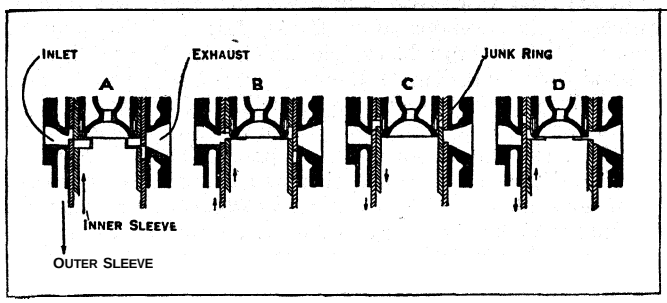

FIG. 17.—DIAGRAM SHOWING ACTION OF THE DAIMLER SLEEVE VALVES

up into the cylinder head, where they art: sealed by the junk ring during the period of maximum pressure and temperature at the beginning of the firing stroke (C). In D. the exhaust is already well opened at the beginning of the exhaust stroke. The sleeves are now again moving to the position shown in A.

SPECIAL TYPES OF INTERNAL COMBUSTION ENGINES

The Humphrey Internal Combustion Pump.—If the water within a partially filled, vertically placed U-tube be displaced it will perform nearly isochronous oscillations about its position of rest. H. A. Humphrey (1906–9) has ingeniously utilized the oscillatory motion of a large water-column to effect the raising of great volumes of water from a lower to a higher level.

A diagrammatic view of the simplest form of the Humphrey

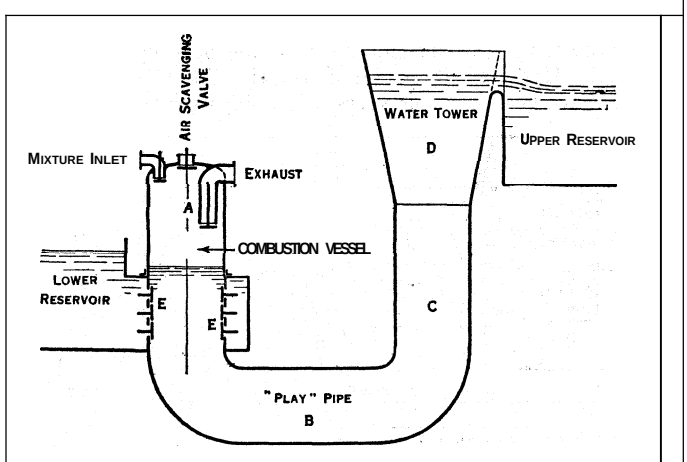

FIG. 18.—DIAGRAM OF THE HUMPHREY INTERNAL COMBUSTION PUMP

pump is given in fig. 18. ABCD is the U-tube the arm A being closed and forming the combustion vessel, while the splayed-out arm D is open and in free communication with the upper reservoir. Through the mixture inlet an explosive charge of gas and air is introduced into A and electrically fired; the pressure developed by the explosion drives down the water level in A, correspondingly raising it in D, thus producing delivery into the upper reservoir. The great momentum of the moving water column causes the downward motion in A to continue until the pressure in the combustion vessel becomes less than atmospheric; the exhaust valve then opens by its own weight and at the same time the air scavenging valve is opened by the atmospheric pressure; the burnt gases are now discharged into the atmosphere. By this time the level in A has fallen below that in the lower reservoir and a new supply of water then enters through the nest of valves E E; during the whole of this period water is evidently being delivered into the upper reservoir. The column then comes momentarily to rest, and during the return swing to the left the rising level in A first closes the exhaust valve by its impact and next compresses above it a mixture of residual exhaust and scavenge air; when the column is thus again brought to rest the pressure in the upper part of A being considerable, the column begins its second swing to the right and in the course of this the pressure again falls to less than that of the atmosphere but this time, by means of a suitable interlocking gear, the exhaust and air scavenging valves are held closed; the mixture inlet valve, however, opens and an explosive charge of gas and air enters A. The second swing of the column to the left then compresses this fresh charge in A, and the cycle is then repeated. The Humphrey pump thus works on a modified four-stroke cycle (*see* above, "Gas Engines"), but with strokes of unequal length, the working (expansion) stroke being particularly long, which makes for its high efficiency. The cycle-frequency depends upon the mass of water in the "play" pipe, and is determined by varying the length of this pipe; a frequency of 15 to 30 cycles per minute is commonly employed. The pump is very quiet, as the exhaust takes place at practically atmospheric pressure, and is suitable for lifts up to 150 feet. The pump is also built to work on a two-stroke cycle; and later designs provide for the use of oil as fuel.

At the Metropolitan Water Board's 300 horse-power installation at Chingford, Essex, England, are four pumps each with a cylinder A seven feet in diameter, and each designed to lift 40 million gallons per diem; and a fifth, with a five-foot cylinder dealing with 20 millions per diem. These are all operated by producer gas supplied by four Dowson gas producers using anthracite as fuel. The consumption per actual pump-horse-power hour is only about 0·9 lb. of anthracite.

The Still Internal Combustion Steam Engine.—Commonly some 30% of the total heat of the fuel used in a Diesel engine is carried away in the exhaust gases at a (full load) tem-

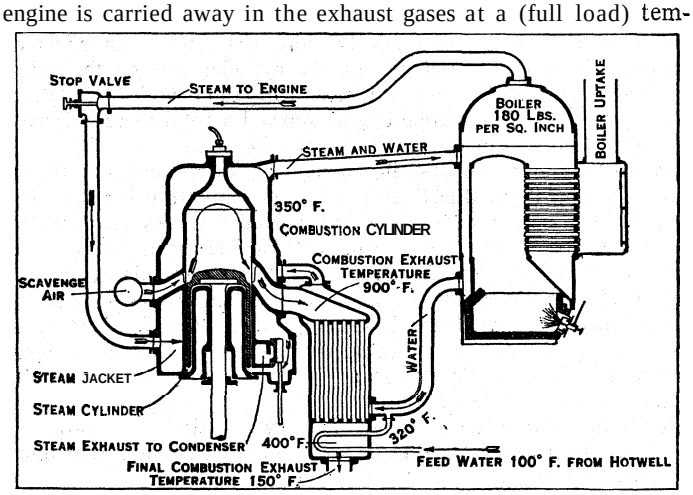

FIG. 19.—THE STILL INTERNAL COMBUSTION STEAM ENGINE

perature of some 800–900° F, and, in favourable circumstances, a saving in running costs can be effected by utilizing this heat in special types of steam boiler. W. J. Still has gone further by arranging for the exhaust and jacket heat to add directly to the power output of single-acting Diesel engines; this he has effected by enclosing the lower portion of the working cylinder, and arranging for this end to work as an ordinary high-pressure condensing steam engine.

The method adopted is illustrated by fig. 19. Above the piston the usual Diesel sequence of operation is performed The upper (Diesel) part of the cylinder is heavily water-jacketed, and the lower part is steam-jacketed; in the steam-jacket works a slide-

valve by which admission of steam to the lower end of the cylinder is regulated; the exhaust steam from the cylinder passes into an ordinary condenser. The water-jacket is connected at its top with the upper part of an auxiliary oil-fired steam boiler (shown on right), and at its lower end, through a feed-heater, with the bottom of the same boiler. Through this feed-heater passes the exhaust from the Diesel end of the working cylinder, entering at a temper-

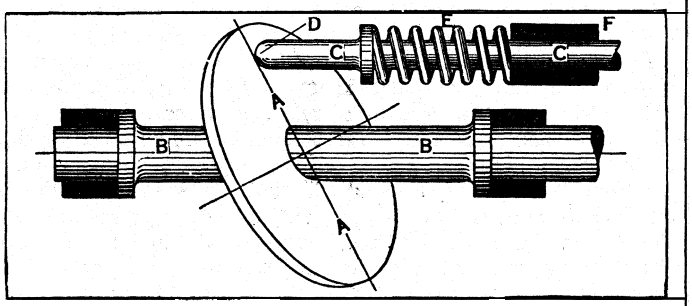

FIG. 20.— THE "SWASH-PLATE"

ature of, say, goo° F and leaving at the much reduced temperature of some 150° F only, thus giving up heat to the water system. This heated feed-water then enters the cylinder jacket, and receives some further heat by conduction through the working barrel, thereby rising in temperature to, say 350° F. The water (and steam) circulation continues through the upper pipe to the auxiliary steam boiler, in which a pressure of 180 lb./sq.in. is shown.

From the top of the boiler dome is taken the dry working steam to the steam jacket and thence, via the slide valve, to the lower end of the working cylinder. In this way heat conducted through the upper part of the cylinder liner (or "working barrel"), together with much of the heat ordinarily wasted in the exhausted burnt gases is recovered and utilized, and at full load it is claimed that up to 7 lb. of steam may be obtained per B.H.P. hour of the engine, with an increase of about 20% in power output, and much improved economy in fuel consumption. The cylinder liner in the Still engine is usually only about one-third of the normal thickness, and is ribbed externally to improve its heat-conducting properties.

Trials by C. B. Boys showed that, per B.H.P. hour, 3.28 lb. of steam was obtained from the jacket alone, and 6·0 lb. from the jacket and exhaust gases jointly; also that the mean effective pressure from the Diesel end of the cylinder was go lb./sq.in., while that from the steam end was 14 lb./sq.in., twice per cycle; accordingly this four-stroke engine showed a total mean effective pressure per cycle of go + 2 × 14 = 118 lb./sq.in.

A four-cylinder Scott-Still engine, 22 in. diameter X 36 in. stroke, giving 1,250 B.H.P. at 120 rev. per minute using solid (or "airless") injection with automatic fuel inlet valves (see DIESEL ENGINE), tested by the Marine Oil Engine Trials committee, showed a fuel consumption of only 0·354 lb. per B.H.P. hour at full load, corresponding to an indicated thermal efficiency of 40·9%, and a brake thermal efficiency of 36.9%. In this engine the steam side was arranged to operate on the compound principle, one high-pressure cylinder exhausting into a receiver whence the remaining three cylinders derived their steam supply Scott-Still engines are also often arranged with some cylinders as ordinary single-acting Diesels and the rest as combined Diesel-steam units as above described.

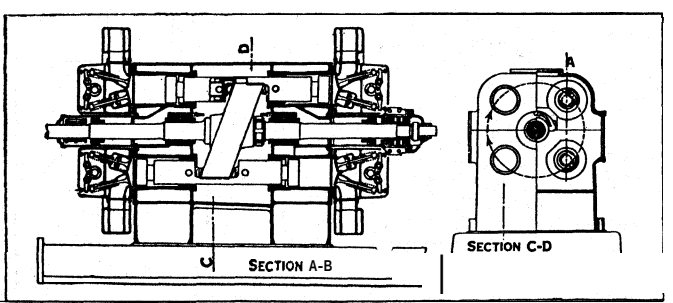
In the 1928 Scott-Still marine Diesel engine the general method of waste-heat recovery was unchanged but the steam cylinders were separate double-acting cylinders of normal type. The 3,000 B.H.P. Scott-Still engine of 1928 design, for example, comprised six single-acting two-stroke solid injection Diesel cylinders of 27 in. bore and 4; in. stroke, working in conjunction with two double-acting steam cylinders of 25 in. bore and 45 in. stroke at a normal speed of 105 rev. per minute.

The Still engine involves the addition of a feed heater, an auxiliary boiler, a condenser, and all the associated steam engine mechanism to the ordinary Diesel engine; but it enjoys, among others, the following valuable compensating advantages:— (I) An extremely high fuel economy. (2) By firing-up the auxiliary boiler the total mean effective pressure can be substantially increased thus enabling the engine safely to carry a big overload. (3) Steam from the auxiliary boiler serves for starting the engine, and the cylinders are well heated when the Diesel parts come into operation; the use of compressed air for starting is thus avoided. (4) Manoeuvring is also simplified, and again the use of compressed air is rendered unnecessary.

The **Michell** Crankless Engine.— This engine was rendered possible by the invention of **A.** G. M. Michell in 1905 of the famous "Michell thrust block," in which the theoretical conditions laid down by the late O. Reynolds were first definitely incorporated. Prior to the introduction of the Michell bearing, multiple collared bearings were invariably used, in which experience showed that the maximum thrust pressure practicable was about 60 lb./sq.in. Michell soon showed that 500 lb./sq.in. at 1,750 rev. per minute could be maintained continuously, with a bearing temperature not rising above 125° F; later, improved bearings were constructed which functioned continuously under a thrust pressure of 3,000 lb./sq.in.; and under special test conditions as much as 13,000 lb./sq.in. has been successfully borne.

-Briefly, in-the Michell bearing the-rubbing surfaces are capable of tilting, thus becoming slightly inclined to one another in the direction of motion, so that the oil film between them is wedge-shaped with the thicker edge at the entrance. **A** continuous flow of oil between the surfaces is thus induced and the film constantly renewed, thus effectively preventing actual metallic contact from occurring. In these circumstances the coefficient of friction is reduced to about ·0018, *i.e.,* only some $\frac{1}{20}$ of the value when the rubbing surfaces are maintained strictly parallel to each other.

A plane disc fixed obliquely on a rotating shaft is an old mechanical device for obtaining reciprocating motion, and was illustrated and described as long ago as 1841 by Willis in his classic Principles of *Mechanism* wherein also it is shown that if the shaft rotates uniformly a simple harmonic motion of the reciprocating piece results. The device is illustrated in fig. 20; **AA** is the "swash-plate" or "slant," mounted obliquely upon a shaft BB, and CC is a rod whose end is kept always in contact with the plate as indicated. Obviously, if the shaft BB rotates on its axis the rod CC will reciprocate. Conversely, if CC reciprocate,—and friction is not too great—it will communicate to BB an angular motion through a semicircle in making its stroke from right to left; by a second rod similar to CC, placed to the left of the swash-plate the shaft can be caused to perform a second semicircle, thus completing a revolution. This is the *modus operandi* of the swash-plate engine; CC becomes the piston and piston rod, the spring E the working impulse, and the bearing F the engine cylinder. Hydraulically-operated multi-cylindered swash-plate engines have been used for years in warships for training the big



BY COURTESY OF THE NATIONAL GAS ENGINE CO

FIG. 21.—NATIONAL-MICHELL CRANKLESS ENGINE

guns; these engines are both of single- and double-swash-plate design, the latter having two swash plates set back to back, conferring valuable balancing qualities.

The nature and action of the Michell crankless gas engine will now be clear from Inspection of the diagram fig. 21, showing a "slant" with eight cylinders, arranged in opposed pairs spaced equally around, with their axes all parallel to that of the shaft. The working pressure is communicated to the "slant" through Michell thrust slippers having spherical seats, as indicated. As the engine operates on the four-stroke cycle (see above "Gas En-

gines"), opposed pistons are coupled together by means of a yoke in order to effect the suction strokes.

Eight 280 horse-power National-Michell crankless engines, each direct-coupled to a Michell gas booster, were installed at the works of the Australian Gas Light Co. of Sydney, N.S.W. Each unit delivers 500,000 cu.ft. of gas per hour at a pressure of 7·25 lb./sq.in., when running at its normal speed of 750 rev. per minute. (G. A. Bu.)

INTERNATIONAL, THE. A number of international associations or congresses of Labour and Socialist bodies have at various times adopted the title of the "International," and three of them are of historic importance. The first of these, having for its full title the International Working Men's Association, was established in 1864, and came to an end ten years later after a troubled existence. This was commonly known as "The International," and is thus termed historically. Founded under the leadership of Karl Marx and Engels—Marx himself drew up its programme in 1866—it was in some of its elements a revolutionary body and as such is revered by the Conimtinists of the 20th century.

The Second (Socialist) International, was founded 15 years after the demise of the International, and constituted, down to the outbreak of the World War, a body representative of the world's Labour-Socialists. The war brought irreconcilable differences and consequent secessions, and the establishment of a Bolshevist Government in Russia led to the formation in 1919 of the Third (Communist) International, also known as the Komintern, which now leads the world's revolutionary forces, the Second (Socialist) International adhering to moderate views and the parliamentary principle. The Second and Third Internationals thus exist (1928) contemporaneously. In the following sections, the history of these three bodies is described in some detail.

THE (FIRST) INTERNATIONAL

The International Working Men's Association, commonly called "The International," was formed in London in 1864. It was a society of working men of all nations, somewhat like a cosmopolitan trades union, but bearing a still closer resemblance to an international social science association for discussing and furthering the rights of labour. The occasion of its formation is commonly alleged to be the visit of some French workmen to the London Exhibition of 1862. In the course of their visit the labour question was discussed, and a desire for the further interchange of ideas expressed. Nothing decisive was done till 1864, when a great public meeting of working men of all nations was held at St. Martin's hall, London, and a provisional committee was appointed to draft the constitution of the new association.

The first four congresses of the International, held at Geneva (September 1866), Lausanne (1867), Brussels (1868) and Basle (1869), marked the rapid development of the association. It gained its first triumph in the effectual support of the bronze-workers at Paris during their lock-out in 1867; and it repeatedly aided the English trade unionists by preventing the importation of blackleg labour from the Continent. It soon spread as far east as Poland and Hungary, and it had affiliated societies with journals devoted to its cause in every country of western Europe.

Anarchism v. Socialism.—It was supposed to be concerned in all the revolutionary movements and agitations of Europe, gaining notoriety as the rallying point of social overthrow and ruin. Its prestige, however, was always based more on the vast possibilities of the cause it represented than on its actual power. Its organization was loose, its financial resources insignificant; the Continental unionists joined it more in the hope of borrowing than of contributing support. At the successive congresses its Socialist tendencies became more and more pronounced; it declared its opposition to private property not only in railways but in mines and the soil, holding that these should revert to the community. The principle of inheritance was saved only by a narrow majority. In 1869 M. Bakunin, the Russian anarchist, with his immediate followers, joined the association, and at once asserted his character as the "apostle of universal destruction."

The relation of the association to the Communard rising at Paris in the spring of 1871 has been the subject of much dispute. It is now agreed that the International as such had no part in originating it, but its French members joined in it heartily. After the fall of the Commune the general council of London, Karl Marx included, issued a long and trenchant manifesto, approving its action and extolling the "glorious vanquished." From the fall of the Commune the decline of the association is to be dated. The English trade unionists, intent on more practical concerns at home, never took a deep interest in its proceedings; the German Socialists were hindered by law from corporate action; America was too remote. But it found its worst enemies within its own ranks; there was a deep division between the Socialists led by Marx and the anarchists led by Bakunin and the Swiss Federation of the Jura at the congress of 1872, held at The Hague, when Bakunin, being expelled by the Marx party, formed a rival International, which found its chief support in Spain and Italy. The old International now transferred the seat of its general council to New York; but it survived only long enough to hold two more congresses (Geneva 1874, Philadelphia 1876) and then quietly expired.

The party of Bakunin, styling themselves "autonomists," had a bloodier history. The programme of this party concentrated on the violent destruction of the State, passing over subsequent difficulties. It endeavoured to realize this in the great communal risings in southern Spain in 1873, when its adherents took part in the general insurrection, and at Alcoy, San Lucar de Barrameda and elsewhere were for a short while in power. They failed in leadership and organization, and were suppressed, though not without difficulty, by the national troops. The "autonomists" lingered on till 1879, when the collapse was complete of an association which once extended from Hungary to San Francisco, and alarmed the minds of men with visions of universal ruin. (X.)

THE SECOND (SOCIALIST) INTERNATIONAL

The Second International was constituted in 1889, 15 years after the disappearance of the First. Unlike the latter, it possessed no powerful central authority and its early meetings were mainly devoted to discussion of the tactics and methods of the affiliated national parties, but from 1911 onward the question of war and peace received more attention. It had already been discussed at the congress of Amsterdam in 1903, and from that date Jaurès began the study of the question which inspired his book, *L'Armée* nouvelle. At the congress of Stuttgart in 1903 the question was again discussed, at greater length, and Hervé's denunciation of all "patriotism" led Bebel and Volmar to declare that the Social Democrats would instantly rise to defend Germany if ever she were attacked.

Conditions Before the War.—The European horizon steadily darkened, especially after 1911. The Agadir incident, the Italo-Turkish War and the Balkan wars, in succession, made the menace of a general conflagration appear imminent, and the efforts of the Socialist parties to avert the catastrophe became more urgent and strenuous from that time. Their effortsculminated in the extraordinary congress (1912) at Basle, called to consider the international situation and the action to be taken by Social Democrats to prevent war. A manifesto was issued, exhorting all workers to unite to secure from their Governments a pacific foreign policy.

This problem of peace was put on the agenda for the tenth congress of the International which was to have been held in Vienna two years later, in Aug. 1914. The congress would have coincided with the 50th anniversary of the founding of the International in London in 1864. For this occasion Austrian Socialists had prepared an illustrated commemorative album in which Kautsky, Victor Adler and others had related the history of the Socialist movement during the last half century. This document, which appeared in print at the moment when the World War broke out, was distributed ten years after as a souvenir among members of the executive committee of the International when they met in the former capital of the Habsburgs in June 1924. The album contains, among other things, a series of medallion portraits of 66 members of the B.S.I. (International Socialist Bureau), which had its headquarters before the war in the Maison du Peuple at Brus-

sels. Lenin's portrait is not among them, although he was a member of the bureau for many years; but there are Rosa Luxemburg and C. G. Rakovsky, together with Jaurks, Ebert (the future president), also Stauning, Branting and MacDonald, who later became premiers of Denmark, Sweden and Great Britain respectively. There are delegates of trade unions too, but these are few and far between. The bureau, representing all the live forces of Socialism, met for the last time at the Maison du Peuple, Brussels, on July 29 and 30, 1914.

Even at that moment, when the world already lay under the shadow of war, optimism still prevailed. Adler regarded a war between Germany and France as a moral impossibility; Haase, chairman of the Social Democratic group in the reichstag, relied at this eleventh hour, not on humanity, but on the pusillanimity of the kaiser. Jaurks, speaking on the evening of July 30 for the last time, still affirmed his confidence in a pacific solution, but prophesied in a flash of inspiration that if, in spite of all, war were let loose on the world by its masters, then at the close, each nation would turn upon those responsible for the disasters of the war and say: "Go, and seek pardon from God and man." The next day he was assassinated in Paris, and a state of war had been declared in Germany.

The bursting of the storm put an abrupt end to all international activities (see SOCIALISM). While the war lasted no single meeting of the executive committee took place, but some tentative efforts were made to revive international action. The most important of these were an attempt by the Dutch-Scandinavian committee (vigorously supported by Camille Huysmans, secretary of the Second International) to convene an international congress at Stockholm in 1917, and that of the Italian Socialist Morgari'to convoke conferences at Zimmerwald (Sept. 1915) and at Kienthal (April 1916). The first of these efforts (the projected Stockholm conference) proved abortive mainly because of the refusal of the Allied Powers to grant passports to the delegates; at the Zimmerwald and Kienthal conferences only certain groups of the international proletariat were represented, and from these elements there was presently to emerge the Communist International known as the Third International.

Activity After the Armistice. — On the morrow of the Armistice the need for international unification was felt with renewed force. Conferences were summoned successively at Berne (Feb. 1919), Lucerne (Aug. 1919) and Geneva (Aug. 1920) with a view to re-establishing the Second International. Meanwhile, however, the so-called Third or Communist International had been formed at Moscow, and for some time parties or groups who were unwilling to be affiliated to either the Second or the Third grouped themselves in a Workers' International Union of the Socialist parties with Vienna as its centre — hence the name "Vienna International." (The principal groups concerned were the British I.L.P., the German Independent Socialists and the Austrian Social Democrats.) In the beginning of 1920 this organization tried to bring about the unification of all proletarian organizations, and succeeded in calling together in Berlin a reunion of the executives of the three groups in April 1922. But this effort at reconciliation ended in complete failure.

Since then the Communist International has steadily accentuated its opposition to Social Democracy. On the other hand the points of dispute between Vienna and London became progressively less In 1921–22 the French, English, German, Italian and Belgian Socialists, who were adherents either of the Vienna International or the Second International, met first in Paris, then in Frankfurt, and of one accord adopted the resolutions which have since become famous as the "Frankfurt Resolutions." Anticipating the Dawes scheme, these demanded the reduction of the German debt to a reasonable figure, and, further, demanded the end of military occupations of former enemy territory and the annulment of inter-Allied debts.

Congress at Hamburg. — By December of the same year these two internationals had agreed to call a Socialist international congress at Hamburg. This took place on May 27, 1923, when the International was reconstituted — the Communists being excluded — and the conditions on which parties or groups could be admitted were defined. Agreement was reached with difficulty on a Franco-German text which, drawing on the Marxian vocabulary for its somewhat heavy terminology, appealed to "those who acknowledged the aim of the working class to be the replacement of the capitalist mode of production by the Socialist mode of production and who see in the class struggle (*lutte* des classes) which manifests itself in political and economic action the means of emancipating the working class."

But when it came to translating this text into English the British delegates raised a discussion, arguing that the words "*lutte* des classes" — the touchstone of Socialism on the Continent — were not in current use in England; that the extremists, who alone used the expression, spoke not of "class struggle" but of "class war," and that it would be better in these conditions to retain the idea but to paraphrase it in such a way as this: "independent political and industrial action of the workers' organizations." And so it was arranged. The Franco-German text was retained, for it could only have been altered at the cost of emasculation; but for British consumption a free translation was allowed.

The present writer has thought it necessary to report this little incident, as it cannot fail to be instructive, showing as it does that, in spite of community of words and, on the whole, unity of tactics, English Labour men and Continental Socialists do not speak quite the same language. Now, these differences of terminology are the outward expression of other more deep-rooted differences arising out of the widely differing environment in which contemporary Socialism is formed and developed. On reading such prewar books, for instance, as the *Études* socialistes of Jean Jaurks, Ramsay MacDonald's *Socialism* and Society or Kautsky's Das Erfurter Program, we see how widely the Socialism of Jaurks, instinct with the spirit of the French Revolution, and still more the Socialism of Ramsay MacDonald, who drew inspiration from the pacific and fraternal idealism of Christianity, is to be differentiated from the more "materialist" and more "economic" Socialism of the German Marxians.

Since the war, however, these differences have become less acute, even from the theoretical point of view. A sort of amalgam has been established between the various national parties. German Socialism has become less doctrinaire;. French Socialism has drawn nearer to Marxianism under Guesdist influence; the Socialism of the I.L.P. has almost completely captured the English working-class movement. Between those parties which recognise Social Democracy as their basis, there exists not only international unity of organization but unity of programme.

This emerges clearly from the two first congresses of the new International. The Hamburg congress of 1923 succeeded beyond all expectations. There were present 630 delegates from 30 countries, representing 7,000,000 affiliated members. During the debates, which lasted five days, the following points were discussed: international action against international reaction, working-class policy on an imperialist peace, the eight-hour day, and the reform of international social legislation. But the most important achievement of the congress was the fusion of the London and Vienna groups and the adoption of the statutes of the new "Labour and Socialist International" (L.S.I.).

In the three years preceding the second congress of the new Second International (Aug. 1925) that organization was finally consolidated, and began to make itself more and more felt in international politics; its congresses have been held regularly at the prescribed intervals. There is no gainsaying the fact that direct action by the workers and the existence in all Western countries of a powerful Socialist party (either working within the Government or using its influence from outside) have to a very large extent determined the new policy which eventually produced the London agreement on reparations (1924) and the Locarno pact of mutual guarantee. To be convinced of this we have only to look for a comparison at the resolutions passed at Hamburg on the reparations problem and those at Marseilles on security. There can be no better instance of the influence which Socialism has acquired over the various Governments and of its emergence as the decisive factor in matters of international policy. (For bibliography see the article SOCIALISM.) (E. VA.)

THE THIRD (COMMUNIST) INTERNATIONAL

The Communist International (abbrev Komintern) is the international organization of the Communist party of all nations, founded in 1919. It is also called the Third International. In structure and programme it differs from the First and Second. Communism sympathises unreservedly with the first International, founded under the leadership of Marx and Engels, whose policy was essentially one of active revolution. As, however, its organization lacked a definite central point and had not its roots in party associations, its practical manifestation, the Paris Commune, was bound to fail. Lenin evolved his theory of revolutionary movement from the lessons of the failure of the Commune, and arrived at the conclusion that a successful revolution might begin as a spontaneous popular upheaval, but could only achieve and retain victory in the form of an organized and systematically controlled movement which could not only put down all opposition, but could at once organize the resources of the country.

Birth of the Third International. — In 1889, when the Socialist Labour movement had recovered its force, the Second International (see above) was founded. Up to 1914 this represented the international organization of the Socialist-Labour movement as a whole. The constructive importance of the Second International, from the point of view of the Communist parties, lay in the fact that it organized and grouped labour in trade unions, co-operatives, educational associations and political parties. The Second International already contained a Bolshevik opposition which refused to assimilate with the larger body. It was led by Lenin, who was a member of the International Bureau (B.S.I.) of the Second International in 1914. In 1914 the Second International collapsed. The Communists date the epoch of the Communist International from this moment. This epoch emerged out of a transitional period comprising the first three years of the war, during which Lenin struggled to "transform the imperialist war into a civil war." The foundations of the Third International were laid at the conferences of Zimmerwald and Kienthal in Switzerland. It only achieved real authority, however, when the leaders of the German army conceived the idea of making the Russian February revolution more extreme. The German supreme command brought Lenin and Trotsky to Russia in the fond hope that the fire of the Russian revolution which they were kindling in Russia would stop at the frontiers of Germany.

The Third International was not formally founded till March 1919. Up to that date the Communist parties believed that they would be able to break up the Socialist parties from within and transform the Second International bodily into a Communist organization in the tempest of the world revolution. Especially during the episodes of the Soviet republics in Bavaria and Hungary, and even after their collapse, during the labour troubles in Britain, Germany, Italy, etc., Moscow continually believed the outbreak of world revolution imminent every hour, and expected that the Socialist parties could be simply absorbed in the Communist parties. As it grew ever plainer that this hope (which at first was shared by Lenin) was Utopian, the Communists devoted even greater energy to their own International.

Fundamental Principles. — The following are their basic principles:

1. The Communist International is the organization of the Communist parties of each nation; it is therefore revolutionary. Its chief purpose is to accelerate the development of events towards world revolution. It rejects any compromise or co-operation with bourgeois parties. Similarly it rejects parliamentarism as a normal method of political development. In certain circumstances it advocates a unity of front with Socialist parties, including the Second International. This is, however, never more than a temporary and tactical co-operation. The Communist International is honest enough to state openly that it is only ready to support the Socialist parties so far as "the hangman's rope supports the convict." The aim of the Communist International is the creation of really revolutionary proletarian parties which shall be the advance guard of the revolution, and the combination of them in a great homogeneous international Communist party. Their headquarters are only "for the moment," as Lenin said, and probably not for long, in Moscow; later they will move to countries where the economic system and the proletariat alike are more advanced, so soon as one such country achieves a Soviet constitution.

2. The Communist International is no loose organization like the Second International, but an association bound together by a common programme and principles, and receiving its orders from a central organ, the bureau of the Third International. This central organ does not merely issue general rules of conduct, which may be carried out or not by the individual national parties according to their own convictions and views of the general situation; it lays down policy to the smallest details. The men at the head of Communist parties have been repeatedly changed under orders from the International, and tactics (*e.g.*, the question of co-operation with the Socialist parties, or the attitude to be adopted towards parliament) have often been defined in detail by "resolutions of the International bureau. This central organ of the Communist International is indubitably in close personal and political touch with the Russian Government, the Soviet of People's Commissaries.

3. The individual Communist parties are, despite a general uniformity, not all organized on the Russian system. The Communist parties of Western Europe are "open parties" which anyone may join. In some countries the Communist parties are proscribed by law. Wherever it is possible, a sort of military organization probably exists, exactly as in the Nationalist and Fascist parties.

4. In matters of internal policy the individual parties are, as already stated, strongly influenced by the Communist International, but there are great differences between the nations. In countries where democracy is firmly based and parliamentary tradition of long standing, the tactics of the Communist parties are correspondingly modified. Communists take part in parliament, bring forward legislative motions, etc.; at times they even co-operate with the Socialist parties. This is, however, only a temporary tactical move, the ultimate aim being always world revolution. The formation of the so-called "unified front" is a means to an end and a tactical move. The organized workmen in the trade unions are to be captured in such a way that the trade unions gradually come under the influence of the Communist parties.

The conditions of affiliation to the Communist International prescribe that every party which desires affiliation to the C.I. must develop a systematic and persistent Communist activity within the trade unions, works committees, co-operative societies and other mass organizations of workmen. Within these organizations it is necessary to organize cells, which by persistent and continuous work must win the unions, etc., to the cause of Communism. The Communist cells must be completely subordinated to the party as a whole.

Developments Outside the Industrial Proletariat. — Since the aim of the Communist International is world revolution, and since the state of the Continent of Europe has grown much less disturbed since 1921, the chief aim of the Communist International proved unattainable. The revolution had taken the offensive at isolated points, but failed to develop into a world-wide movement. The International therefore put forward officially the doctrine that sudden enthusiasm alone will not bring about world revolution; this must be achieved by a strict organization which must first be created. Such an organization, however, presupposes a compact Communist international unified front.

The Communist International began by continuing the traditional policy of the Second International. It desired to be an organization of manual labour. But in Russia the actualities of the situation soon forced the party to admit the peasants as members (at first only the poor peasant, later the medium peasant). A Peasants' International was founded in 1923, but made slow progress. Nevertheless, it then became possible to embrace the extremist agrarian movement — a matter of the greatest importance in countries where large estates are common. The rather unexpected pronouncement was therefore made that "the peasants have become the natural allies of the workmen." Thus a link was forged with what had been the oldest revolutionary movement in Europe. To-day, indeed, with the emergence of the peasants from

serfdom, their status and feelings, especially in central Europe, have changed radically. It is most unlikely that revolutionary feelings will ever become widespread among them.

Oriental and Colonial Propaganda.—Far more important is the connection between the Communist International and parties and currents of thought which may be described as the heart of the movement for national and economic independence among the colonial and semi-colonial territories of Asia and Africa. Countries such as India, China and the wholly independent Japan are already represented in the Communist International by considerable parties, although these parties differ very markedly from those of Western Europe. The psychological bases for intensive Communist propaganda in Asia are, firstly, the appalling conditions in the newly developed enterprises (women's and children's labour, long hours of labour, barrack conditions for workmen); and secondly—perhaps more important—the breakdown of the social structures of these countries. Throughout Asia the family is the basis of society. Industry destroys this, and nothing comes to replace it. But man, in the Far East, cannot live except as member of a community. He cannot grasp the idea of an abstract existence, secured simply by a contract of labour. Existence is uprooted, and all his instincts revolt against an economic system which attempts to make him into an individual. This revolt finds its plainest expression in the Communist movement, the essence of which is thus the resistance of the social instincts to the destructive influences of industrial life.

Furthermore, the restrictions placed by the United States and Australia upon immigration, the restrictions placed on Indian emigration to Africa, the unfortunate results which attended Chinese labour conditions in South Africa, combined with the insistence laid by the white races on the preservation of racial distinctions, have created a real and practical feeling of unity among all coloured races and nations throughout the world—a feeling which extends throughout all Africa and Asia, and as far as the negroes of America. In the face of this racial antagonism, Soviet Russia is the only Power to-day which stands on principle for racial equality and full equality of rights for all races on their own territory.

Thus Communist propaganda directed against the influence of European capitalists and the partizans of racial superiority in Asia has an easy task. Even Japan has been led by similar motives to a political *rapprochement* with Soviet Russia. Communist propaganda in Asia and Africa is therefore adapted to local conditions. Social and national considerations take the first place; less insistence is laid on the purely economic factor.

The resentment against capitalist exploitation, combined with the struggle against the Imperialist European Powers and against the United States, inevitably draws the leaders of those movements towards Russia, and thus towards the Communist International. This connection has been developed by special congresses to the oriental peoples (as that of Baku in 1920), and has certainly been exploited by the Russian Government to further Russia's traditional foreign policy in Asia. In all these countries the small tenant farmers are particularly susceptible to the allurements of the Communist programme.

In the last few years, however, the economic antagonisms have become intensified in the Far East also, especially in China. Chinese industrialists and capitalists have rejected the communistic influence, which has frequently made itself felt by very drastic means, and this class antagonism in the Far East has undoubtedly caused a weakening in the authority of the Third International. (E. LE.)

Results up to 1939.—The Communist International has been a bond between Soviet Russia and Communist parties in the capitalist bourgeois states. The aim has been the "formation of the front line of a world-revolution," and the hope was that no country with an active Communist Party would find it possible to participate in a European counter-revolutionary movement. Communists in capitalist Europe would prevent their countries undertaking war against Russia.

During the depression, which became serious in 1929, the situation changed. In Germany and Eastern Europe, dictatorships of the Right crushed the Communist parties, and parliamentarianism itself. In the three years immediately preceding the outbreak of the European war in 1939, Fascism developed into an international of the Right opposed to an international of the Left. In Spain the issue was fought out in the civil war of 1936–39. In France a "Popular Front" Government was formed, consisting of a political alliance between the various Leftist groups that all had a common opposition to Fascism. Soviet Russia encouraged such "Popular Fronts" as an antidote to Fascism and as a temporary substitute for active revolutionary movements in capitalist countries. But this distinction of international Leftists and international Rightists broke down with the Nazi-Soviet rapprochement of Aug. 24, 1939.

INTERNATIONAL ADVERTISING ASSOCIATION.

A federation of groups and individuals, organized to advance the interests of all who create, sell or use advertising, and to increase its usefulness to the consuming public. Founded in 1905, at a time when nearly all activities of organized advertising were centred in local advertising clubs, this organization began its existence as the Associated Advertising Clubs of America. The scope of membership soon became world-wide, as nearly a hundred advertising clubs in foreign countries became affiliated with the organization, and in 1914 the name was changed to the Associated Advertising Clubs of the World.

With the formation of national associations in various special fields of advertising, another category of membership was added to provide for affiliation of these groups, and in 1926 the organization was renamed the International Advertising Association. By this time, the British and continental associations had developed sufficiently to maintain strong organizations within their respective national borders, and in 1929 three separate associations were established. The American association became the Advertising Federation of America, representing the broad interests it serves in North America. Its objectives, at least in theory, are the same as those of the other divisions. They are:

(1) To provide a common forum and a central medium for co-operative effort on behalf of all interested in advertising.

(2) To elevate the standards of advertising practice and to combat any unfair competitive methods in its sale.

(3) To help increase the effectiveness of advertising as an instrument of distribution, with its resulting benefits to business and the general public.

(4) To determine and disseminate more accurate knowledge of the functions of advertising in business, and its social and economic values.

(5) To aid in raising the standards of education and training for advertising practitioners.

The Advertising Federation of America is a non-profit organization; officers and directors serve without pay. The membership is made up of national groups, local advertising clubs and sustaining members (individuals or corporations). Operation expenses are met by subscription dues of sustaining members and affiliation dues of national groups and advertising clubs.

The original National Vigilance Committee was appointed by the Advertising Federation in 1912, and local vigilance committees were appointed by advertising clubs to eliminate the kind of advertising that harms all who have a legitimate interest in honest advertising. These vigilance committees grew into the Better

Business Bureaus, of which there are now more than 50 established in principal cities of the United States and Canada. These bureaus are joined in a National Association of Better Business Bureaus, which is an affiliated member of the Advertising Federation of America.

In 1927 the Advertising Federation of America established a Bureau of Research and Education for the purpose of determining facts and disseminating information to help increase the effectiveness of advertising and promote a better understanding of its functions in business and society. This Bureau carries on a continuous program of research, with chief emphasis upon studies relating to the economic and social values of advertising.

INTERNATIONAL BUREAUX. The beginnings of the international movement may be traced back for more than a century. In 1823, for the first time, scientific congresses were held in Germany, to which representatives of other countries were invited. France, England and the United States soon followed this example. The need was soon felt for permanent bureaux to carry out decisions made. This was the origin of international bureaux, some official and some private bodies, dealing with the widest range of subjects: Agriculture, trade and industry; communications and transport; labour; medicine and hygiene; economics and finance; law and administration; arts and sciences; humanitarianism, religion, morals and education; sport and travel; feminism; international languages; bibliography and documentation; disarmament.

In 1909 there were 300 such bureaux; in Nov. 1912, 510. The World War was a serious hindrance to international life, and a large number of private bureaux were closed. After the war it took a long while to re-establish international relations. Many of these bureaux became inter-allied in character and several years passed before they again became really international.

An international handbook (*Annuaire* de la vie internationale) was founded in 1905, and published in 1905, 1906 and 1907 by the Institut international de la Paix. Another series was published in 1908–09 by the International Bibliographical Institute, and in 1912 by the Union of International Associations with the aid of the Carnegie Foundation. Since the World War the League of Nations has become the centre for international bureaux. Four editions of the Handbook of International Organizations have been published, in 1921, 1923, 1925 and 1926. Only such bureaux as replied to the questionnaire sent out by the secretariat of the League of Nations were included and, therefore, certain omissions were inevitable. Nevertheless, it can claim to give a fairly complete survey of international life at the present day. The last edition contains about 400 entries. This shows a decided decrease in the number of international bureaux since 1912. An examination of the dates of foundation discloses a still greater diminution; for, since 157 were founded after the World War and eight during the war, it follows that of the 510 bureaux recorded in 1912, 250 at most survived. These figures prove clearly the fatal effect of the war on international relations and the long time required for their re-establishment.

The geographical distribution of these international bureaux is of interest. Switzerland heads the list with 83 bureaux. Then comes France, 74; Great Britain, 63; Belgium, 60; the Netherlands, 40; the United States, 22; Germany, 19; Italy, 8; Austria, 6; Denmark, 6; Sweden, 4; other countries, 12, one in each. The importance of these bureaux varies greatly. Several will be found under separate headings (see RED CROSS, etc.). Bureaux founded on general treaties, that is to say, based on international conventions, signed by the various States, should be classed separately.

Bureaux Based on International Conventions (Addresses as in 1928).

Advisory committee for the international protection of nature Pounded, 1913. Seat, Basle: 22 Spitalstrasse.

Central international office for the control of the liquor traffic in Africa, 1919. Brussels: Ministry for Foreign Affairs.

Central Office for international railway transport, 1893. Berne: 36 rue Monbijou.

International bureau for the publication of customs tariffs, July 5, 1890. Brussels: 38, rue de l'Association.

International bureau of commercial statistics, 1913. Brussels: Ministry of Finance.

International bureau of the Pan American postal union, 1912. Montevideo.

International bureau of the telegraphic union, 1868. Berne: 1, Effingerstrasse.

International bureau of the universal postal union, 1874. Berne: 2, Schwanengasse.

International bureau of weights and measures, 1875. Paris: Parc de St. Cloud.

International Central-American office, 1908. Guatemala: 10a, calle Oriente, No. 1.

International commission for air navigation, July 11, 1922. Paris: 20, avenue Kléber.

International commission for the decennial revision of nosological nomenclature, 1900. No permanent secretariat.

International conference for promoting technical uniformity on railways, 1882. Berne: Federal Railway Department.

International conference for the study of epizootics, 1920. Paris.

International exchange service, 1886. Brussels: Belgian International Service, 45 rue des Longs-Chariots.

International hydrographic bureau, 1919. Monaco: 3 avenue du Port.

International institute of agriculture, 1905. Rome: Villa Umberto 1.

International institute of refrigeration, 1920. Paris: 9, avenue Carnot.

International prison commission, 1880. Groningcn (Netherlands).

International public health office, 1907. Paris: 195 Bd. St. Germain.

Office of the American international union for the protection of trade marks, Dec. 6, 1927. La Havane: 55, caile de Trocadero.

Permanent court of arbitration, 1899. The Hague.

United international bureaux of industrial, literary and artistic property, 1885. Berne: 7 Helvetiastrasse.

Article 24 of the Covenant has defined the relations of the League of Nations with international bureaux in the following terms:

"There shall be placed under the direction of the League all international bureaux already established by general treaties if the parties to such treaties consent. All such international bureaux and all commissions for the regulation of matters of international interest hereafter constituted shall be placed under the direction of the League.

"In all matters of international interest which are regulated by general conventions but which are not placed under the control of international bureaux or commissions, the secretariat of the League shall, subject to the consent of the Council and if desired by the parties, collect and distribute all relevant information and shall render any other assistance which may be necessary or desirable.

"The Council may include as part of the expenses of the secretariat the expenses of any bureau or commission which is placed under the direction of the League."

In practice these relations have been, up to now, somewhat vague. Four international bureaux have been placed under the direction of the League: The international bureau for assistance, from June 1921; the international hydrographic bureau, from Oct. 2, 1921; the central international office for the control of the liquor traffic in Africa, from Jan. 11, 1922; and the international commission on air navigation, from July 1922.

The bureaux which existed before the League of Nations was founded show no eagerness to surrender their autonomy and merely maintain contact with the international bureaux section of the secretariat of the League of Nations—of which M. Nitobé (Japan) was the director for seven years, and since 1927, M. Dufour-Féronce (Germany).

The League of Nations publishes a quarterly bulletin of information on the work of international organizations, containing a summary of the proceedings of the congresses and conferences held in the period. Further, the League of Nations allocates to the Union of International Associations at Brussels a subsidy for the publication of a collection of international resolutions; vol. i. appeared in 1923. It contains the resolutions passed by 15 conferences and congresses. When it is remembered how many bureaux there are, it will be realized that an enormous number of volumes will be required to contain all their resolutions. (E. CL.)

INTERNATIONAL CHAMBER OF COMMERCE, a world trade institution, with headquarters at Paris, established in 1920, following a preliminary meeting of the chief business interests of Belgium, France, Great Britain, Italy, and the United States, held at Atlantic City, N.J., in 1919. At the time of the Tenth General Congress and twentieth anniversary meeting of the Chamber, in Copenhagen, 1939, there were 34 countries with na-

tional committees, and 20 countries with organizations or business concerns otherwise affiliated—a total of 54 countries. This organization works for world trade promotion through advocacy of broad international economic policies, reduction of trade barriers, and providing a central clearing house for information and exchange of views on the part of business men.

The Chamber has a council exercising the functions of a board of directors; it meets usually at Paris three times a year. The president has the advice of an executive committee of members of the council on matters arising in intervals between council meetings. At the head of the departmentalized staff, which includes specialists in the principal fields of business and international relations, is the secretary-general.

In each country where there are numerous members of the international body there is a national committee, forming the essential link between the International headquarters and the domestic business community. Direct contacts between one national committee and another afford means for settling questions of special interest arising in the trade relations of the different countries. The British national committee has offices in London, and the American committee has offices in Washington. The national committees also maintain their own special representatives at the Paris headquarters.

Biennially the International Chamber holds a general congress in the capital city of one of the affiliated countries. The Copenhagen Congress in 1939 was attended by more than 1,000 delegates from Europe, Asia, Africa, Australasia, North and South America; previous congresses were held in Berlin (1937), Paris (1935), Vienna (1933), Washington (1931), Amsterdam (1929), Stockholm (1927), Brussels (1925), Rome (1923), London (1921).

In the membership are "organization members" consisting of chambers of commerce, trade and industry associations, and "associate members" consisting of individuals, firms and corporations engaged in business. In addition there is a special "Publications Service" membership for libraries. (C. D. S.)

INTERNATIONAL DATE LINE. If a voyager travel eastward to the Antipodes and thus "anticipate the sun," his timing will be 12 hours in advance; if another travel westward, then his will be as much in arrear. There will thus be a difference of 24 hours when they meet. To avoid confusion, mariners chose the 180° meridian as a convenient line (known as the International Date Line), at the crossing of which they changed the name of the day, forward if going west; backwards if going east. The International Date Line, largely consequent on American initiative, while retaining the 180° meridian in the Pacific, is arranged so as to bring the Aleutian islands and Alaska into the same dating as America, and certain of the South Sea islands into the same dating as Australia and New Zealand.

INTERNATIONAL HARVESTER COMPANY, THE, for many years a leader in the manufacture of farm-operating equipment, and also a large manufacturer of farm and industrial tractors and motor trucks, was originally formed in 1902 under the laws of New Jersey, and acquired at that time the farm-implement properties and lines of a number of old established concerns, notably the McCormick and Deering companies. In 1913 the company was divided into two organizations, International Harvester Company of New Jersey and International Harvester Corporation, the latter taking over the foreign business and the manufacture, in the United States, of tractors, motor trucks and other so-called "new lines." In 1918 the two companies were merged into the present International Harvester Company. Fifteen manufacturing plants and two twine mills were (1940) in the United States; and seven manufacturing plants and four twine mills in Canada, France, Germany, Sweden and Australia. In addition there were 195 branches and sub-branches located in the United States and Canada; while sales agencies were maintained in 153 principal centres in foreign countries. International Harvester Company leases iron ore mines in Minnesota, and operates coal mines in Kentucky. It owns steel furnaces and rolling mills in South Chicago, together with a by-product coke plant. There nere (1940) 21 affiliated companies which represented two main groups of activity: manufacturing and selling. Another activity is the purchase and sale of Manila fibre in both the Philippine islands and the United States. The company also owned a plantation in the province of Matanzas, Cuba, for the production of sisal fibre for binder twine.

As of Oct. 31, 1939, total current assets were $279,584,150, and total current liabilities were $36,113,628, leaving a net working capital of $243,470,522. Other financial statistics for the year ended Oct. 31, 1939, were: Net income, $12,980,059; surplus for the year, $470,615; total surplus, $79,841,269; and total assets, $402,433,637. The capital stock authorized is $100,000,000 7% preferred cumulative (par $100) and 6,000,000 shares of common (no par), of which on Oct. 31, 1939, there was outstanding $81,672,400 preferred and 4,245,729 shares of no par common with a stated value of $169,829,160. (S. B. W.)

INTERNATIONAL INSTITUTE OF AGRICULTURE. An international institution founded in 1905 on the initiative of Victor Emanuel III., king of Italy. A Californian merchant, David Lubin, convinced of the political as well as the economic importance of maintaining a proper balance between industrial and agricultural development, had come to the conclusion that in an age of international trade, of trusts, and concentrated capital, agriculture would be unable to hold its own in the economic arena against the coalesced forces of industry, commerce and finance unless organized effort, under government auspices, placed it in possession of a knowledge of crop conditions and available supply of farm products in all producing countries. He argued that on an international market, such as that for cereals, cotton, etc., prices are determined by world and not by national conditions, that information on these conditions was not then available for the farmer and the consumer as it was not procured for all countries through concerted, co-ordinated, international effort. Each country did as much or as little as it saw fit in the field of crop-reports, estimates, and statistics; reliable information was entirely missing for many important links in the chain of production; and this left the field open to the price manipulator whose activities affected injuriously farmers, traders, manufacturers and the public at large, disturbing the relative values of farm and industrial products, and replacing stability by speculation. After attempting in vain to draw the attention of persons in authority in the United States to the need of an initiative to ensure concerted effort in this field, Lubin came to Italy and laid his ideas before the king, who deeming the matter worthy of attention instructed his Government to enquire into it. On their favorable report the king took the initiative of inviting the Governments of all countries to Rome to consider the advisability of founding a permanent international organ for gathering, assembling and disseminating reliable information on the production and trade in agricultural staples and to study the needs of agriculture with regard to credit, co-operation, and marketing facilities. Thirty-six Governments answered the invitation, in May 1905 their representatives met in Rome, and signed a convention establishing in that city the International Institute of Agriculture.

The I I A., which opened its doors in 1908, was a pioneer in the field of international economic co-operation, being the first of those permanent official international organs which have since become so familiar a feature of the post-war world. Seventy-four Governments are affiliated to the institute which they support by annual contributions fixed by the convention of 1905 and subsequently raised to meet the depreciation of the currency in which they are paid.

In the field of crop reporting and agricultural statistics the I.I A. has achieved much; largely as a result of its efforts these government services have greatly improved in the several countries, which send in their data regularly to the institute at Rome where they are summarized and published at monthly and sometimes more frequent intervals, thus keeping all concerned regularly posted on the expansion or shrinkage of actual and prospective supplies of the staples. With the financial assistance of the International Education Board it undertook in 1925 to organize the first international agricultural census to be taken in 1930–31 by all countrics on a plan proposed by the institute to secure

comparable data. It follows the work done in the different countries in the science and practice of agriculture and in agricultural economics (credit, co-operation, marketing) its functions being informative. It promotes contacts in the agricultural world and for this purpose has organized a Permanent Committee of Agricultural associations and an International Scientific council consisting of 22 commissions of experts. It co-operates with the International Labour Office of Geneva through a Joint Advisory Agricultural committee on which both bodies sit; it is represented on the Consultative Economic Committee of the League of Nations. It has become the recognized world centre for co-ordinating congresses on matters of interest to agriculture: soil chemistry, forestry, seed breeding, wheat growing, fertilizers, etc.

The I.I.A. is governed by a permanent committee of delegates appointed by the affiliated governments, and by a general assembly of government delegates meeting, as a rule, once every two years in Rome. The staff is international. The I.I.A. publishes a monthly *Bulletin of Agricultural and Commercial Statistics*, a monthly *International Review* of *Agriculture*, a *Yearbook of Agricultural Statistics*, a *Yearbook of Agricultural Legislation*, and a large number of special studies. (O. R. A.)

INTERNATIONAL LABOUR ORGANIZATION, THE. The I.L.O.* is an official international institution created by the 1919 peace treaties. Its membership consists of countries (64 having been members immediately prior to the withdrawal from the organization of the axis powers). Each country is represented in the organization through its government, and its most representative organizations of employers and workers. The I.L.O. grew out of the movement for international legislation which developed before the war of 1914–18. During the inter-war period the International Labour conference adopted 67 international conventions and 66 recommendations establishing international labour standards which. having been approved after the most thorough and prolonged investigation and discussion by a world industrial parliament representative of governments. employers and workers, became one of the main formative influences upon the development of social legislation in many countries; the conference also served as an international centre for the discussion of common problems by responsible representatives of governments, employers and workers, in the course of which increasing attention was devoted after 1929 to the economic aspects of social policy and to the problem of full employment.

The I.L.O. remained an active body during World War II. The New York conference of the organization in 1941 was attended by representatives of 34 states, and gave the organization an official mandate "to give authoritative expression to the social objectives confided to it, in the rebuilding of a peaceful world upon the basis of improved labour standards, economic advancement and social security." President Roosevelt, addressing the closing session of the conference at the White House, referred to the "essential part" which the I.L.O. "with its representation of labour and management, its technical knowledge and experience," will have to play "in building up a stable international system of social justice for all peoples everywhere." Anthony Eden, replying on behalf of the British government at a debate in the house of commons on Dec. 2, 1942, expressed the hope that the I.L.O. will "become the main instrument giving effect to article 5 of the Atlantic Charter."

ORIGIN AND CONSTITUTION

The idea of protecting labour by international conventions may be traced back to the economic and humanitarian theories of a few thinkers who a century or more ago foresaw the necessity of international economic co-operation to forestall and minimize some of the inherent evils of modern industry, and causes of international discord and war. Notably Robert Owen, an English industrialist, who submitted memoranda on this subject in 1818 to the Congress of Aachen, and Daniel Le Grand, a French industrialist, who later advocated the adoption of identical protective measures in different countries for the protection of wage-earners, did much to sow the seed of a new order in international relations.

The ineffective conference convened by the German government in 1890 enunciated a few general principles, and finally in 1900 at the Paris exposition a private organization, encouraged and subsidized by certain governments, was established with headquarters in Basle, Switzerland, known as the International Association for Labour Legislation. The founders were the real pioneers who prepared the way for the I.L.O. in 1919. The association held a technical conference in 1905 to draft two labour conventions, one dealing with the limitation of night work for women in industry, the other with the prohibition of white phosphorus in the match industry. In 1906 a diplomatic conference adopted these drafts and a few states ratified them. Similarly in 1913 a technical conference drafted two conventions, one to prohibit night work for young persons in industry, the other for a 10-hour day for women and young persons, but the diplomatic conference called to validate them in the autumn of 1914 never met on account of World War I.

Labour in the Peace Treaties. — Prior to World War I, workers' organizations as a rule, with some exceptions in England and Germany, took little interest in protective labour legislation, or in legal machinery for dealing with labour and industrial conflicts. The war, however, made the working classes aware of the magnitude of the stake they had in national defense and national life. Early in and throughout the war there arose a demand that labour participate in making a peace at the end of the war that would compensate somewhat for the heavy sacrifices required of labour to win the war, viz., the A.F. of L. manifesto in America in 1914, the Leeds conference (1916) of trade unions of Allied countries, the Berne conference (1917) of trade unions of neutral countries and the Central powers, and the London (1918) conference of the Inter-Allied Socialists.

In Feb. 1919 at Berne the trade unions demanded a labour charter and suggested that the old association with its labour office should be transformed into a great official organization of international labour legislation. The peace conference had already on Jan. 29, as its first official act, constituted a commission for international labour legislation under the presidency of Samuel Gompers, "to enquire into the international means necessary to secure common action on matters affecting the conditions of employment." After 35 sittings in February and March the commission presented to the peace conference a draft convention creating a permanent organization for the international regulation oi labour questions. This draft was approved with minor amendments, and without waiting for the signature or ratification of the treaty of peace, the conference adopted on April 28, 1919, the second part of the report of the commission as a declaration, and ordered both convention and declaration inserted in the peace treaty. Thus under the title "Labour" they became sections I and II of part XIII of the treaty of Versailles, and the charter and constitution of the I.L.O. At the same time a preparatory committee was constituted to prepare for the first session of the International Labour conference to be held in Washington.

Principles and Procedure of the Organization. — The preamble of the constitution of the I.L.O. defines the principles on which it was founded as follows:

1. Universal peace based on social justice, and implying equitable conditions of labour.

2. Regulation of labour conditions to be accomplished internationally because the failure of any nation to adopt humane conditions of labour hinders their adoption in other countries.

Among principles and methods of special importance, article 41 of the constitution enumerates: labour not to be treated as a commodity; right of association; adequate wages for a reasonable standard of living; the 8-hour day and 48-hour week as a general aim; weekly rest day; abolition of child labour, and special protection of young persons; equal pay for equal work; equitable treatment of foreign workers; enforcement system to include women inspectors. These are not limiting but are merely guiding principles of policy.

The organization thus founded was implemented with another

"first" in history by its tripartite machinery for operations. It has two essential organs: The International Labour conference of representatives of the members, meeting "from time to time as occasion may require and at least once in every year"; and The International Labour Office controlled by a governing body, and serving as a permanent secretariat for both the organization and the conference. The tripartite or three-party character of the conference whereby the freely chosen representatives of employers, workers and governments debate annually and take action eventuating in international legislation in matters affecting their common interests as well as those of nine-tenths of the population of their respective countries is a real democratic feature that runs through the entire organization and all its processes. All the standing and special committees of the conference, the governing body and its committees, and delegations to other international agencies are set up and function as far as possible on this principle. Much of the success of the organization is properly attributed to the system of tripartite representation. It has brought the organization into a direct relationship with employers' and workers' organizations in the different countries, and through these organizations, with their members, and has thereby secured for decisions taken by the conference and the governing body a type and degree of public interest and support which have often been able to influence public policy effectively. The social forces and economic interests directly affected by decisions share through their organizations in the process by which the conference and governing body have reached these decisions and there has thus been enlisted in support thereof a preponderance of responsible and informed opinion.

The conference is composed of four delegates from each of the member states; two are government delegates, and two represent respectively employers and workers, chosen by the governments in agreement with the industrial organizations, if such organizations exist, which are most representative of employers and workers, as the case may be, in their respective countries. The conference deals with questions put on its agenda by the governing body, and sent to the member governments four months before the conference meets. After debating the questions on its agenda, and the annual report or world survey of labour conditions, presented by the director, the conference may and usually does adopt recommendations or draft conventions, by a two-thirds vote, and resolutions by a majority vote.

Conventions which are adopted by the conference in accordance with this procedure do not thereby become binding on the members of the organization, but, in virtue of the constitution, each member has two specific obligations in respect of such conventions. The first is absolute, the second conditional. The absolute obligation is that each member undertakes that it will, within the period of one year at most from the closing of the session of the conference, or, if it is impossible owing to exceptional circumstances to do so within the period of one year, then at the earliest practicable moment and in no case later than 18 months from the closing of the conference, bring the convention before the authority or authorities within whose competence the matter lies, for the engagement of legislation or other action. The conditional obligation is that each member undertakes that it will, if it obtains the consent of the authority or authorities within whose competence the matter lies, communicate the formal ratification of the convention and take such action as may be necessary to make effective the provisions of the convention. The obligation to submit conventions to the competent authorities applies in the same manner to all members without regard to how their representatives voted at the International Labour conference at the time when the convention in question was adopted. The "competent authorities" are the authorities competent to give effect to the provisions of the convention by legislation or whatever other action may be necessary to implement its provisions in a particular country.

In the case of a recommendation, member states agree to report the action taken, but with respect to ratified draft conventions, additional obligations ensue. Members must respect equally all clauses contained in a convention and allow mutual supervision of their application of these clauses. Art. 22 of the constitution requires an annual report to the conference with a list of measures taken for such application. These reports are compared and debated by the conference on the basis of its own committee's report on their examination, and the report of the director assisted by a technical committee of experts.

Number of Ratifications of Conventions

I. By Conventions:

1st Session (Washington 1919)
1. Hours of work (industry) 23
2. Unemployment 31
3. Childbirth 16
4. Night work (women) 31
5. Minimum age (industry) 29
6. Night work (young persons) 31

2nd Session (Genoa, 1920)
7. Minimum age (sea) 32
8. Unemployment indemnity (shipwreck) 28
9. Placing of seamen 27

3rd Session (Geneva, 1921)
10. Minimum age (agriculture) 20
11. Right of association (agriculture) 32
12. Workmen's compensation (agriculture) 23
13. White lead (painting) 27
14. Weekly rest (industry) 32
15. Minimum age (trimmers and stokers) 32
16. Medical examination of young persons (sea) 33

7th Session (Geneva, 1925)
17. Workmen's compensation (accidents) 19
18. Workmen's compensation (occupational diseases) 30
19. Equality of treatment (accident compensation) 36
20. Night work (bakeries) 12

8th session (Geneva, 1926)
21. Inspection of emigrants 21

9th Session (Geneva, 1926)
22. Seamen's articles of agreement 25
23. Repatriation of seamen 17

10th Session (Geneva, 1927)
24. Sickness insurance (industry, etc.) 16
25. Sickness insurance (agriculture) 11

11th session (Geneva, 1928)
26. Minimum wage-fixing machinery 22

12th Session (Geneva, 1929)
27. Marking of weight (packages transported by vessels) 35
*28. protection against accidents (dockers) 4

14th Session (Geneva, 1930)
29. Forced labour 20
30. Hours of work (commerce and offices) 10

15th Session (Geneva, 1931)
31. Hours of work (coal mines) 1

16th Session (Geneva, 1932)
32. Protection against accidents (dockers) rev. 1932 9

16th Session (cont.)
33. Minimum age (non-industrial employment) 7

17th Session (Geneva, 1933)
34. Fee-charging employment agencies 5
35. Old-age insurance (industry, etc.) 3
36. Old-age insurance (agriculture) 3
37. Invalidity insurance (industry, etc.) 3
38. Invalidity insurance (agriculture) 3
39. Survivors' insurance (industry, etc.) 1
40. Survivors' insurance (agriculture) 1

18th Session (Geneva, 1934)
41. Night work (women) rev. 15
42. Workmen's compensation (occupational diseases) rev. 14
43. Sheet glass works 7
44. Unemployment provision. 4

19th Session (Geneva, 1935)
45. Underground work (women) 22
46. Hours of work (coal mines) rev. 2
47. Forty-hour week 1
48. Maintenance of migrants' pension rights 4
49. Reduction of hours of work (glass-bottle works) 6

20th Session (Geneva, 1936)
50. Recruiting of indigenous workers 3
51. Reduction of hours of work (public works) 1
52. Holidays with pay 4

21st Session (Geneva, 1936)
53. Officers' competency certificates 9
54. Holidays with pay (sea) 3
55. Shipowners' liability (sick and injured seamen) 3
56. Sickness insurance (sea) –
57. Hours of work and manning (sea) 4

22nd Session (Geneva, 1936)
58. Minimum age (sea) rev. 6

23rd Session (Geneva, 1937)
59. Minimum age (industry.) rev. 2
60. Minimum age (non-industrial employment) rev. –
61. Reduction of hours of work (textiles) 1
62. Safety provisions (building) 2

24th Session (Geneva, 1938)
63. Statistics of wages and hours of work 10

Total 884

*Convention No. 28 (1929) in accordance with art. 23, par. 2 of the constitution ceased to be open for ratification Oct. 30, 1934 when No. 32 came into force.

THE I.L.O. IN OPERATION

The first conference was convoked at Washington in Oct. 1919, the

second, devoted to maritime questions, at Genoa in 1920, and then 23 successive conferences at Geneva, the 25th session meeting there in 1939. From these 25 conferences have come the total legislative product of the organization to date. They cover 22 years of its history and the building of the International Labour code which is the chief function prescnhed in the constitution of the organization. The standards of working conditions found in the 67 conventions adopted, to which the nations of the world arc invited to conform, "are not the arbitrary result of theory, but the product of labourious research, comparison and discussion," to quote Director John G. Winant's report to the 25th conference. The acceptance of this invitation to conform is indicated by the 884 ratifications registered up to July 1942. At least two-thirds of those in recent years are from non-European countries. The indirect influence of these standards is difficult to measure, but it is undoubtedly very great both in non-member states, and in the colonies, dependencies and mandated territory of member and non-member states alike.

The subject matter and extent of these conventions is shown by the titles in the table opposite, which gives the number of ratifications of each, by conventions, and by states.

It is worth noting that 15 conventions with 136 ratifications deal with social insurance, and 13 with maritime questions constituting the basis of an internationa! seamen's code which had received increasing acceptance after 1937. Also noteworthy is the fact that 50 nations have ratified some part of the labour code, and, of the conbers, 10 and 1 of the 28, 1939 388 or were ratifi' members, 15 or mo that the in force of by more showing "international obligations to maintain these standards were being increasingly accepted by the members of the organization." (See *International Labour Code 1939*, Montreal, 1941, a handbook of over 900 pages, arranging by subject matter the provisions of all conventions and recommendations adopted.)

Recommendations adopted by the conference receive the same intensive preparation and discussion as the conventions but do not involve a formal international obligation. They treat of measures still in the formative stage, or lay down a detailed policy not suitable in a convention. The influence of recommendations, however, may be just as far-reaching, as illustrated by one adopted in 1923 which suggested a sort of model code for labour inspection. Belgium, Spain, Sweden and Switzerland brought their systems at once in harmony with it; Rumania and Estonia made it the basis of new systems in their countries; later Cuba, Ecuador and Venezuela modelled their inspection services on it.

Ratifications.—Efforts to determine mathematically the significance of ratifications are usually difficult and unsatisfactory. For one thing the number of member states fluctuates. It was 55 at the end of the first decade, and has been as high as 64 since. A better measure of interest and participation on the part of members is the attendance at the conferences. In recent years that has averaged about 50 states with a large proportion having complete tripartite delegations. Even at the Extraordinary session in New York in 1941, no less than 34 nations were officially represented, and 22 delegations included workers' and employers' delegates. Perhaps less than one-third of the possible number of ratifications have been registered, but this is not surprising when we consider that a certain number of conventions could not be ratified by all states, despite their general character. Maritime conventions, for example, interest only states which have coasts and ships. In many states industry is of little importance, and labour legislation hardly exists, or conditions under which wage-earners work make certain conventions inapplicable. The International Labour Office has always taken the view that conventions cannot be ratified subject to reservations. The result has been to reduce the number of ratifications but to increase the effectiveness and uniformity of the obligations resulting from ratifications. Other reasons may delay ratification in countries where international action is in its infancy and there is a natural hesitation to contract obligations which seem to threaten output or competitive capacity in international markets. When weighted by indirect results and certain "intangibles" that are known to hare an important bearing on social justice and world peace, there can be no reasonable doubt but that substantial progress has been achieved.

Regional Activities.—The I.L.O. has developed regional machinery for handling inter-.American social and labour questions. This machinery takes the form of the labour conferences of the American states, the first of which met at Santiago de Chile in 1936, the second at Havana in 1939, and the third was invited at the Havana conference to meet in Mexico after the lapse of a suitable interval. The labour conferences of American states are supplemented by the inter-American conferences on social security established by a statute adopted by the first Inter-American Social Security conference at Santiago de Chile in Sept. 1942 Regional conferences of representatives of labour inspection services for western and eastern Europe respectively met at The Hague in 1935 and at Vienna in 1937. Proposals for Asiatic regional conferences have frequently been made.

Special **Conferences.**—Questions which cannot be adequately dealt with by representatives of employers and workers engaged primarily in manufacturing industry have been handled in special conferences. Maritime questions have been dealt with from the outset in special maritime conferences and a Joint Maritime commission consisting of shipowners' and seamen's representatives has been constituted to advise the Office regarding its maritime work. The meeting of the Joint Maritime commission, held in London in June 1942, adopted important resolutions regarding seamen's welfare and safety measures for seamen in wartime. A permanent agricultural committee was established in 1936 in order to secure representation for the complex social structure of agriculture, including agriculturalists in countries where the proportion of wage-earners in agriculture is relatively small.

The World Textile conference (Wash., 1937) and the World Coal conference (Geneva, 1938) are other examples.

The International Labour Office, a Research and Information Centre.—The work of the I.L.O. is not confined to preparing international conventions, securing their ratification, and watching over their application. The constitution gives it powers and charges it with duties of research, investigation and publication of facts on the state of the world with respect to labour, social justice and peace. In 1919 the Office became not only the secretariat of the conference, and of the governing body, without which neither would have accomplished a tithe of the work that both have achieved, but also a great clearing house of information on social questions not hitherto dreamed of by the strongest national governments. It has accumulated a special library in Geneva of over 200,000 volumes, the like of which exists nowhere else, and it has access to sources of information which no single government possesses, and greater freedom of expression. Its chief publications are: *International Labour Review* (Monthly), including since July 1, 1940, the weekly *Industrial and Labour Information; Legislative Series* (Quarterly), reprints and translations of laws and regulations; *Yearbook of Labour Statistics* (Trilingual), unemployment, hours of work, wages, prices, migration, etc.; *I.L.O. Yearbook*, survey of social and economic movements and labour legislation; *Industrial Safety Survey* (Quarterly), problems of accident prevention; *Studies and Reports,* vols. and monographs presenting the more elaborate and permanent results of research on industrial relations, economic conditions, employment and unemployment, wages, hours of work, industrial hygiene, safety, housing, co-operation, social insurance, agricultural labour and maritime labour, etc.; *Documents of the Conference* (annual), questionnaires and reports, final record, and texts of draft conventions and recommendations; *Report of the Director,* perhaps the most useful document of the year in international relations, comparable for the world as a whole to the president's annual message on the state of the union to congress in the U.S.A., and to the chancellor of the exchequer's budget speech in the house of commons in Great Britain; *Official Bulletin* (at irregular intervals), official information on the work of the I.L.O.; *Minutes of the Governing Body* (at irregular intervals), full records of discussions and decisions; *International Directory of Cooperative Organizations* (at irregular intervals, 10th in 1939).

Larger undertakings include: *Enquête sur la Production* (in French only), 1925, 5 vols., 6,000 pp.; *Legislación social de América Latina* (in Spanish only), 2 vols., 1928–29; *Occupation and Health,* two vol. encyclopaedia of industrial hygiene, 1930–34, 2,309 pp. supplemented by brochures regarding new discoveries, Processes, safeguards and remedies and by a practical manual, *Industrial Environment and Health, Practical Methods of Investigation,* 1936, 336 pp.; and *Constitutional Provisions Concerning Social and Economic Policy,* 1943.

On the basis of standards adopted by the Int. Lab. conference and by regional and technical conferences and committees, and of the information from all parts of the world collected in the discharge of its duties as a clearing house, the Office has been able to afford technical advice and assistance regarding labour legislation and administration to numerous governments, and has frequently detached members of its staff or of its expert committees to assist in the framing of legislation or administrative measures or to give evidence before royal commissions and similar bodies. In the field of social insurance, such advice and assistance has been given at their request to the governments of Great Britain, U.S.A., Argentina, Bolivia, Brazil, Canada, Chile, Cuba, Ecuador, Mexico, Peru, Uruguay, Venezuela, Greece, Turkey, etc. Office missions have co-operated in the early development of social legislation in countries such as China and Egypt.

The staff of the Office are not representatives of their own countries, but members of an international civil service whose duties are not national but international. On taking up their appointments they give an undertaking that they will exercise in all loyalty, discretion and conscience the functions that have been entrusted to them, will discharge their functions and regulate their conduct with the interests of the I.L.O. alone in view; and will not seek or receive instructions from any government or other authority external to the I.L.O. In order to assure the independence necessary for the discharge of their international duties they have been accorded diplomatic immunities. The Office's personnel numbered at one time over 400, drawn from 35 nations, all fluent in the use of French and English, and many commanding several of the 30 languages used in the translation of materials assembled for the various sections of the staff. During World War II the number was little more than a quarter as many but included a larger proportion of key men and women in the higher executive, planning and research field who were stationed at the working centre in Montreal, at the branch offices or

with the small nucleus left in Geneva, or assigned to field duty in many countries.

The Governing Body.—Originally composed of 24 members but by amendment of Art. 7 of the constitution, effective in 1934, the governing body is a board of directors composed of 32 (16–8–8) representatives of governments, employers and workers. Half of the government representatives are appointed by the members of chief industrial importance, and 6 of the 16 must come from non-European states. The governing body appoints the director, prepares the budget, and administers the Office through the director, and maintains contact with the governments of members dealing directly (Const. Art. 11) with ministries of labour and labour departments, and maintains contact with the organizations of employers and workers in the several member states. The director appoints the staff but is subject to the instructions of the governing body and responsible to it for the efficient conduct of the Office, and for such other duties as may be assigned to him. In normal years the budget has varied from 7,000,000 to 10,000,000 Swiss gold francs. For 1940 it was reduced to 9,000,000 which Director Winant at the 25th conference in 1939 pronounced "inadequate to enable the organization to meet the calls which are made upon it." It was again reduced, however, to less than 8,000,000, and by June 1940 the situation in Europe had become such that the basis for this calculation was destroyed. The budget expenditure for 1940 finally amounted to approximately 5,000,000, and that for 1941 to a little over 4,000,000. For 1942 and 1943 a regular budget of a little over 4,000,000 Swiss gold francs was approved and a supplementary reconstruction credit of 1,000,000 voted for each year.

The directors of the organization, appointed by the governing board have been: Albert Thomas, 1920–32; Harold B. Butler, 1932–38; John G. Winant, 1939–41; Edward J. Phelan, acting director, 1941– (confirmed with all the powers and responsibilities of director by the governing board at its 90th session, N.Y., Oct. 1941).

The Crisis of **the** War Years and **the** Postwar **I.L.O.** Program.— The I.L.O. was prepared to meet the strain of war. In Oct. 1938 the governing board discussed the policies and functions of the I.L.O. in a period of prolonged crisis or war, and in Feb. 1939 it decided unanimously to appoint an emergency committee (4–2–2) from its own membership, which could meet more easily and rapidly than the larger body, and if the emergency committee could not meet, the officers of the governing board were authorized to make any immediately necessary decisions. The emergency committee was reconstituted and continued by the governing board at its N.Y. meeting in 1941.

As anticipated, the continuation of independent work and the necessary communication between members and the Office soon became impossible in Geneva, and in Aug. 1940 satisfactory arrangements were made with the approval of the Canadian government for the transfer temporarily to the dominion of the personnel necessary to carry on the work of the organization. About one-fifth of the former Geneva staff was so transferred by Sept. 1940 and carried on its work in new quarters generously supplied by McGill university. Also as anticipated the war brought new and acute problems, led to an intensification of social and labour problems in some areas, and in others sped the formulation and application of social legislation.

In 1941 an Extraordinary conference of the organization met at New York, Oct. 27–Nov. 5 with a concluding session at the White House, Washington, D.C. on Nov. 6. The session was characterired by a general debate regarding postwar reconstruction, the keynotes of which may be recapitulated as follows:

The forces of freedom were victorious in 1919, but their victory was followed by the frustration which culminated in the early summer of 1940, partly on account of the failure to grapple adequately with the social and economic problems of the period following the last war. After World War II the problem of reconstruction will present itself against a background of world-wide economic and social changes unprecedented in scale and rapidity. Permanent international co-operation, especially in the economic and social fields, has therefore become even more imperative than during the inter-war period. Though such co-operation can be made effective only by the combined leadership of the great powers, its purpose must be wider than the interests of a few great powers, an economic democracy between the nations devoted to the organization of an economy of abundance in the common interest of the peoples of all lands being the only practicable alternative to the recurrence of world-wide wars. In such an economic democracy vigorous national action must be enlisted within the framework of a better organized international order. Such action must pursue constantly broadening social objectives. It can be effective only in so far as economic policy is regarded as essentially a technique for achieving social objectives. It is therefore essential that the experience of organized labour and organized management should be brought to bear directly upon the planning and execution of international economic policies. The I.L.O. is a unique instrument for that purpose, and should therefore be accorded **a** major role in the reconstruction of the postwar world. To that end it should be represented in any peace or reconstruction conference following the war.

At the close of this debate the conference adopted resolutions regarding postwar emergency and reconstruction measures, the Atlantic Charter, planning for the regulation of economic and social conditions in the mercantile marine, the establishment of a World Textile Office, and similar questions. The resolution on postwar emergency and reconstruction measures, in addition to suggesting the advisability of utilizing the experience and resources of the organization by associating the Office with such measures and having the I.L.O. represented in any peace or reconstruction conference following the war, also suggested that governments should set up representative agencies for the study of the social and economic needs of the postwar world which should consult with the appropriate organs of the I.L.O. The resolution endorsing the Atlantic Charter endorsed the social and economic principles of the charter, requested that the fullest use be made of the machinery and experience of the I L.O. in giving effect to these principles, and pledged the full co-operation of the I.L.O. in their implementation.

The New York conference was folloued by a meeting of the emergency committee of the governing body, held in London in April 1942, which, with the support of the representatives of the United States, British, Chinese and other governments, instructed the I.L.O. to scrutinize the plans and proposals made by governments or international agencies concerning economic and financial policy in the postwar world from the standpoint of their social implications. There is no other international institution that has had the same continuous contact with millions of the peoples of all lands for over 20 years, and has kept the sympathies and confidence of the workers' organizations, and won an increasing respect and confidence from employers' organizations and governments as well. Therefore its contribution to the next peace treaty, and to the herculean task of winning a durable peace after military operations cease must be correspondingly great.

INTERNATIONAL LAW, PRIVATE. Private international law means that law which is applied to the judicial adjustment of divergent private interests of an international character, whether between individuals or an individual and a state, as distinguished from the law applicable to the settlement of relations between states, which is called public international law. The court necessarily determines which state-law has to be applied, since, ex *hypothesi,* the persons interested or the circumstances are related to different states with differing systems of law which meet in competition. Hence comes the expression "conflict of law or laws" used by some writers.

Certain states which have codified most of their law have included some main rules of international law, *e.g.,* the statute introducing the German civil code, while other countries have been parties to treaties on the subject and in both classes the rules become binding on their courts. The most prominent series of conventions in Europe are those of The Hague, one being of Nov. 14, 1896, three of June 12, 1902 and four of July 19, 1905 selecting the rules on the validity of marriage and marriage contracts, their effects on property and status, divorce and judicial separation, guardianship of minors and interdicted persons, testamentary and intestate succession and parts of judicial procedure. It seems that Germany, Italy, Holland, Portugal, Rumania and Sweden are parties to all these conventions of 1902 and 1905 while Austria and Switzerland are parties to those on the validity of marriage, divorce and separation and guardianship of minors; but France and Belgium have since renounced on grounds of public order.

In Ibero-America we have the several treaties of Montevideo of 1889 signed by the republics of Argentina, Bolivia, Paraguay, Peru and Uruguay, dealing with domicil, capacity, family rights, property, juridical acts, marriage settlements, successions. prescription, jurisdiction, commercial law, maritime law, bills of exchange, bankruptcy, etc,

Personal Law.—Great Britain did not sign any of the above Hague Conventions, and this chiefly was for the very good reason that personal law, as conceived by the signatories, means the law of the nationality, while in Great Britain and nearly all the British colonies it means the law of the domicil; the whole basis therefore of these conventions was alien to the theory that a man's personal law by which he means and expects his rights to be governed is that of his domicil, *i.e.*, the country in which he has established himself and with whose conception of legal relations he must be deemed to have identified himself. The opposing theory treats him as carrying about with him the law of his nationality.

"Domicil" (*q.v.*) primarily refers to the domicil of his father at the child's birth, known as his domicil of origin, which he can change; but he must actually remove himself and become resident in another country, intending that to be his new home with no present intention of leaving it, so that there must be a combination of fact and intention. An English court judges acquisition of a new domicil without regard to the iaw of the place where the new abode is constituted (*Casdagli* v. *Casdagli,* 1919, A.C. 145; *In re Annesley, post).* The English law cannot conceive of a man without a domicil, and therefore when in doubt as to the acquisition or abandonment of a new one. it treats him as having still or reverting to his domicil of origin. Some foreign systems, *e.g.*, the Argentine, when it cannot discover his domicil, treats him as domiciled where he actually is.

Renvoi.—The necessity of applying foreign law to the solution of the forensic difficulties which arise between two systems of law, one of which applies the personal law of nationality and the other that of the domicil, has given birth to the doctrine of *renvoi,* which chiefly concerns successions. The problem, first recognized in France in the Forgo case (Clunet, 1883, 64), may be stated as follows. When an Englishman dies domiciled in France, the French court applies to his succession the law of his nationality, that being his personal law as conceived in France, and it treats the English law, including English international law, as being that personal law of nationality, although in fact there is strictly speaking no English law for nationals. It discovers that an English court would apply the law of the deceased's domicil to the succession, that being in fact the internal law of France, with the result that the French court under the doctrine of *renvoi* applies the French internal law to the succession. In the case of *In re Annesley,* 1926, Chancery at p. 707, the ccurt recognized and followed the French law of *renvoi,* but the judge suggested that the same result would follow by rejecting the same doctrine as being part of English law; which means that if the succession was open in England instead of France, the English court would apply the French internal law as being the law of the domicil and would not enquire whether or not the French court would throw back to the internal law of England as the law of the deceased's nationality. In the result, both courts would apply the same law of succession and this solution has the virtue of simplicity, but it is not yet settled that England rejects the doctrine as being part of its own law.

While domicil formed the usual criterion in the later middle ages and onwards, it was subjected to a considerable reverse by the Civil Code of the French, commonly called the Code Napoleon, under the influence of intense national feeling, and nationality now governs France and the many nations which have followed her lead, *e.g.*, Belgium, Germany, Holland, Italy, Spain, etc., though it is nowhere possible entirely to discard the former rule in all legal relations England and the States and colonies which derive from her, as well as Scotland and Ireland and the United States, adhere to the domicil theory and this is the case in most Spanish-American States, chiefly for the reason that States receiving large numbers of immigrants find it the most convenient rule.

In commercial matters English courts were slow to recognize personal law and as late as Lord Eldon's time they held that the capacity of a person to contract depended on the law of the place where the contract was made. Perhaps unfortunately, this has since been discarded in dicta of the personal law, but in the United States this is not universally the case, while Dicey in his *Conflict of Laws* suggests that the old rule still applies to ordinary commercial contracts.

By German law, "if a foreigner in Germany enters into a legal transaction for which he is not competent or is restricted in his competency, he is to be deemed competent as to such transaction to the extent that he would be competent by German law This, however, does not apply to transactions relating to family rights or succession or dispositions of foreign immovables." It would seem from Pillet *(Droit Int. Privé,* 176) that after some vacillation the French decisions only protect contractants on French soil in the case of fraud by a contracting foreign incapable. Guardians, tutors, curators of minors have authority from the country which appoints them, whether it be that of the domicil or the nation. There is some doubt whether in France a guardian can trade on behalf of a foreign minor (Valery, *Droit Int. Privé,* 893).

A British court will not entertain a petition for divorce unless the husband is domiciled within its jurisdiction; but many foreign countries, basing competence on residence, apply the national law of the parties. There is some doubt whether countries like Spain, which does not admit divorce *a vinculo* within its jurisdiction, will recognize the divorce of a Spanish subject by a foreign competent court. Legitimation by subsequent marriage of the parents depends also on the personal law of the father as determined either by domicil or nationality. English law, in the absence of express contract, considers the law of the husband's domicil to govern the effect of marriage and that of a settlement of personal property; but this domicil may be a new domicil chosen to be the immediate home of the newly married, in each case known as the matrimonial domicil *(Peters* v. *Quebec Cite',* 1908, 33 Quebec Sup. Court. 361; *Union Government* v. *Larkan,* 1916, S. Africa, A.D. 212).

Personal property is for the purpose of succession treated as forming one mass located in the place where the succession is "opened," *i.e.*, generally the domicil of the deceased. Until 1926, few countries except England and those deriving from her, caused real property to descend in a different manner from personal property. These conditions, however, have been altered by the Administration of Estates Act, 1925, real property and personalty now descending in the same manner. It is remarkable that, while property relations as between husband and wife are governed by the law of the matrimonial domicil, although this be abandoned *(De Nicolls* v. *Curlier,* 1900, A.C. p. 33), this does not apply to rights of succession, which change with change of domicil.

Lex Situs.—The law of the territory in which they are situate governs immovables in almost every particular, although English practice in the sphere of jurisdiction admits of certain personal processes such as injunction and accounting. An action for the sum of money secured by a foreign mortgage is also allowed, for the reason that the security is subsidiary to the debt, but the court will go further'and even order the foreclosure of the mortgage in default of payment. This cannot often happen since in some countries, such as Ireland, foreclosure is unknown and in many colonies the right is severely restricted, while the system of conveyancing, where it does not consist in conveying the estate to the mortgagee, does not admit of foreclosure. This is necessarily the case under the Torrens system of registration *(see* Burge, *Colonial and Foreign Laws,* v. pt. ii., ed. W. A. Bewes). By way of illustrating the principal rule, the law which, in the absence of agreement, imposes community of assets on husband and wife cannot in the Cape be evaded by a postnuptial agreement valid in Natal where it was made *(Union Government* v. *Larkan,* supta). It may in passing be said that property given to a wife for her separate use is not within the classes of property to which community applies *(De Serre* v. *Clarke,* L.R. 18 Equity, 587); but this decision may be open to exceptions.

Lex **Loci Actus.**—The form of a document and the validity of its execution, *i.e.*, its extrinsic qualities, are governed by the law of the place where it is executed, in the absence of any evidence to the contrary. Its intrinsic qualities, which affect the country where its performance is to take place, are controlled by the law of the latter place; where it will not be enforced if it is *contra*

bonos mores, contrary to any positive law or public policy (see *Law Quarterly Review* for 1921, xxxvii. 3, 5). There also the capacity of the parties, etc., may be considered. In countries where a system of registration of documents is essential for complete security or, as sometimes, for any operative effect, it is necessary that the document should be such as can be registered in the place where it is to take effect. This is specially so in the case of immovables. There is an exception to the general rule in the case of a will of personal property; for Lord Kingsdown's act of 1861 legalized three forms of will made by a British subject abroad besides that of his last domicil, viz., that of the place where the will is made, that of the testator's domicil at the time when the will is made, that of his domicil of origin, when in the British dominions; but the last does not apply to a will offered for proof in Great Britain. Another exception occurs in England where an instrument affecting land within the meaning of the Statute of Frauds must conform to its requirements wherever it is made (*Leroux* v. *Brown*, 1852, 12 C.B. 801). Not all nations are as strict as the English in rejecting documents in foreign form affecting immovables.

Lex Loci Contractus.— The law of the contract is generally the same thing as the law of the instrument. If they differ, an English court would enquire what is the proper law of the contract, with a tendency to favour the place where it is to be carried out (*lex loci solutionis*). This again is chiefly a matter of the intrinsic qualities of the contract. The contract of marriage must usually conform to the law of the place of the marriage, but exceptions are allowed under such laws as the Foreign Marriage Act 1892, which, however, in the absence of treaties, are not always binding on other Powers.

The law of the practice of the court (*lex fori*) naturally governs any action whether of an international character or not, and this rule includes the form and remedy. Prescription and limitation of actions are usually treated as belonging to this law, but when a right has become non-existent by the law which properly governs it, it will not be enforced anywhere else.

Foreign Judgments.— Rights which have been declared by a judgment of a competent foreign court have sometimes to be enforced in another country. In England such judgments, whether of foreign or colonial courts, are enforced by action, treating the sum of money awarded as due under the fiction of a promise to pay. Unlike the practice in many countries, no enquiry is allowed into the merits; but a defence is open on the ground of absence of jurisdiction, and since the action is on contract, defences as on contract are allowed. Declaratory judgments of rights of property are founded on territorial jurisdiction, while those of status depend on domicil or nationality as the case may be. No *exequatur* is required in either case. Judgments in *personam* when to be enforced abroad, *e.g.*, on contract or for a wrong, must be clothed with an order called *exequatur*, *i.e.*, "let it be carried out," and then the original judgment is executed and no new judgment is pronounced, as in England. This system in a reciprocal form has been introduced into the British empire under the Administration of Justice Act 1920, and by c. 33 of the same year, reciprocal enforcement of maintenance orders (other than affiliation orders) was provided for. It is to be noticed that many countries assume greater jurisdiction than is acquiesced in by other countries, but this excessive claim is, of course, valid for internal purposes. Under the doctrine of reciprocal treatment as between States, so popular on the Continent, the foreign courts will often refuse to enforce an English judgment except in the English way, which involves a new action. (W. A. B.)

BIBLIOGRAPHY.—The best authority on the history of private international law to the end of the 18th century is Lainé, *Introduction au droit international privé* (2 vols., 1888). *See* also L. v. Bar, *The Theory and Practice of Private International Law* (Enp. trans. 1892); Bate, *Notes on the Doctrine of Renvoi* (1904); J. Westlake, *A Treatise on Private International Law* (7th ed., 1925); A. V. Dicey, *Conflict of Laws* (ed. *A. B.* Keith, 4th ed., 1927).

UNITED STATES

The topic under consideration is almost universally called the conflict of laws, following the usage of Judge Story's classic treatise. Since each State of the United States is from the point of view of its law independent of each other State, and since every transaction of importance has an inter-State character, occasions for the application of the principles of private international law are much more frequent than in England and the law has therefore been much more fully developed by the courts.

Jurisdiction.— At the outset one is met with the question of jurisdiction, that is (for this purpose) the power of a State, with or without judicial action, to create legal interests which other States will recognize and enforce. Jurisdiction may be obtained in three ways: by physical power, by legal relation and by submission.

(a) Within the territory of a nation or State there is jurisdiction over every person or thing in it, except as such jurisdiction is prevented by some principle of public international law, such as the protection extended to ambassadors. Where, however, a thing is carried into a State by the act of God, as by a tempest, jurisdiction, at least for some purposes, is not exercised over it till the owner has a chance to remove it, and the same rule is followed where property is brought in by a wrongdoer, without the will or procurement of the owner (*Edgerly* v. *Bush*, 81 New York 199). A full jurisdiction is not exercised over a vessel temporarily in port (*Hays* v. *S. S. Co.*, 17 How. [U.S.] 596; *Brown* v. *Duchesne*, 19 How. [U.S.] 183) or over railroad cars passing through the territory (*P. P. Car Co.* v. *Pennsylvania*, 141 U.S. 18).

(b) The relation of allegiance to a nation, or of domicil within a State even though it is a division of a nation, is a ground for exercising jurisdiction. Thus, the United States may impose a tax upon its citizen (*Cook* v. *Tait*, 265 U.S. 47) and any State upon its domiciliary (*Kuntz* v. *Davidson County*, 6 Lea [Tenn.] 65); so a court of one of the United States may render a judgment against its domiciliary (*Henderson* v. *Staniford*, 105 Massachusetts *504*).

(c) Submission to jurisdiction may be established by express consent of the subjected person, as by appearance in court or by accepting the terms of a contract to that effect (*Grover and Baker S. M. Co.* v. *Radcliffe*, 137 U.S. 287). Submission may also be established by proof that the subjected person has voluntarily caused an event to happen within the State, and is thereby submitted to any legal consequence of the event; or has permitted a thing in which he has property to be within the State, whereby his interest in the thing is subjected to the jurisdiction of the State.

Jurisdiction to reach by garnishment a claim due to one's debtor rests upon jurisdiction over the garnishee (*Harris* v. *Balk*, 198 U.S. 215).

Jurisdiction to grant a divorce depends upon the domicil of the spouses. Ordinarily both have the same domicil. A wife may, however, acquire a domicil separate from her husband (*Williamson* v. *Osenton*, 232 U.S. 619), and in that case neither party can obtain a legal divorce at a new domicil unless the other spouse has consented to the separate home or by his misconduct caused it, or has appeared in the proceedings (*Haddock* v. *Haddock*, 201 U.S. 562; *Bonner* v. *Reandrew*, 203 Iowa 1355).

Marriage is governed in the last analysis by the law of the domicil of the parties; but it is based upon a valid agreement of marriage, and the validity of that agreement is governed by the law of the place of marriage (*Commonwealth* v. *Lane*, 113 Massachusetts *458*). Legitimacy is governed by the law of the domicil of the parent with whom the relation is to be established, whether at birth (*Moore* v. *Saxton*, 90 Connecticut 164) or from the later time of legitimation (*Scott* v. *Key*, 11 Louisiana Annual 232).

Property.— All immovable property is governed in all respects by the law of the country where it is situated (*Clark* v. *Graham*, 6 Wheaton [U.S.] 577). The transfer of title to chattels *inter vivos* is governed by the law of the place of the chattels at the time of transfer. This title once accrued will ordinarily be recognized in any State into which the chattels are brought (*Emery* v. *Clough*, 63 New Hampshire 552). Where, however, a mortgage or other lien on a chattel is created in one State, and all require-

ments of the law of that State are satisfied, it is held in some States that if brought into another State the lien will not be recognized unless the requirements of the second State for the recognition of such liens are satisfied *(Hervey* v. *Rhode Island Locomotive Works,* 93 U.S. 664), but the preferable and prevailing view is otherwise (*Langworthy* v. *Little,* 12 Cushing [Mass.] 109). The administration of a trust of chattels is governed by the law of the State where the creator of the trust intended the trust to be managed (*Greenough* v. *Osgood,* 235 Massachusetts 235). The inheritance of movables, while governed in the last resort by the law of the situs, is determined by the law of the domicil of the deceased owner at the time of his death *(Moultrie* v. *Hunt,* 23 New York 394). Upon the marriage of an owner of movable property, the other spouse acquires such an interest in the property then held as is given by the law of the husband's domicil at the time of marriage *(Harral* v. *Harral,* 39 New Jersey Equity 279).

Contracts. — Capacity to enter into a contract, including a contract of marriage, is governed by the law of the place of contracting *(Milliken* v. *Pratt,* 125 Massachusetts 374); and the form necessary for the validity of the contract is governed by the same law *(Scudder* v. *Union National Bank,* 91 U.S. 406). There is great dirierence of opinion as to what law determines whether an agreement which is in due form is legally binding. Some courts hold that this is determined by the law of the place of contracting; some, by the law of the place of performance; some follow the English rule, and determine the validity of the contract by the law intended by the parties. The first view is the best accredited, and is likely to prevail.

Questions as to the performance or breach of a contract depend upon the law of the place of performance. Thus the acts required of sureties are those laid down at the place for the principal to perform *(Cox* v. *U.S.,* 6 Peters [U.S.] 172). What constitutes payment (*Graham* v. *Bank, 84* New York 393), the time for payment *(Stebbins* v. *Leowolf,* 3 Cushing [Mass.] 137), the allowance of days of grace on a note (*Bowen* v. *Newell,* 13 New York 290), the proper medium of payment *(Benners* v. *Clemens,* 58 Pennsylvania 24), the rate of interest and the measure of damages, all depend upon the law of the place of payment. The form of protest for non-payment of a bill is also regulated by the law of the place of payment, but the necessity for notice of non-payment of a bill and the nature of the notice depend upon the law of the place where the obligation arises (*Aymar* v. *Sheldon,* 12 Wendell [N.Y.] 439). The validity of an assignment of a contract is determined by the law of the place of assignment *(Miller* v. *Campbell,* 140 New York 547).

Wrongs. — The law governing an act or its result is the law of the State where the act or resulting event took place; the State where any proximate result of an act takes place may make that event wrongful. Whether the result was a legal wrong is determined by the law of the place where it happened (*American Banana Co.* v. *United Fruit Co.,* 213 U.S. 347); whether the act itself was justified is determined by the law of the State where the actor did his act.

Judgments. — A foreign judgment creates an obligation which is both recognized and enforced in another State, whether the judgment is at law or in equity, and whether it is for the plaintiff or the defendant; and it is equally binding though a suit between the same parties with the same subject-matter was pending in the other State, and even if proceedings were first begun there *(Paine* v. *Ins. Co.,* 11 Rhode Island 411); nor do mistake of law or of fact or irregularity of local practice in the foreign court affect the binding nature of a judgment. It is often said that a foreign judgment may be impeached for fraud, and indeed it may usually, like a domestic judgment, be so impeached in equity; but by the better view it cannot be so impeached at law, though this doctrine is sometimes referred to the Constitution and confined to inter-State judgments (*Christmas* v. *Russell,* 5 Wallace [US.] 290; Gray, J., in *Hilton* v. *Guyot,* 159 U.S. 113). The judgment must be for a sum of money of ascertained amount; if the amount is uncertain the judgment cannot be enforced; but it may be for an amount payable from time to time, like a decree for alimony, and it will then be enforced as to all overdue payments *(Lynde* v. *Lynde,* 181 U.S. 183).

A judgment for the doing of an act, except the mere payment of money, is not directly enforceable in another court, even of the same State. It is therefore impossible to enforce a foreign decree that an act be done by the defendant, such as making a conveyance, either by decreeing the conveyance without judicial investigation or by regarding it as made *(Bullock* v. *Bullock,* 52 New Jersey Equity 561).

Administration. — Estates administered by a court are administered in accord with the law of the State where the administration is had. Each State may administer such things only as are within its jurisdiction; so that in the case of an estate part of which is found in each of two or more States administration must generally be undertaken independently in each State. In the case of administration of the estate of a deceased, the executor or administrator gets power to collect claims owing to the deceased from, and is obliged to pay claims against the deceased by, the statutes of the State of his appointment; and he can neither sue nor be sued on such a claim in another State *(Johnson* v. *Powers,* 139 U.S. 156). In cases, however, where no domestic administrator has been appointed and there are no local creditors to be prejudiced, a foreign administrator may collect claims due the deceased (*Wilkins* v. *Ellett,* 108 U.S. 256).

Recognition and Enforcement of Foreign Rights. — A right having been created by the appropriate law, the recognition of its existence follows everywhere (Folger, J., in *King* v. *Sarria,* 69 New York 24). So a body created as a corporation in one State will be recognized as such in another State *(Bank of Augusta* v. *Earle,* 13 Peters [U.S.] 519). This is true even though the right so created is absolutely illegal in the State which recognizes it. Thus, a polygamous or incestuous marriage contracted in a State where it is valid will be recognized as a legal status of that kind even in a State where it is illegal (*Sutton* v. *Warren,* 10 Metcalf [Mass.] 451); though it need not be treated as a so-called "Christian" marriage would be. It is merely recognizing a foreign fact. A slave for the same reason must be recognized as such even in a free State. It is true that if a slave comes into a free State he cannot be restrained by his master; not because he ceases to be a slave, but because in such a State there is no right in a master to restrain a slave (Ware, J., in *Polydore* v. *Prince,* Ware [U.S. district court] 402).

Though a foreign right will always be recognized as existing, it does not follow that it will be given any legal force. No foreign right will be enforced unless the law of the State so provides. Where a right has once been created by the proper law it will be enforced in another State even where it would not originally have been created by that State on the same facts *(Greenwood* v. *Curtis,* 6 Massachusetts 358), but enforcement of a foreign right will be denied where it would be illegal to carry it out, as where the right was created in evasion or fraud of the domestic law *(Hill* v. *Spear,* 50 New Hampshire 253), or against public policy or morality *(Emory* v. *Burbank,* 163 Massachusetts 326). So where a foreign marriage is valid and the spouses come into a State where it is regarded as incestuous they may not cohabit as man and wife in that State *(State* v. *Brown,* 47 Ohio 102).

No governmental right of another State will be enforced, like a right to taxes or a claim for a criminal fine: and for the same reason an alimentation claim created to save the State from the burden of support of a dependent person will not be enforced in another State.

Remedy. — The remedy afforded for the enforcement of a foreign right is such only as a State may choose to allow. The State may open its courts to whom it pleases; but foreigners are usually allowed free access to courts *(Roberts* v. *Knights, 7* Allen [Mass.] 449). No action can be brought if it may bring into question the title to foreign land; nor can a foreign right be enforced which requires for its proper enforcement a procedure which the court of forum cannot provide.

Where suit is brought in a foreign court, all matters relating merely to the remedy are determined by the law of the forum.

Thus the law of the forum determined the proper parties, the proper form of action (*LeRoy v. Beard*, 8 How. [U.S.] 451), the exemptions from attachment (*Mineral Point* R.R. v. *Barron*, 83 Illinois 365), the right to set-off (*Gibbs* v. *Howard*, 2 New Hampshire 296), the right to confess judgment (*Hamilton* v. *Schoenberger*, 49 Iowa 385). The law of the forum determines whether action is barred for usury (*Gale* v. *Eastman*, 7 Metcalf [Mass.] 14) or for failure to comply with the statute of frauds, where usury or the statute of frauds goes rather to the remedy than to the right. If it is claimed that remedy is barred by the statute of limitations, it is the statute of the forum which decides (*Townsend* v. *Jemison*, 9 How. [U.S.] 407), unless indeed some statute which has power to do so has actually extinguished the right. That may happen where it was a condition of the right at the time of its creation that it should be exercised within a certain time (The Harrisburg, 119 U.S. 199).

The rules of evidence applied are those of the forum; and so presumptions of fact are determined by the law of the forum (*Hoadley* v. *Transportation Co.*, 115 Massachusetts 304). The measure of damages, since it has to do with the nature of the right of action, must be determined by the law of the State where the action arose; it is not a question of remedy (Paynter, J., in R.R. v. *Whitlow*, 105 Kentucky 1; see *Meyer* v. *Estes*, 164 Massachusetts 457). So interest, where given by way of damages, is regulated by the law of the place of payment, not of the forum (*Peck* v. *Mayo*, 14 Vermont 33; *Healy* v. *Gorman*, 15 New Jersey 328; *contra*, *Ayer* v. *Tilden*, 15 Gray [Mass.] 178).

Where, however, a statutory regulation of damages amounts not to a settlement of the rules for measuring compensation but to a limitation (irrespective of the amount of damage) of the amount allowed to be recovered, it has to do with remedy rather than with right, and is governed by the law of the forum (Finch, J., in *Wooden* v. R.R., 126 New York 10; compare R.R. v. *Babcock*, 154 U.S. 190).

BIBLIOGRAPHY.—The classical treatise is J. Story, *Conflict of Laws* (1st ed. 1834); the latest and most trustworthy is H. F. Goodrich, *Conflict of Laws* (1928). See also "Restatement of the Conflict of Laws," *American Law Institute*. (J. H. BE.)

INTERNATIONAL LAW, PUBLIC, the general term for the law governing the relations and intercourse of States *inter se*. The parties are States and not nations, so that the word "international" does not accurately define the scope of the subject. Nor do authors always confine themselves to its proper limitation. Thus the rules relating to nationality and naturalization, extradition, patents, trade marks, etc., which affect States on the one side and foreign persons on the other, are generally included among the subject-matter of international law. There is a special branch of international law, known as Private International Law (*see* INTERNATIONAL LAW, PRIVATE), which deals exclusively with the relations of persons belonging to different States, in which States as such are not parties.

The term "international" was first used by Bentham, who observed: —

"The word *international*, it must be acknowledged, is a new one; though, it is hoped, sufficiently analogous and intelligible. It is calculated to express in a more significant way the branch of law which goes commonly under the name of 'law of nations,' an appellation so uncharacteristic that, were it not for the force of custom, it would seem rather to refer to internal jurisprudence. The chancellor d'Aguesseau has already made, I find, a similar remark; he says that what is commonly called *droit des gens* ought rather to be termed *droit entre les gens*." (Introduction to the *Principles of Morals and Legislation.)* But Franciscus and Victoria had already in the 16th century used the Latin form *jus inter gentes*.

There has been much controversy as to the aptness of the use of the word "law" in this connection. "Strictly speaking," observed Lord Chief Justice Coleridge in his judgment on the Franconia case (R. v. *Keyn*, 2, Ex. *D.* 63), "international law is an inexact expression, and it is apt to mislead if its inexactness is not kept in mind. Law implies a lawgiver and a tribunal capable of enforcing it and coercing its transgressors, but there is no common lawgiver to sovereign States, and no tribunal has the power to bind them by decrees or coerce them if they transgress. The law of nations is that collection of usages which civilized States have agreed to observe in their dealings with one another. What these usages are, whether a particular one has or has not been agreed to, must he matter of evidence. Treaties and acts of States are but evidence of the agreement of nations, and do not, in England at least, *per se* bind the tribunals. Neither certainly does a consensus of jurists, but it is evidence of the agreement of nations on international points, and on such points, when they arise, the English courts give effect as part of English law to such agreement." Sir James Stephen took a similar view.

This was declared by Lord Russell of Killowen to be based upon Austin's definition, which was too narrow and relied too much on force as the governing idea. "If," he added, "the development of law is historically considered it will be found to exclude that body of customary law which in early stages of society preceder; law, which assumes definitely the character of positive command coupled with punitive sanctions. But even in societies in which machinery exists for the making of law in the Austinian sense, rules or customs grow up which are laws in a very real sense of the word, as for example the law merchant. Under later developments of arbitrary power, laws may be regarded as the command of a superior with a coercive power in Austin's sense: *'Quod placuit principi, legis vigorem habet.'* In stages later still, as government becomes more frankly democratic, resting broadly on the popular will, laws bear less and less the character of commands imposed by a coercive authority, and acquire more and more the character of customary law founded on consent. . . . I claim, then, that the aggregate of the rules to which nations have agreed to conform in their conduct towards one another are properly to be designated international law." (Address at Saratoga Springs [N.Y.]; see *Law Quarterly Review*, p. 311, 1896.) This recalls Blackstone's definition: "The law of nations is a system of rules, deducible by natural reason, and established by universal consent among the civilized inhabitants of the world, in order to decide all disputes, to regulate all ceremonies and civilities, and to ensure the observance of justice and good faith in that intercourse which must frequently occur between two or more independent States, and the individuals belonging to each." (*Commentaries on the Law of England*, 4th ed., iv. 66.) The current English narrower view owes its origin chiefly to the influence of John Austin, and the current broader one to that of Sir Henry Maine. The increasing popularity of references to international arbitration (*see* ARBITRATION, INTERNATIONAL), the adoption of a large number of special treaties making such references compulsory in certain cases, the establishment of an increasing recourse to the court for the decision of difficulties between States created by The Hague "Convention for the pacific settlement of disputes between States" of 1899 (*see* PEACE), the adoption of fixed rules of law in the international conventions in 1899 and 1907 dealing with many of the most controversial questions of international usage, and the creation of the League of Nations and its Permanent Court of International Justice (*q.v.*), have so transformed the subject that if, as Lord Coleridge said, law implies a law-giver and a tribunal capable of enforcing it, these conditions are now, at any rate, partly fulfilled. We shall see below to what extent it may be necessary to regard power of enforcement against transgressors as requisite to give international law the character of law properly so-called,

Sanctions. — The subject of the enforcement of international law, or its "sanctions," has given rise to much controversy. The word "sanction" is derived from the Lat. *sanctio*, which in turn is derived from *sancire*, to consecrate. In its original sense *sanctio* means consecration. From this followed the sense of religious obligation. Thus *sancire legem* is used by Roman writers as meaning that observance was made obligatory, but without reference to the idea of there being a remedy or penalty for non-observance.

Bentham, who worked out the theory of legal sanctions as applied to modern law, describes them as equivalent to pleasures and pains derived from fout different sources. These are physical, political, moral and religious.

Austin's analysis of this vague subdivision led him to a more precise determination of the relationship of sanctions to law, viz., that a law properly so-called is a command and its sanction is the power to enforce obedience to it. Stated briefly, any other kind of law according to Austin is not positive law but merely called so by analogy. Applying this test to international law he concludes that the law obtaining between nations is not positive law; for every positive law is set by a given sovereign to a person or persons in a state of subjection to its author. The law obtaining between nations is only law set by general opinion with duties which are only enforced by moral sanction, by fear on the part of nations, or by fear on the part of a sovereign, of provoking general hostility, and incurring its probable evils, in case they should violate maxims generally respected. *(Province* of *Jurisprudence determined,* and ed., 1861, p. 177; Austin explains his view more fully at p. 127.)

Sir H. Maine's somewhat indirect answer to Austin may now be taken as the view held at least by British theoretical writers. "Austin," he said, "has shown, though not without some straining of language, that the sanction is found everywhere, in positive law, civil and criminal. This is, in fact, the great feat which he performed, but some of his disciples seem to me to draw the inference from his language that men always obey rules from fear of punishment. As a matter of fact this is quite untrue, for the largest number of rules which men obey are obeyed unconsciously, from a mere habit of mind. Men do sometimes obey rules for fear of the punishment which will be inflicted if they are violated, but compared with the mass of men in each community, this class is but small; probably it is substantially confined to what are called the criminal classes, and for one man who refrains from stealing or murdering because he fears the penalty there must be hundreds of thousands who refrain without a thought on the subject." (*International Law,* p. 50.)

The view, however. that a law is not devoid of binding character because there is no authority to enforce its observance hardly requires justification at the present day. The fact that any well-established international usage is observed, and that States invariably endeavour to answer any reproach of departing from such usage by explanations showing that the incriminated act is justified by recognized rules of international law, is evidence of its binding character. As the late Prof. Rivier, one of the leading authorities on Roman law, as well as an international jurist of eminence, has expressed it: "The law of nations is positive law because States wish it to be so. They recognize its compulsory character and proclaim it. As they are their own legislators and make their common laws by express or tacit consent, they attest explicitly and implicitly their conviction that its principles are binding upon them, as judicial principles, as law. Innumerable public acts, affirmations, declarations and conventions are there to prove it. On the other hand, never in any published official act of the present age, verbal or written, has a State dared to declare that it did not consider itself bound by the law of nations and its principles." (*Droit des gens,* 1896, i. 22.) With this we may compare Savigny's words: "A community of judicial conscience can be formed among nations like that which positive law creates in the bosom of one people. The foundations of that intellectual community are constituted partly by a community of race, partly and especially, by a community of religious convictions. Such is the basis of the law of nations which exists principally among European Christian States. . . . We are entitled to look upon this law as a positive law, although it is an incomplete judicial formation." (*System des heutigen, römischen Rechts,* 1840, 1., s. 11.) States, as Prof. Rivier says, have again and again solemnly declared their determination to abide by the principles of international law. Witness the Declaration of Aix-la-Chapelle of Nov. 1;, 1818, in which the representatives of five Powers, Austria, France, Great Britain, Russia and Prussia, solemnly stated that "the sovereigns in forming this august union have regarded as its fundamental basis their unchangeable resolution never to depart, either amongst themselves or in their relations with other States, from the strictest observance of the principles of the law of nations, principles which, in their application to a permanent state of peace, can alone effectively guarantee the independence of each government and the stability of the general association." In the negotiations for the Treaty of London concerning the Black sea (Mar. 13, 1871), at which seven Powers were represented, Austria-Hungary, France, Germany, Great Britain, Italy, Russia and Turkey, a resolution on the sanctity of treaties was annexed to the first protocol, stating that the plenipotentiaries recognize that it is an essential principle of the law of nations that "no Power can liberate itself from the engagements of a treaty, nor modify the stipulations thereof, unless with the consent of the contracting powers by means of an amicable arrangement." Even in 1908, when Austria-Hungary proceeded to the annexation of Bosnia-Hercegovina without obtaining the prior assent of the high contracting Powers, who under the Treaty of Berlin of 1878 had granted her temporary occupation of the annexed provinces, the protests of the Powers concerned were answered by Austria-Hungary declaring that she had done nothing contrary to the law of nations or affecting the sanctity of treaties, because the Powers had given their tacit consent to the practical transformation of her temporary into a permanent occupation.

The public opinion of the civilized world, in fact, plays in an ever-increasing degree the part of a sanctioning authority. With the growth of international intercourse and international interdependence the danger of isolation or of discredit or even of "boycotting" becomes a matter of increasing importance in the conduct of States. The national press and periodical literature, with exceptions no doubt, are among the chief factors in the development of this public opinion, but it is by no means dependent upon them. Personal intercourse among citizens of the same country, and between statesmen, politicians and citizens of different countries has a still greater effect in the creation of the mental attitude of nations towards each other. This exposes any departure from recognized usage or any disregard for international obligations to such reprobation throughout the whole world, that, far from taking advantage of the absence of any coercive method of enforcing obedience to the principles of international law, States compete with each other in asserting their strict fidelity to such principles. And now successive diplomatic conferences have codified many of the chief branches of international usage, thus diminishing the possible cases in which States can take advantage of the uncertainty of the law and, by quibbling over its interpretation, escape from its obligations.

Sources **and** Foundations. — It is usual, following Wheaton's classification *(Elements,* 1885, pp. 22 et *seq.*), to enumerate the sources of international law in the following groups: text-writers of authority as witnesses of usage; treaties of peace, alliance and commerce; ordinances of particular States, prescribing rules for the conduct of their commissioned cruisers and prize tribunals; adjudications of international tribunals; written opinions of official jurists given confidentially to their own government; history of wars, negotiations, treaties and other transactions relating to the public intercourse of nations. It is in these different classes of opinions and precedents that writers have been in the habit of searching for those arguments and analogies on which have been built up the system and principles called international law.

Wheaton, it is seen, regarded text-writers as witnesses of the usage of nations. He explains his meaning as follows: '(Without wishing to exaggerate the importance of these writers, or to substitute in any case their authority for the principles of reason, it may be affirmed that they are generally impartial in their judgment. They are witnesses of the sentiments and usages of civilized nations, and the weight of their testimony increases every time that their authority is invoked by statesmen, and every year that passes without the rules laid down in their works being impugned by the avowal of contrary principles." This distinguished writer's quasi-explanation of the sources of international law is extremely vague. He masses together cause and effect, private and public opinions, usage and exceptions. Oppenheim has endeavoured to give a more scientific explanation of the growth and development of international law, and objects to calling sources of international law what are mere factors influencing its growth:—

". . . Custom and treaties," he observes, "are the two exclusive sources of the law of nations. When writers on international law frequently enumerate other sources besides custom and treaties, they confound the term 'source' with that of 'cause' by calling sources of international law such factors as influence the gradual growth of new rules of international law without, however, being the historical facts out of which these rules receive their legal force. Important factors of this kind are: Opinions of famous writers on international law, decisions of prize courts, arbitral awards, instructions issued by the different States for the guidance of their diplomatic and other organs, State papers concerning foreign politics, certain municipal laws, decisions of municipal courts. All these and other factors may influence the growth of international law either by creating usages which gradually turn into custom, or by inducing the members of the family of nations to conclude such treaties as stipulate legal rules for future international conduct.

"A factor of the special kind which also influences the growth of international law is the so-called comity (*Comitas gentium, Convenance et courtoisie internationale, Staatenkunst*). In their intercourse with one another States do observe not only legally binding rules and such rules as have the character of usages, but also rules of politeness, convenience and good-will. Such rules of international conduct are no rules of law, but of comity. The comity of nations is certainly not a source of international law, as it is distinctly the contrast to the law of nations. But there can be no doubt that many a rule which formerly was a rule of international comity only is nowadays a rule of international law. And it is certainly to be expected that this development will go on in future also, and that thereby many a rule of present international comity will in future become one of International Law." *(International Law,* 1905, s. 19.)

Precedents. — We prefer to regard international law as deriving the rules composing it from practically the same sources as domestic law, and to attribute to text-writers more or less the same value in its development as in that of the private law of nations. The same primary rules of conduct are appealed to between States as between individuals, and precedents play exactly the same part wherever human actions are concerned. In both cases what has been done before commends itself when the responsibility of taking steps pledging the future is concerned. Statesmen on whom great responsibility impends, on whom the conduct of momentous negotiations has devolved, and who will have to render an account of their work to the sovereign or nation they represent, preserve an argument in their own favour in departing as little as possible from any course taken in previous similar circumstances. Precedents, moreover, are arguments for acceptance by their adversaries or counter-negotiators. In fact, in diplomacy even more than in matters of domestic government precedents play a dominant part in the growth of usage. These precedents are often in themselves originally local usages, such as grew up in the intercourse of the Italian communities. Italy, in fact, served as a laboratory for early diplomatists and writers. It was in the intercourse of these active and ambitious States that grew up the very notion of a foreign diplomacy and the necessity of rules of conduct in this miniature Europe, with its perpetual antagonisms and jealousies, its balance of power, its idea of a State distinct from a nation and of a community of States elbowing each other in their daily contact. It was there that grew up the institution of passports, the distinction between armed forces and civilians, international comity, and in fact the very notion that States have an interest in the observance of law and order among them. In the same way the active commercial intercourse in the Mediterranean led, in the common interest, to the development of rules of the sea in time of peace, and later to others in time of war.

In the north of Europe, again, out of the active commercial intercourse among the Baltic and North sea communities grew rules of the sea in the same common interest. It was the Thirty Years' War, with its revolting cruelty, which brought out the contrast between the more humane practice of war as an art in Italy and the mere bludgeonry which prevailed in the brutal struggle which disgraced the first half of the 17th century. The brutality of the struggle turned thinkers' attention to the need of formulating rules for the protection in time of war of non-combatants and the innocent subjects of absolute sovereigns, the treatment of the sick and wounded, the prohibition of wanton pillage and the other horrors which shocked the awakening conscience of northern Europe. It was the starting-point of the age of text-books.

Authoritative Text-writers. — The first effective work, the one which was the first to influence sovereigns and statesmen, was Grotius's *De jure belli ac pacis* (Paris, 1625), which practically exhausted the theoretical arguments in favour of the new subject. Nobody has in fact since brought to light any new conception of the foundations of international law. An exhaustive and masterly treatise having been published, no further subsequent treatise was necessary to show what all men were beginning to feel. He sublimated the feelings of his age, and having arrived at the pure substance, the work of proving the need of his subject was disposed of for all time. Pufendorf (1632–97), who, in the sequence of effective text-writers, succeeded Grotius, endeavoured to base international law on an ethical basis accepted by all peoples without necessity for a common creed or standard of morals, but it is doubtful, whatever may have been the extent to which he stimulated the study of jurisprudence, whether he did much in advancing the practical development of the law of nations. His book *De jure naturae et gentium* (1672), as its name indicates, based international law on what he called the law of nature, a subject which has much exercised the minds of jurists searching for an ethical basis for existing law.

The scientific mind of Leibnitz (1646–1716) revolted against this theoretical and doctrinaire tendency of Pufendorf and other writers, who were following with feeble tread in the giant footsteps of Grotius. He saw that the practice of nations was taking a course dictated by the current moral standards of civilized society, and that the philosophizing of the text-book writers was leading them away from that actual practice which they should use as data for their conclusions. Natural science, moreover, had taught him the risk of theorizing on imperfect data, and while writing a history of Brunswick it occurred to him that treaties and diplomatic documents generally were the substances and tests of the publicist's laboratory. His *Codex juris gentium diplomaticus* (1693–1700) gave a more precise direction to speculations on the subject.

The next great writer of authority united all the qualities of a practical lawyer and jurist. This was Bynkershoek (1673–1743). He was the first writer on international law who dealt with public maritime law as a matter demanding special treatment and involving a set of principles not called into action in territorial warfare. A magistrate administering the law in a great commercial country, whose interests were on or across the high seas rather than within the narrow European limits of Holland, Bynkershoek, like Leibnitz, searched for his data in the actual practice of nations in their intercourse with one another. He applied his clear, legally trained mind to deriving principles from practice instead of endeavouring to build up a practice on abstract principles. It was he who first generalized the different isolated usages which had grown up at different spots in northern Europe in the interest of maritime defence, and evolved from practice the principle that dominion seawards was limited to the extent to which it was possible to enforce it (cannon-shot range), a principle which not only created the legal institution of territorial waters, but has since been imported into other branches of international law, and has indirectly influenced the suppression of fictitious blockades and fictitious occupations of territory.

A contemporary of Bynkershoek was Christian de Wolff (1679–1754), a philosopher, mathematician, theologian, lawyer and disciple of Leibnitz. Wolff's great work on the *Institutions of the Law* of *Nature and Nations* is a learned and accurate treatise drawn from all the well-known sources of knowledge, and, just as Grotius based his demonstrations on the then imperfect knowledge of public events of his time, Wolff based his on the more accurate sources of information which had grown up under the influence of Leibnitz, and created a connected system out of the

scattered fragments available. But his book was written in Latin at a period when scholarship had declined, and its influence was only felt after Vattel (1714–67) wrote his *Droit des gens, ou principes de la loi naturelle appliquées à la conduite et aux affaires des nations et des souverains* (1758). His book had all the charm, although Vattel was a Neufchhtelois. of the French writers of his time, and he it was who popularized the study of international law. His book was based chiefly on the work of Wolff; in it he gave what was best amongst his predecessors without attempting to add anything original of his own. It became the handbook of statesmen and jurists, and has never ceased to be quoted by them down to the present day.

But the opinions of jurists in international law can have little more than the value of criticism and co-ordination. They have seldom served to make law, though they have the weight of all statements made by those who have made a special study of any branch of law, as to what they had gathered to be the existing practice at the time when they wrote, or as to the trend which they showed that practice might be taking. Great lawyers and writers like those we have mentioned, and such as Lord Mansfield. Sir William Scott, Chief Justice Marshall and others, have done the work of classifying facts, deducing conclusions from them and connecting rules with psychological and ethical motives, and have thus sent a current of higher intelligence through the subject which has raised it to its present methodical form. Still international law remained a wide field for controversy. Authors were agreed on general principles, but when these general principles were applied in practice, the shortcomings of unwritten usage often caused as much difficulty as that which the appeal to principles was intended to overcome.

Hague and London Conferences. — What may be called the first enactment of rules of international law was the Declaration of Paris of 1856 (q *v.*), but the great work of codification, or rather of reducing into writing the rules which had been floating as an unwritten law in the conscience of Europe, was undertaken by The Hague Conferences, which may be said to be and to have created an entirely new factor in the domain of international law. Two of the conventions adopted in 1899 completed work which had already been commenced long before, viz., those on the usages of war and on the adaptation of the Geneva Convention to naval war. The third established methods for the pacific settlement of international difficulties, including the formation of The Hague Court of Arbitration. Recourse to the latter was purely optional, but the other two conventions have been absorbed into the national law of the ratifying countries, and thus have also the domestic sanction States give to their own laws. The work of the Conference of 1907 was of a much wider and more exhaustive character than that of 1899. It comprised, besides revised conventions on the matters dealt with in 1899, new conventions on the following subjects: Opening of hostilities; position in naval war of enemy's merchant ships at beginning of hostilities; conversion of merchant vessels into warships; rights and duties of neutral States in naval war; the laying of automatic submarine contact mines; the bombardment of undefended places by naval forces; treatment of fishing vessels, postal correspondence and capture generally in maritime war; and recovery by force of contract debts. It also adopted a convention for the creation of an International Prize Court of Appeal, which led to the calling of a fresh conference on prize law. This conference sat in London from Dec. 4, 1908, to Feb. 26, 1909, and was confined to representatives of the following countries: Great Britain, France, Germany, United Stales of America, Italy, Austria-Hungary, Russia, Japan, Holland and Spain. It adopted a series of rules on naval warfare relating to blockade in time of war; contraband of war; unneutral service; destruction of neutral prizes; transfer to neutral flag; enemy character; convoy; and resistance to search and compensation.

Standard of Right Conduct. — Underlying the details of both the new international legislature and the new international judicature are certain principles which may some day have to be officially defined. These principles have necessarily fluctuated with the standard of morals of each period. With the contemporary development of the public conscience, they are undergoing changes and a betterment which it is not desirable to check by yet nailing them up as immutable articles of faith. Till quite recently it was usual to speak of the common standard of right conduct prevailing throughout the Christian world, a standard to which responsible statesmen tried to adjust their direction of the affairs of State. The admission of Japan into the councils of the Great Powers has introduced a non-Christian element whose standard of conduct was not identical with nor based upon Christian morals. Turkey, though admitted in 1856 to European councils, remained rather the occasion of their deliberations than a deliberating party. Her new position as a constitutional State, with a code of morals at any rate in some essentials distinct from that of Christian peoples, will add a further new non-Christian element into the moral foundations of international conduct. The influence of western Europe, however, in both Japan and Turkey, has hitherto in all external development been paramount. Japan, after examining all the existing systems, has even adopted the best she found in Western morals, and in her schools inculcates Christian ethics as a subject *per se* without reference to Divine revelation or authority. Turkey, too. has the advantage of possessing a code of morals which produces so high a standard of right conduct in private life that very little in the way of morai lessons will have to be learned by the Ottomans from Western civilization. As regards practice, it is unreasonable to expect that the high estimate of the moral standard of west European civilization, which is cherished by those who profess its principles, should be accepted by other peoples with unqualified assent.

The very notion of the "right of conquest," and that the victorious are entitled to an indemnity without reference to any question of right and wrong or of justice and injustice, shows that there are principles in actual practice which lie outside and have no analogy in the principles of private law. In the partition of Africa, native States have been treated as non-existent except as local bodies. They have been annexed to European States without reference to their will or consent. Treaties have indeed been made with them, but they have rather been regarded as evidence of prior occupation than as involving any question of native right. The test in the distinction between civilized and uncivilized States which is regarded as warranting exclusion from enjoyment of the right to consideration as independent States, and admission to the community of the civilized world, is in practice the possession of a regular government sufficient to ensure to Europeans who settle among them safety of life and property. Every country, in principle, possessing such a government has *prima facie* the rank of a State and is entitled to treatment as a civilized community. Treaties made with it for the purpose of extra-territorial jurisdiction are intended merely to take into account a difference of judicial institutions but are not supposed to detract otherwise from the possession of such equality and independence. This principle has no analogy in private morals, and has been, slight as it is, more honoured in the breach than the observance. If indifference to native right has provoked reaction, it has been on the part rather of philanthropists than of statesmen. Their movement for the protection of African aborigines has, however, resulted in at least one great international charter for the prevention of the further degradation of African aborigines, viz., the General Act of Brussels of 1885. A vigorous outcry has also been raised against the methods of the Government of the Congo State. But the agitation ought not to be confined to this part of Central Africa. Other Governments are also in fault. In fact, the contact of the European with Central Africa has, throughout, with few exceptions, been one of barbarous practice quite inconsistent with the principles which Christian missionaries have been sent to teach the African native.

European enterprise in Asia has had still less justification. The action taken for the repression of the "Boxer" movement in China, like previous European incursions, had no essential characteristic distinguishing it from the incursions of the Northmen. The Japanese took part in the "Boxer" expedition, and the example of respect for native right and of orderly self-restraint they set has been universally acknowledged. But the lesson is one d

greater significance than one of comparative ethics. The rise of the power of Japan and her obvious determination to constitute herself the champion of the races of eastern Asia has widened the scope of international law, and we may now regard China as henceforth under the protection of the same principles as European States.

Fundamental Principles.— The three chief principles of inter-State intercourse, those, in fact, on which international law is based are:—

1. Recognition of each other's existence and integrity as States.
2. Recognition of each other's independence.
3. Recognition of equality, one with another, of all independent States.

As regards the first of these principles *see* STATE. From the principle of independence it follows that every State has a right to change its form of government and to enjoy the free exercise of its internal energies. This is subject only to the limitation that in the exercise of this right other States or their subjects shall not be molested or otherwise suffer. The equality of all independent States entitles them to respect by other States of all the forms of ceremonial and to the same treatment by others, where their interests are identical, whether they are strong or weak. This principle has often been violated, but it is, nevertheless, acknowledged wherever possible, as in diplomatic conferences relating to all matters of an economic, hygienic, industrial or social character. Even at the Conference of Algeciras, though the Powers immediately concerned from a political point of view were only Great Britain, France, Germany and Spain, the following were also represented as having economic interests in Morocco, viz., Austria-Hungary, Italy, Russia, Belgium, Holland, Portugal and Sweden.

Ships on the high sea being regarded as detached portions of the national territory, there is also the derived principle of the freedom of the high sea, of the independence and equality upon it of the ships of all nations subject only to due respect being paid to the independence and equality of all others and to such conventional restrictions as States may impose upon themselves (*see* TERRITORIAL WATERS). This principle is re-enunciated in the preamble to the Convention of 1907 on the laying of automatic submarine contact mines (*see* PEACE CONFERENCES).

The Hague Conventions are based on these principles, to which there is a tendency to add another, viz., the right to arbitration in certain cases. This principle is set out more or less tentatively, it is true, but it is being completed by separate treaties of compulsory arbitration in connection with the cases referred to. It is enunciated in the following article of the Convention of 1907 for the pacific settlement of international disputes:—

"In questions of a legal nature, and especially in the interpretation or application of international conventions, arbitration is recognized by the contracting Powers as the most effective, and, at the same time, the most equitable means of arranging disputes which diplomacy has failed to settle. Consequently, it is desirable that, in disputes regarding the above-mentioned questions, the contracting Powers should, if need be, have recourse to arbitration, in so far as circumstances permit." (Art. 28.)

The principle of arbitration has also been adopted in reference to the recovery of contract debts under the fallowing article of the "Convention respecting the limitation of the employment of force for the recovery of contract debts":—

"The contracting Powers agree not to have recourse to armed force for the recovery of contract debts claimed from the Government of one country by the Government of another country as being due to its subjects or citizens. This undertaking is, however, not applicable when the debtor State refuses or neglects to reply to an offer of arbitration, or, after accepting the offer, renders the settlement of the *compromis* impossible, or, after the arbitration, fails to comply with the award." (Art. 1.)

The codification of international law itself, begun at The Hague and London Conferences, is an admission of the binding character of the primary principles set out above.

One of the chief tendencies of contemporary reform is also to restrict the effect of fictions and reduce rights to the limits of their practical application. Between two alternatives, the one to assert rights which cannot possibly be maintained by force such as claims to dominion over portions of the high sea (*see* HIGH SEA, WATERS, TERRITORIAL), "paper blockades" (*see* BLOCKADE) and fictitious occupations of territory (*see* OCCUPATION), and the other to require actual physical assertion, a medium course is growing up, viz., that of recognizing potential assertion, *i.e.*, assertion limited to physical possibilities. With the aid of the Institute of International Law, the International Law Association and other reforming agehcies (*see* PEACE), expert opinion in these matters is becoming homogeneous throughout the civilized world, and the ground is being prepared for a clearer understanding of these fundamental principles by the statesmen and State officials who have to apply them in practice.

The outstanding developments in international law since the World War are so distinctive that it has been considered expedient to deal with them under separate headings, rather than to attempt to present them in any one general article. The attention of the student is especially drawn to the following articles: ARBITRATION, INTERNATIONAL; BLOCKADE; CONTRABAND; CONVOY; COVENANT; INLAND WATER TRANSPORT; LABOUR LAWS; LEAGUE OF NATIONS; MANDATE; MIGRATION; MINORITIES; NEUTRALITY; PERMANENT COURT OF INTERNATIONAL JUSTICE; PRIZE and PRIZE COURTS AND PRIZE LAW; SANCTIONS AND GUARANTEES; TREATIES; VISIT AND SEARCH; WAR, LAWS OF; WASHINGTON CONFERENCE. (T. B.)

INTERNATIONAL MERCANTILE MARINE COMPANY, an American corporation engaged in the transportation of passengers, mails, live stock, merchandise, and other goods between various parts of the world. It was incorporated June 6, 1893. under the laws of the State of New Jersey, as the International Navigation Company, with a perpetual charter which provides, in addition to the purpose enumerated above, for the "purchasing, owning and holding of stocks, bonds and other securities" On October 1, 1902, the charter was amended, the capital was raised to $120,000,000, and the White Star. Leyland, Atlantic' Transport and Dominion Lines were acquired, and the name of company changed to International Mercantile Marine Company

The White Star Line was sold on January 1, 1927, for £7,000,000 to the Royal Mail Steam Packet Company The Red Star and Leyland Lines have also been sold and the service of the Atlantic Transport Line has been discontinued.

The Dominion Line had previously been consolidated with the other lines. At the end of 1926, before these disposals, the company's fleet consisted of 100 vessels of approximately 1,091,000 gross tons.

In 1929 a recapitalization plan was adopted whereby an authorized issue af 720,000 shares of capital stock of no par value, all of one class, took the place of the former preferred stock (each share of which received $20 in cash and one share of the new stock) and the common stock (each share of which received one-fifth of a share of new stock).

The company owns the United States Lines Company which regularly operates the United States Lines between New York, the English Channel ports and Hamburg, between New York and London and between New York, Cobh (Ireland), Liverpool, Glasgow and Belfast, maintaining these services with vessels which it owns United States Lines Company also operates chartered vessels on the America France Line from North Atlantic ports of the United States to French ports; the American Hampton Roads–Yankee Line from North Atlantic ports of the United States to East Coast English and German ports; Oriole Lines from North Atlantic ports of the United States to Liverpool, Manchester, Dublin, Belfast and Glasgow and the American Pianeer Line from Atlantic and Gulf ports of the United States to Australia and Far East ports. Through a subsidiary, the company also owns the Panama Pacific Line, which is operated by U.S. Lines Company between New York and San Francisco.

Two vessels, "Manhattan" and "Washington" of United States Lines are the largest and finest steamers of American construction, and a third vessel of similar type, the s s. '(America" was

delivered and put into service in Aug. 1940. Including this new vessel, there are 33 vessels with a gross tonnage of approximately 293,000, employed in the company's services.

The company also owns through a subsidiary the large office building at No. 1 Broadway, New York city. (J. M. F.)

INTERNATIONAL NEWS SERVICE. Organized in 1906, this news service furnishes 150,000 words of "live" news daily from all parts of the world to both morning and afternoon newspapers and also to radio stations for broadcasting. INS maintains a regular staff of some 600 correspondents, including some of the foremost authoritative reporters, writers and editors in the field of journalism. It has in addition a staff of 8,000 "string" correspondents at every active or potential source of news. Branch officesare maintained in the principal cities of all foreign countries and in 57 cities of the United States. INS dispatches are supplied by high-speed leased telegraph and types of coverage are available for newspapers of all circulations. (B. A. EL.)

INTERNATIONAL PAYMENTS. The observer who learns that, during a given year, England imported £100,000,000 worth of raw cotton from the United States, and sold £50,000,000 worth of coal to the Continent, and that simultaneously Austria, Hungary, Finland and other countries raised loans totalling $200,000,000 in New York, can be excused for wondering exactly how these huge sums of money are remitted. Even if he is conversant with the theory of the balance of trade (*q.v.*), or has learnt that "imports pay for exports," and even if he knows something of the principles of Foreign Exchange (*q.v.*), he may still be excused for a failure to realize how it works out in actual practice.

In reality the process of remittance from country to country is extremely simple, and the chief stumbling blocks are the existence of different currencies, the huge sums involved and the use of technical terms by those engaged in the business. The easiest way to approach the question is by the examination of the normal financial relations between individual and individual.

Take the case of: (1) Brown, a butcher, who banks at bank A; (2) Jones, a farmer, who banks at bank B; (3) Smith, a needy relative of Jones, who banks at bank C.

Brown buys cattle from Jones and in due course owes him £50. Smith buys meat from Brown, also to the tune of £50. Finally Smith goes to Jones and borrows £50 In each case, to settle the amounts outstanding, the payer, whether he be debtor or lender, draws a cheque for £50 in favour of the payee, whether he be creditor or borrower. The cheque is drawn on the drawer's bank, and paid by the payee into his own bank.

The result is that bank B holds a cheque for £50 drawn by Brown on bank A and relating to his purchase of cattle. Bank C holds a cheque for £50 drawn by Jones on bank B and relating to his loan to Smith. Bank A holds a cheque for £50 drawn by Smith on bank C, and relating to his butcher's bill. To clear these three cheques, three operations are necessary in the case of each one. The first of these is the crediting of the payee's bank account with £50, and the third is the debiting of the drawer's bank account with £50. These are effected simply by entries in the banks' ledgers. The second, which in theory appears more complex, is the transfer of funds from bank to bank, for bank A owes bank B £50 on Brown's cheque, bank B owes bank C £50 on Jones's cheque, and bank C owes bank A £50 on Smith's cheque. In practice, to effect these settlements, representatives of each bank meet together in a local place of refreshment, present their cheques to each other and proceed to cancel them out. It remains to add, in case this last sentence seems very picturesque, that the London Clearing House is said to have originated in a coffee-house.

Now it makes no difference whether or not these cheques were for £50 or £5,000,000, or whether Brown turns into the Mammoth Meat Packing Syndicate, Jones into the Incorporated Graziers' Society and Smith into a civic corporation or even into an important national government. In theory the banks can cancel out the cheques and in practice they have devised means of doing so. The obstacle of the huge amounts involved has clearly been overcome, and the only necessary condition is that the drawers and banks are together good for the amount, however large it may be.

Examples of International Payments.—In the article upon FOREIGN EXCHANGES, it is explained that each bank maintains balances with other banks, called its "agents" or "correspondents," in every important financial centre of the world. A London bank will keep a dollar balance in New York, a franc balance in Paris, a mark balance in Berlin, and so on; and American, French and German banks will do the same. We can now construct cases parallel to the three already cited. (1) Brown, a cotton grower in Alabama, sells $10,000 worth of cotton to Jones, a Manchester spinner. (2) Jones sells £2,000 worth of cotton yarn to Schmidt, a Bremen manufacturer of shirts. (In this calculation, for the sake of simplicity, £1=$5=Mks. 20.) (3) The Bremen city corporation raise a loan of $10,000 in New York.

Now here the currency question must be dealt with. Brown wants to be paid in dollars, and Jones can only pay in sterling. Jones, in his turn, wants sterling from Schmidt, who can only pay in marks; and while the Bremen corporation raise a dollar loan, and so undertake to pay principal and interest in dollars, they want their money in marks.

The key obviously lies in bankers' foreign balances.

(a) Brown draws a bill for $10,000 on Jones, and sells it to his American bank for $10,000, less discount. So Brown gets his dollars. The American bank sends the bill to its London agent, who presents it to Jones, who pays it with £2,000. This sum of £2,000 is placed by the London bank to the credit of the American bank's balance with it. This settles Brown and Jones.

(*b*) Jones, when he sold his yarn, told Schmidt to have a confirmed (or irrevocable) credit of £2,000 opened in his (Jones's) favour at a London bank. Schmidt arranged for his Bremen bank to do this with their London agents, where they (the Bremen bank) kept their balance. Once this credit is opened, Jones goes straight to the London bank, identifies himself, hands over the documents relating to the shipment of cotton yarn to Schmidt, and gets his £2,000. The London bank debit the Bremen bank's balance with them to the tune of £2,000, and the Bremen bank debit Schmidt's account Mks. 40,000, plus their own charges. This settles Jones and Schmidt.

Now for the Bremen corporation and their loan. The investors in New York who bought the loan paid $10,000 in dollars over to the New York issuing house, and the issuing house lodged them to the credit of its account with its New York bankers. It next instructs its bankers to remit Mks. 40,000, which is the mark equivalent, to the Bremen corporation. The New York bank decides to do this through London, so it instructs its London agents to transfer £2,000, the sterling equivalent, from their balance to the Bremen corporation bank's balance, which may be with them or with another London bank. This is done, and the Bremen bank's London agents advise them of the receipt of £2,000, on account of the Bremen corporation's New York loan. Whereupon the Bremen bank credit the Bremen corporation with the mark equivalent of £2,000; *i.e.*, with Mks. 40,000. This settles the loan.

Now just as, in the first instance, no money passed between banks A, B and C, so, in this instance, the total of sterling held in London on either American or German account, remains unchanged. In the first of the last three transactions, the American bank's London balance was increased by £2,000; in the second, the Bremen bank's London balance was decreased by £2,000; in the third, the American balance lost £2,000 to the Bremen balance. The result is a complete "cancel out."

Other Methods.—In the first instance, the debt was paid by means of a bill of exchange; in the second through the medium of a banker's credit (see BILL OF EXCHANGE, FOREIGN EXCHANGE); in the third by direct instructions to the bank immediately concerned. In either case the debtor could have bought a banker's draft, mail transfer, cheque or telegraphic transfer drawn in the creditor's currency. The banker's foreign balance would have lost or gained in the same way.

Recent Historical Instances.—One or two cases from recent history may in conclusion be cited.

(1). American Liberty bonds can be tendered at par in pay-

ment of debts due to the American Government. On one occasion the British Government, in anticipation of a coming instalment due on the American debt, paid sterling over to an international finance house's office in London, and arranged for the house to credit the British Government with the equivalent in dollars in New York. It next instructed the finance house to use those dollars to buy Liberty bonds at the current Wall street price, which was then 90. These bonds were tendered in settlement of the instalment to the American Government, who, by its own law, was bound to accept them at par.

(2). When the franc collapsed in the spring of 1924, the French Government arranged for credits to be opened in its favour by banks in London and New York. In other words, these banks engaged to lend the French Government pounds and dollars on demand up to the limits of the credits. The French Government broker then went on the Paris Bourse and sold pounds and dollars to the market, so arresting the fall in the franc. Long before the credits were exhausted, the worst of the crisis was over. The essential point was that the French Government had previously arranged for an adequate supply of pounds and dollars.

(3). When the pound and, later, the lira were stabilized, the British and Italian Governments arranged credits in New York. If speculators had tried to break the stabilization by selling pounds or lire for dollars, the Governments concerned would have drawn on their New York credits, and so put up all the dollars needed to buy up the pounds or lire the speculators were selling.

In short, the system of banker's foreign balances, even if only held in one common foreign centre such as London, provides a ready means of transferring funds from one centre to another right across the world. For the maintenance of these foreign balances by the banks themselves, and for the reasons why the banks add to them and deplete them on their own account, the reader is referred to the article on EXCHANGE, FOREIGN. (See also BALANCE OF TRADE; BANKING AND CREDIT; BILL OF EXCHANGE; CHEQUES.) (N. E. C.)

INTERNATIONAL SOCIETY FOR CONTEMPORARY MUSIC, an organization founded at Salzburg, in 1922, by a number of leading modern musicians, with the object of promoting closer international musical relations by means of annual festivals devoted to representative modern works drawn impartially from all countries. Edward J. Dent, who later became professor of music at Cambridge university, was elected president, and yearly festivals have since been regularly held. The society embraces some 20 different branches in the principal countries, with headquarters in London. In 1938 Professor Dent was succeeded as president by Edwin Evans, critic and writer on music.

INTERNATIONAL TELEPHONE AND TELEGRAPH CORPORATION, a holding, service and management company, incorporated under the laws of the State of Maryland, U.S.A., having its principal office in New York city. This corporation was organized to develop electrical communication in all its branches in the international field. Its business (July 1, 1940) may be briefly summarized as follows:

(1) Subsidiary companies own and operate telephone systems in Argentina; the states of Rio Grande do Sul and Parana in Brazil; in Chile; Shanghai, China; Cuba; Mexico; Puerto Rico; the city of Lima and surrounding territory in Peru; Rumania and Spain. Subsidiary companies also own and operate the radiotelephone stations in Argentina, Brazil, Chile, Peru, Puerto Rico and Spain. The corporation also owns a one-half interest in a company operating submarine cables connecting Cuba with the United States. Most of the I. T. & T. telephone systems provide international service via the above-mentioned radio stations or connecting physical lines with other principal countries of the world. (2) Subsidiary companies manufacture electrical equipment and apparatus related principally to telephone, telegraph, cable and radio operations. Factories and sales organizations are in Antwerp, Berlin, London, Madrid, Paris, Shanghai, Sydney, Tokyo and most of the other principal cities of the world.

International Telephone and Telegraph Corporation holds two-thirds stock interest in American Cable & Radio Corporation which, through subsidiaries, controls the following operating companies: (1) All America Cables and Radio, Inc.; this system interconnects 24 countries and islands in the Americas and provides, through associated and connecting systems, cable and radio communication with the rest of the world. (2) Commercial Cable Company, which owns and operates a system of cables between the U.S. and Europe. (3) Mackay Radio and Telegraph Company, which operates domestic and international point to point radiotelegraph service, marine radiotelegraph service, and maintains a radio and electrical apparatus manufacturing subsidiary, Federal Telegraph Company of Newark, N.J. (4) Part interest in Commercial Pacific Cable Company, which owns and operates cables furnishing communications between the U.S. and Hawaii, the Philippine Islands and the Far East. The authorized capital stock of International Telephone and Telegraph Corporation is 15,000,000 shares, without par value, of which 6,399,002 were outstanding in the hands of the public at June 30, 1940, at which date it had funded debt outstanding of $35,000,000 in 4½% debenture bonds due July 1, 1952, $50,000,000 in 5% debenture bonds due Feb. 1, 1955, and $14,700,000 in 4½% notes due Dec. 30, 1948, subject to annual amortization in respect to which $400,000 was due on Dec. 30, 1940.

INTERNATIONAL TRADE ASSOCIATIONS AND CONGRESSES. The first striking demonstration of the international character of modern civilisation was the great exhibition of 1851, itself a temporary and loose international association for economic ends. Its successor of 1862 (the International Exhibition in London) contributed to the formation of the first regular association which sought to modify economic conditions by international effort, the International Working Men's Association (see INTERNATIONAL, THE). At about the same time the growth of international trade led to the earliest official international unions, such as that constituted by the International Telegraphic convention of 1865, and the General Postal union of 1874 (see POST AND POSTAL SERVICES). Quite exceptional was the International Sugar union of 1864 which consisted of four countries only and was dissolved in 1875; its successor of 1902 is treated below.

The International Metrical union of 1875 dealt with one of the fundamental elements of civilisation; the Latin Monetary union was formed in 1865 but, extended only to five States, failed to prevent the dissociation of the currencies after the war of 1914–18.

Agriculture. — Although association is notably difficult in agriculture, one of the most effective and beneficent of international associations is the International Institute of Agriculture founded by a conference at Rome in 1905. Due to the firm resolve of a single individual, David Lubin, to create an organisation to minimise the disadvantages under which the unorganised farmers faced the organised railways and buyers, the Institute is a union of States practically universal in scope. Its main work is the publication of complete statistics of crops of all kinds throughout the world, of trade and stocks and of freights and prices. Having established a standard average for the world crop in each product it can produce from the current statistics continually received estimates of the available supplies, which are of the greatest value in stabilising prices and guiding markets. The Institute also studies other international aspects of agriculture, such as comparative legislation, wages, plant diseases. It eschews domestic questions.

The International Seed-testing association founded in 1924, after a series of international conferences, is an important addition to the scheme of international co-operation for agriculture; its members are the official seed-testing associations in the chief agricultural countries.

Private interest in this field is represented by the International Agricultural commission which dates from 1889 and has held numerous international congresses, and by the World Agricultural society, of American origin.

Separate branches of agriculture have their own international institutions such as the International Association of Poultry Instructors and Investigators (1912), the International Dairy federation (1903), and the Permanent Committee of International Congresses of Beekeeping (1897).

The preservation of food is even more Important than its production from the international point of view, and with the Inter-

national Institute of Agriculture may be associated the International Institute of Refrigeration. Founded in 1920 (to take the place of a similar association dating from 1900) by an international convention, it is a union of upwards of 30 States and is devoted to the study of cold storage in its scientific and practical aspects. It is governed by two committees, one representing every member State and one containing only 17 persons in all. The United States of America is represented specially in the Institute by the American Association of Ice and Refrigeration.

PERMANENT ASSOCIATIONS

Industry. — International exhibitions, apart from their direct function of celebrating and displaying the achievements of the world's work, are instrumental in the formation of more permanent associations for common effort. From international congresses held in connection with the universal exhibitions at Vienna in 1873 and Paris in 1878 resulted what may be called the first steps in international legislation for industry. They were concerned with the protection of "industriai property" or property in ideas applied in manufacture or embodied in manufactured products (*see* PATENTS and TRADE MARKS). The first Convention dated 1883 at Paris was followed by the Agreements of Madrid (1891) and the additional Act of Brussels (1900). These instruments were revised at Washington in 1911 and again at The Hague in 1925, though the instruments signed on the last occasion have come into force, only as regards a few countries, including, however, Great Britain, Canada, Germany and Italy. They contained provisions designed to safeguard rights in patents, designs, industrial models and trade marks, and to prevent false indications of origin on goods. The signatory States, 38 in number, of these international measures are known collectively as the International Union for the Protection of Industrial Property, and an International Bureau of the Union was set up at Berne, of which the most important function is the international registration of national trade marks to be protected in the territories of all the States which are parties to the Special Agreement for the International Registration of Trade Marks (one of the Madrid agreements of 1891). The International Union is at present little more than the relation created by a multilateral treaty or common undertaking between several States to enforce certain domestic legislation.

The American counterpart of the above arrangement for the international registration of trade marks is the Pan American Convention of Buenos Aires, 1910, revised at Santiago in 1923, under which two registration offices were to be set up, one at Havana for North America, and one at Rio de Janeiro for South America, but the latter office has not in fact been opened, as several signatories failed to ratify or withdrew from the Convention.

A scheme for the establishment of an International Patent Office at Brussels was considered at a Conference at Paris in 1919, and subsequently a Convention was signed at Paris in 1920, but has not yet become effective. The International Association for the Protection of Industrial Property is a non-official association devoted to the subject in a general way, making specific proposals for official adoption in connection with the international regime established by the above mentioned Agreements and Unions.

Special Industries.--Of international associations relating to a single industry or trade the International Federation of Master Cotton Spinners' and Manufacturers' Associations is the best example. Founded in 1904 to conserve the common interests of the cotton industry in all parts of the world, this Federation of 21 International Associations, through its Committee of Management, exercises positive functions of considerable importance, especially in connection with the supply of raw cotton; in particular, it tabulates statistics of the consumption of cotton by mills and of the stocks held by them, and other data which are now regarded as essential to the proper conduct of the industry.

A similar but smaller Federation of Linen Trade Associations was founded in 1909, but its activities have been suspended since the war of 1914–18. The International Wool Conference, representing six European countries (including Great Britain) meets periodically.

Among other International Trade Associations which are primarily concerned with the direct interests of a single industry or trade, are the International Committee of the Wine and Spirit Trade founded in 1900 by the International Vintners' Congress held on the occasion of the Universal Exhibition at Paris of that year; the International Federation of Master Tailors, 1910, and the International Federation of Seed Crushers (1910, reconstructed 1920) and the Permanent International Bureau of Motor Manufacturers (1919).

All these are private associations of manufacturers or traders, or of their national representative bodies. The absence of such bodies in the case of some of the largest staple trades such as coal, oil, iron and steel, and rubber is worthy of note. On the other hand the number of international associations for the workers in particular trades (see LABOUR) is very large. For the lighting industry the International Committee on Photometry was founded by the International Gas Congress (1900), and succeeded in 1913 by the International Commission on Illumination constituted by nationai committees from 10 countries.

Power. — The universal aspects of power production are thoroughly studied by the World Power Conference which held its first meeting in 1924 in connection with the British Empire Exhibition at Wembley. The purpose of this Conference, which has a permanent Executive Council, is to consider how the various sources of power may be adjusted nationally and internationally; it is representative of practically the whole world, and works through a series of plenary conferences at long intervals with more frequent sectional meetings. Earlier provision for co-operation between the workers of all countries in this field was made by the International Electrotechnical Commission (1906) consisting of National Committees of 19 countries in which America, North and South, is well represented, and in 1925 was founded the International Union of Producers and Distributors of Electricity, whose first Congress, held in 1926, was attended by representatives of 13 nations. Specialisation has led to the formation of the International Conference of the Leading High Tension Electric Systems, at whose session in June 1927 the above-mentioned bodies and 28 countries were represented.

Commerce. — The first instance of co-operation between States on a multilateral basis in the sphere of international trade or commerce in the proper sense is the Convention of 1890 whereby the International Bureau for the Publication of Customs Tariffs was established. Its functions are simply to supply in five languages (English, French, German, Italian and Spanish) the current Customs Tariffs of all countries. Practically the whole world subscribes to this work.

This modest organ remained the only one in the international body politic to function for the health of commerce until 1921, when the International Bureau of Commercial Statistics began its work. The aim of the States in founding this Bureau, going beyond mere collection of statistical information, was to facilitate the comparison of national statistics by unification on the basis of a common nomenclature which had been elaborated by the Convention of 1913 which established the Bureau. It accordingly publishes an annual bulletin of co-ordinated statistics of imports and exports.

An older, private association for the advancement of statistics of all kinds is the International Statistical Institute, which was founded in 1885, and includes representatives from a large number of States; its permanent office dates from 1913.

International congresses of a non-official character dealing generally with commerce and industry began to be held in the eighties of last century, and were organised periodically by the International Congress of Chambers of Commerce and Commercial and Industrial Associations until the World War. In 1919 a Conference held at Atlantic City (U.S.A.) of representatives of commerce from that country, Great Britain, France, Italy and Belgium, decided to found the International Chamber of Commerce which held its first Congress at London in 1921, where 35 countries were represented, and thenceforward others biennially, the fourth Congress at Stockholm in 1927 being attended by 800 delegates from 35 countries. The International Chamber has also a permanent organisation consisting of National Committees electing

representatives to a Council whose decisions are carried out by the Secretariat. The actual members of the International Chamber are either bodies such as local Chambers of Commerce, and National Trade Associations, or individual firms or companies.

The main aim of the Chamber is to foster international trade by promoting harmonious commercial relations between the various national interests, the domestic side of their work, and to remove restrictions on trade, the more public side of their work, which brings them into contact with the framework of laws and regulations within which trade has to find its way.

At their 1921 Congress the International Chamber adopted 27 Resolutions dealing with subjects ranging from Double Taxation to the Reform of the Calendar, and from the Channel Tunnel to Reconstruction in Poland. While a good many of these Resolutions dealt with matters of temporary importance connected with the War's upheavals, others dealt with matters of permanent interest to Commerce such as double taxation, international arbitration, unification of tariff nomenclature, treatment of commercial travellers, and in these cases the preliminary work of this International body has been followed either by bilateral government action or by definite provision of the reforms desired in international conventions, such as the Protocol on Arbitration Clauses of 1923, and the Convention on Arbitration Awards of 1927, which give effect precisely to the resolution on this subject of 1921 referred to above. The International Chamber has itself established a Court of Arbitration for commercial disputes and appoints Arbitrators.

With a view to facilitating the passage into law of the measures, which international opinion indicates as appropriate for the benefit of commerce, the International Parliamentary Conference on Commerce was founded in 1914, and its Assembly in 1927 was attended by representatives of 43 countries, appointed for the most part by the'national Parliaments themselves. It brings together the experience of the several legislative bodies in dealing with commercial matters, and its activities are thus complementary with those of the International Chamber. At the meeting of this Conference in 1919 yet another Association was founded, the International Institute of Commerce which, under the direction of the General Council of the Parliamentary Conference, is concerned with commercial statistics and legislation, including Commercial Treaties; its membership (17 States have officially adhered), is relatively restricted.

The Union of International Fairs, founded in connection with the International Fair of Milan (1925–6), describes itself sufficiently. There is no corresponding body for international exhibitions, though these have, as we have seen, been instrumental in promoting the formation of many international associations of various kinds. Their popularity has, however, increased to the point at which it has become necessary to suggest some understanding among the chief industrial countries as to their limitation.

Mention of separate associations for special industries or trades has already been made. An Association of a different type is the International Sugar Union of 1902, being an isolated example, apart from the earlier Sugar Union of 1864, of a Union of States for the regulation, for economic and not humanitarian reasons, of the trade in a single commodity. It provided for the abolition of bounties and the limitation of protective duties and, to supervise the execution of the various provisions of the Convention, created an international committee with a permanent office at Brussels. The Union worked effectively until 1912 when Great Britain left it; it ceased entirely in 1920.

Transport and Communications. — As is natural, the field of transport and communications is well covered by international bodies. International association among shipping companies did not take proper shape until the 20th century however, for the so-called Shipping Conferences which were first formed in the seventies of the 19th century, though they may include fleets under several flags, are hardly to be regarded as "international" in the sense in which the word is used in this article. They are limited in scope of course to specific trades and correspond rather to those limited industrial associations which are formed by the organised groups of a few countries for definite business purposes such as the regulation of competition (see under SHIPPING, TRUSTS and CARTELS). The Baltic and White Sea Conference (1905) has a much wider scope than its title indicates. Representing shipowners and shipbrokers in 19 countries it is the main authority for the standard form of charter party. It also seeks to *fix* minimum freights. The International Maritime Committee for the unification of Maritime Law had been founded in 1897 and itself created the national committees through which it works in 16 countries. The Committee was responsible for the initial preparation of the International Conventions on collisions and salvage signed at the Brussels diplomatic Conference in 1910 which have since been widely adopted as national law. Conventions on the limitation of shipowners' liability, maritime mortgages and liens, and bills of lading, which the Committee similarly prepared, have also been adopted by diplomatic Conferences and their inclusion in the national legislative systems is proceeding.

The Permanent International Association of Navigation Congresses (1902) consisting of representatives of 43 governments and other bodies and individuals deals mainly with technical matters.

The International Shipping Federation (1909), a federation of the shipowners' associations of 8 European countries, is concerned exclusively with their interests as employers. The International Shipping Conference which first met in 1921, consists of the national organisations of the shipping industries in 15 countries and is concerned with the general policy of the shipping industry in all questions other than labour. It seeks to establish uniformity in practice and action; it co-operates with the International Chamber of Commerce.

The group of international associations which deal with railways illustrates well the international regulation of the world. As long ago as 1882 the International Conference for promoting Technical Uniformity on Railways was founded at Berne (Switzerland being regarded as the "turn-table" of Europe) to develop international railway traffic and uniformity in certain railway equipment; this is an association of States, or of State Railway Administrations, the members consisting of those European States in which the railways are of standard gauge, and thus form a system capable of unification.

In 1885 there was founded an International Association of the Railway Congress, replaced in 1919 by a body of the same name whose effective members are the Railway Administrations of all the important countries of the world (except Russia); its functions are to promote general railway progress by congresses and publications.

The well known Berne Convention for the carriage of goods by rail of 1890, revised in 1924, and adopted by the same States as those represented in the Technical Conference described above, provided the common rules whereby goods could be sent over the railways of any number of these States by a single consignment, and this necessitated the establishment of the Central Office for International Railway Traffic at Berne in 1893, an institution created by the States themselves which has financial duties as a clearing house between the several railway administrations, and powers to settle disputes referred to them by the latter.

POST-WAR RECONSTRUCTION

The post-war reconstruction of European transport included new institutions for facilitating the international working of railways. The International Railway Wagon Union was founded in 1921 by the Convention of Stresa, again by the standard gauge countries of Europe, to manage the common user of wagons. A little later as a consequence of resolutions of the Conference at Porto Rosa (November 1921) and Genoa (May 1922) the International Railway Union, which includes the railway administrations of all the larger European countries, not excluding Russia and Spain, and also those of China and Japan, came into being with the general function of unifying and improving railways and railway working. It is preparing a scheme of nomenclature for international tariffs and a basis for international statistics.

The European Time Table Conference which secures correspondence in the timing of the principal European passenger services on the standard gauge railways, was put on a permanent foot-

ing as from 1923 by the Lucerne Conference, while the Union for International Users of Passenger Rolling Stock established by the same Conference regulates the reciprocal use of passenger rolling stock by the several administrations, also for Europe only.

America has her own International Railway Association in the shape of the Permanent Pan American Railway Committee founded in 1902 with the specific object of securing the construction of a through railway joining the United States and Mexico to Central and South America. This is an offshoot of the Pan American Union and its members are the American Republics concerned.

The common interests of the more restricted types of transport are cared for by the International Union of Tramways, Local Railways, and Public Motor Transport which corresponds with, and originated in the same year (1885) as, the International Association of Railway Congresses; it was reconstructed in 1919. Its members include local transport undertakings and public bodies.

Road transport in general is represented by the International Association of Kecognised Automobile Clubs (1904) on the more private and sporting side, and by the Permanent International Association of Road Congresses (1908), an association of 38 governments.

The organ for the international control of air traffic is the International Commission for Air Navigation which, under the International Air Convention of 1919, makes rules dealing with the registration, marking and airworthiness of aircraft, and with the issue of certificates of competency for their operating crews, with the lights and signals to be used, by aircraft, and the conduct of air traffic generally. The Commission does not administer these rules or otherwise directly control air transport, but the establishment by a central body of these governing rules, which are adopted of course by the parties to the Convention (now some 25 in number), shows how this latest form of transport is internationalised to a definitely greater degree than shipping, the form with which it has the strongest analogies.

Somewhat similar to the International Maritime Law Committee is the International Technical Committee of Legal Experts for Aviation (Comité International Technique d'Experts Juridiques Aeriens) established in pursuance of recommendations of the International Conference on Private Aerial Law of 1925. It consists of experts appointed by over 30 States and prepares draft international conventions on legal questions such as, for example, the liability of the carrier by air for loss and damage.

Private interest in aviation is co-ordinated by the International Aeronautic Federation (1905) and commercial effort by the Air Traffic Association (1919), which consists of certain important air service companies. The former body is an association of Aero Clubs which is concerned with flying as a sport and the records it authenticates are internationally accepted.

Communications. — Postal and telegraphic services naturally called for their appropriate international organs at an early stage, as has already been stated. The Postal Union is now truly universal in scope, embracing some 175 different countries including dependencies. Ordinary and wireless telegraphic communications have their corresponding unions and international bureaux dating respectively from 1865 and 1906, while the recent International Advisory Committee on Long Distance Telephone Communications brings together the administrations of some 18 European countries (for further details *see* POST and POSTAL SERVICES).

What was described by Mr. Hoover in his closing address as the largest international conference in history, the third International Radio Telegraph Conference of Washington, held in October and November, 1927, brought together representatives of over 70 different Governments and of all the important Wireless Companies as well as those of several international institutions among which were the International Commission for Air Navigation and the International Shipping Conference. This Conference after a thorough survey of the great developments which had taken place in radio telegraphic communication since the last Conference, that of 1912, reached unanimous conclusions in the shape of the International Radio Telegraph Convention and Regulations of November 25, 1927; this instrument was signed by representatives of over 70 Governments, and provided for the general control of radio electric communication and for the assignment of different bands of wave lengths covering the whole range from about 6 metres to 30,000 metres to the various services such as, for example, long distance trans-oceanic services and broadcasting. The new Convention came into force on January 1, 1929, and instituted a new international body in the shape of a Technical Advisory Committee with the function of studying technical and related questions on this subject. This is attached to the existing International Bureau of the Telegraph Union which acts as the Secretariat of the Radio Telegraph Union and will continue to carry out any administrative duties arising out of the revised Regulations which the Conference adopted.

Professional. — The Permanent Committee of International Congresses of Actuaries (1895) is devoted generally to the interests of that profession and the International Association of Accountancy (1911) seeks to systematize terminology and practice in book-keeping. They are both private organisations, but the former has public administrations among its members and the latter receives some State subventions.

Miscellaneous. — The International Co-operarive Alliance was founded in 1895 to develop co-operative methods in all countries and relations between the national societies, while in 1924 the International Co-operative Wholesale Society, consisting of all the European national societies of this kind, was founded with a similar object (*see* CO-OPERATION). Advocating a similar ideal, but for adoption by the various Governments and not individuals, the International Committee to promote universal Free Trade was founded in 1921 and embraces the national Free Trade Societies of 14 countries. Its counterpart in the shape of a union of societies for the promotion of economic nationalism or separatism not unnaturally does not exist.

Relation to League of Nations. — This habit of associating internationally and this endeavour to treat the world as one for an ever-increasing number of purposes, grows continually and has a cumulative effect. Only a world-wide catastrophe such as the war of 1914–18 can interrupt it, and that war has in the sequel had the effect of greatly stimulating these international movements, and it has given them a supreme international association of States, the League of Nations, which serves to focus their various efforts, and to secure that real effect is given to those of their aims which the world is generally ready to adopt.

The Covenant of the League of Nations lays down in Article 24 that there shall be placed under the direction of the League all international bureaux already established by general treaties, if the parties to such treaties consent, and that all such international bureaux and all commissions for the regulation of matters of international interest hereafter constituted shall be placed under the direction of the League. The bureaux here referred to are of course the creation of States; unofficial international bureaux or associations may at their request be placed under the League's directions; the tendency, however, is for such international bodies not to do so, but to work with the League Organizations. The execution of the extensive programme which the World Economic Conference of 1927 laid down, in the sphere of international economic questions, and which covers mostly the same ground as the recommendations of the various International Associations dealt with above, is entrusted to the Economic Committee of the League of Nations, aided by the Consultative Committee. It has been decided that on the latter body should be represented the International Chamber of Commerce (3 members), while co-operation is intended with such bodies as the International Management Institute and the International Co-operative Alliance.

Representatives of several international organizations, such as the International Shipping Conference, took part in the General Conference on Communications and Transit in 1927, and provision is made in the new statute for this branch of the League for the participation in its work in an advisory capacity of representatives of international organizations. It is thus becoming clear that these bodies, for the most part private in origin and constitution, are likely to find in this sphere the opportunity for their most effective work, since they can contribute to the work

of the paramount official international association the best available experience and generally matured policy.

International law has so far made no provision for giving a definite status to international associations, but the question of regularizing their position (which is especially desirable when they are not the creation of specific agreement between States) is on the agenda of the League of Nations Committee for the Codification of International Law for 1928.

BIBLIOGRAPHY.—The Handbook of International Organisations published by the League of Nations gives particulars of international associations on all subjects; the League's Quarterly Bulletin gives particulars of international conferences held or forthcoming, also a list of current publications by international organisations.

P. B. Potter in his "Introduction to the Study of International Organisation" (1922) has chapters on international associations, official and private, and gives a brief bibliography. More recent and full is W. Kaufmann's "Les Unions Internationales de Nature Economique" (1924) with a full bibliography published in the Recueil des Cours de l'Académie de Droit International. See also MONETARY CONFERENCE. (E. J. E.)

INTERPELLATION, a term meaning, in general, an interruption, more particularly used of a method of procedure adopted in some of the legislative chambers of continental Europe, especially those of France and Italy. It was originally confined to the asking of a question, after due notice, on some affair of State. It is now, however, the chief means by which the policy or action of the Ministry of the day is challenged. An interpellation can be brought on without the consent of the minister to be attacked; it is usually made the subject of a general debate, and ends with a vote of confidence or want of confidence in the Ministry.

INTERPENETRATING MOULDINGS, in architecture, are mouldings of the same or different profiles, which meet at an angle, as at the top of an arch or the corner of an opening, and instead of stopping at the line of intersection, are carved as though they passed through each other and continued on until received by some projecting member or surface. Such a juncture is known as an interpenetration. This treatment is characteristic of flamboyant Gothic (see FLAMBOYANT STYLE), especially in France and Germany.

INTERPLEADER: see PRACTICE AND PROCEDURE.

INTERPOLATION, in mathematics, the process of obtaining intermediate terms of a series of which particular terms are known; from the Latin *interpolare*, to alter, or insert something fresh, connected with *polire*, to polish. The logarithms, for instance, shown in Table I, may be regarded as terms of a series,

TABLE I.

No.	Log.	1st diff. +
2·70	·4314	
		16
2·71	·4330	
		16
2·72	·4346	
		16
2·73	·4362	
		16
2·74	·4378	
		15
2·75	·4393	

and the logarithm of a number between 2·70 and 2·75 may be found by interpolation from the table. The process of obtaining the logarithm of a number lying outside these limits would be *extrapolation*; the formulae which apply to interpolation apply in theory to extrapolation, but in practice special precautions as to accuracy are necessary. The present article deals only with interpolation.

The term is usually limited to those cases in which there are two quantities, x and u, which are so related that when x has any arbitrary value, lying perhaps between certain limits, the value of u is determinate. There is a given series of associated values of x and of u, and interpolation consists in determining the value of u for any arbitrary value of x, or the value of x for any arbitrary value of u, lying between two of the values in the series. Either of the two quantities may be regarded as a function of the other; it is convenient to regard one, x, as the independent variable, the other, u, being treated as the dependent variable, *i.e.*, as a function of x. If, as is usually the case, the successive values of one of the quantities proceed by a constant increment, this quantity is to be regarded as the independent variable. The two series of values may be tabulated, those of x being placed in a column (or row), and those of u in a parallel column (or row); u is then said to be tabulated in terms of x. The independent variable x is called the argument, and the dependent variable u is called the entry. Interpolation, in the ordinary sense, consists in determining the value of u for a value of x intermediate between two values appearing in the table. This may be described as direct *interpolation*, to distinguish it from inverse interpolation, which consists in determining the value of x for a value of u intermediate between two in the table. Graphically, the data for interpolation are certain ordinates of the graph of u with regard to x, and direct interpolation consists in deducing the magnitude of any other ordinate whose position is given, while inverse interpolation consists in determining the position of an ordinate whose magnitude is given. The methods employed can be extended to cases in which the value of u depends on the values of two or more independent quantities $x, y, \ldots$

The subject will be treated under three heads: I. Direct Interpolation (equal intervals), II. Direct Interpolation (unequal intervals), III. Inverse Interpolation.

I. DIRECT INTERPOLATION (EQUAL INTERVALS)

1. Notation and Arrangement. — We have a table showing the values of a quantity u corresponding to values of a quantity x. The values of x proceed by a constant increment h. We denote the values of x by $\ldots x_0, x_1, x_2, \ldots$, so that $x_m \equiv x_0 + mh$; and the corresponding values of u are $\ldots u_0, u_1, u_2 \ldots$ We want to find us, which is the value of u corresponding to $x_\theta = x_0 + \theta h$; for preciseness, we can say that θ lies between -1 and $+1$.

The first step, usually, is to arrange the u's in a vertical column, followed by columns containing the successive differences. The differences of the u's are the first *differences*, those of the first differences are the second differences, and so on. These are also called differences of the first, *second* ... order.

The differences, like the u's, have to be distinguished by suffixes. There are three systems, the advancing-difference, the receding-difference and the central-difference. On the *advancing*-difference system, $u_1 - u_0$ is regarded as the first difference of u_0, and is denoted by Δu_0, so that $\Delta u_1 - \Delta u_0$ is $\Delta^2 u_0$; on the receding-difference system, which is less important, $u_1 - u_0$ is the first difference of u_1. On the *central-difference* system, $u_1 - u_0$ is a difference corresponding to the interval between u_0 and u_1, and is therefore denoted by $\delta u_{\frac{1}{2}}$, so that $\Delta^2 u_{-1}$ is $\delta^2 u_0$; there is also a symbol μ for the mean of any two adjacent entries in a column, so that $\mu u_{\frac{1}{2}} \equiv \frac{1}{2}(u_0 + u_1)$, $\mu \delta u_0 \equiv \frac{1}{2}(\delta u_{-\frac{1}{2}} + \delta u_{\frac{1}{2}})$, and so on. The system is more fully set out in the article CALCULUS OF DIFFERENCES.

2. Fundamental Principle. — The methods which we are considering are, in general, applicable when the result of taking successive differences is to bring us ultimately to differences of a certain order, say the kth, which are practically constant, so that the differences of the next order, the $(k+1)$th, are zero or at any rate are negligible. The fundamental principle then is that we assume that interpolation can be performed as if these latter differences were actually zero. The implication of this assumption will be considered further in §6. The assumption may, in the case of a mathematical table, be made as a matter of course; for the table is constructed so as to be used in this way. In other cases it must be justified by the facts.

3 Interpolation by First Difference. — In Table I. we see that, as x increases, u increases steadily. We therefore use the

principle *of* proportional parts, *i.e.*, we assume that for any increase in x there is a proportional increase in u. Thus we can say that the logarithm of 2·725 is ·4346+8 (where "+8" denotes the addition of 8 to the last figure of the tabulated entry, *i.e.*, means ·0008)=·4354; and similarly log 2·7225=·4350.

Algebraically, we express the relation between x and u by saying that u is of the form $p+qx$. It follows that the formula for u_θ is

$$u_\theta = u_0 + \theta(u_1 - u_0) = u_0 + \theta\Delta u_0. \qquad (1)$$

Graphically, this means that we take the upper boundary of the graph, between u_0 and u_1, to be a straight line joining the tops of the corresponding ordinates.

To find log 2·724 we should have to add ·4 of 16=6·4. But it would be incorrect to write the result as ·43524; for this would imply that we could find the logarithm to five decimal places, which the table does not enable us to do. We can do either of two things. If we only want the best value, to four places, that we can get, we must take ·4 of 16 to be 6, so that our answer is ·4352. But a better method, if we are going to use log 2.724 for further calculation, is to retain an extra two or three figures in our work. We therefore, for the time being, write the logarithm in the form ·4352 40 or $\cdot 4352^{40}$; any extra figures retained in this way are dropped at the conclusion of our work, the preceding figure being adjusted if necessary. This principle applies throughout the whole of our work.

As stated above, the table shows that as x increases u increases steadily. But this does not mean that the second differences of u are absolutely zero; it only means that when we are working to four places of decimals they are negligible. That they do exist, can be seen either by taking more correct values, as in Table II., or by taking values of x at greater intervals, as in Table III.

3·o	·4771		

Similarly we could detect the existence of differences of the third or a higher order.

The sequence of differences, of whatever order, will present some irregularities. These are due to the fact that the tabulated values are necessarily not exact. Thus in Table I. the occurrence of the difference 1 j immediately following a series of 16's is due to the entry for 2·74 being slightly too large (as will be seen from Table II.), while the entry for 2·75 is slightly too small. A similar explanation applies to the 57 in Table II.: the entry for 2·73 is too small, and that for 2·74 is too large.

4. Interpolation with Second Differences.—If we have to use second differences, but do not need third differences, the formula is

$$u_\theta = u_0 + \theta\Delta u_0 + \tfrac{1}{2}\theta(\theta-1)\Delta^2 u, \qquad (2)$$

in which $\Delta^2 u$ may be either $\Delta^2 u_0$ or $\Delta^2 u_{-1}$. It is usually best to take the one which lies nearest in the table (see Table II. or Table III.); thus if θ lies between $-\frac{1}{2}$ and $+\frac{1}{2}$ we should use $\Delta^2 u_{-1}$, but if it lies between $+\frac{1}{2}$ and $+\frac{3}{2}$ we should use $\Delta^2 u_0$.

In most cases in which this formula has to be used, $\Delta^2 u$ is small: a convenient form for calculation is then

$$u_\theta = u_0 + \theta\{\Delta u_0 - \tfrac{1}{2}(1-\theta)\Delta^2 u\} \qquad (3)$$

5 General Formula.—The general formula, involving differences beyond the second, may be written in terms of advancing differences or of central differences.

(i.) The advancing-difference formula is

$$u_\theta = u_0 + \theta\Delta u_0 + \frac{\theta(\theta-1)}{2!}\Delta^2 u_0 + \frac{\theta(\theta-1)(\theta-2)}{3!}\Delta^3 u_0 + \cdots, \qquad (4)$$

in which the coefficients of $u_0, \Delta u_0, \Delta^2 u_0, \ldots$, are those of the powers of A in the expansion of $(1+\Delta)^\theta$ by the binomial theorem. If differences of order exceeding k are negligible, the series ends with a term in $A^k u_0$. This is known as the Gregory-Newton formula.

(ii.) The central-difference formula is of two forms, but we need only consider one, viz., that which uses u_0 and the central differences on or adjoining a horizontal line through it. Thus (see §1) the differences involved are

$$u_0,\ \mu\delta u_0 \equiv \tfrac{1}{2}(\delta u_{-\frac{1}{2}} + \delta u_{\frac{1}{2}}),\ \delta^2 u_0,\ \mu\delta^3 u_0 \equiv \tfrac{1}{2}(\delta^3 u_{-\frac{1}{2}} + \delta^3 u_{\frac{1}{2}}),\ \delta^4 u_0 \cdots$$

Let us write (*see* CALCULUS OF DIFFERENCES)

$$\begin{aligned}
c_1 &\equiv \mu\delta u_0 - \tfrac{1}{6}\mu\delta^3 u_0 + \tfrac{1}{30}\mu\delta^5 u_0 - \tfrac{1}{140}\mu\delta^7 u_0 + \cdots \\
c_2 &\equiv \delta^2 u_0 - \tfrac{1}{12}\delta^4 u_0 + \tfrac{1}{90}\delta^6 u_0 - \tfrac{1}{560}\delta^8 u_0 + \cdots \\
c_3 &\equiv \mu\delta^3 u_0 - \tfrac{1}{4}\mu\delta^5 u_0 + \tfrac{7}{120}\mu\delta^7 u_0 - \cdots \\
c_4 &\equiv \delta^4 u_0 - \tfrac{1}{6}\delta^6 u_0 + \tfrac{7}{240}\delta^8 u_0 - \cdots \\
c_5 &\equiv \mu\delta^5 u_0 - \tfrac{1}{3}\mu\delta^7 u_0 + \cdots \\
c_6 &\equiv \delta^6 u_0 - \tfrac{1}{4}\delta^8 u_0 + \cdots
\end{aligned}$$

Then the formula is

$$u_\theta = u_0 + c_1\theta + c_2\frac{\theta^2}{2!} + c_3\frac{\theta^3}{3!} + c_4\frac{\theta^4}{4!} + \cdots \qquad (6)$$

6. Basis of Formulae.—Formulae (1) and (2) may be regarded as particular cases of (4), differences after the first in the one case, and after the second in the other, being negligible. But it is more instructive to consider them separately.

(i.) For first-difference interpolation we take the upper boundary of the graph to be a straight line; and this straight line must obviously pass through the tops of the ordinates representing u_0 and u_1. Or, conversely, taking Table I. for an illustration, let us suppose that we have the graph drawn with absolute accuracy. Then, if we are unable to measure the magnitude of u_0 and u_1 and intermediate ordinates to a greater accuracy than is represented by four significant figures, we are unable to see that it is anything but a straight line. The equation to the graph must therefore be taken to be $u_\theta = u_0 + \theta\Delta u_0$.

(ii.) Now suppose that (see Table II.) we are able to measure to a degree of accuracy represented by six or seven significant figures. Then the boundary of the graph will appear to be a parabola, its equation being of the form $u = p + qx + rx^2$. To determine p, q, and r we require three ordinates. If we take these to be u_0, u_1, and u_2, the equation to the graph becomes $u_\theta = u_0 + \theta\Delta u_0 + \frac{1}{2}\theta(\theta-1)\Delta^2 u_0$; if we take them to be u_{-1}, u_0, and u_1, the equation is $u_\theta = u_0 + \theta\Delta u_0 + \frac{1}{2}\theta(\theta-1)\Delta^2 u_{-1}$. The connection between the equation being of the form $u=p+qx+rx^2$ and the formula not going beyond second differences is that, if u is of this form, second differences of the u's are o. Table IV. illustrates this for the particular case of $u \equiv x^2$.

TABLE IV.

x	o	1	2	3	4	5	...
$u \equiv x^2$	o	1	4	9	16	25	...
1st diff.	1	3	5	7	9	...	
2nd diff.	2	2	2	2	...		
3rd diff.	o	o	o	...			

(iii.) Finally, suppose that differences beyond those of order k are negligible, and let us, for simplicity, take k to be even and $=2g$. Then u is a polynomial in x, of degree $k \equiv 2g$. If we want to use advancing differences, we find the constants in this polynomial by passing a curve of degree k through the tops of the

ordinates $u_0, u_1, u_2, \ldots, u_{2g}$; and we then get the formula

$$u_\phi = u_0 + \phi\Delta u_0 + \frac{\phi(\phi-1)}{2!}\Delta^2 u_0 + \cdots + \frac{\phi(\phi-1)\cdots(\phi-2g+1)}{(2g)!}\Delta^{2g}u_0 \qquad (7)$$

If, on the other hand, we pass the curve through the tops of the ordinates $u_{-g}, u_{-g+1}, \ldots, u_{-1}, u_0, u_1, \ldots, u_{g-1}, u_g$, we get the central-difference formula for u_θ in terms of $u_0, \mu\delta u_0, \delta^2 u_0, \ldots, \delta^{2g}u_0$.

(iv.) An important fact is that, viewed algebraically, there is no essential difference between the advancing-difference formula and the central-difference formula. If, as in (iii.), we pass a curve of degree $2g$ through the tops of the ordinate $u_0, u_1, u_2, \ldots, u_{2g}$, the formula for u given by this curve is a central-difference formula for interpolation between $u_{g-\frac{1}{2}}$ and $u_{g+\frac{1}{2}}$, but it is also an advancing-difference formula for interpolation between u_0 and u_1, and a receding-difference formula for interpolation between u_{2g-1} and u_{2g}.

7. Central-difference Formulae. — A central-difference formula, in the general sense, is one which involves differences, or pairs of differences, lying on or close to a horizontal line in the table. There are several of these, but they are all equivalent either to (6) or to a formula constructed on the same principle but involving $\mu u_{\frac{1}{2}}, \delta u_{\frac{1}{2}}, \mu\delta^2 u_{\frac{1}{2}} \ldots$. Three of these, known to Newton but subsequently discovered by other writers, may be mentioned.

(a) The Newton-Gauss formula is a zigzag formula involving $u_0, \delta u_{\frac{1}{2}}, \delta^2 u_0, \delta^3 u_{\frac{1}{2}} \ldots$.

(b) The Newton-Stirling *formula*, easily obtained from the above, involves $u_0, \mu\delta u_0, \delta^2 u_0, \mu\delta^3 u_0, \ldots$, and becomes (6) if the coefficients of $\theta, \theta^2, \theta^3, \ldots$ are collected.

(c) The *Newton-Bessel* formula involves $\mu u_{\frac{1}{2}}, \delta u_{\frac{1}{2}}, \mu\delta^2 u_{\frac{1}{2}}, \delta^3 u_{\frac{1}{2}} \ldots$. If the coefficients of $\theta-\frac{1}{2}, (\theta-\frac{1}{2})^2, (\theta-\frac{1}{2})^3, \ldots$ in this formula are collected, we get an alternative formula to (6), for use throughout an interval in the table.

8. Sub-tabulation. — When the values of u have been tabulated for values of x, proceeding by a difference h, we may want to deduce a table in which the differences of x are h/n, where n is an integer. For the common case of $n=10$, we can proceed by two steps, first halving the interval, and then dividing the new interval into fifths.

(i.) For halving the interval we have

$$u_{\frac{1}{2}} = \tfrac{1}{2}(U_0 + U_1), \qquad (8)$$

where

$$U \equiv u - \tfrac{1}{8}\delta^2 u + \tfrac{3}{128}\delta^4 u - \tfrac{5}{1024}\delta^6 u + \ldots. \qquad (9)$$

(ii.) For any other value of n than 2 we use a formula due to J. D. Everett. If we write $+=1--8$, Everett's formula is

$$\left.\begin{aligned} u_\theta = \theta u_1 + \frac{\theta(\theta^2-1^2)}{3!}\delta^2 u_1 + \frac{\theta(\theta^2-1^2)(\theta^2-2^2)}{5!}\delta^4 u_1 + \cdots \\ + \phi u_0 + \frac{\phi(\phi^2-1^2)}{3!}\delta^2 u_0 + \frac{\phi(\phi^2-1^2)(\phi^2-2^2)}{5!}\delta^4 u_0 + \cdots \end{aligned}\right\} \qquad (10)$$

For actual calculation we replace $\theta u_1 + \phi u_0$ by $u_0 + \theta\Delta u_0$. Then, if we write

$${}_\theta V_n \equiv \frac{\theta(\theta^2-1^2)}{3!}\delta^2 u_n + \frac{\theta(\theta^2-1^2)(\theta^2-2^2)}{5!}\delta^4 u_n + \ldots \qquad (11)$$

we have, for interpolation between u_0 and u_1,

$$u_\theta = u_0 + \theta\Delta u_0 + {}_\theta V_1 + {}_{1-\theta}V_0, \qquad (12)$$

the successive values of θ being $1/n, 2/n, \ldots, (n-1)/n$. For interpolation between u_1 and u_2 we have, with the same succession of values of θ,

$$u_{1+\theta} = u_1 + \theta\Delta u_1 + {}_\theta V_2 + {}_{1-\theta}V_1. \qquad (13)$$

The values of ${}_{1-\theta}V_1$ in (13) are exactly the same as those of ${}_\theta V_1$ in (12), but in the reverse order. The process of constructing the new table is therefore very simple.

II. DIRECT INTERPOLATION (UNEQUAL INTERVALS)

9. When the differences of consecutive x's are not all equal, we use formulae analogous to ordinary interpolation-formulae, but with the differences prepared in a special way. The best-known formulae are Newton's (original) formula and Lagrange's formula; the former uses ('divided" differences.

Let the tabulated values of x be . . . , a, b, c, d, . . . , the corresponding values of u being denoted by . . . , f(a), f(b), $f(c)$, $f(d)$ . . . . Then our table is of the form:—

x	u	Divided Differences			
		1st	2nd	3rd	. . .
a	$f(a)$				
		$f(a,b)$			
b	$f(b)$		$f(a,b,c)$		etc.
		$f(b,c)$		$f(a,b,c,d)$	
c	$f(c)$		$f(b,c,d)$		etc.
		$f(c,d)$			
d	$f(d)$				

In this table

$$\left.\begin{aligned} f(a,b) &\equiv \frac{f(b)-f(a)}{b-a}, f(b,c) \equiv \frac{f(c)-f(b)}{c-b}, \ldots \\ f(a,b,c) &\equiv \frac{f(b,c)-f(a,b)}{c-a}, f(b,c,d) \equiv \frac{f(c,d)-f(b,c)}{d-b}, \cdots \\ f(a,b,c,d) &\equiv \frac{f(b,c,d)-f(a,b,c)}{d-a}, \ldots \\ &\text{etc.} \end{aligned}\right| \qquad (14)$$

The quantities $f(a,b)$ . . . in the first line are called *divided differences of the first order*; those in the second line are *divided differences of* the second *order*; and so on. If u is a polynomial of degree k in x, the divided differences of order $k+1$ are all 0. It should be observed that the value of any divided difference is independent of the order in which the u's involved in it are arranged; thus $f(a,b)=f(b,a)$, $f(a,b,c)=f(a,c,b)$, etc.

Newton's formula for unequal intervals is

$$f(x) = f(a) + (x-a)\,f(a,b) + (x-a)(x-b)f(a,b,c) + \cdots, \qquad (15)$$

the series continuing until the differences are zero or negligible. This formula covers all those with which we have so far dealt; thus the Newton-Gauss formula (§ 7) is obtained by taking the x's in the order 0, 1, −1, 2, −2, ...

The method was subsequently modified by Newton, in a manuscript written in 1676 but not known to the world until 1926. Another method, similar to this modified method, but not identical with it, is that of '(adjusted differences."

Lagrange's formula is

$$\left.\begin{aligned} f(x) = {} & \frac{(x-b)(x-c)(x-d)\ldots}{(a-b)(a-c)(a-d)\ldots} f(a) \\ & + \frac{(x-a)(x-c)(x-d)\ldots}{(b-a)(b-c)(b-d)\ldots} f(b) \\ & + \frac{(x-a)(x-b)(x-d)\ldots}{(c-a)(c-b)(c-d)\ldots} f(c) + \ldots. \end{aligned}\right| \qquad (16)$$

This gives exactly the same result as Newton's formula. It is not so convenient for calculation as the latter, and it does not show how many u's have to be taken into account; but it is important in dealing with the theory of the subject.

III. INVERSE INTERPOLATION

10. Inverse Interpolation: Simple Cases.—In all cases of inverse interpolation we have to pay special attention to the degree of accuracy of the result. This depends largely, in ordinary

cases, on the initial figure of the first difference.

If the first difference is practically constant, inverse interpolation is very simple. The direct formula

$$u_\theta = u_0 + \theta \Delta u_0$$

gives

$$\theta = (u_\theta - u_0)/\Delta u_0.$$

If we have to go to second differences, the direct formula is

$$u_\theta = u_0 + \theta \Delta u_0 + \tfrac{1}{2}\theta(\theta - 1)\Delta^2 u$$
$$= u_0 + \theta\{\Delta u_0 + \tfrac{1}{2}(\theta - 1)\Delta^2 u\},$$

where, if θ lies between 0 and 1, $\Delta^2 u$ may be either $\Delta^2 u_{-1}$ or $\Delta^2 u_0$. We can calculate the expression in { } by taking an approximate value of θ; and then θ is found more accurately by dividing $u_\theta - u_0$ by this expression.

11. General Formula.—If third or higher differences have to be taken into account there are two methods.

(i.) We can use the genera! formula (6), viz.:

$$u_\theta = u_0 + c_1\theta + c_2\frac{\theta^2}{2!} + c_3\frac{\theta^3}{3!} + c_4\frac{\theta^4}{4!} + \cdots,$$

and proceed by successive approximations. By transposition and division, we get

$$\theta = \left(u_\theta - u_0 - c_2\frac{\theta^2}{2!} - c_3\frac{\theta^3}{3!} - c_4\frac{\theta^4}{4!} - \cdots\right) \div c_1.$$

We begin with an approximate value of θ. Substituting this on the right-hand side, we get a closer approximation; and so on.

(ii.) The above method is only applicable when the intervals in x are equal. An alternative method, suitable for cases of unequal intervals, but not always applicable, is to invert the table—*i.e.*, to interchange the x column and the u column and find divided differences of the x's—and proceed by direct interpolation.

Steffensen, *Interpolation* (1927). See also Duncan C. Eraser, *Newton's Interpolation Formulas* (1927) and *Isaac Newton*, Memorial volume (1927) See also CALCULUS OF DIFFERENCES. (W. F. S)

INTERPRETATION, in general, the action of explaining, or rendering the sense of an obscure form of words or an unknown tongue into a language comprehended by the person addressed. In legal use the word is employed in the sense of ascertaining the meaning of the language of a document. (See CONTRACT; WILL, etc.) It is usual for statutes to contain definitions and the British Interpretation Act of 1889 is of general application. This term is used similarly in the United States.

INTERREGNUM, strictly a period during which the normal constituted authority is in abeyance, and government is carried on by a temporary authority specially appointed (Lat. inter, between, and *regnum,* reign). Though originally and specifically confined to the sphere of sovereign authority, the term is commonly used by analogy in other connections for any suspension of authority, during which affairs are carried on by specially appointed persons. The term originated in Rome during the regal period when an *interrex* was appointed (traditionally by the senate) to carry on the government between the death of one king and the election of his successor (see ROME: *History).*

The most noteworthy use of the term "interregnum" in post-classical times is that of the Great Interregnum in German history between the death of Conrad IV. (1254) and the election of Rudolf of Habsburg (1273). See GERMANY: *History.*

INTERRUPTED CONTINUOUS WAVES, in radio, are waves obtained by the interruption at audio-frequency in a periodic manner of an otherwise continuous wave.

INTER-STATE COMMERCE includes the movement of passengers and freight from one State to another, and the agencies and facilities by which the transfer is accomplished; it comprises the mechanism and services of trade, transport and communication between citizens of different States. Broadly defined, the term commerce applies to a wide range of economic services, to exchange or distribution in general, but as here used it is limited to the traffic and trade that crosses State boundaries in the internal or domestic commerce of the United States. Foreign trade is not included, nor are communication agencies and services.

Inter-State commerce may be carried on by an individual or a partnership but it is for the most part conducted by corporations, which, like those concerned with production, tend to become larger, their activities being increasingly subject to regulation by the States and particularly by the Federal Government. In the interest of public safety the facilities employed by rail, highway, ocean and air carriers must conform to standards fixed by State and national laws whose enforcement is furthered by Government inspection of equipment of many kinds. Corporations must compete in inter-State commerce by methods that are "fair," and the accounts, finances, charges and services of carriers are comprehensively regulated by the national Government.

The principal agencies by which inter-State freight and passenger movements, or trade and travel, are effected, are the steam and electric railways. the vessels operated coastwise and on the Great Lakes, the rivers and canals; the carriers operating motor trucks and buses, and the aeroplanes. Carriers other than railroads subject to the Inter-State Commerce Act of 1887 as amended to date include pipe line companies (other than water companies), sleeping car, express, telegraph and telephone companies. Inter-State motor carriers are regulated by the Motor Carriers Act of 1935. Inter-State carriers by water are regulated in part by the Inter-State Commerce Commission, but mainly by the United States Maritime Commission which was created by the Act of 1936, and whose powers are derived from that and previous merchant marine acts. A Federal Trade Commission was created by the Act of Sept. 26, 1914, to prevent unfair competition in commerce. The Civil Aeronautics Act of 1938, as amended in 1940, gives the Civil Aeronautics Board and the Secretary of Commerce jurisdiction over inter-State air facilities and services.

Volume of Inter-State Commerce.—The volume of inter-State as distinct from intra-State commerce is not stated in official records, but it is well known that most goods shipped between points within the United States or sent to or received from foreign countries pass State boundaries. The larger share of the total traffic of rail, water, highway and airway carriers being goods carried from one State to another, reference to the tonnage transported by these several carriers will indicate the magnitude of inter-State commerce in the United States.

During the year 1939, the railroads in the United States transported 940,182,560 tons of revenue freight. This was the tonnage originating on their several lines. Some freight moved over more than one road. The total freight service was the equivalent of the movement of one ton nearly 334 billion miles, the number of tons and the ton miles having decreased largely as a result of the business depression of 1929. There were 7 tons and over 2,565 ton miles of railroad freight per inhabitant in 1939, and, as the average distance a ton was hauled was nearly 354 m., it is evident that most of the traffic must have been inter-State.

The domestic water-borne commerce of the United States in 1929 moved coastwise and on the Great Lakes and other inland waterways totalled 407,000,000 short tons. This total was temporarily cut nearly in half by the business depression. After 1932 the tonnage again increased and by 1937 it had regained all its former volume. The number of tons moved on rivers and canals is greater than the tonnage of the Great Lakes; but, as the average length of haul on the Great Lakes is much longer, the ton-mileage for the Great Lakes (in 1938) was 49 billions as compared with 17 billions for the traffic of rivers and canals. The major portion of this large traffic on the Great Lakes was contributed by coal. iron-ore, wheat and stone. Traffic on rivers and canals consists largely of bulk shipments of minerals, steel. petroleum, sand and stone. There is a large volume of traffic carried coastwise, a part of which is intercoastal via the Panama Canal, through which, in 1939, 7,716,016 long tons of cargo moved, the average length of haul being 5,000 nautical miles.

In 1939, 51,550 common carrier motor buses were registered, but there were in addition 86,700 buses, most of them operated by

contract carriers and school authorities. On the same date the total mileage of surfaced highways, inter-State and intra-State, was over 360,000 miles. The number of motor trucks operated by contract, common and private carriers in intra-State and inter-State operations, was nearly 4,500,000 in 1939. The total number of registered motor vehicles was about 30 million.

The bureau of public roads of the U.S. department of agriculture has conducted surveys in several States to determine the nature and volume of motor passenger and freight traffic. In a small State like Connecticut, with its dense population and highly diversified industries, and with the city of greater New York close by, there would be a large use of the highways, and it was found that 27·5% of the motor freight tonnage on the Connecticut highways was inter-State traffic. In Texas, however, a much smaller share of the motor truck transportation is inter-State. Inter-State motor traffic is a small share of the total because 80% of motor hauls are less than 20 miles long. Air transport routes are characteristically long and most air services over regular routes are inter-State. Aeronautics is making rapid progress in the U.S. and greater development has been made than in any other country, and commercial air transport promises to be much larger. Its early development was slow because it did not receive Government subsidies, while European countries gave large aid to companies to enable them to maintain passenger and package air transport services. In 1939 there were 17 companies engaged in scheduled air line operations and in addition there was a large number of other companies engaged in air transporting for hire. The number of passengers carried by the scheduled air lines in 1939 was 1,912,051. Express matter carried weighed nearly 7,000,000 pounds. During the year ending Feb. 1940, scheduled aeroplanes flew 86,300,000 miles. Air mail transport in the United States is well developed and is rapidly increasing. In 1940 the aeroplanes carrying mail were travelling 150,000mi. a day, the annual air mail traffic having reached 18,500,000,000 pound-miles. On Sept. 1, 1927, the American Railway Express Co.—now the Railway Express Agency—made an agreement with the air lines for an air express service. In 1940, the annual air express traffic reached a total of 6,700,000,000 pound-miles. Some package freight of high value is carried by aeroplanes when an emergency requires fast service. In general, air transportation has so developed that large passenger planes are regularly operated between the principal cities. There are day services and over-night services between the Atlantic and Pacific seaboards. Most air services, passenger, mail and express, are inter-State.

Freedom of Inter-State Commerce in the United States.—The commerce passing State boundaries in the United States has become of great volume. No State imposes trade restrictions. The United States throughout its wide territory is a single commercial unit with full freedom of internal trade. In this regard the United States is in marked contrast with Europe, where racial and historical causes have brought about the existence of many nations each concerned with safeguarding its own internal trade against the undue encroachment of the commerce of other countries.

Freedom of inter-State commerce has been as great an aid to political success as to economic welfare. The commerce clause of the Constitution made a united country possible; in spite of sectional divergencies and a civil war, the nation has been held together and the States have grown into an indissoluble union because industry, trade, transport and communication have known nothing of State boundaries or of political differences.

Power of the United States Government over Inter-State Commerce.—The power "to regulate commerce with foreign nations, and among the several States" is vested in Congress by the Constitution which also stipulates that "No State shall, without the consent of the Congress, lay any imposts or duties on imports or exports, except what may be absolutely necessary for executing its inspection laws"; also that "No State shall, without the consent of the Congress, lay any duty on tonnage." The Constitution provides that Congress shall levy no tax or duty "on articles exported from any State," and that "No preference shall be given by any regulation of commerce or revenue to the ports of one State over those of another. Nor shall vessels bound to or from one State be obliged to enter, clear, or pay duties in another." These prohibitions in the Constitution prevent restrictive regulation of commerce while the positive power granted to Congress is comprehensive and has been so interpreted by Congress and the Supreme Court as to make regulation positive and constructive. In regulating, Congress can promote inter-State commerce, and that, to an increasing extent, has been the policy of the Federal Government.

The interpretation of the commerce clause of the Constitution, through a long series of Supreme Court decisions, has tended to narrow the powers of the States and to broaden those of the Federal Government over inter-State, and indirectly over intra-State commerce. Chief Justice Marshall laid a broad and secure foundation for Federal authority in 1824, in the case of *Gibbons* v. *Ogden* (g Wheaton *1*). In this classic decision, denying to the State of New York the power to grant to a steamboat company a monopoly of steam navigation in the waters of the State to the exclusion of others owning vessels licensed by the United States, the chief justice enunciated the principle that has guided the Supreme Court in all subsequent interpretations of the commerce clause when he said:—"By virtue of the comprehensive terms of the grant, the authority of Congress is at all times adequate to meet the varying exigencies that arise, and to protect the national interests by securing the freedom of inter-State commercial intercourse from local control."

The extension of the power of Congress over inter-State (and incidentally intra-State) commerce by legislation and court decisions has affected all four categories of commerce and carriers—commerce by waterways, railroads, highways and air.

Federal Regulation of Inter-State Shipping.—Among the Supreme Court decisions defining the boundaries of State and Federal power over shipping was *Sinnot* v. *Davenport* (22 Howard 227) which in 1860 held unconstitutional a law enacted by Alabama in 1854 requiring special State registration of all vessels navigating waterways in the State. The court ruled that a vessel enrolled by the United States cannot be compelled to secure State registration. Likewise in 1871 the Supreme Court annulled a law enacted by Alabama in 1866 imposing a tax of $1.00 per ton on all vessels operating upon the navigable waters within the State. The States may tax ships as property, but may not levy a tonnage tax (*Cox* v. *the Collector*, 12 Wall. 204). A State is also without power to impose port wardens' fees upon ships entering its ports (*Steamship Company* v. *Port Wardens*, *6* Wall. 31, decided 1867), or to place an occupation tax on persons or corporations employing vessels in a manner authorized by a U.S. licence (*Moran* v. *New Orleans*, 112 U.S. 69, decided in 1884).

These Supreme Court decisions negatived attempts of the States to burden the facilities of commerce. The legislative policy of Federal regulation has been a positive one. Harbours have been improved and inland waterways have been canalized and extended; the Shipping Act of 1916 and the Merchant Marine Acts of 1920, 1928 and 1936 provide for aiding and regulating shipping. Moreover, the Inter-State Commerce Act, particularly as amended by the Transportation Act of 1920, empowers the Inter-State Commerce Commission to establish through routes and rates by railroads and waterways and thus to promote the use of waterways by making them a part of a co-ordinated system of rail and water lines for the service of inter-State commerce.

Regulation of Inter-State Commerce by Rail.—The main carriers of inter-State commerce in the United States are the railroads. The Federal regulation of railroads which began with the Inter-State Commerce Act of 1887 has been extended in scope by subsequent laws until it now applies comprehensively to all such carriers engaged in inter-State commerce. Moreover, inter-State and intra-State commerce and railroad services are so interrelated that the Federal Government in exercising its plenary power over inter-State commerce incidentally limits in large measure the regulation of intra-State trade and traffic by the States. The U.S. safety laws apply to all railroad equipment; railroad finances are regulated by the Inter-State Commerce Commission which must approve of the location and construction of proposed railroads and of the issue of securities; and the States may not

establish intra-State rates that unreasonably discriminate against the inter-State charges fixed or authorized by the Federal Commission.

When the States began to regulate railroad rates, shortly after 1870, some of the States fixed rates on all railroad traffic including both that moving within and that crossing State boundaries, but in 1886 the U.S. Supreme Court in *Wabash* v. *Illinois* (118 U.S. 557) held that the States could not fix the rates on inter-State traffic. To do so would be to regulate inter-State commerce over which the United States has jurisdiction. For 25 years after this decision by the Supreme Court no question was raised as to the power of the States to fix rates on intra-State traffic that were *per se* reasonable, but in 1911 the Railroad Commission of Louisiana complained to the Inter-State Commerce Commission that the railroad rates fixed by the State authorities of Texas on traffic within that State were so much lower than the inter-State rates as to discriminate against traffic from Louisiana into Texas and to prevent Shreveport, La., from competing with Houston and Dallas for the trade of north-eastern Texas. The commission decided in favour of the complainant and ordered the railroads to cease the discrimination which they did by raising the rates that had been fixed by Texas. This order of the Inter-State Commission and this action of the carriers were sustained by the U.S. Supreme Court in 1914 in the so-called Shreveport decision (234 U.S. 342). The principle established by this decision was extended and strengthened in the Transportation Act of 1920 by which the Inter-State Commerce Commission was given authority to prescribe rates and fares to take the place of intra-State rates that the Commission has found to discriminate unjustly against inter-State or foreign commerce.

To carry out the rate-making provisions of the Transportation Act of 1920 and to enable the carriers to obtain a reasonable return on their property, the Inter-State Commerce Commission raised rates and fares on all railroad traffic, intra-State as well as inter-State. The State of Wisconsin had fixed passenger fares by statute at 2 cents a mile. The State Commission did not change the statutory fare, but the carriers secured a Federal Court decree enjoining the State from fixing the intra-State fare at 2 cents. The Supreme Court (257 U.S. 563) upheld the Federal statute and order of the Inter-State Commission. Likewise, on the same day that it handed down this decision, the Court, in *New York* v. *the United States* (257 U.S. 591), upheld the Inter-State Commerce Commission's order raising New York intra-State railroad rates and fares to the level of inter-State rates, and set aside a contract provision in the charter of the New York Central railroad which had limited the fare on the main line of that road between Albany and Buffalo to 2 cents a mile, the Court holding in effect that the State in requiring such a fare to be charged was unjustly discriminating against inter-State passenger traffic subject, at that time, to a charge of 3.6 cents per mile.

Federal Authority over Inter-State Commerce by Highways. — The U.S. Supreme Court, in a series of decisions, has defined the boundaries of State and Federal authority over highway carriers engaged in inter-State commerce, just as the powers of the States and the nation over commerce by railroads have been determined by judicial interpretation. In 1923 the State of Michigan enacted a law requiring all motor carriers for hire upon the roads of the State to secure a certificate from the public utilities commission. The act also provided that such motor carriers for hire should be common carriers subject to the laws applicable thereto and should be required to carry insurance or furnish an indemnity bond. A motor carrier engaged solely in inter-State transport on a contract basis contested the validity of the law and the U.S. Supreme Court held that "It is a burden on inter-State commerce to impose on plaintiff (a private inter-State carrier) the . . . liability of a common carrier, and the obligation of furnishing such indemnity bond" as conditions precedent to engaging in inter-State commerce. The Court also held that a State could not by legislative fiat convert a private carrier into a common carrier, "for that would be taking private property for public use without just compensation" (***Duke*** v. Public *Utilities Commission,* 266 U.S. 570).

A man desiring to operate a common carrier bus line between Seattle, Wash., and Portland, Ore., was granted an authorizing certificate by Oregon, but was refused one by Washington. The director of public works in Oregon ruled that there was no need for another carrier and denied the petition because "under the laws of the State, the certificate may not be granted for any territory which is already being adequately served." The Supreme Court, however, held that the law was a regulation of inter-State commerce forbidden by the commerce clause of the Federal Constitution *(Buck* v. *Kuykendall,* 267 U.S. 307, March 2, 1925). However, in later decisions, particularly in *Stephenson* v. *Binford* (287 U.S. 251 decided Dec. 5, 1932) the Supreme Court has upheld the power of the States to regulate the use of its highways for gain by contract as well as common carriers, and the States are thus able to regulate motor carriers thoroughly subject to the limitation that the States may not prevent, or unreasonably burden, inter-State commerce.

These and other decisions of the Federal courts have given effect to a generai definition of the powers of the States and of the United States respectively, which were clearly stated by the Supreme Court as early as 1915 in the case of *Hendrick* v. *State of Maryland* (235 U.S. 610) when the Court declared that "In the absence of national legislation covering the subject, a State may rightfully prescribe uniform regulations necessary for the public safety and order in respect to the operation upon its highways of all motor vehicles — those moving in inter-State commerce as well as others. . . . The reasonableness of the State's action is always subject to inquiry in so far as it affects inter-State commerce, and in that regard it is likewise subordinate to the will of Congress."

Federal Aid and Regulation of Air Transportation. — Congress encourages the development of air transportation by liberal aid. The Air Commerce Act of May 20, 1926, provided that all aircraft operated inter-State or to foreign countries were to be registered and rated by the secretary of commerce who was also empowered to establish airways and equip them with necessary lights, signals and landing fields, other than terminal landing fields or airports. The regulation of the services and charges of the air carriers began with the enactment of the Civil Aeronautics Act of 1938.

The Government has greatly aided the establishment and development of air-line services by liberal payments for the carriage of mail. Such payments have been made large enough to enable the air-lines to maintain and develop the services needed in the interest of the public, the Government and national welfare. The Civil Aeronautics Board fixes the compensation to be paid.

While terminal airports are provided by municipalities and to a lesser extent by the air-line companies, the Government has aided largely in the construction of municipal airports. The Work Projects Administration, to provide work for the unemployed, has constructed a large number of airports for the municipalities.

The enforcement of the Act of 1938 was vested in a Civil Aeronautics Authority of five men. The Act also provided for an Administrator, who was to have charge of establishing civil airways, surveying airports, and developing a national system of airways. The Act of 1938 also provided for a Safety Board of three men to investigate air carrier accidents. Congress, in 1940, gave the Civil Aeronautics Authority a new title, the Civil Aeronautics Board, and associated it with the Department of Commerce. The Board is independent of the secretary of cammerce as regards its interpretation and enforcement of the Civil Aeronautics Act. The functions exercised by the Administrator include jurisdiction over safety regulations. The Safety Board was discontinued.

The States and municipalities are establishing landing fields and airports in large numbers and the Federal Government is adding to and extending the established air routes, equipping them with temporary landing fields, with signal lights and radio apparatus. Conditions favourable to a rapid future development of inter-State and foreign air commerce have been established.

Prohibition of Combinations in Restraint of Inter-State Commerce. — The Antitrust (Sherman) Act of July 2, 1890, as

amended and strengthened by the Clayton Act of Oct. 15, 1914, makes illegal contracts or combinations in the form of trusts, or otherwise, in restraint of inter-State or foreign commerce. In 1896, in the case of the *United States* v. *Trans-Missouri Freight Association* (166 U.S. 290), the Supreme Court held that the law applied to all combinations in restraint of inter-State or foreign commerce, including those that had previously been considered reasonable under the common law. This literal interpretation of the law hampered the development of large-scale organization in the conduct of commerce until 1911, when, in the Standard Oil company case (*United States* v. *Standard Oil Co.*, 221 U.S. 1) the Supreme Court enunciated and applied the "rule of reason," the effect of which was to hold that the Sherman Act prohibits only such combinations and restraints as were illegal at common law. This decision was not satisfactory to those who favoured a stringent curb on combinations, and the Clayton Act was passed to define more specifically what combinations or restraints were prohibited and to extend the law more definitely to agreements made to fix prices for the purpose of lessening competition or creating monopoly. The act, however, exempted labour and agricultural organizations from the provisions of the antitrust laws. The Clayton Act did not, in fact, strengthen the Sherman Act of 1890, the general terminology of the original law having proved more comprehensive than the more specific definitions and specifications of the later act.

Railroad rate agreements and railroad consolidations, which by the decision of the Supreme Court in the Trans-Missouri Freight Association case in 1896 and the Northern Securities case in 1904 (*Northern Securities Co.* v. *United States*, 193 U.S. 197) had been brought under the prohibitions of the Antitrust Act, were, by the Transportation Act of 1920, made legal when approved by the Inter-State Commerce Commission.

Fair Competition in Inter-State Commerce.—In 1914, Congress enacted a law, approved on Sept. 26, "to create a Federal Trade Commission and to define its powers and duties." The purpose of the act was "to prevent persons, partnerships, or corporations, except banks, and common carriers subject to the acts to regulate commerce, from using unfair methods in commerce." The commission of five members is given ample powers of investigation. If the commission finds that methods of competition prohibited by law are being employed it may order the violator of the law to desist from such practices. If the order is not obeyed, the commission may apply to a U.S. circuit court of appeals to enforce the order. As the court has the power to affirm, modify or set aside the order, the Trade Commission is in reality more an investigating than a regulatory agency. It has, however, served a useful purpose, not only because it may proceed upon its own motion, but also for the reason that it may be called upon by the attorney-general to report upon the manner in which a corporation that has been found by a court to be violating the antitrust laws is carrying out the court's decree. The Trade Commission may also be directed by "the President or either house of Congress to investigate and report the facts relating to any alleged violation of the Antitrust Acts by any corporation."

The Anti-trust laws of 1890 and 1914 have been enforced, broadened in scope, and made increasingly effective by many decisions of the United States Supreme Court. The decision of the Court in the case of the *United States* v. *Socony-Vacuum Oil Co.*, rendered May 6, 1940, went so far as to condemn as illegal an agreement of oil refining companies to pay independent refineries such a price for their excess or "distress" gasoline as to enable them to save their properties and continue in business when their existence was threatened by acute conditions resulting from a sudden excess in oil output caused by the opening of new wells. The Court held that "Conspiracies under the Sherman Act (of 1890) are on the common law footing; they are not dependent on the doing of any act other than the act of conspiring." An agreement to raise the price of a commodity that enters into interstate commerce is a violation of the Federal Anti-Trust Law irrespective of the reasonableness of the price agreed upon or of the purpose and intention of the members of the combination to pay a price that may be reasonable. The obvious purpose of the Court is so to interpret the statutes as to assure to consumers the full benefit of competition.

The U.S. domestic commerce, most of which is inter-State, is changing constantly with the evolution of industry and industrial processes, with the shifting of the major centres of production of the leading staples of manufacture, and with improvements in transport agencies and in methods of transport. Moreover, while commerce is increasing in volume, large-scale organization of business is more and more taking the place of small enterprises For these reasons, inter-State commerce is the subject of frequent legislation and of an increasing administrative regulation.

BIBLIOGRAPHY.—The statutes concerning the regulation of inter-State commerce by the United States may be found in convenient form in *Barnes' Federal Code 1919* and its *Cumulative Supplement*. The U.S. Supreme Court decisions referred to in the article contain a large amount of historical and economic information. The *Annual Reports of the Inter-State Commerce Commission*, and *Annual Report of the Chief of Engineers U.S. Army*, Volume on "Commercial Statistics" are to be consulted for statistics of the volume of domestic traffic by rail and water. *See* also E. R. Johnson, G. G. Huebner and G. Lloyd Wilson, *Transportation Econoinic Principles and Practices* (1940), which contains much information concerning railroad, highway, ocean and air traffic in the United States. (E. R. J.)

INTERSUBJECTIVE, in psychology, means that which pertains at once to a number of conscious beings. So whatever is experienced simultaneously by several minds is described as intersubjective experience; and whatever is valued in the same way by a number of persons is said to have intersubjective value. The term is more especially used in conjunction with the term intercourse (intersubjective intercourse) to denote the intercourse of several minds. J. Ward lays stress on intersubjective intercourse as a potent factor in the development of the human mind.

See J. Ward, *Naturalism and Agnosticism* (1907), *Psychological Principles* (1920); R. Goldscheid, *Entwicklungswerttheorie* (1908).

INTERVAL, a space left between the component parts of a continuous series, a pause in continuous action, a period of time intervening between two other points of time. (Lat. *intervallum*, space between the palisades on a rampart [*vallum*], or between the rampart and the tents of the legionaries,) In military language "interval" is the lateral space between men or bodies of troops, measured from the flank of one body to the flank of the next. It is used in contradistinction to "distance," the space from front to rear.

In medical language "interval" is used of the intervening periods between attacks of a disease, particularly of the periods of a normal condition of mind sometimes experienced by an insane person, a "lucid interval."

In music, an interval is the distance separating one note from another in respect of pitch. It is named according to the number of degrees of the scale, otherwise the number of alphabetical notes, included by the two notes which constitute it. Thus E to F, E to F sharp and E to F double sharp are all seconds because there are in each case two degrees of the scale included. Similarly E to G, E to G sharp and E sharp to G are all thirds because there are three alphabetical notes included in each case. It is obvious, however, that the actual intervals are not the same in these cases and additional qualifying terms are therefore employed. Thus E to F, E to F sharp and E to F double sharp are minor, major and augmented second respectively; while E sharp to G, E to G and E to G sharp are similarly diminished, minor and major thirds.

Intervals beyond the 9th are regarded as repetitions and classed as compound. (*See* MUSIC.)

INTESTACY, in English law, applies to the case of a person who dies leaving property but no will or one which fails to operate. It is also applied under the Administration of Estates Act, 1925, to cases where a person dies leaving a will which does not dispose of all of his property; such a person is intestate so far as his undisposed property is concerned and the rules as to intestacy apply to this property.

Formerly the devolution of property where its owner died intestate depended upon whether such property was realty or personalty. At common law the realty vested immediately on the

owner's death in his common law or customary heir while his personalty vested in the ordinary before the Probate Act of 1857 and after that act in the judge of the court of probate. This rule was modified by the Conveyancing Act of 1881, but the Transfer of Land Act, 1897, which enacted that fees simple should be administered by the personal representatives of the deceased owner did not affect this rule until the probate court appointed administrators of the real property of an intestate if vested in his heirs. Now, by the Administration Act of 1925, all that is changed; and on the death of a person absolutely intestate all his property, real and personal, vests in the judge of the court of probate until that judge appoints an administrator. It is to be remembered in this connection that a hereditary title of honour is, in law, realty but that modern legislation has no application to it and that it descends according to the old law of inheritance, *i.e.*, to the heir even notwithstanding any will of the deceased owner or any claim of creditors.

Until Jan. 1, 1926, on the death, intestate, of an owner of heritable estates in land, *i.e.*, estates in fee simple and estates in fee tail, his fee simple estates vested in his heir and his fee tail in the heir of his body. On the other hand his personalty vested, as before mentioned, in trust, after payment of his debts, for his next of kin according to the Statute of Distribution, 1670–71. The Administration of Estates Act, 1925, has, so far as England is concerned, abolished the whole law of inheritance. Henceforth an heir will take only as a person mentioned in the grant of an estate in land. The heir of the body of a deceased tenant in tail will take under this head, and when property is limited to a person and on his death to his heir, it will vest in his heir, notwithstanding his will, as the rule in Shelley's case has been abrogated. Subject to these limitations, on the death of an owner of real and personal property intestate all his estate vests in his administrators on their appointment by the court. They hold his real estate on a trust for sale; this and the personalty form a joint fund for the payment of his debts and subject thereto such fund is to be distributed among the persons entitled under that Act. If there are no such persons the fund goes to the Crown as bona vacantia.

By the Administration of Estates Act, 1925, not merely the law of inheritance but the ancient preference of the male over the female line is abolished. On the death of a spouse intestate if the other spouse survives he or she will be entitled absolutely to all the deceased's personal chattels, a first charge of £1,000 on the estate whether the deceased died childless or not and a life interest in half of the rest of the estate: if the deceased died childless the life interest is in the whole of the residue. Subject to this the whole estate is divided equally between the descendants of the deceased, grandchildren of deceased children taking equally their parent's share, no share of an infant to vest absolutely until the infant comes of age or marries. Meanwhile the infant's share is to be held in trust for him by the administrators who have power to apply the income for the infant's maintenance and half of his prospective share for his advancement. If there are no descendants then the estate is to go to the deceased's parents equally or, if one is dead, to the survivor. If both are dead the estate goes to the brothers and sisters of the whole blood equally, descendants of a deceased brother or sister to any degree taking per stirpes, *i.e.*, by family, the interest which their deceased ancestor would, if he were alive, have taken, per capita, *i.e.*, as an individual member of the inheriting class. If there are no brothers or sisters of the whole blood those of any of the half blood succeed in the same way and if there are none of them then the grandparents, or such as may be surviving, succeed. If there are no grandparents surviving the property both real and personal goes to the Crown as *bona vacantia*.

It will be well to notice that the Administration of Estates Act makes three great changes as to the devolution of property on death. First, the whole law of inheritance is abolished and all an intestate's property devolves beneficially on his statutory next of kin; secondly, representation of a deceased ancestor is inherited in the collateral line, and thirdly no relative beyond the grandparents and their descendants is entitled to claim as next of kin. (J. A. ST.)

Scotland.—In the law of Scotland heritage descends to the heirs-at-law while the free movable estate of the intestate is divided amongst the heirs *in mobilibus* who are the next of kin and those entitled to share in the succession under the Intestate Movable Succession Acts, 1855 to 1919. The heir of the heritable (*i.e.*, real) property, if one of the next of kin, must collate with the next of kin if he wishes to share in the movables Proximity of kin is reckoned in the same order as in the case of inheritance. The Intestate Movable Succession Acts, among other changes, allow the issue of a predeceasing next of kin, not more remote than brothers and sisters, to come in the place of their parent in succession to an intestate; give the father of an intestate dying without issue one-half of the movable property in preference to brothers or sisters; and if the father be dead, a similar preference entitles the mother to succeed to the whole, failing the father and brothers and sisters; they admit brothers and sisters uterine in the absence of brothers and sisters german or consanguinean, also father and mother.

There are now rights of succession in both heritage and movables between a mother and her illegitimate issue under the Legitimacy Act. 1926, s. 9 (4). (J. WA.)

United States.—The devolution of both real and personal property is governed in all States by statute. The American legislation at an early period disregarded the common law rules of inheritance that gave preference to the eldest male and to males over females, and was modelled upon the civil law rules of inheritance as set forth in the 118th Novell of Justinian and followed by the English statute of distributions governing the devolution of personal property. The distinction between real and personal property remains important inasmuch as in most States realty vests immediately upon the death of the intestate in his heirs, whereas the title to personalty vests in the administrator for benefit of the next of kin. Between the time of the intestate's death and the appointment of an administrator, title to the personalty remains in abeyance but relates back to the intestate's death upon the grant of letters of administration. Furthermore, the devolution of realty is governed by the law of the State where it is situated, but personalty descends according to the law of the deceased's domicile.

The different State statutes of distribution have infinite variations The rights of the surviving spouse are uniformly favoured. Curtesy (*q.v.*) is generally abolished, though dower (*q.v.*) is widely retained, the widow generally being required to elect between dower and the right to such distributive share as she would be entitled to under the statutes. The right of representation is generally limited to lineal descendants or close collaterals, and except where representation is permitted, kindred of the degree nearest to the intestate succeed to the exclusion of those of more distant degree, degree of kindred being reckoned according to the civil law principles. When all the heirs are of an equal degree of consanguinity, they commonly take per capita, but where they stand in different degrees the more remote take only per *stirpes*. Such States as California, Louisiana, New Mexico and Texas, where the civil law of Spain was once in force, have retained many features of intestate succession peculiar to the civil law. (J. M. LA.)

INTESTINAL OBSTRUCTION (ILEUS), in surgery, a condition in which the onward passage of the intestinal contents is prevented. It is often associated with strangulation of the gut, leading to gangrene, and with systemic poisoning due to the absorption of toxins, resulting from the changes in the intestinal wall. The sole availing treatment is surgical, and that at the earliest possible moment. Intestinal obstruction may be conveniently divided into acute and chronic.

Acute Intestinal Obstruction.—One of the most urgent of surgical emergencies. The following are its chief causes: (1) strangulation by bands or adhesions or through apertures; (2) volvulus; (3) acute intussusception; (4) congenital malformations of the intestines; (5) the impaction of foreign bodies. Acute obstruction is also the natural termination of chronic obstruction, and often accompanies appendicitis and hernia (*qq.v.*).

(1) *Strangulation* by Bands or Adhesions or through Apertures.—These bands may result from stretching of inflammatory adhesions left by a former peritonitis, and are commonly situated between different parts of the mesentery or between the mesentery and another organ such as the appendix. A loop of bowel passes under a short constricting band and cannot return, or if the band is long it may form a noose in which the bowel is strangled (fig. 1.) A coil of intestine may also slip into a hole in the mesentery or omentum or find its way into a pouch of peritoneum, forming what is known as an internal hernia. The patient is abruptly seized with acute abdominal pain associated with collapse. The pain is usually referred to the umbilicus, but this is no guide to the situation of the lesion. Vomiting is persistent, and starts the earlier as the obstruction is higher in the intestinal tract. Ultimately it becomes faecal. There is no obvious tumour; constipation is present, the abdominal walls are flaccid at first, but if no relief is obtained become tender when peritonitis ensues. In cases not treated by operation the average duration is five to seven days, and death takes place from exhaustion or from toxaemia following peritonitis.

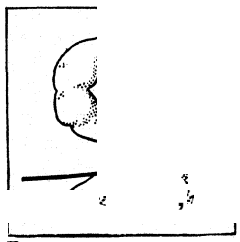

FIG. 1.—I STRANGLED BY A BAND OF TISSUE

(2) *Volvulus* is a twisting of the gut usually preceded by chronic constipation. There are two chief varieties: (1) in which the bowel is twisted upon its mesenteric axis (fig. 2); (2) in which it is wound round another coil of intestine. The sigmoid flexure is the commonest seat for volvulus. When once present, plastic peritonitis fixes the coil in position and the blood supply becomes obstructed. The acute symptoms start abruptly and are those of internal strangulation, but the pain at first is more intermittent in type. There is usually early tenderness over the spot and constipation is absolute. Much distress is occasioned by abdominal distension from flatus, which develops with remarkable rapidity. The swelling is localized at first. Spontaneous natural cure is unknown, and without surgical interference death is inevitable.

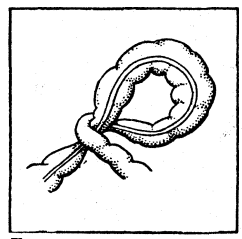

FIG. 2.—BOWEL TWISTED UPON ITS MESENTERIC

(3) *Acute Intussusception* forms about 30% of all cases of intestinal obstruction, and is the most common variety found in children. More than 50% of the cases are found during the first ten years of life, and half that amount in babies under one year; the large preponderance is in males. By intussusception is meant an invagination or protrusion of a part of the intestine in the lumen of the intestine immediately below it; the lower part of the intestine may be said to have swallowed that immediately above it. The mesentery attached to the upper portion is necessarily dragged in with it. The condition may be seen by referring to the diagram (fig. 3). It is to the constriction of the vessels in the entering mesentery and later to their possible complete obstruction that are due the late serious phenomena of intussusception, *e.g.*, gangrene or rupture of the gut. Peritonitis also ensues, and by the formation of adhesions between the serous coats of the entering and returning parts leads to irreducibility of the intussusception. Spontaneous reduction of the invagination sometimes occurs, but the common result is gangrene with perforation of the intestine and acute septic peritonitis. Occasionally when there is no perforation adherence takes place between the segments, and the gangrenous portion sloughs off and is discharged by the rectum. The cause of intussusception is said to be violent peristaltic action, however produced. Polypoid tumours or masses of worms, or masses of irritating ingesta, are said to lead to its occurrence. X Dolore and R. Leriche, however, contend that the primary factor is congenital mobility of the caecum, and that this explains why two-thirds of the cases occur in children less than one year old. Intussusception is met with in four chief situations: (a) the ileo-caecal, which is said to be the most frequent, constituting 44% of all cases (Treves); (b) the enteric variety, involving the small intestine; (c) the colic form; (d) the ileo-colic, the ileum being invaginated through the ileo-caecal valve. Intussusception may be acute or chronic, sometimes lasting intermittently for years. The acute form is the most common. In young children there is severe pain, at first paroxysmal but later continuous; vomiting is less early and less continuous than in strangulation by bands, and tenesmus, much straining and the passage of blood and mucus from the anus are common. Collapse soon supervenes. Early in the case the abdomen is but little distended, and in about half the cases a distinct tumour can be felt. Sometimes the invaginated gut presents at the anus. Chronic intussusception occurs more frequently in adults than in children; the symptoms may resemble chronic enteritis and be so indefinite that the nature of the illness remains undiagnosed until an acute attack supervenes, or the patient succumbs to the diarrhoea, vomiting and haemorrhage.

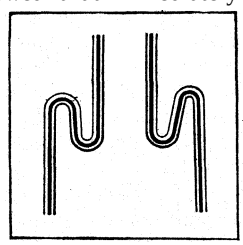

FIG. 3.—VAGINATION OF INTESTINE INTO PART BELOW

(4) *Congenital* Malformations of the Intestines.—Persistence of Meckel's diverticulum, a structure which passes between the navel and the middle of the ileum and represents the nutrient canal of the foetus, may act as a band. Cases have been recorded in which the small intestine ended in a blind pouch. Imperforate anus is a fairly frequent occurrence in young infants, but attention is usually called to the condition. Partial strictures of the intestine, if the stricture be not too narrow, may pass unnoticed for years, and final complete obstruction may result from a blockage of the stricture by some foreign substance such as a plug of hard faecal matter or a fruit stone.

(5) Impacted Foreign Bodies.—These are gall-stones, faecal concretions (enteroliths) and foreign bodies swallowed by accident or otherwise, though knives, coins, pipes, flints, etc., swallowed by jugglers, are known to have passed by rectum without injury. The caecum and duodenum are favourite situations for obstruction. Foreign bodies may remain weeks or months in *situ* before giving rise to serious symptoms. Their diagnosis has been much simplified since the introduction of the X-rays.

Chronic Intestinal **Obstruction.**—The causes of chronic obstruction are very numerous, and may be divided into the following groups: (1) intra-intestinal conditions, *i.e.*, the impaction of foreign bodies and impaction of faeces; (2) affections of the intestinal wall such as stricture, new growths in the intestine, particularly those of a malignant type, adhesions or matting together of the intestines from peritonitis or kinking of the gut from disease of the mesenteric glands; (3) chronic intussusception; (4) compression of the bowel by a tumour or bands developing outside the intestine. Of these the commonest are malignant growths and faecal impaction.

The general symptoms of chronic obstruction are more or less alike. The patient is attacked with gradually increasing constipation, which may alternate with diarrhoea which is generally set up by the irritation of the retained faeces. In obstruction due to malignant growths low in the rectum the character of the motions is changed, they become scybalous, pipe-like or flattened. The abdomen becomes distended, and at intervals severe symptoms may supervene, consisting of pain and vomiting with complete constipation owing to some temporary complete obstruction. The attacks usually pass off, and relief may be obtained naturally or by the administration of a purgative, but they have a tendency to recur and in malignant disease to increase to complete obstruction. Finally a seizure may persist and take on all the characters of an acute attack, and death may supervene from exhaustion, perforation or peritonitis, unless immediately treated. When it arises from simple stricture no tumour is to be felt, but in malignant disease the tumour may frequently be palpated, unless during an acute attack, when the abdomen is much distended with gas.

(1) Faecal Impaction is not uncommon in adult females who have suffered from chronic constipation. The common seat of the blockage is in the colon, chiefly in the sigmoid flexure and in the

rectum, but it may occur in the caecum. The accumulation may form a doughy tumour, which in parts may be nodular and intensely hard. The causes are due to the state of the contents of the bowel itself, to congenital or acquired weakness and diminished expulsive power of the bowel, or to painful affections of the anus, fissures, piles and painful bladder affections. The acute symptoms are always preceded by a prolonged period of malaise; the breath is offensive and the tongue foul, and the temperature may be raised from the absorption of toxins. Faecal impaction requires the regular and repeated administration of large enemata, given through a long tube, together with the administration of calomel and belladonna. Large impacted masses in the rectum may be broken up and removed by a scoop.

(2) *Strictures* of the Intestinal Wall.—Simple strictures are infrequent, and are dealt with by the operation of lateral anastomosis. They follow dysenteric or tuberculous ulceration or the passage of gall-stones. Stricture due to carcinoma of the intestinal wall occurs usually in the old or middle-aged, and the symptoms come on insidiousiy. As soon as the condition is diagnosed an attempt should be made to remove the tumour if freely movable, or if this is not possible to afford relief by short-circuiting the intestine or by colotomy.

(3) Chronic *Intussusception* has been frequently mistaken in the diagnosis for rectal polypus, cancer, tuberculous peritonitis, etc. (Treves). If diagnosed it may be reduced by inflation with air, but frequently too many adhesions are present for this to be possible, and laparotomy with excision of the mass should be undertaken; the results are said to be very encouraging.

(4) *Compression* of the Bowel due to a tumour or bands external to the bowel may occasionally give rise to obstruction. An exploratory operation should be undertaken for the excision of the tumour, or the separation of adhesions and release of the bowel, or if the intestines are much matted together by peritonitis an intestinal anastomosis may give relief. Obstruction due to paralysis of the muscular coat of the intestine has been described (adynamic obstruction), but its existence is a subject of dispute.

(H. L. HE.)

INTESTINE, in anatomy, the lower part of the alimentary canal; in man and mammals divided into the small intestine, from the pylorus to the iliocaecal valve, and the large, reaching from the caecum and colon to the end of the rectum. The word is frequently applied to the whole of the alimentary canal in invertebrates. (See ALIMENTARY CANAL.)

INTOXICATION, poisoning, or the action of poisons, whether of drugs, bacterial products or other toxic substances, and hence the condition resulting from such poisoning, particularly the disorder of the nervous system produced by excessive drinking of alcohol. (*See* INEBRIETY, LAW OF, and DRUNKENNESS.)

INTRANSIGENT, one whose attitude is that of an irreconcilable. The term is used chiefly of politicians of an advanced type; those in complete antagonism to the existing form of government; but is especially applied on the continent of Europe to members of legislatures holding extreme Radical views. The word is also used non-politically, in the sense of intractability and intolerance.

INTROIT: see PLAINSONG.

INTROSPECTION, in psychology, the process of examining the operations of one's own mind with a view to discovering the laws which govern psychic processes (Lat. *introspicere,* to-look within). The introspective method has been adopted by psychologists from the earliest times, more especially by Hobbes, Locke, Berkeley, Hume, and English psychologists of the earlier school. It possesses the advantage that the individual has a more direct and fuller knowledge of his own mind than of any other mind, and is able therefore to observe its action more accurately under systematic tests. On the other hand it has the obvious weakness that in the total content of the psychic state under examination there must be taken into account the consciousness that the test is in progress. This consciousness necessarily arouses the attention, and may divert it to such an extent that the test as such has little value. Such psychological problems as those connected with the emotions and their physical concomitants are especially defective in the introspective method; the fact that one is looking forward to a shock prepared in advance constitutes at once an abnormal psychic state, just as a nervous person's heart will beat faster when awaiting a doctor's diagnosis. The purely introspective method has of course always been supplemented by the comparison of similar psychic states in other persons, and in modern psychophysiology it is of comparatively minor importance.

See PSYCHOLOGY, ATTENTION, etc.; G. F. Stout's *Manual of Psychology* (1919).

INTUITION, a term employed in philosophy and in ordinary life in many different meanings, some of which indeed are not only different but opposite. To disentangle them all adequately would require a discussion of the philosophical conceptions which lie at their several bases. The salient points may be indicated as follows. The constant element in the meaning of the term is that of direct or immediate apprehension.

Difficulty of Definition.—The difficulties and differences arise from different views as to what really is apprehended directly, as distinguished from what oniy appears to be so apprehended. One thing all would probably be agreed upon, namely, that the term intuition excludes all inference, all discursive reasoning, which is an indirect rather than a direct mode of apprehension. For the rest, however, the views are very conflicting. Some would include under intuition both sense intuition (or sense perception), like seeing a patch of colour, and conceptual or intellectual intuition, like grasping that "things equal to the same thing are equal to one another." Some would restrict the term to sense intuition only, and exclude all intellectual or conceptual elements from it. And others, again, employ the term to denote a process that is hardly comparable with ordinary sense-perception or with ordinary intellectual intuition. This is true not only of certain mystics, but also of some philosophers. In ordinary life, moreover, the term is often used to cover beliefs or prejudices which one cannot justify or excuse. Now even if intuitions may need no justification, it is a flagrant fallacy to treat every unwarranted opinion as an intuition, not to say an inspiration.

In Spinoza's Philosophy.—In the history of modern philosophy the term intuition occupies a prominent position chiefly in the philosophy of Spinoza, in the moral philosophy of the so-called intuitionist or intuitionalist school, and in the philosophy of Bergson. The intuitionist school of moral philosophy is dealt with in the articles ETHICS and ETHICS, HISTORY OF. So we need only add a few words about intuition in the thought of Spinoza and of Bergson. Spinoza distinguished three main grades of knowledge or cognition. The lowest is that which is merely empirical, and does not rise above sense-perception; the next higher stage is what may be called scientific knowledge, the knowledge acquired by careful reasoning about observed phenomena—at this stage knowledge is no longer confined to mere particulars, more or less in isolation from each other, but includes the laws which connect them and gives them a certain orderliness. At the highest stage human knowledge rises to the comprehension of the whole universe as one inter-connected, self-dependent system, a complete pattern, so to say, of which the laws discovered at the second stage are the continuous but single strands. This highest kind of knowledge Spinoza called "intuitive knowledge" (*scientia* intuitiva). It rises above empirical and scientific knowledge, but it grows out of them; they culminate in it. Spinoza did not want to deprecate either sense perception or ordinary conceptual activity when he set up "intuitive knowledge" as the goal of intellectual and spiritual endeavour.

In Bergson's Philosophy.—In the philosophy of Bergson the case is rather different. His stress on intuition is definitely a protest against what he conceives to be the excessive tribute usually paid to intellect, or intelligence, and to science as the ripest fruit of intelligence. Bergson's advocacy of the claims of intuition is one aspect of the growing recognition in recent decades of the part played by instinct, as contrasted with intelligence in human life. For Bergson intuition is simply "instinct that has become disinterested, self-conscious, capable of reflecting upon its object

and of enlarging it indefinitely." Intelligence, according to Bergson, has for its original function the construction and use of inorganic tools in the service of life. It is, therefore, most at home in the world of inert solids. Now, for the practical purpose of making tools it is convenient to treat material bodies as discrete units each divisible ad *libitum.* But when intelligence becomes theoretical, and seeks to explain life and thought as well as inert matter, then it leads astray. For it tends to treat all things as if they consisted of lifeless matter, and the whole of reality is reduced to a dead mechanism, for intelligence is unable to comprehend life.

This defect of intelligence must be made good by intuition, which as instinct is moulded on life, so that its procedure is organic, not mechanical. When the consciousness which slumbers in instinct awakes, when it is wound up into intuition instead of being wound off into action, it can reveal the most intimate secrets of life. Intuition leads us to the very inwardness of life as successfully as intelligence guides us into the secrets of matter. Human consciousness is predominantly intellectual. But man is not entirely lacking in intuition, which functions whenever our deepest interests are at stake. "On our personality, our liberty, on the place we occupy in the whole of nature, on our origin and, perhaps, also on our destiny, it throws a light feeble and vacillating, but which none the less pierces the darkness of the night in which the intellect leaves us." And it is the function of philosophy to seize, to expand, and unite these floating intuitions, and so to introduce us into the spiritual life. Still, intuition must not be divorced from intellection, nor philosophy from science. A philosophy which rises upon and above scientific foundations is a very different thing from mere mysticism.

Largely as the result of Bergson's stand against the exaggerated estimate of the conceptual or intellectual elements in human orientation, various other thinkers have voiced the claims of what has been called the non-rational elements in human knowledge. It is possible that the pretensions of some forms of rationalism need checking. But the non-rational is apt to be rather inarticulate, and it is easy for obscurity to harbour the irrational as well as the merely non-rational or merely non-conceptual. (See also KNOWLEDGE, THEORY OF; LOGIC; ETHICS).

See H. Bergson, *Introduction* to *Metaphysics* (1912) and *Creative Evolution* (1922); *R.* Miiller-Freienfels, *Irrationalismus* (1922).

(A. WO.)

INTUITIONISM: see INTUITION; ETHICS and ETHICS, HISTORY OF.

INULIN, in chemistry, a starch-like carbohydrate $(C_6H_{10}O_5)_{6n}$, known also as alantin, menyanthin, dahlin, synanthrin and sinistrin. It occurs in many plants of the large family *Compositae,* to which the elecampane (*Inula Helenium*) belongs; and forms a white tasteless powder, sparingly soluble in cold water, very soluble in hot water and insoluble in alcohol. It is coloured yellow by iodine, and reduces ammoniacal silver and gold solutions, but not Fehling's solution. Heated with water or dilute acids, it is converted into laevulose (d-fructose). (See CARBOHYDRATES.)

INVALID COOKERY. As the aim in invalid cookery is to build up bodily weakness and strengthen the tissues, light and nourishing food should be given that entails a minimum of effort for the digestive organs. Small, frequent meals should be the rule, and these ought to be served as daintily as possible to attract the eye of the patient. Hence, moulds and other receptacles used for invalid cookery should be small. Where possible, broiled or steamed food is best, as by these methods the maximum of nourishment is conserved. Never give fried food to invalids. The best invalid food for many serious cases is milk. Doctors' special orders should be followed accurately. As a general rule, unless otherwise ordered, a fever patient requires a fluid diet, mainly milk. Milk may be mixed with lime water or barley water, or peptonized powders are sometimes used for those patients who find difficulty in taking large quantities of plain milk, but allowance should be made for dilution.

Where "solids" are permitted, corn-starch, arrowroot, patent barley and egg jellies are recommended. Beef juice and meat extracts, though excellent in certain cases, should not be given to patients suffering from rheumatic troubles. Diabetic cases are not generally allowed starch and sugar, but plenty of fats and proteid are required. Saccharine should be substituted for sugar and gluten and proteid breads are useful. Gastric patients generally need peptonized foods, and when convalescent they may take beef juice or light meats; *e.g.,* chicken or lamb. In tuberculosis it is very necessary to give plenty of nourishing food, especially milk, fats and oils; *e.g.,* cream, fat bacon, yolks of eggs, etc. Lemon and orange juice and thin barley water are useful invalid drinks. Where iced water is given great care should be taken that the ice is pure and well washed.

Barley water can be made either with uncooked chicken barley or cooked pearl barley; many doctors advise the former method The barley water is needed for cleansing purposes. For this, wash 2 oz. of uncooked chicken barley, place in a jug and pour over it one pint of boiling water; allow to stand until cool and strain off the clear liquid. Serve with a slice of lemon. Ordinary barley water is prepared by boiling 2 oz. of washed pearl barley in one pint of water until quite soft. Strain off the liquid. Flavour with lemon and sweeten to taste.

Oatmeal gruel is made with patent groats, English fine oatmeal or Scotch meal; for infants the fine oatmeal or prepared groats is best. Mix one teaspoonful with a little cold water; stir in half a pint of cold water; boil for fifteen minutes stirring all the time to keep free from lumps; strain and mix with half the quantity of milk; reheat, and sweeten and flavour to taste.

(J. A. SI.)

INVALIDITY PENSIONS. It is a generally accepted principle in almost all civilized countries that where an employed person becomes permanently incapacitated for work through sickness or accident he should receive from some source regular periodical payments with a view to preventing him from falling into destitution. Provision of this kind may be made in several different ways. In the case of persons employed by the State, local authorities, statutory undertakings or many establishments, provision is usually made under a superannuation scheme towards the cost of which contributions are paid by the employer and ordinarily by the employees also. Where the incapacity is due to an accident or an industrial disease arising out of the worker's employment, the worker becomes entitled to relief under the laws relating to workmen's compensation. (See WORKMEN'S COMPENSATION.) It is, of course, also open to any individual employed person to make provision for himself by private insurance. There remains, however, a large residue not covered by any of these forms of provision and in most countries the State has assumed the responsibility of making provision against the risk of invalidity amongst the general body of workers who are not otherwise protected.

In Great Britain such provision was first made in 1911 as part of the scheme of national health insurance. (See NATIONAL INSURANCE: Health.) Under that scheme an insured person who is rendered incapable of work through sickness or physical or mental disability is entitled in the first instance to receive sickness benefit up to a maximum period of 26 weeks, and if incapacity continues beyond the end of that period he remains entitled to weekly payments at a reduced rate in the form of disablement benefit for so long as his incapacity continues, until he attains the age of 65, when the provisions of the old age pensions scheme become available.

Under the Blind Persons Act, 1920, a person who is so blind as to be unable to perform any work for which eyesight is essential is entitled to a pension at the age of 50 on the same conditions as are applicable to persons of 70 under the general scheme of non-contributory old age pensions. (See OLD AGE PENSIONS.)

In all countries except Great Britain, State provision against invalidity is made not in conjunction with the State scheme of sickness insurance but ordinarily in association with the scheme of old age pensions, or in some cases under an entirely independent scheme. The essential difference between the schemes in force in most European countries and the British scheme is that the former involve the conception of invalidity as a permanent physical condition requiring the minimum amount of supervision,

whereas under the latter the payments are subject to the furnishing at short intervals of proof of continued incapacity for work.

It is interesting to note that although several European countries had not, up to 1928, adopted general compulsory schemes of insurance against sickness, schemes of compulsory insurance against permanent invalidity were in operation in every country except Hungary, Norway, the Baltic States and parts of Switzerland. The schemes are ordinarily on a contributory basis, the cost being shared between employers, workers and the State. In some countries the schemes apply only to certain classes of workers, for example, in Austria, to miners and salaried employees only, and in Denmark, only to such persons as have voluntarily insured themselves against sickness.

German System.—The following short summary of the German scheme will give an indication of the general character of the schemes in operation in most European countries:

In Germany a scheme of insurance for invalidity and old age pensions for all manual workers was introduced in 1889 and a scheme for salaried workers in 1912. Under the former scheme the State contributes a fixed sum annually towards each pension, while under the latter it makes no contribution towards the pension but bears the whole cost of administration. The contributions are graded according to earnings and are shared equally between employers and employed. The amount of the pension also varies in accordance with earnings and with the number of contributions paid. An insured person is entitled to a pension if, after he has exhausted his title to sickness insurance benefit, that is to say after 26 weeks of incapacity, he remains incapable, owing to sickness or infirmity, of earning one-third of his usual wages. A small additional allowance is made in respect of each dependent child of the insured person. The attainment of age 65 is treated for the purposes of the scheme as equivalent to permanent invalidity, and pension is thereafter payable for life. The scheme is administered by insurance boards composed of Government officials and representatives of employers and insured persons. These boards have been pioneers in preventive and curative work and have provided sanatoria, hospitals and other institutions in which preventive and remedial treatment is given. Treatment in such institutions may in suitable cases be substituted for the invalidity pension.

In Australia a non-contributory scheme of invalidity pensions, of which the whole cost is met by the State, has been in operation since 1908. Up to 1928 no State scheme had been introduced in Canada, South Africa or New Zealand. In the United States also there is no public provision for insurance against invalidity.

(E. HA.)

INVAR, an alloy of nickel and steel, characterized by an extremely small coefficient of thermal expansion; it is specially useful in the construction of pendulums and of geodetic measuring apparatus, in fact, in all mechanical devices where it is an advantage to avoid temperature compensation. The name was chosen as expressing the invariability of its dimensions with heat. (*See* CLOCKS; GEODESY.)

INVARIABLE PLANE, in celestial mechanics (*q.v.*), that plane on which the sum of the moments of momentum of all the bodies which make up a system is a maximum. It derives its celebrity from the demonstration by Laplace that to whatever mutual actions all the bodies of a system may be subjected, the position of this plane remains invariable.

INVENTIONS AND DISCOVERIES. The act of invention, like many other human activities, is difficult to define precisely. The distinction often made between invention and discovery is not logically justifiable. For example, the great advance which primitive man made in the first use of pottery may be viewed either as the discovery of certain properties of burnt clay or as an invention in forming and hardening clayey materials into valuable utensils. As in this instance, most cases of inventive progress include both an element of discovery and an element of invention.

Definitions of the process of invention set up in the patent laws of most countries involve three fundamental ideas; novelty, utility and the ability of the device to work. With regard to the third point, for example, the rules of the U.S. patent office require that an inventor prove, on demand, that his device is operable. This is why inventors of pretended "perpetual motion" machines are asked first to demonstrate a working model. But even in patent law, exactness of definition of invention is difficult as is witnessed by the continual stream of patent cases in the courts of most countries.

The history, of invention begins before that of mankind. Many inventions have unquestionably been made by animals; for example, nests, a crude use of tools, the beginnings of language. It is probable, furthermore, that no distinction of kind can be drawn between the most modern inventions of man and very ancient animal "inventions" which have been crystallized into instincts like those of the ants or bees or in bodily devices like the flexible backbone of vertebrates, the force-pump heart or the warm blood of birds and mammals. It is customary and justifiable for evolutionists to speak of the "invention" of the backbone by some species of primitive worm which developed the ability to stiffen itself against the flowing water of ancient streams.

In the history of mankind as distinct from that of his more ancient animal ancestors, the most fundamental and useful inventions were made, undoubtedly, before recorded history. Many lists of the "world's greatest inventions" have been prepared, all widely different. The following list of seven has no unusual authority but is perhaps defensible.

Most important of all human inventions is probably the invention-discovery of the function of the seeds of plants, resulting in agriculture and in freeing mankind from dependence on accidental finds of food. Next in practical importance although perhaps first in time, was the discovery of how to control fire. Third was the invention of pottery. These three are prehistoric. Their combined effect was to free man in considerable degree from threats of immediate starvation. Fire made available (by cooking) some foods not previously edible. Pottery dishes made it possible to cook foods more successfully and to store them for hours or days; pottery may have been both the result and partially the cause of settled houses, for fragile dishes could not be carried on daily wanderings and pot-stored foods in cave or hut created an incentive to return to that same spot at nights. Two other inventions of great human importance seem to have been made in ancient Babylonia, or close by in Indo-Persia. One is the invention of writing; the other the invention of standards of measurement, weight, time and money.

Two other great inventions are modem ones: the germ theory of disease imagined by Pasteur and the invention of tinned food The method of preserving food in tins or other containers is probably defensible as the greatest of all inventions in historic times. Its effect has been to relieve mankind of dependence upon the annual harvest, since food can be carried over from year to year, or upon the local food supply, since canned food can be imported. It has been said that modem canned food for his armies would have enabled Napoleon to conquer the world. It is impossible to date the invention of food preserving precisely or to ascribe it to any individual. Like many of the world's greatest inventions and discoveries, the art was developed gradually over many years and by many individuals. It is significant that of the seven inventions just suggested; seeds, fire, pottery, writing, standards, the germ theory and canning, all except Pasteur's discovery are hopelessly anonymous.

Other lists of this kind often include speech, the domestication of animals, the concept of medical treatment, the invention of weapons, the development of a form of government, the erection of buildings, and others. In each instance there seem definite reasons for assigning these to lesser rank. Whatever theory one accepts as to the origin of speech, there can be little doubt that it was a slow development, beginning even in animals and characterized by a long series of small inventions; a word here, a bit of grammar there, rather than by any definite inventive act. The same is true of the ideas of leadership and government—devices also familiar, in some degree, to man's animal cousins and probably to his ancestors.

Man's first rude huts probably grew naturally out of shelters

made accidentally by fallen branches or perhaps in imitation of animal nests and lairs, like the nests that orang-utans still make in trees. Weapons, in the form of sticks or hurled stones, were probably also ape possessions long before man. One human invention of real importance was, however, that of the chipping or grinding of flint to make a sharp edge—an invention probably made many times independently in prehistoric days. The bow and arrow, incomparably the cleverest invention of prehistoric weapon makers, is of unknown history. There is some reason to believe it Asiatic and perhaps as ancient as the post-Neanderthal type of man.

The domestication of animals is another development probably slow, accidental and mutual; for the animals first domesticated must have gained much more than they lost by association with man. It is far more probable, for example, that dogs first adopted man than that man singled out the wild dog for a companion. The idea that mankind itself could cure its bodily ills—the central idea of medicine—is inextricably entangled historically with the ideas of religion and of magic; indeed it can scarcely be said, even now, that any large percentage of mankind has real confidence in medical science as distinct from trusted, but mysterious, skill.

In addition to these items, prehistoric times must be credited with the beginnings of mechanics, hydraulics, metallurgy, navigation, chemistry and many other arts, including painting and sculpture, well known from the caves of France. To prehistoric mechanics we owe the lever, the wedge, the saw and probably the pulley and rope. That remarkable invention, the wheel, was probably conceived in Europe or in Asia Minor relatively late in prehistoric times, for the Asian migrants into North America who survived as the American Indians did not possess it. Among the most surprising facts in the history of invention is that this simple and useful idea seems never to have occurred to so large a fraction of the human race.

The first known examples of practical hydraulics are the irrigation canals of Babylonia, but it is probable that both canals and wells were known to still earlier Asian peoples for the same purpose. Well drilling for water might be given rank, indeed, as one of man's really great inventions, were it not that it probably came about naturally and accidentally through the cleaning and deepening of springs as the water receded in times of drought. Drainage, sewerage and internal water supply to houses seem to have been arts begun in Babylonia and reasonably well understood by the time of the great Cretan civilization of nearly four thousand years ago. It is probable that man's first iron was obtained from meteorites found on the ground; perhaps accidentally as a result of trying to chip flint weapons out of the hard, heavy mass. Copper holds rank as probably the first metal made by fire from its ores. Both the Egyptians and the Babylonians evidently understood the metallurgy of this metal more than six thousand years ago.

Among the items of prehistoric chemistry are glazes for pottery, fluxes for use in working gold and other metals, and some knowledge of opaque glass for beads; all of these were already highly developed at the time of the first recovered civilizations of Babylonia. Navigation, probably first discovered by the accident of floating on a log, seems to have developed independently and very differently at different places and times; as witness craft so diverse as the inflated skin boats of Asia, the American Indian canoe, the dug-out tree trunks of Africa and the Pacific Islands, and many others.

Last among great prehistoric inventions should be mentioned lamps and clothes, making man in some degree independent of darkness and cold. The adoption of clothing is so largely instinctive that it seems to have happened over and over again with almost every conceivable material and with infinite variety of custom. The origin of lamps is still uncertain, although the first form was undoubtedly a crude wick floating in a dish of oil and was probably invented by those unknown forerunners of the Babylonians to whom we also owe, it is believed, the knowledge of copper and of irrigation, the invention of writing and not improbably that of the wheel.

Within historic times, one interesting lost chapter of the history of invention is that of the beginnings of mechanism; of things like treadmills and waterwheels and pumps. The first definite records of such things go back to the Greek mechanicians of Alexandria, including Archimedes. However, the picture of mechanics and hydraulics in their day is already that of a well-developed science with a considerable history behind it. It is probable, too, that Greek miners were using stamping and grinding machines for ores several centuries earlier. Mechanical grist mills rotated by oxen, to replace the prehistoric mortar, devices to lift water for irrigation, primitive water clocks to measure time by the drip of fluid through a hole, are other candidates for the honour of the world's first mechanism. To decide between them is now impossible.

The present century is characterized by what is called technology; it is sometimes called the "machine age." This modern civilization, differing in many fundamentals from any previous period of world culture, may be said to depend upon five basic inventions and discoveries. First of these, both in time and in importance, is the discovery of the use of coal as fuel and the resulting invention of a practicable steam engine. The principle of the steam engine was known 17 centuries ago. What made it practicable was coal fuel. Second is the improvement of the metallurgy of iron and steel; the chief steps of this being the perfection of the blast furnace, of the Bessemer converter and of the modern rolling mill. Third is the development of electric power; beginning with the physical researches of Oersted, Ampere, Henry and Faraday and culminating in modern dynamos and motors. More recent developments of electricity promise to revolutionize this science and to make it much more useful to man, as a result of the perfection of vacuum-tube methods of handling electrons, such as are used in radio. The fourth basic invention which may be said to support modern technology is the internal combustion engine, with its application to automobiles, motor boats, aircraft and other vehicles. The fifth is cement. Some observers might add others to this list; for example, telephony, cheap aluminium, the aeroplane or printing. It may be objected, however, that these are adjuncts to modern technology and improvements produced by it in the advantages of life, rather than fundamentals which lie at modern civilization's roots.

One invention in a somewhat different field is defensible, however, as among the most fundamental and important of modern times. This is the invention of the joint-stock, limited-liability company, typified by the modern corporation. It would be possible to argue that no social device in human history has accomplished so successfully the divorce of business policies or industrial undertakings from the hazards of individual human lives. Another gain to be credited to the idea of corporate organization is perfected continuity of information and experience from one generation to another.

Calculations are often made of the percentage of modern wealth due to invention, discovery and technology, as distinct from the unaided efforts of man. The following table summarizes one such estimate, rough but perhaps approximately correct for the average annual earnings of the citizens of the United States. It should be noted, however, that in no case are these earnings due solely to invention or to its results. The growing ability of men to work together with each other (as is typified by the corporation) has become, in this modern world, one essential of the production of any income.

It is probably significant that among the activities shown in the table on p. 547, the one with the lowest percentage use of modern technology (fisheries) is the lowest in total earning capacity.

Since the beginning of the 20th century there has developed, chiefly in the United States, a system of invention and discovery which promises revolutionary results. This is what has been called "organized research." Large American corporations have establish well-equipped laboratories staffed by engineers and scientific men of proved ability. The idea is that the co-operative effort of organized, well-equipped staffs of specialists will progress farther and faster in scientific research and in invention or discovery than is possible to the so-called "garret inventor" working alone with limited equipment and meagre funds.

Annual Income in the United States of America

Activity	Total annual income (added value)	Estimated percentage of annual income due to the use of technology	Total annual earnings of
	Thousand million of dollars	%	Thousand million of dollars
Farms.	15·0	80	12·0
Forests	3·0	50	1·5
Fisheries	·2	10	·02
Mines. . . .	8·0	95	7·6
Transportation (including railways) . . .	9·0	100	9·0
Manufactures . . .	26·0	90	23·4
Commerce. . . .	30·0	85	25·5
Total . . .	91·2	87·7 (average)	79·02

It is noteworthy that this idea of co-operative research has been tried twice before in human history; first by Aristotle under the patronage of Alexander; second by the Alexandrian school in Egypt under the auspices of the Ptolemies. Little of permanent value in the field can be credited to the efforts of Aristotle. The Alexandrian school has a better record, since it is probable that the discoveries of fundamental principles in geometry, mechanics, hydraulics and pneumatics together with significant advances in optic: were accomplished by the Alexandrian group. It is still too soon to determine the value to the world of the renewal of co-operative research. The danger of mere "organized mediocrity" has been suggested. It remains to be seen whether it can be avoided as co-operative research laboratories grow older and perhaps lose inspiration. It is already certain, however, that such co-operative investigation is able to pay dividends of almost immediate utility and money to the individual corporations which use it.

The constituents of what might be called "inventive ability" have not yet been made clear by the psychologists. The mental processes of an inventor may be separated, perhaps into two superficially different methods. One is sometimes called the "Edisonian" method, because of its supposed employment by Thomas Alva Edison. This consists in trying all conceivable possibilities more or less at random. For example, when Edison desired a suitable filament for his electric lamp his procedure, it is said, was to test every thread-like or wire-like material which could be obtained. Thus was it discovered that carbonized bamboo fibre was a suitable material.

The other manifestation of the inventive process is what is loosely called the flash of genius; a sudden inspiration, apparently accidental, which provides the germ of the invention. Although the psychology of such inspiration is quite unknown, it may perhaps be suggested that, after all, the process does not differ so markedly from the first and seemingly more laborious method. It is conceivable that the conscious inspirational flash which solves the inventor's problem really results from long turning over in his mind of the characteristics of the desired invention.

In any inventive process, therefore, it is probable that the essential thing is the inventor's ability to put together, either actually or in imagination, facts the possible mutual relations of which are not obvious. If this be true, the mental processes of the inventor must be nearly the same as those of the author inventing fictional plots. In both cases there must be added, however, a saving salt of critical ability; enabling an author to select plot combinations which are reasonable and workable, and an inventor to select for physical trial the particular imagined combinations of ideas which are most apt to bring practical success. (E. E. F.)

INVENTORY, a detailed list, schedule or enumeration in writing, of goods and chattels, credits and debts, and sometimes also of lands and tenements.

(See also BANKRUPTCY; EXECUTORS AND ADMINISTRATORS; STOCK-TAKING.)

INVERARAY, royal burgh and county town of Argyllshire, Scotland. Pop. (1931) 455. It lies on the southern shore of a bay, where the river Aray enters Loch Fyne, 40 m. directly N.W. of Glasgow, and 85 m. by water. Near the church stands an obelisk in memory of the Campbells who were hanged, untried, for their share in the Argyll expedition of 1685 in connection with the duke of Monmouth's rebellion. The ancient market-cross is supposed to have been brought from Iona in 1472 The chief industry is the herring fishery. The town originally stood on the north side of the bay, clustering round an ancient baronial hold, but it was removed to its present site in the middle of the 18th century. Inveraray became a burgh of barony in 1472; and Charles I., while a prisoner in Carisbrooke castle, raised it to a royal burgh in 1648. Much has been done for it by the ducal house of Argyll, whose seat, Inveraray Castle, was built between 1744 and 1761 from designs by Robert Adam. The earls and dukes of Argyll were great planters of trees — mainly larch, spruce, silver fir and New England pines — and their estates around Inveraray are aniong the most finely-wooded in the Highlands. Duniquoich, a timbered conical hill, adjoins the castle on the north.

INVERCARGILL, the chief town of Southland county, South Island, New Zealand, 139 m. by rail S.W. by W. from Dunedin. Pop. (1936) 25,772. It lies on a deep estuary of the south coast named New River Harbour, which receives several streams famous for trout-fishing. It is the centre of the large grazing and farming district of Southland; and has a number of factories, including breweries, foundries, woollen mills and timber-works. The plan of the town is rectangular, with wide streets; and there is a fine open reserve. The harbour is deep and well sheltered, but the greater part of the trade passes through the neighbouring Bluff Harbour, the port of call and departure for steamers for Melbourne and Hobart. Southland was a separate province between 1860 and 1870, but, failing financially as such, rejoined the parent province of Otago. The town is the regular starting-point of a journey to the famous lakes Wakatipu and Te Anau, which are approached by rail.

INVERCLYDE, BARON: *see* BURNS, SIR GEORGE.

INVERELL, a town of Gough county, New South Wales, Australia, on the Macintyre river, 341 m. N. of Sydney, with which it is connected by rail. Pop. (1933) 5,304. It is the centre of an agricultural district producing, chiefly, wheat and maize; the vine is also grown and excellent wine is made. There are silver, tin and diamond mines near the town. Inverell became a municipality in 1872.

INVERFORTH, ANDREW WEIR, 1ST BARON (1865–), British shipowner and administrator, was born at Kirkcaldy, Scotland, on April 24, 1865. He was educated at Kirkcaldy and afterwards adopted a business career, founding in 1885 the firm of Andrew Weir and Co., shipowners and merchants, of London and Glasgow. Having made a large fortune in business, in April 1917 Mr. Weir entered Lloyd George's government as surveyor-general of supply at the War Office, and held this post until Jan. 1919. The same year he was sworn of the privy council and raised to the peerage. He was minister of munitions and supply from Jan. 1919 to March 1921.

INVERNESS, royal burgh, seaport and county town, Inverness-shire, Scotland. Pop. (1931) 22,582. It lies on the Ness. It is an important railway centre, 118 m. N. of Perth by the L.M.S.R. Owing to its situation at the north-east of Glen More, the beauty of its environment and its fine buildings, it is held to be the capital of the Highlands; and in summer it is visited by many tourists. The present castle dates from 1835, and stands on the site of the ancient fortress, blown up by the Jacobites in 1746. Of the churches, the High or Parish church has a tower containing one of the bells which Cromwell removed from Fortrose cathedral. On the left bank of the river stands St. Andrew's Episcopal Cathedral, erected in 1866. Public buildings include a library and museum, with a collection of Jacobean relics, in Castle Wynd. In front of the Town Hall (1882) stands the Forbes memorial fountain, and near it is the old town cross of 1685; at the foot of the latter, protected since the great fire of 1411, is the famous stone called Clach-na-Cudain (Stone of

the Tubs), from its having served as a resting-place for women carrying water from the river. The old gaol spire, slightly twisted by the earthquake of 1816, serves as a belfry for the town clock.

Half a mile to the west of the Ness is the hill of Tomnahurich (Gaelic, "The Hill of the Fairies"). The open spaces include Victoria park; the Ness, islands, connected by a bridge with the mainland; and the ground where the Northern Meeting — the most important athletic gathering in Scotland — is held.

Inverness is the great distributing centre for the Highlands, and the annual sheep and wool market is well known. Petroleum is the largest import. Its industries, however, are not extensive, and consist mainly of tweed manufactures, brewing, distilling, nurseries, saw-mills, granite works, an iron foundry and railway shops. There is some shipbuilding and a considerable trade with Aberdeen, Leith, London and the east coast generally. The Caledonian Canal passes within 1 m. of the town on its western side. In Muirtown Basin are wharves and at Clachnaharry the Canal enters Beauly firth. The harbour, formed by the mouth of the Ness, covers about three acres. There are piers and a breakwater at Kessock at the river mouth, with excellent anchorage and a slipway at the junction of the Ness with the Firth. The river at Inverness is crossed by four bridges and a railway viaduct.

Inverness was one of the chief strongholds of the Picts, and in 565 was visited by Columba with the intention of converting the Pictish king Brude, who is supposed to have resided in the vitrified fort on Craig Phadrick, 1½ m. W. of the town. The castle is said to have been built by Malcolm Canmore, after he had razed the castle in which Macbeth according to tradition murdered Duncan. William the Lion (d. 1214) granted the town four charters, by one of which it was created a royal burgh. Of the Dominican abbey founded by Alexander III. in 1233 hardly a trace remains. On his way to the battle of Harlaw in 1411 Donald of the Isles burned the town, and 16 years later James I. held a parliament in the castle to which the northern chieftains were summoned, of whom three were executed for asserting an independent sovereignty. The house in which Queen Mary lived in 1562, when denied admittance to the castle, stands in Bridge street. At the north end of the town Cromwell built a large fort, but with the exception of a portion of the ramparts it was demolished at the Restoration.

INVERNESS-SHIRE, highland county, Scotland, bounded north by Ross and Cromarty, and the Beauly and Moray firths, north-east by the shires of Nairn and Elgin, east by Banff and Aberdeen shires, south-east by Perthshire, south by Argyllshire and west by the Atlantic. It includes the Outer Hebrides south of the northern boundary of Harris, and several of the Inner Hebrides and is the largest shire in Scotland. Its area (excluding water) is 2,695,094 ac., of which more than one-third belongs to the islands. The county comprises the districts of Moidart, Arisaig and Morar in the south-west, Knoydart in the west, Lochaber in the south, Badenoch in the south-east and the Aird in the north. Excepting comparatively small and fertile tracts in the north on both sides of the river Ness, in several of the glens and on the shores of some of the sea lochs, the county is wild and mountainous and the scenery is very beautiful. There are more than 50 mountains exceeding 3,000 ft., among them Ben Nevis (4,406), the highest mountain in the British Isles, the extraordinary assemblage of peaks forming the Monadhliadh mountains in the south-east, Ben Alder (3,757) in the south, and the group of the Cairngorms on the confines of the shires of Aberdeen and Banff. Almost the whole mainland part of the county is occupied by the younger highland schists and metamorphic rocks, with many isolated patches of granite, of which the largest is on the eastern boundary, including Cairngorm. Athwart the county from south-west to north-east strikes Glen More, the Great Glen, or Glen More-nan-Albin, an old fault or line of earth-fracture along which displacements have occurred during more than one geological period. It contains Loch Lochy and Loch Ness, and through it was constructed the Caledonian canal (*q.v.*). Only in the north-east of the shire, and extending up Glen More midway along Loch Ness, does the Old Red Sandstone replace the typical highland rocks (On the islands, *see* HEBRIDES and SKYE.)

Rivers and Lakes. — In the north-west the Beauly river (16 m.) is formed by the confluence of the Farrar and the Glass. The Enrick (18 m.), rising in Loch-nan-Eun falls into Loch Ness, just beyond Drumnadrochit. The Ness (7 m.), emerges from Loch Dochfour and enters the sea to the north of Inverness. The Moriston (19 m.) flows out of Loch Clunie and falls into Loch Ness 4 m. south of Mealfourvounie (2,284 feet). The Lochy (g m.), issuing from the loch of that name, runs parallel with the Caledonian canal and enters Loch Linnhe at Fort William. The Spean (18 m.), flowing westwards from Loch Laggan, joins the Lochy as it leaves Loch Lochy. The Nevis (12 m.), rising at the back of Ben Nevis, enters Loch Linnhe at Fort William. The Leven (12 m.) drains a series of small lochs to the north-west of Rannoch, and the Dulnain (28 m.), rising in the Monadhliadh mountains, enters the Spey near Grantown, falling in its course nearly 2,000 ft. The Truim (15½ m.), rising close to the Perthshire frontier, flows into the Spey. Three of the larger rivers of Inverness-shire finish their course in other counties. These are the Spey, which for the first 60 m. of its course belongs to the shire; the Findhorn (70 m.), rising in the Monadhliadh mountains a few miles north-west of the source of the Dulnain; and the Nairn (38 m.), rising within a few miles of Loch Farraline. The two falls of Foyers are celebrated for their beauty, but their volume is affected, especially in drought, by the withdrawal of water for electric power works derived from the river Foyers. Other noted falls are Moral on the Enrick and Kilmorack on the Beauly.

There are many hill tarns and little lakes, considerably more than 200 being named. Loch Kess, the most beautiful and best known, is 22½ m. long, 1¾ m. broad at its widest point and 751 ft. deep. It is the largest body of fresh water in Great Britain, and forms part of the scheme of the Caledonian canal. Loch Oich (4 m. long) and Loch Lochy (9½ m.) also form portions of the canal. Loch Arkaig (12 m.) lies in the country of the Camerons, Achnacarry house, the seat of Lochiel, the chief of the clan, being situated on the river Arkaig near the point where it issues from the lake. The old castle was burnt down by the duke of Cumberland, but a few ruins remain. Loch Quoich (6 m.) lies north by west of Loch Arkaig, and Loch Garry (4½ m.) a few miles to the north-east; Loch Morar (11½ m. long by 1½ broad) is only about 600 yd. from the sea, to which it drains by the river Morar, which falls over a rocky barrier. The loch is 1,017 ft. deep and is thus the deepest in the United Kingdom. Loch Ericht, partly in Perthshire, is 14½ m. long and lies at a height of 1,153 ft., being thus the highest lake of such large size in Great Britain. It is finely situated in wild highland country at the foot of Ben Alder. Loch Laggan (7 m.) and Loch Treig (5½ m.) in the south are situated in the midst of natural forests. The principal salt-water lochs on the Atlantic seaboard are Loch Hourn ("Hell's Lake," so named from the wild precipices rising sheer from the water), running inland for 14 m. from the Sound of Sleat and separating Glenelg from Knoydart; and Loch Nevis (14 m.), a few miles farther south.

The parallel roads of Glen Roy, a glen with a north-easterly to south-westerly trend, a few miles east of Loch Lochy, presented a problem that long exercised geologists. At heights of 1,148 ft., 1,067 ft. and 835 ft., there run uninterruptedly along each side of the glen terraces of a width varying from 3 to 30 feet. They are now generally taken to be the gently sloping banks of lakes dammed up at different levels successively by glacier ice. Further evidences of glacial action are abundant in many places, in the form of roches moutonnées, striations, moraines, etc. At several points on the coasts remains of old marine terraces are seen at 100 and 25 ft. above present sea-level.

Among the finer glens are Glen Urquhart and Glen Moriston to the west of Loch Ness, Glen Feshie in the east, and Glen Nevis at the southern base of Ben Nevis. Glen Garry, to the west of Loch Oich, gave its name to the well-known cap or "bonnet" worn both in the Highlands and Lowlands. In Glen Finnan, at the head of Loch Shiel, Prince Charles Edward raised his standard in 1745. The great straths or valleys are in the north and east, the chief among them being Strathfarrar, Strathglass and Strathnairn, and the heads of Strathearn and Strathspey.

History.— To the north of the boundary hills of the present counties of Argyll and Perth (beyond which the Romans attempted no occupation) the country was occupied in Roman times by the Picts. The territory was afterwards called the province of Moray, and extended from the Spey and Loch Lochy to Caithness. These limits it retained until the 17th century, when Caithness (in 1617). Sutherland (in 1633) and Ross-shire (in 1661) were successively detached. Towards the end of the 6th century Columba undertook the conversion of the Picts, himself baptizing their king, Brude, at Inverness; but paganism died hard and tribal wars prevented progress. In the 11th century, after the death of Duncan, Scotland was divided between Macbeth and the Norwegian leader Thorfinn, who took for his share the land peopled by the northern Picts. Malcolm Canmore, avenging his father, defeated and slew Macbeth (1057), and at a later date reduced the country and annexed it to the kingdom of Scotland. Insurrections continued until the reign of David I., when colonists of noble birth were settled in various parts of the shire. After the battle of Largs (1263) the Norse yoke was thrown off. In 1300 Edward I.'s expedition to Scotland passed through the northern districts, his army laying siege to Urquhart and Beaufort castles. After the plantation the clan system gradually developed and attained in the shire its fullest power, the chief being the Frasers, Chisholms, Grants, Camerons, Chattan, Macdonalds of the Isles, Clanranald Macdonalds and Macleods. The clans were constantly fighting each other, or their sovereigns.

In many quarters the Protestant movement made no headway, the clansmen remaining steadfast to the older creed. At the era of the Covenant, Montrose conducted a campaign in the interests of the royalists, gaining a brilliant victory at Inverlochy (1645), but the effects of his crusade were speedily neutralized by the equally masterly strategy of Cromwell. Next Episcopacy appeared to be securing a foothold, until Viscount Dundee fell at Killiecrankie, that battle being followed by a defeat of the Highlanders at Cromdale in 1690. The futile rising headed by Mar in 1715 led to a combined effort to hold the clans in check. Forts were constructed at Inverness, Kilchumin (Fort Augustus) and Kilmallie (Fort William); Wade's famous roads–exhibiting at many points notable examples of engineering—enabled the king's soldiers rapidly to scour the country, and general disarming was required.

Prince Charles Edward's attempt in 1745 had the effect of bringing most of the clans together for a while; but the clan system was broken up after his failure and escape. Heritable jurisdictions were abolished. Even the wearing of the Highland dress was proscribed. The effects of this policy were soon evident. Many of the chieftains became embarrassed, their estates were sold, and the glensfolk, impoverished but high-spirited, sought homes in Canada and the United States. As time passed and passion abated, a proposal to raise several Highland regiments for the British army was entertained with surprising favour, among the regiments then enrolled being the 79th Cameron Highlanders. Fort George, afterward the depot of the Seaforth Highlanders, 12 m. N.E. of Inverness, was begun in 1748.

Stone axes and other weapons or tools have been dug up in the peat, and prehistoric jewellery has also been found. Lake dwellings occur in Loch Lundy in Glengarry and on Loch Beauly, and stone circles are numerous, as at Inches, Clava, and in the valley of the Ness. Pictish towers or brochs are met with in Glenbeg (Glenelg), and duns (forts) in the Aird and to the west and south-west of Beauly and elsewhere. Among vitrified forts the principal are those on Craig Phadrick, Dundbhairdghall in Glen Nevis, Dun Fionn or Fingal's fort on the Beauly, near Kilmorack, Achterawe in Glengarry and in Arisaig.

Forests and Fauna.— Deer forests occupy an enormous area, particularly in the west, in the centre, in the south and south-east and in Skye. From the number of trees found in peat bogs, the county must once have been thickly covered with wood. Strathspey is still celebrated for its forests, and the natural woods on Loch Arkaig, in Glen Garry, Glen Moriston, Strathglass and Strathfarrar, ana at the head of Loch Sheil, are extensive. Part of the ancient Caledonian forest extends for several miles near the Perthshire boundary. Many of the rivers and several of the lochs abound with salmon and trout, the salmon fisheries of the Beauly, Ness and Lochy yielding a substantial return.

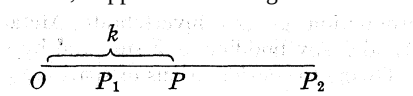
Agriculture.— The percentage of land under crops is small, and almost half the total area is mountain and heath. The Aird and Beauly districts, some of the straths and several of the glens are fertile. Oats are the predominant crop, barley is grown (mostly for the distilleries), but the wheat acreage is trifling. Turnips and potatoes are grown. About one-third of the holdings are crofts of five acres or under, and only about one-seventh of the holdings are over 30 acres. The operations of the Crofters' Commission (1886) have been beneficial in improving the condition of the people. The hills furnish good pastures. The flocks of sheep are heavy, the chief varieties on the uplands being Cheviots and black-faced and in some of the lower districts Leicesters and half-breeds. Of the cattle the principal breed is the Highland, the largest and best herds of which are in the Western Isles. Polled and Shorthorns are also reared, and Ayrshires are kept for dairy purposes, Highland ponies are raised on the hill farms.

Industries.— Excepting the industries carried on in Inverness, these are almost entirely confined to distilling—at Fort William, Carbost, Muir of Ord and some other places—brewing, wool and flax spinning, milling and (near Inverness) artificial manures. The catering for the wants of sportsmen and tourists, however, provides employment for many. The fisheries are of great value, especially at Fort William and in the Hebrides. Schemes to develop the industrial use of water power are in progress near Fort William.

Communications.— Rail communication in the shire is somewhat restricted, but the L.M.S. railway enters the shire from the south near Dalwhinnie and runs to Inverness via Aviemore and Daviot. Another portion of the same system also reaches the county town from Nairnshire. The Dingwall and Skye railway passes along the southern shore of Beauly Firth. In the south-west the L.N.E. railway enters the county 2 m. N.W. of Rannoch station and terminates at Mallaig, via Fort William and Banavie, sending off at Spean Bridge a branch to Fort Augustus. There is also communication by steamer from Glasgow with the piers of the Caledonian canal and with the Western Isles. Considerable shipping reaches Beauly and Inverness by way of Moray Firth.

Population and Government.— The population was 82,082 in 1931, when 31,474 persons spoke Gaelic and English, and 3,123 Gaelic only. The only considerable towns are Inverness (pop. in 1931, 22,582) and Fort William (2,527). The county returns three members to parliament with Ross and Cromarty. Inverness forms a sheriffdom, with resident sheriffs-substitute at Inverness, Fort William, and Portree, and is under school-board jurisdiction.

INVERSION, a term used in the study of geometric figures. To take a simple case, suppose in this figure



that $OP=1$, $OP_1=\frac{1}{2}$, and $OP_2=2$. Then $OP_1 \cdot OP_2 = OP$. Let us say that $OP=k$. Then it is evident that there is an infinite number of points P_1, P_2 on the line such that $OP_1 \cdot OP_2 = k$. A geometric transformation which replaces each point P_1 by a point P_2 such that $OP_1 \cdot OP_2 = k$ is called an *inversion*. In such case O is the centre of inversion and k is the *radius* of inversion. As P_1 moves nearer to O, P_2 moves farther away. As P_1 approaches P, P_2 also approaches P. In general we say that, when $xy=k$, x and y are inversely proportional, one decreasing as the other increases. We may also say that if $y=f(x)$, we may inversely consider x as a function (implicit) of y.

INVERTEBRATA, a term commonly used in zoology to denote all those animals not possessing a backbone (*e.g.*, insects, snails, worms), in contradistinction to the Vertebrata (*q.v.*), in which a backbone, or some structure representing it, is present. The animals thus brigaded together do not form in any sense a natural assemblage, but the term is none the less a very convenient one. For the purposes of this dichotomous division the Protochordata (*Amphioxus, Balanoglossus* and the Tunicata, *qq.v.*) are included in the Vertebrata, though they have no true vertebral

column. (See ZOOLOGY, ZOOLOGICAL NOMENCLATURE, INVERTEBRATE EMBRYOLOGY.)

INVERTEBRATE EMBRYOLOGY. The word embryology means literally the science of the fruit of the womb (Greek ἔμβρυον), but in practice its meaning is extended to embrace all forms of individual development or life-history, whether that development takes place within the mother's womb, as in a human being, within a shell, as with a chicken, or freely in the open, like the frog tadpole.

The term invertebrate is a comprehensive one which includes all animals that are not vertebrates. There are two grades of animals, *viz.*, the Protozoa and the Metazoa. The first consist either of single cells, or of small masses of protoplasm with numerous nuclei, but not divided into cells, or, finally, of small groups of similar cells connected with one another, all of which are similar to one another and which carry out the same functions in the animal. When the animal reproduces they all take part in this act, so that the mother disappears in giving rise to her offspring. The bodies of the Metazoa, on the other hand, are composed of cells which are not all alike, but which are differentiated into sheets called tissues, which have different tasks to fulfil in the economy of the animal. When reproduction takes place this is carried out only by some of the cells, and so a distinction is made between the "germ-cells," which undergo development and give rise to new individuals, and the "soma" or body which carries out the other functions, such as digestion, movement, excretion, etc., and which shelters and nourishes the germ.

The life-history of the Protozoa (*q.v.*) exhibits essentially the same phenomena as that of the Metazoa, but for practical considerations it is not included in an account of the embryology of the Invertebrata. The Metazoa include about 16 distinct groups of animals, termed "phyla" (Greek φῦλον, race). One of these phyla consists of the Vertebrata or back-boned animals to which we ourselves belong; all the rest are called Invertebrata.

The invertebrate phyla are (1) the sponges (Porifera, *q.v.*), (2) the sea-anemones, corals, polyps and jelly-fish (Coelenterata, *q.v.*), (3) the flat-worms (Platyhelminthes, *q.v.*), (4) the proboscis-worms (Nemertea), (5) the thread-worms (Nematoda, *q.v.*), (6) the arrow-worms (Chaetognatha, *q.v.*), (7) the segmented worms (Annelida, *q.v.*), (8) the articulates or jointed-legs (Arthropoda, *q.v.*), (9) the shell-fish and cuttle-fish (Mollusca, *q.v.*), (10) the spiny-skinned radiates (Echinodermata, *q.v.*), (11) the wheel-animalcules (Rotifera, *q.v.*), (12) the moss-animals (Polyzoa, *q.v.*), (13) the foot-axis animals (Podaxonia), (14) the lamp-shells (Brachiopoda, *q.v.*) and (15) the Enteropneusta (*q.v.*), worms, breathing by slits in the wall of the gut, which constitute a bridge between the Invertebrata and the Vertebrata.

The reproduction of the invertebrate Metazoa takes place by two methods,—by budding or fission and by sexual germ-cells or gametes. Owing to considerations of space we can only consider reproduction by germ-cells.

The gametes are of two kinds, termed male and female, which normally must unite with one another before development is possible. The male cells are produced by a special type of individual called a male, the female cells by another type, the female. Occasionally both are formed in the same individual, which is then termed a hermaphrodite. The product of the union of a male and a female gamete is a zygote. The general structure of these cells is remarkably constant throughout the whole range of the Metazoa, from the sponges up to man himself. The female cell, the egg or ovum, has stored in its protoplasm deposits of reserve material or yolk, which enable the zygote to carry on its existence till it is able to obtain food from the outside.

These deposits vary enormously in bulk and bear little or no relation to the size of the future organism, but solely to the time which must elapse before food is available from outside, and the amount of the deposit regulates the size of the egg. Thus the egg of a woman is only $\frac{1}{125}$ in. in diameter, whereas that of a hen (termed "the yolk") is, as we all know, the size of a golf-ball. When an egg has very little yolk it is termed *alecithal*. When there is a good deal of yolk massed towards one pole the egg is said to be telolecitkal; when the yolk is in the centre surrounded by a skin of protoplasm, the egg is called centrolecithal. The Echinodermata (star-fish, sea-urchins, etc.) have, with few exceptions, alecithal eggs; the eggs of Mollusca (snails, clams and cuttle-fish) are telolecithal, whilst those of Arthropoda (crabs, spiders, insects, etc.) are centrolecithal.

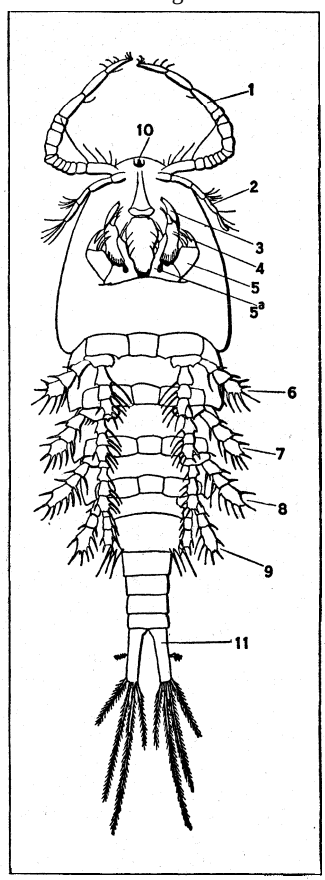
The male gamete, the sperm or spermatozoon, is, when young, a simple rounded cell indistinguishable from a young female cell, but as it grows and ripens it undergoes remarkable changes. A vibratile filament termed the tail grows out from close beside the nucleus; the nucleus shrinks, expelling the nuclear sap and becomes converted into a small dense mass, termed the head, and the whole of the protoplasm is then sloughed off. The sperm, in virtue of the possession of a tail, is endowed with the power of locomotion; its task is to seek the female cell and to unite with it. When the head touches the surface of an egg the screw-like motion of the tail drives it in. As soon, however, as it is immersed in the protoplasm of the egg, the egg reacts by producing a membrane at its surface termed the vitelline membrane, which may be regarded as the primitive egg-shell, within which the zygote completes the first stages of its development. This membrane, in most cases, cuts off the tail of the spermatozoon, and in all cases prevents more spermatozoa from entering, so that all the potencies of the father who produces the male germ-cell are conveyed into the egg by a single nucleus, a fact which has a most important bearing on theories of heredity (*q.v.*). Once inside the egg, the spermatozoon head absorbs fluid and swells up to form a normal nucleus. (See CYTOLOGY.) The two nuclei now approach one another and become placed side by side to form the compound nucleus of the fertilized egg or zygote. In some cases the two components, male and female, can be distinguished from one another in the zygote nucleus during the first divisions of the egg, and it is then seen that the plane of division always cuts male and female portions of the nucleus symmetrically, so that equal portions of paternal and maternal nuclear substance are distributed to each daughter-cell. (See REPRODUCTION.)

Both the eggs and the male cells in all Metazoa divide twice during the process of ripening; these divisions in the male-cell give rise to four equal spermatids, all of which develop into spermatozoa, but in the case of the female germ cell they give rise to the ripe egg and to three minute vestigial cells termed polar bodies. The polar bodies, or at least one of them, adheres to the egg for some time, and the area to which they cling is known as the animal pole of the egg; the opposite pole towards which yolk is massed is known as the vegetative pole. In small and moderate-sized eggs the spermatozoon enters at the vegetative pole and makes its way upwards towards the female nucleus, which descends to meet it after having divided to form the second polar body; the path taken by the entering sperm seems to fix the future median plane of symmetry of the embryo.

There are two phases of development, such as are exemplified by the unhatched chick and the frog tadpole: they are termed respectively the embryonic and the larval phases. In the embryonic phase, the young organism is protected from the outside world by an egg-shell or within the womb of the mother and derives its nourishment either from stores of yolk or from the mother's womb. In the larval phase on the other hand, the young animal moves freely about and has to escape from its enemies and obtain its food by its own efforts. In every life-history there is both an embryonic and a larval phase; for no egg is ever thrust out naked into the world. Every one during the earliest part of development, as we have already seen, is protected by a vitelline membrane; and no animal is hatched exactly like the adult parent. Every animal undergoes a shorter or longer period of growth after birth during which it changes its shape and proportions and this part of its life-history may justly be called a larval phase. The first question to be settled is how these two phases are related to one another—which is the primary and which is the derived one?

A comparison with one another of allied species leaves no doubt that the larval phase is generally the primary mode of development and that the embryo is usually merely a concealed

and modified larva. This could be proved by instances selected from any invertebrate phylum, but more familiar cases are seen amongst the vertebrates. Everyone is acquainted with the tadpole larva of frogs and toads, and with its fish-like organs adapted to its life in water. The tadpole has three feather-like gills projecting from the head on each side, and between these gill-clefts, reaching into the throat, it has a flattened tail fringed with a fin. Now, in the West Indies there is a tree-frog, *Hylodes,* which lays its eggs far from water. From these eggs there emerge, not tadpoles, but froglings ready to take up their life on land. Nevertheless, if the covering of the egg be dissected off half way through development there will be found inside it a tadpole with gills and tail. These organs have no meaning in the embryonic life—they can be explained only if we assume that the embryo was formerly a larva.



FROM SHIPLEY AND MACBRIDE, "ZOOLOGY" (CAMBRIDGE UNIVERSITY PRESS)

FIG. 1.—MALE WATER FLEA (CYCLOPS SP.)
1. Antennule. 2. Antenna. 3. Mandible. 4. Maxillule. 5. Maxilla. 5a. Maxillipede. 6, 7, 8, 9. Forked trunk limbs. 10. Eye. 11. Tailfork

We are now faced with the question, what is the meaning of the larval phase? If we base our reasoning on a broad comparative view, we shall be driven to the conclusion that the larva is a recapitulation of a former adult condition of the race. We find amongst the invertebrate phyla a typical anatomical structure common to the overwhelming majority of the members of each group, but there is always a minority of species with aberrant structure. When we examine the young stages of these aberrant members, *i.e.,* their latest larval phases, we find that during this period of their life they possess the typical structure of the group. As no comparative anatomist doubts for a moment that the aberrant members have been derived from more typical ancestors, this means that these aberrant forms in their later development repeat or recapitulate the history of the race. A good example of this phenomenon can he found amongst the oar-footed Crustacea (Copepoda). Certain species such as *Achtheres* attach themselves to the gills of fish and nourish themselves by sucking the blood. These develop into shapeless maggots devoid of limbs—except the third pair of jaws with which the copepod clasps the gill-filament of the host. But when first hatched from the egg, *Achtheres* is a free-swimming copepod with a typical head, thorax and abdomen and two pairs of swimming legs. In such cases, where the immediate ancestry of the species is clear and undisputed, the meaning of the larval phase is also quite clear, and we are therefore justified in adopting the same explanation for earlier larval stages, corresponding to which living adult forms embodied in other species are no longer to be found. Behind the first larval stage we come to the embryonic stages, to which a similar explanation must be applied, and so we are led back step by step to the fertilized unsegmented ovum, which on this interpretation represents the original unicellular protozoon from which all the higher animals are descended.

But if the whole course of development is thus to be regarded as a series of superposed recapitulations, these are by no means close and accurate reproductions of the ancestral history which they represent. Like human memories, they have suffered blurring and distortion, and like human memories also, the earliest ones have suffered most, and we shall presently study the principal influences which have brought about this distortion. But since the life-history of every species in the same phylum is a separate edition of the same history, and since the distorting influences vary from species to species, by the aid of a truly comparative embryology we can eliminate most of these secondary alterations from the primitive history and thus restore—not in minute detail, but in broad outline—the general course of the development of animal life on the earth.

We have seen that the primary type of development is generally the larval, and that the essential nature of the larva is to be active. All its organs are functional—its nature is expressed by its habits. Therefore a larval stage is a *recapitulation* of a former series of habits which the ancestors of the present race possessed; and the passage to the present state of affairs, the last stage in evolution, was a change of habits.

The recapitulation of ancient habits in the earlier stages of the life-history therefore means that the change to modern habits took place when the animal had reached a certain size, hut when it was still capable of growth and modification. The new habits, by causing the animal to use some of its organs more and others less, produced alterations in its structure through the stimulation of the growth of the more used organs and the inhibition of the growth of the less used ones; these alterations in succeeding generations were produced more and more easily and on slighter stimuli; in a word, the tendency to produce them became more deeply ingrained in the organism, till finally—as in the embryonic phase—they supervened without any external stimulus at all. As the new habits prove more advantageous in getting food and promoting growth, the change from larva to adult comes on at earlier and earlier periods of growth, and so the larva is usually very small compared to the adult. But occasionally the reverse change has taken place—the adult phase has become more dangerous, and serves not for feeding and growth, but chiefly for mating. In this case the larval stage may be more and more prolonged and the full-grown larva may be actually larger than the adult; this is the case with most moths and butterflies. In the case of certain salamanders such as the axolotl, the same change has taken place, and here the adult phase under ordinary circumstances is suppressed altogether; the animal mates and lays its eggs whilst still a larva. By exposing such animals to abnormal conditions, however, the lost adult phase may be brought to light. (*See* METAMORPHOSIS: Experimental.)

The larva is very small compared to the ancestral stage which it represents. For instance, organs repeated in series which act together and form a physiological unit, are represented in the larva by shortened series—sometimes organs which are in pairs are represented only by one. Thus the larva of Achtheres has two pairs of swimming limbs, whereas the normal copepod has four pairs. Occasionally the normal type of environment to which the larval organs are adapted has been changed. This difficulty may be met in two ways; either the larval phase is transformed into an embryonic one—as in Hylodes—or the larva is forced to change its habits, and then its ancestral features may be almost entirely obscured. This is the case with many larvae of insects.

In the actual history of the race, the transition from one set of habits to another and the accompanying changes of structure must have been gradual; but it often happens that in the course of time the transitional habits are not suited to the available environment and the corresponding stage is very rapidly passed through. During this period of rapid change the animal takes no food. and relies on the stores accumulated in the previous stage. See METAMORPHOSIS.

In embryonic stages yolk impedes the process of cell-division. In the normal cell this process is accompanied by a stiffening of the protoplasm; the two daughter-cells at the moment of division seem, as it were, to round themselves off by a kind of coagulation. This stiffening does not last, however, and after the division is completed the protoplasm again becomes semi-fluid and the two cells flatten themselves out against each other. When much yolk is present it acts exactly like water mixed with honey; it dilutes the protoplasm. Hence the amount of stiffening previous to cell-

division is much less, the division proceeds slowly and the cells produced are clumsy and large. During the period of relaxation, the daughter-cells often fuse with one another and the process of division is undone. When very much yolk is present, cell-division becomes quite impossible and only division of nuclei takes place.

In such eggs, where the protoplasm is concentrated at one pole, development proceeds rapidly in this area, whereas at the opposite

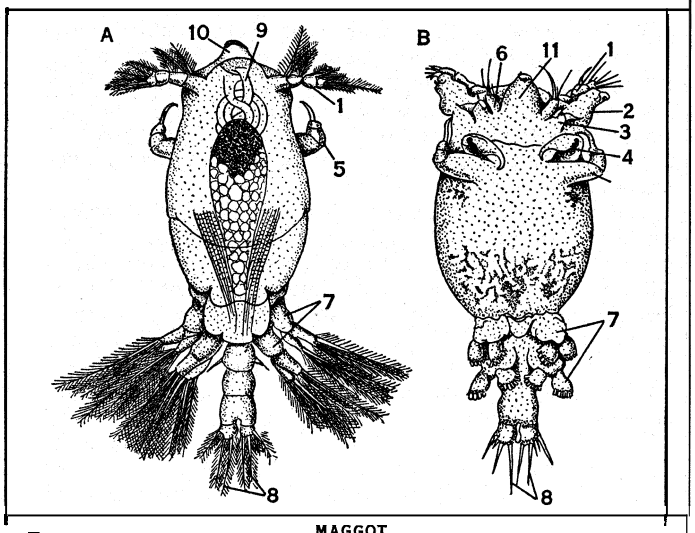


FIG. 2.—LARVA OF THE GILL-MAGGOT (ACHTHERES AMBLOPLITIS). A. Dorsal view. B. ventral view. 1, 2, 3, 4, 5 as before; 6. mandible; 7, forked trunk limbs; 8. cordal fork; 9. gland producing adhesive filament; 10. upper lip; 11. under lip

pole it is at first at a complete standstill. So the embryo gradually acquires the features of the adult, whilst bearing attached to it a huge sac filled with yolk. Such eggs are termed meroblastic, as opposed to holoblastic eggs, in which the whole egg is divided into cells. The yolk-sac is eventually surrounded by a layer of cells budded from the edges of the developing area; and as the organs of the embryo become formed the yolk is gradually digested, and conveyed by blood-vessels to the growing part of the body. The yolk-sac shrinks and its covering is eventually incorporated in the skin of the young animal. Amongst invertebrates meroblastic eggs are found amongst Cephalopoda (cuttle-fish), and it is a ludicrous sight to see a miniature squid attached to one pole of a large egg.

The organs of the embryo, as opposed to those of the larva, are functionless, and where they are not transformed into adult organs they are apt to be almost entirely suppressed; thus in the embryo of the earthworm no trace remams of the broad equatorial belt of cilia, which is so characteristic of the trochophore larvae of other worms and which forms their principal means of locomotion. So, too, in the embryonic development of most snakes no traces of the ancestral limbs are preserved.

The embryonic phase can be divided into three stages, which are respectively (a) segmentation of the egg, (b) formation of germ-layers, and (c) organogeny.

The segmentation of the egg means its division into a large number of cells or blastomeres. In the eggs of the most primitive creatures, in which there is little or no yolk, the blastomeres are almost equal in size to one another, and as they increase in number they separate from one another in the centre, so that they become arranged like a balloon round a cavity. This cavity is called the blastocoele or primary body-cavity, and the whole balloon is known as the blastula. In the case of the Echinodermata, Driesch has proved that the cells of the blastula not only look like each other, but are really like each other in their potencies, for if the blastula be cut into pieces any piece of sufficient size will round itself off so as to form a new blastula of reduced dimensions, which will develop into a perfectly normal larva.

When the distorting influence of yolk is absent or not much developed, the blastula stage can be detected in life-histories belonging to all the invertebrate phyla. Thus in Mollusca it is clear in the development of the limpet (Patella) and the pond-snail (Paludina), amongst Arthropoda in the development of the fairy-shrimps (*Branchipus*), and of the water-fleas (Copepoda), amongst sponges it is seen in Oscarella, whilst it is almost universal amongst Coelenterata, Echinodermata, Nemertea (proboscis-worms) and Brachiopoda. In the sponge Oscarella, the coelenterate *Eudendrium* and in Echinodermata, the blastula is a larval stage, and therefore it may be legitimately considered as a recapitulation of a common ancestor of all the Metazoa. There exists even at the present time a hollow bell-like organism consisting of ciliated cellstied together by protoplasmic filaments. This creature is termed Volvox, and it is sometimes regarded as a compound Protozoon allied to the simple Flagellata.

The "formation of layers" implies the transformation of this balloon into a double-layered cup termed the gastrula, by the in-pushing of one of its sides. The inner layer, which is called *endoderm,* gives rise to the digestive layer lining the gut—the outer layer or ectoderm to the skin. From the inner layer pockets or cellular outgrowths are given off which give rise to body-cavity and muscles and these are termed the mesoderm. Ectoderm, endoderm and mesoderm are the three germinal layers. The gastrula can be recognized as a stage in the development of all Metazoa except sponges. It exists as a larva amongst the Echinodermata and, in modified form, amongst Coelenterata, in which it is known as the planula. The inner layer in the most primitive forms arises as a process of in-bending or invagination. It looks exactly as if it were pushed in by an invisible finger. The opening produced by this process is called the blastopore. The process of invagination can be analysed into three factors. There is (a) a process of growth and multiplication of cells at one point on the blastular wall which produces lateral pressure; (*b*) an alteration in character of the cells of the blastular wall. Although after the process of invagination has begun the cells at the animal pole look just the same as before, they have lost some of their original powers—for Driesch has proved that if the upper part of the blastular wall be cut off after this event, though it is able to round itself and form a new blastula, this blastula is incapable of further development; it has become ectoderm. The new cells formed in the zone of growth are from the beginning divided into two categories, one being ectoderm and the other endoderm; (c) a tendency to flow inwards towards the interior of the blastocoele. It is obvious that mere lateral pressure due to increased growth would be relieved by a bending outwards as well as by a bending inwards, and Driesch has shown that under abnormal circumstances this can actually happen with the gastrula of the sea-urchin. There must, therefore, be a special factor in normal development to ensure that invagnation or bending inwards takes place. This we may call inward cytotaxis.

The planula differs from the typical gastrula in that the in-growth of endoderm is a solid mass of cells, not a finger-shaped tube. This mass subsequently becomes hollowed out by the absorption of its central cells and forms the lining of the gut., Indeed, the Coelenterata might be regarded as retaining throughout their lives the gastrula type of structure. In some Coelenterata, such as *Aurelia* (the common jelly-fish), and Urticina (a common sea-anemone), the planula is replaced by a hollow gastrula and the blastopore becomes the mouth of the animal. If we have to decide whether the planula or the hollow gastrula gives the most faithful recollection of a distant ancestor, we must decide in favour of the gastrula. For in the history of the race there must have been continuity of function; at every stage in the process the animal must have been a working machine. Now, a solid mass of cells could not serve as an organ for digesting food, but a hollow tube is adapted to this end. Hence we conclude that the gastrula and not the planula gives us the truest picture of the ancestor.

The sponge Oscarella, as we have already seen, is hatched as a typical ciliated blastula. But it does not become converted into a gastrula. The hinder cells lose their cilia and become granular; in this stage the larva is termed an amphiblastula and the majority of sponges are hatched in this stage. The amphiblastula, like the planula, attaches itself to the bottom by its anterior end, but this end now flattens out and then becomes bent inwards and upwards whilst it is overgrown by a great extension of the granular cells

which form the outer dermal layer of the sponge. If we call the inbending of the ciliated cells invagination, then this invagination takes place at the opposite pole from that at which it occurs in the planula. From these ciliated cells the gastral or inner layer of the sponge and the so-Ealled flagellate chambers are derived.

How shall we interpret this metamorphosis? If a blastula-like animal was the ancestor of all the Metazoa, there must have been a remote period in the world's history when the seas swarmed with this type and when nothing higher was in existence. If some of these blastulae, instead of seeking a living in midwater, like the rest of their brethren, descended to the bottom to feed and found it profitable to do so, then in this divergence of habit amongst members of the same strain we should have the explanation of the primary cleavage between the phyla Porifera and Coelenterata. Similar divergences of habit have taken place at every stage in the history of life.

The free-swimming blastulae in their search for food perhaps gradually substituted for a random rolling motion a screw-like motion in one direction, and so the posterior end became specialized for the capture and swallowing of food, whilst the front part became the organ of locomotion. So the gastrula grew out of the active blastula, and the cells at its anterior end being the first to encounter changes in the environment, became transformed into a sense-organ with stiff sense-hairs and alternately gave rise to the first nervous centre. Such a sense-organ has been demonstrated by Duerden in the planulae of certain corals. But the very same difference of habit which manifested itself at the blastula stage, supervened again. Some of the gastrulae sought the bottom and attached themselves there; these gave rise to the great army of plant-like polyps and sea-anemones which constitute the major portion of the Coelenterata. But there was a minority amongst the Coelenterata which never abandoned the original free-swimming life; these are represented in our present seas by the beautiful comb-bearers (Ctenophora) which propel themselves by eight radiating bands of ciliaarranged in little transverse combs. These bands culminate in a beautiful sense-organ resting on a nervous cushion—situated, unlike the nervous centres of other Coelenterata, in front. Out of animals somewhat like these the evolution of most of the higher invertebrates has proceeded. The ctenophore is nothing but an active, sensitive, glorified gastrula, and in the life-history of the flat-worms (Platyhelrninthes) the memory of this ancestor is preserved as *Müller's larva.* This larva, after a brief free-swimming life, sinks to the bottom and flattens out and becomes converted into a leaf-like flat-worm or turbellarian crawling on its cilia. Miiller's larva is an oval organism with a sense-organ at one pole and along its sides eight ciliated lobes which correspond to the eight meridians of combs in the ctenophore.

In the life-history of the proboscis-worms (Nemertea) a'larva termed the *Pilidium* occurs, which also seems to be a memory of a ctenophore-like larva. It is shaped like a helmet with a strongly developed sense-organ at its apex. Below there is a wide sac-like gut opening by a wide blastopore. The ciliated ribs have coalesced into a wavy circular band which, however, retains two side-lappets like the lobes of Muller's larva. The pilidium, however, is transformed into the Nemertine worm by an abrupt metamorphosis which, doubtless, represents an extreme compression of an originally long life-history, and which it has been impossible up to the present to interpret satisfactorily.

The trochophore larva which appears in the life-history of not only the shell-fish (Mollusca) but also the Polyzoa and the segmented worms (Annelida) is a further development of the ctenophore-like gastrula. The typical trochophore is an almost spherical larva, with an apical sense-organ at one pole essentially similar to the sense-organ of Miiller's larva and the *Pilidium.* Round the equator is a belt of powerful cilia, by the aid of which the larva moves. This band is termed the prototroch: Wilson has shown in the case of *Patella* and Waltereck has proved in the case of the worm *Polygordius* that this ring consists at first of four separate lozenge-shaped patches, in which the cilia are arranged in transverse combs. The trochophore may thus represent a four-ribbed ctenophore-like ancestor. Below the prototroch there is, as in the *Pilidium,* a sac-like gut opening by a wide blastopore, which changes into a narrow langitudinal slit, that becomes closed up so as to form a seam-like ciliated groove, except in front, where an opening persists which forms the mouth. In the primitive worm *Polygordius* there is an opening also at the hinder end of the seam which is the anus. In the case of other trochophores, the anus is usually formed as a new opening at the hinder end of the seam. In these processes we clearly have blurred memories of a history which converted the wide single opening into the gut possessed by the Coelenterata and the flat-worms (Platyhelminthes), into two openings, a mouth for taking in food and an anus for ejecting waste. Since the nemertine worm also has an anus, the pilidium larva represents only the early stage of the trochophore ancestor before the division of the blastopore and the later stage is obscured by the metamorphosis.

The second great advance shown by the trochophore is the formation of a true mesoderm. Two large cells, which in the early trochophore form part of the wall of the hinder part of the gat, are ejected into the primary body-cavity or blastocoele. Here each cell begins a process of active growth and multiplication. The daughter-cells are budded off in front, whilst the original mother-cell remains behind; in this way a band-like mass of cells, the so-called *mesodermal band* is produced, which develops a cavity termed the secondary body-cavity or *coelom.* From the wall of this cavity the germ-cells are developed, and it develops tube-like extensions which reach the exterior and form the so-called *coelomoducts.* Some of these serve as genital ducts (their primary function) and others secondarily acquire an excretory function. In front of the coelom a pair of string-like ingrowths of the skin or ectoderm cells become hollowed out to form vesicles or tubes. These are the primary excretory organs or *nephridia.*

The coelom turns up in other phyla where the trochophore larva is not formed, as for instance in the arrow-worms (Chaetognatha) and in the Brachiopoda. In these two phyla it is formed as a pair of hollow pouches of the gut, and on the same principles of interpretation which we employed in the case of the planula, we regard the out-pouching of the gut as the primitive method of forming the coelom, and the ejection of cells from the gut-wall as a secondary modification of this process.

If we now follow the trochophore in its gradual process of development into a worm and a mollusc respectively, we find that the change in the first case consists in the gradual lengthening of the body behind the prototroch. The intestine becomes drawn out into a long tube and the mesoderm into a long band. This

band becomes broken by cross fission into a series of blocks, in each of which a section of the coelom is formed by the absorption of the central cells. The skin becomes indented by a series of grooves corresponding to these blocks, and so the well known appearance of the segmented worm is produced. The prototrochal cells are then absorbed or cast off and the worm sinks to the bottom and begins its burrowing life, varied by brief seasons of spasmodic activity, during which it swims through the water by undulatory movements. These movements are carried out by alternate contractions of the longitudinal muscles on both sides,

and these muscles are developed out of the lateral walls of the segments of the mesodermal bands. When, however, the trochophore develops into a mollusc a different set of changes supervene. The body behind the prototroch becomes arched dorsally into a protuberance known as the visceral hump, inside which is contained the larval stomach. On the apex of the hump a saddle-shaped groove of thickened cells makes its appearance. This is the so-called shell gland, and by this gland a horny cap, the first rudiment of the shell, is secreted. On the ventral surface of the post-trochophoral body, a ciliated wedge-shaped projection grows out, along the line of the ciliated groove which marks the position of the sealed-up blastopore. This is the foot, by which the mollusc moves. In primitive Mollusca this movement is just a gliding by means of cilia over the bottom, but in more advanced and larger forms the ciliary movements are replaced by muscular wrigglings. We can now catch a glimpse of the divergences of habits which led to the separation of the two great groups of Annelida and Mollusca. The trochophore stock, like the more primitive stock represented by Miiller's larva, sought their food on the bottom. Under these circumstances two different modes of life were open to them. They might either seek their food in the most superficial layer of the bottom deposit, and in this case they became molluscs; or they might burrow into it, and in this case they became segmented worms (Annelida). But, as we have already pointed out, the Annelida really lead a double life; in all the more typical forms burrowing alternates with rapid swimming excursions through the open water. The accentuation of this later habit, and the gradual forgetting of the tendency to burrow led to the evolution of the great phylum Arthropoda, or jointed-leg animals, which contains about three-quarters of the known species of living animals.

The Arthropoda differ from the Annelida in the much greater thickness of the cuticle. The coelom has disappeared, leaving only occasional pocket-like remnants, so that the large body-cavity of the arthropod is really a blastocoele. In the early embryonic development of all the Arthropoda there are developed two well-marked mesodermic bands, just like those of Annelida, and in these transverse segmentation and coelomic pockets appear; in a word it might be said that the embryonic arthropod is an annelid. The three great groups of living Arthropoda, the Crustacea, the Arachnida and the Insecta, differ amongst themselves very much as to the extent to which the larval phase is developed. The Arachnida, except in their most primitive forms, leave the egg-shell with practically all the organs of the adult developed, but amongst the Crustacea the larval phase is strongly developed. It is a memory of the gradual transformation of an annelid into an arthropod and shows that this transformation began in front and gradually progressed backwards as the higher types were evolved.

FIG 4 —AMPHIBLASTULA LARVA OF THE SPONGE, GRANTIA LABYRINTHICA

1. Flagellated cells. 2. Granular cells

The most primitive larval phase found in Crustacea is the nauplius, which has already been mentioned. This phase occurs as a larva in the Phyllopoda (leaf-foot Crustacea), the Copepoda, the Cirripedia (barnacles), the Ostracoda and amongst certain primitive members of the Malacostraca, shrimps, lobsters, crabs, etc. As an embryonic stage it can be detected in the life-history of the highest Crustacea. The nauplius is an oval or cylindrical larva with a single simple eye in front and three pairs of jointed legs, one pair slightly in front of the mouth and the two pairs behind it. The mouth is a transverse slit on the under side overhung by a large lip or labrum. The first pair of limbs consists of a straight rod on each side carrying sensory hairs and is termed the *antennule*: the second and third pair are forked, each limb consisting of a basal piece from which inner and outer branches spring, each having two or three joints. The basal piece on each limb carries an inwardly directed hook which the larva uses for seizing its food. These hooks are termed masticatory hooks. The second pair of limbs eventually becomes the *antennae* of the adult, whilst the last pair become changed into the *mandibles*. In most nauplii the body behind the mouth is totally unsegmented but, as already noted, in the nauplii of the primitive Phyllopoda this region is long and cylindrical and marked out into a multitude of very fine ring-like segments. We may interpret this larva as a reminiscence of an ancestral worm, in which the first two or three segments had developed appendages suitable for grasping food, and in which the cuticle of this region was greatly strengthened, but in which the hinder part of the body retained largely its soft, worm-like character. It must be remembered that the marine worms have soft wing-like outgrowths from their segments known as parapodia, and it is these that are converted into the limbs of arthropods when the cuticle becomes thicker.

Since an arthropod is confined within a rigid cuticle, growth is only possible when this cuticle is thrown off. So the life-history presents the appearance of a series of stages of fixed appearance, known as *instars*, separated by shorter stages known as moults, during which changes in appearance take place. Of course these changes are not really as sudden as they appear, for they have been gradually going on in the soft tissues underneath the cuticle, but they only become manifest when the cuticle is shed.

Want of space forbids us to describe in detail the various moults by which the nauplius larva transforms itself into a phyllopod, a copepod, a cirripede and an ostracod respectively. We propose to give only a brief account of the development of the Malacostraca.

In only the most primitive shrimps such as *Penaeus* is the young organism hatched as a nauplius; in the vast majority of cases, this stage is passed over within the egg-shell and the animal is born as a larva of quite a different kind, termed a zoaea. In the lobster even the zoaea stage is passed through before hatching; the young lobster begins its career as a larva of a more advanced type known as the mysis larva, but in the case of all the shrimps and crabs, the zoaea is the typical larva.

The zoaea is divided into an anterior rounded portion, the cephalo-thorax, and a hinder segmented portion ending in a broad tail fin, the abdomen. The cephalo-thorax ends in front in a spike or rostrum; at the sides of this are two large eye-stalks bearing compound eyes, whilst at the base of the rostrum, the single eye of the nauplius can still be detected. The cephalo-thorax is covered by an undivided shield termed the carapace, the sides of which form free flaps hanging down at the side of the body; between these flaps and the body is a groove in which are the first traces of the gills. Of the naupliar appendages, the antennule has shrunk very much in size, the antenna retaining its forked condition only in the primitive zoaea of Penaeus. In the zoaea of the common crab, for instance, as in most zoaea, the outer branch of this limb has assumed the adult form of a scale, the so-called squame. The mandible is reduced to its basal stump. Behind the mouth come two segments carrying the two additional pairs of jaws, the maxillules and the maxillae, which are common to all Crustacea. Behind the second of these is the groove which marks the limits of the head region, as distinct from the thorax. The segments of the thorax are exceedingly compressed—only the first two carry limbs; these are large forked appendages and are used in swimming. In the zoaea of the shrimp the first three pairs carry limbs. The abdominal segments are without appendages.

No adult crustacean exactly like the zoaea is found living. But if we watch how the larva uses its limbs, we see clearly that it represents a stage in functional evolution between the primitive arthropod represented by the nauplius and one of the higher Crustacea. In the primitive arthropod, swimming and getting food were functions carried out by the same limbs, but when the arthropod became a crustacean, three of the pairs of limbs, mandibles, maxillules and maxilla, were changed into jaws and the swimming function was relegated to the two or three pairs of limbs behind them which in later life became the foot jaws

or maxillipedes. The fact that in the crab zoaea the hinder segments of the thorax and the segments of the abdomen have no limbs may be explained, in the same way as their absence was explained in the nauplius, by the assumption that in the ancestor they were thin and undifferentiated and of little functional importance. In the primitive zoaea of *Penaeus* the second antenna remains, as in the nauplius, large and forked and still aids in swimming as it does in many of the lower Crustacea, and only one pair of maxillipedes is developed; this represents an older ancestral stage than the typical zoaea. Weldon has given a vivid picture of the movements of a crab zoaea; the little creature swims on its back, using the rostrum and a spine which sticks up from its back as a keel; it rows itself by its maxillipedes and uses the abdomen as a rudder. This last observation of Weldon throws a flood of light on the causes which led to the evolution of the abdomen. Strictly speaking, this term is only applicable in the higher Crustacea, in which the primitive uniform series of limbs behind the mouth is interrupted after the eighth limb, and the thoracic limbs or *peraeopods* are succeeded by the much smaller abdominal limbs or *swirnmerets.* The primary reason for the differentiation of the abdomen and the dwindling of its limbs seems to have been its use as a rudder.

The zoaea of the shrimp gradually changes into the adult form by a series of moults. In these moults, some of the legs belonging to the hinder segments of the thorax make their appearance, and begin to take part in the swimming function. In extreme cases as many as six pairs of legs, all similar to one another, may eventually be engaged in this function. The larva now bears a striking resemblance to one of the Schizopod shrimps such as *Mysis,* and for this reason it is known as the *mysis-larva.* The lobster is hatched from the egg in this stage. The mysis-larva evidently represents an ancestor in which the swimming function has been adopted by more legs than was the case with the zoaea ancestor. In the common shrimp the last four pairs of the thoracic limbs, however, do not develop into swimming organs, but remain as rudimentary buds till the final moult gives them their adult form. The mysis-larva is transformed into the adult shrimp by the appearance of the abdominal limbs and the disappearance of the outer swimming branches of the thoracic limbs. In the adult shrimp the thoracic limbs are used only for grasping and walking; swimming is performed exclusively by the abdomen, so that the swimming function which in the nauplius ancestor was performed by the most anterior appendages has been gradually passed back until it has reached the hinder end of the body.

In the life-history of the crab, the mysis stage is missed out, and the zoaea moults four times, whilst still retaining the same general structure and appearance. But at each moult the hinder thoracic appendages become more prominent, although they are never forked and never become functional. The abdominal appendages, too, make their appearance as small buds. Then a final moult takes place at which the zoaea completely changes its shape and becomes a larva of an entirely different type known as the *megalopa.* This larva strongly resembles a small lobster. It has all the last five pairs of appendages of the thorax as unforked limbs, and the abdominal appendages are fully developed and forked and adapted to swimming. At the next moult the megalopa changes at once into a small crab, but all the swimmerets disappear. Now the adult crab possesses four pairs of swimmerets in the female and in the male two pairs of modified swimmerets. The swimmerets in the female are quite normal in structure, but they are not used for swimming, but merely for holding the egg; the swimmerets in the male are modified into styles and are used for transferring the male cells into the female opening. These appendages are only developed as the little crab grows larger and approaches sexual maturity. Now, in the history of the race there is no doubt whatever that the swimmerets of the lobster ancestor became the swimmerets of the crab, and the disappearance and subsequent reappearance of these limbs in the life-history is one of the most curious phenomena of development and throws a great light on the nature of heredity. *We see quite clearly that what is inherited is not a structure as such, but a potency or memory which can embody itself in a structure when the functional necessity for it arises.*

The development of insects shows the paradox that the most modified insects have a long larval life and that their larvae are worm-like in appearance, whilst the development of the lowest and most primitive insects is almost entirely embryonic, and they are hatched resembling their parents in most points except size. Many authorities hold, therefore, that the larvae of insects are secondary modifications of the life-history and have no ancestral meaning whatever; but this explanation is in our view unnecessary. The best known larval form amongst insects is the familiar caterpillar. This creature has a pair of very short antennae in front. At the sides of the mouth are a strong pair of biting blades, the mandibles, followed by two other pairs of jaws; then follow the three segments of the thorax, each carrying, as in all insects, a pair of jointed legs and then the abdomen consisting of ten segments, of which segments II., IV., VI. and IX. carry a pair of soft, unjointed legs. Now, if we examine the lowest and least specialized insects such as the little wingless *Machilis,* which scavenges amongst sea-weed left dry by the receding tide, we find that they also have short antennae, biting mandibles and an abdomen every segment of which carries a pair of unjointed legs; so that we see that the larva of a butterfly may be taken to represent an ancestor which had attained the level of the adult stage of *Machilis.* This conclusion is strengthened by two other sets of facts, viz.: (1) A closely similar caterpillar larva occurs as a phase in the life-history of the wood-wasps, which are primitive Hymenoptera utterly different in structure from the butterflies; (2) if we examine the embryos of insects like the cockroaches, which are hatched as so-called "nymphs" resembling the adult in most features but devoid of wings, we find in these embryos an almost complete series of unjointed abdominal legs. The caterpillar therefore need not be a secondary adaptation, because it occurs as a phase in the life-history of widely differentorders, and it is found as an embryonic phase in life-histories where as a larval phase it is absent.

FIG. 5.—THE PILIDIUM LARVA OF THE NEMERTINE WORM. CEREBRATULUS LACTEUS

1. Apical sense organ; 2. Mesenchyme cells; 3. Mouth; 4. Stomach

The most primitive land arthropod is the worm-like *Peripatus;* in the best-known species of *Peripatus* the development is entirely embryonic and takes place within the oviduct of the mother. In the course of this development a gastrula stage is clearly seen, which has a long slit-like blastopore that closes up in the middle and leaves the two ends open as mouth and anus. In the insect this blastopore is represented by a long groove on the under surface of the yolky egg, from the bottom of which cells are budded into the yolk, and at the two ends of which mouth and anus are formed.

The great difficulty is to explain why the caterpillar stage should be embryonic in such primitive insects as cockroaches, grasshoppers, crickets, etc., and in all the bugs, and larval in the highest insects such as the Lepidoptera (butterflies and moths) and the Hymenoptera. But the caterpillar does not develop continuously into the adult insect or imago. A resting stage, the chrysalis or pupa, intervenes. In this stage the larva is protected in a case either secreted by itself or composed of materials collected by it and stuck together by its secretion. It undergoes profound changes, and becomes changed from a worm-like form to that of an insect with rudimentary wings—in fact it becomes quite similar to the young of a cockroach or a grasshopper when this is just hatched. The wings develop in the primitive forms as external protuberances, in the more advanced forms from the bottom of deep pits. We see, in a word, that the chrysalis of the higher insects corresponds to the nymph of the lower insects. It is exactly as if the insect, having begun as a larva, had gone back

into an embryonic stage. Only a tentative hypothesis as to the cause of this anomaly can be suggested. We know, however, that insects of the cockroach and grasshopper type flourished exceedingly during the Carboniferous period and attained a gigantic size. Such large insects were never again produced. In the period which succeeded to the Carboniferous two catastrophes overtook the world. In the north there was widespread aridity and the pro-

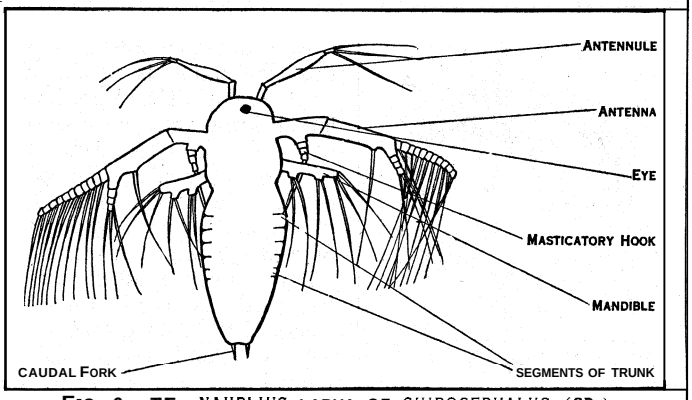

FIG. 6. —THE NAUPLIUS LARVA OF CHIROCEPHALUS (SP.)

duction of extensive deserts, whilst in the south there was an equally widespread ice-epoch. One or both of these climatic changes, it may be suggested, forced the insects which survived them to modify their larval development profoundly. In the higher insects the middle period of development was converted into the chrysalis stage, whilst in the lower insects the earlier part of development, the caterpillar stage, became embryonic. The caterpillar, like the lowest insects, is a scavenger. It was retained as a larval form amongst the higher insects because the parent has had the intelligence to find a suitable environment for the larva and to lay its egg there.

The great group of the Echinodermata (spiny-skinned radiates) have typically life-histories with a very long larval phase and their larval forms are very different from any which we have as yet described. Living Echinodermata consist of four classes of free-living forms, the true star-fish (Asteroidea), the brittle-stars (Ophiuroidea), the sea-urchins (Echinoidea) and the sea-cucumbers (Holothuroidea). Each of these classes has its characteristic larva, but all these larvae are obviously modifications of one type. If we take the common sea-urchin (*Echinus* miliaris) as an example of the Echinodermata, we find that the eggs are small and alecithal, *i.e.*, almost devoid of yolk. They segment rapidly into blastomeres of almost equal size and a typical blastula is formed, the cells of which are provided with flagella. By means of these it rotates within the vitelline membrane, which it very soon bursts; it then escapes and swims freely about as a larva. Within 12 hours cells are budded from one side of the blastular wall into the blastocoele; these cells, which are termed mesenchyme, are a sort of primitive connective tissue. They become massed in two places, right and left, and within these groups little tridents of calcareous matter are secreted which develop later into the larval skeleton. Before this is accomplished, however, one side of the blastula becomes flattened and in the centre of this surface an invagination gives rise to a finger-shaped gut or archenteron and the blastula becomes a gastrula. Within 30 hours, from the apex of this a little bilobed vesicle is cut off which promptly divides into right and left vesicles. These vesicles —outgrowths of the gut—are the rudiments of the coelom. After this event the gastrula becomes converted into what is known as the prism larva. Another side of the larva becomes flattened so that the original sphere becomes a wedge and the tip of the gut bends towards this second surface. In the centre of it there appears a shallow funnel which is the rudiment of the mouth and oral funnel or stomodaeum. This funnel meets and opens into the blind end of the gut and so a complete alimentary canal is established. The gut has now become divided by constrictions into gullet, stomach and intestine and the blastopore forms the anus. The cilia are now restricted to a ring around the edge of the surface into which the mouth opens—and at the lower edges of the surface two blunt lobes or arms grow out. With the appearance of these lobes or arms the prism larva becomes a pluteus or "easel-like" larva, as it was first termed by its discoverer, Johannes Muller. The arms are supported by long spine-like outgrowths of the calcareous tridents. They occur along the course of the ciliated band and the first pair are known as the post-oral arms. But other branches of the tridents extend forwards along the sides of the gullet and mouth and here impinge on the ciliated band and give rise to a second pair of arms, known as the *antero*-lateral pair. Johannes Miiller not having observed his larva in the living active state, placed it wrong way up, with the pointed posterior end above, and compared the four long ciliated arms to the legs of the painter's easel. In order to distinguish this larva from the somewhat similar larva of the brittle-star it is now termed the echinopluteus.

As the echinopluteus grows, it develops four other ciliated arms, two overhanging the mouth termed the pre-oral—the calcareous rods supporting these grow from a median calcareous centre in the dorsal region above the gullet—and two at the sides behind the antero-lateral called the postero-dorsal—each of these is supported by a rod growing from a new centre on the side of the larva. The echinopluteus retains the same general appearance as it grows bigger and older, until at the age of about four weeks it suddenly descends to the bottom and changes into a young sea-urchin. Four crescent-shaped outgrowths from the ciliated band, two placed dorsally and two ventrally, are developed; these in later larval life become very large and on them the main part of the swimming function devolves; but these crescents, termed "epaulettes," are peculiar to the genus Echinus itself and some allied genera. Want of space compels us to describe in briefest outline the change of the echinopluteus into the sea-urchin. The coelomic sacs formed in the prism larva become divided into anterior and posterior halves on each side. From the anterior section on the left side a small rounded vesicle termed the hydrocoele is budded off. Round this bud the whole organization of the future urchin is built up. The hydrocoele becomes bent into a short thick hoop, the ends of which join so that a ring is formed. This becomes the ring canal of the water vascular system. From the ectoderm opposite the hydrocoele a deep pouch is developed which becomes a closed sac. The roof of this sac is called the amnion. Its floor grows out to form the first spines and tube-feet of the future sea-urchin; into the tube-feet, of course, branches of the hydrocoele project. Through the centre of the floor a new intucking marks the position of the adult mouth, which has no known relation to the larval mouth. The whole complex of spines and tube-feet is known as the *Echinus-rudiment*. From the anterior coelomic sac on the right side a small vesicle is budded off the corners of which lie above the gullet almost in the mid-dorsal line. This sac is called the "pericardium." Its floor is bunched up to form a tube and the space—part of the blastocoele—included between the upper wall of the gullet and this floor is called the heart. The tube-like ingrowth pulsates rhythmically and causes the blastocoele fluid to circulate.

As the larva grows older the "Echinus-rudiment" increases in size till it occupies the whole side of the larva. Finally, the "amnion" becomes absorbed and the first tube-feet project freely. Then these feet take hold of the substratum and in a marvellously short time—about half an hour—the larval arms are all absorbed, the ciliated band and ciliated epaulettes vanish. The larval buccal funnel loses its connection with the gullet, shallows out and disappears, and the easel-like larva is reduced to a minute round flattened disc, which then takes up the ordinary creeping life of the sea-urchin.

The larva of the brittle-stars (Ophiuroidea) is also called a Pluteus. In fact it is the original Pluteus which was described by Johannes Muller. It differs, however, in many important respects from the larva of the sea-urchin and for this reason it is now termed the ophiopluteus. The eggs of brittle-stars agree closely with those of sea-urchins in their segmentation, blastula and gastrula stages, and in the way in which mouth arms and coelom are formed. In the early pluteus stage, however, the first arms

to be formed are not the post-oral, but a pair growing out from the sides of the larva. These arms (occasionally present in the echinopluteus) are directed forwards and are the longest arms of the larva. They are followed by antero-lateral, postero-dorsal and post-oral arms, but no pre-oral arms are formed, so that here again we find an eight-armed larva; but the arms are not quite the same as those of the echinopluteus. The arms are stiffened by calcareous rods, but all the rods on the same side of the larva are outgrowths of the same calcareous star. The coelom is formed in the same way as in the echinopluteus; it divides and gives rise to the hydrocoele bud in the same way; but the history of this bud is rather different. It becomes converted into a ring-canal, and this ring-canal gives off five lobes, *but these lobes project, not into an amniotic space, but into the buccal funnel of the larva.* As the ophiopluteus grows older, the ciliated arms become absorbed; but the postero-lateral ones persist and even grow longer. The buccal funnel of the larva shallows out and disappears, thus exposing the first formed tube-feet, which take hold of the substratum and there metamorphosis is completed and the creeping life of the adult is begun. Then the postero-lateral arms finally disappear. *It is to be noted that here the adult mouth is the opening between the buccal funnel of the larva and the gullet and that no new opening is formed.*

The larva of the ordinary starfish is called the *bipinnaria* and seems at first glance very different from both the echinopluteus and the ophiopluteus. Closer examination reveals its essential similarity. The egg segments in the same way and the blastula and gastrula stages are the same; the larval mouth, the coelom and arms are formed in the same way. But the next stage is sausage-shaped. This shape is due to the existence of a long forehead or pre-oral lobe in front of the mouth. Into this the anterior division of the coelom extends on both sides and two sacs fuse into a median sac in front of the mouth. When the ciliated band is formed out of the general ciliated covering of the gastrula, it runs along the sides of the larva to the front end; arrived here it bends backwards along the underside of the pre-oral lobe. This loop of the band is soon constricted off from the rest and forms a special pre-oral ciliated band. Both bands, the pre-oral and the main one, develop outgrowths, but these are not supported by calcareous rods; they resemble the wings (pinnae) of insects, whence the name bipinnaria. The main band of cilia develops a median anterior "pinna." The division of the coelom into anterior and posterior portions takes place as in other echinoderm larvae; and the hydrocoele bud develops as in the sea-urchin, but there is no amnion formed and the primitive tube-feet from their first appearance project freely to the outside. The adult mouth is formed as a new perforation in the centre of the hydrocoele ring. What distinguishes, however, the bipinnaria from the other larvae of free echinoderms is the mode of its metamorphosis into the adult. After swimming about for two months, during which time the hydrocoele and its appendages grow larger in relation to the rest of the body of the larva, the bipinnaria develops at its anterior end between the pre-oral and main ciliated bands a group of three short arms ending in adhesive knobs; by means of these the larva anchors itself to the sub-stratum. It has now become a *brachiolaria.* An oval suctorial disc, consisting of sticky cells, is developed at the apex of the forehead between the bases of these arms; by the contraction of the arms the disc is brought into contact with the substratum (often a bit of seaweed) and so a permanent fixation of the larva is effected and the pre-oral lobe is converted into a stalk. After becoming fixed, the ciliated bands and their pinnae disappear, and the stalk shortens till it becomes a small knob. The buccal funnel of the larva shallows out and disappears, the shortened stalk is attached near the adult mouth to the under surface of the future starfish. Finally, as the hydrocoele and its tube-feet become more and more developed, the starfish wrenches its vestigial stalk loose from its attachment and walks away.

The *auricularia* larva of the sea-cucumbers resembles the bipinnaria in outer appearance. There is a pre-oral lobe, though not as well developed as that of the bipinnaria; and the ciliated band is prolonged into a pre-oral loop on the underside of this lobe but this is never quite cut off from the main band. The band grows out into lobes or pinnae, which, like those of bipinnaria, are not supported by calcareous rods. There is a blunt anterior median one, and the postero-lateral pinnae are long and curved and have been compared to little ears (auriculae), whence the name of the larva. The development of the coelomic vesicle is different in the auricularia from what it is in other echinoderm larvae; it remains unpaired and divides into anterior and posterior halves; the posterior portion subsequently divides into right and left halves. The anterior portion, which represents the left anterior vesicle of other larvae, gives rise to the hydrocoele; this grows round the larval gullet, no separate adult mouth being formed. The auricularia swims about, gradually growing bigger for a fortnight, and then suddenly changes into another larval form known as the *pupa.* This is smaller than the auricularia and its tissues are much more dense and opaque. The first-formed tube-feet grow out into the buccal funnel (larval stomodaeum). When the change into the pupa occurs this stomodaeum deepens and its opening becomes narrowed and practically closed; it is then known as the *atrium.* The atrium shifts from its original ventral position to the left side of the larva and then by the shrinkage of the pre-oral lobe, the opening of the atrium becomes terminal. At the same time the ciliated band of the larva becomes broken into short pieces which re-unite to form circular bands of cilia surrounding the pupa as the hoops surround a barrel.

The first-formed tube-feet project into the enlarged buccal funnel or atrium just as they do in Ophiuroidea; but these tube-feet are not terminal appendages of the radial canals, as they are in the other three classes, but basal ones—the so-called buccal tube-feet, which, in the adult sea-cucumber, are arranged around the mouth and are used to collect food. The radial canals extend along the body of the pupa outside the atrium. After swimming for a few days the pupa loses its ciliated bands and drops to the bottom; it develops a skeleton of calcareous plates almost touching one another and recalling the shell of a sea-urchin. The atrium opens and the tentacles protrude and begin to collect food and tube-feet develop on the radial canals, first on those that lie on the under side of the sausage-shaped animal and then on those that lie on the upper side.

From the descriptions just given it seems clear that the bipinnaria, ophiopluteus, echinopluteus and auricularia are modifications of one original type of larva. In our view, this larva is a recapitulation of an original free-swimming ancestor of all the echinoderms, which, like most free-swimming animals, was bilaterally symmetrical. Like the trochophore, the echinoderm larva gives evidence of having passed through blastula and gastrula stages in the history of the race, but there the resemblance ends.

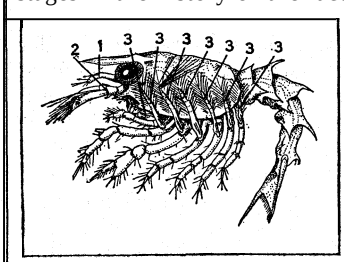

FIG. 7.— THE MYSIS LARVA OF THE AMERICAN LOBSTER, HOMARUS AMERICANUS
1. Antennule; 2. Antenna; 3. The seven pairs of exopodites born by the thoracic limbs

The protoplasm of the cells composing the trochophore blastula is already specialized, so that when these cells are separated from their fellows, they pursue, so long as they live, the same development as they would have done in the intact organism. The cells of the echinoderm blastula, on the other hand, are unspecialized; any sufficiently large portion of the blastula wall will round itself off and form a blastula of reduced size, which will pursue a normal development and give rise to a small normal larva. The echinoderm larva is, therefore, in a much more primitive condition than the trochophore larva from which Annelida and Mollusca have very possibly been derived. We saw that the ciliated band of the trochophore was built up of four discrete groups of ciliated cells which very probably represent the "ribs" of a ctenophore ancestor. The ciliated band of the echinoderm larva shows no such indications; it is not transverse but obliquely longitudinal, crossing the dorsal surface on the pre-oral lobe or forehead and the ventral surface in front of the mouth. The

coelom in the trochophore is a derivative of the growth of two large cells—originally part of the gut wall. This method of formation represents an original gut-pouch, modified in connection with the extreme specialization of the cells of the trochophore; in the echinoderm larva the origin of the coelom from a gut-pouch is obvious. Another difference concerns the fate of the blastopore. This in the trochophore closes up in a longitudinal seam, one end of which remains open as the mouth, while in some very primitive forms the other end remains open as the anus. In the echinoderms the blastopore is always a round hole which persists as the larval anus, and the mouth is a new opening formed apparently completely independently of the blastopore. To sum up, the trochophore and the echinoderm larva both represent simple free-swimming ancestral forms which were, however, markedly different from one another; to trace these back to a common root it is necessary to go back almost to the beginnings of the Metazoa.

The most remarkable feature in the life-history of the echinoderms is their change from the bilateral symmetry of the larva to the radial symmetry of the adult.

It is obvious that no light is thrown on its meaning by the sudden metamorphoses of sea-urchins, brittle-stars and sea-cucumbers. In the life-history of the common starfish (Asteroidea), however, a fixed stage intervenes between the free-swimming phase and the crawling adult. Some members of other phyla desert the open water to seek food at the bottom—and in many cases—owing probably to the existence of powerful currents, they develop the habit of holding on to one place and seizing the food as it drifts past them. All such animals tend to develop tentacles on all sides, for instance, the Polyzoa (*q.v.*). If in the fixed echinoderm ancestor the hydrocoele had already developed its tentacles; then these must have been developed on both sides, and in asteroid, ophiuroid and echinoid larvae a second hydrocoele bearing tentacles is occasionally developed on the right side as well as on the left. But some constitutional peculiarity of the stock favoured the left side at the expense of the right, and so this hydrocoele developed into a ring suppressing the corresponding organ of the right side altogether. The formation of this ring and the functional importance of the organs developed from it is the foundation of the radial symmetry; all the other organs of the body are adapted to it. As the ancestral starfish spread into more tranquil waters, they wrenched themselves loose from their stalks and gave rise to the free living Echinodermata. The Ophiuroidea are only more specialized starfish, and the sea-urchins, when just metamorphosed, are little flat disc-like starfish, in which nothing of the globular form of the adult can be seen. They developed, we may suppose, out of starfish which took to climbing in vertical crevices—situations which mountaineers call chimneys—and in these circumstances the tips of the arms were bent upwards to get a better grip of the cliffs above them and so the globular form was attained. The sea-cucumbers are perhaps the result of a further development of this habit, for from climbing vertical walls to wriggling amongst stones is an easy passage; but the young post-larval sea-cucumber still show traces of the shell of the sea-urchin ancestor from which it was derived.

There still exist at the present day a few stalked echinoderms, represented by the class Crinoidea—the last survivors of an immense multitude of Palaeozoic forms, so numerous at one time that vast masses of limestone are formed of their accumulated remains. The stalk springs from the centre of the back, whilst mouth and anus are both on the opposite surface. The eggs of the only crinoid whose development has been worked out are large and full of yolk, and the earlier stages of development are embryonic, and during the short larval phase the young animal takes no food. Nevertheless, this larva shows in broad outline some resemblance to the bipinnaria, although the cilia are arranged in transverse bands as in the pupa of sea-cucumber. It has a long pre-oral lobe containing a single anterior body-cavity; and at the apex of this lobe there is a sucking disc by which it soon fixes itself and the pre-oral lobe is then changed into a stalk. There is a larval buccal funnel or stomodaeum, which, however, never opens into the gut, since the larva takes no food, and into this funnel the first tentacles project just as they do in Ophiuroidea and Holothuroidea. But the changes which supervene after the larva is fixed are quite different in the Crinoidea from what they are in Asteroidea. The buccal funnel of the larva, instead of being pressed closer to the substratum, as it is in the starfish, is rotated backwards till it reaches the posterior pole of the larva, which is, of course, directed upwards towards the open water. Then it opens and the ciliated tentacles spread out and collect the microscopic plants and animals that swim freely through it. We now see that the wide distinction between the fixed and free echinoderms rests ultimately on a different choice of food. When the ancestral echinoderm began to hold on to the ground with its pre-oral lobe and to grope about in the water with its tentacles for food, two courses were open to it—it might either bend downwards to grasp what was drifting beneath it, or reach upwards to attain what was floating above it—the first course led to the development of the free echinoderms, the second to the crinoids.

If we search through the animal kingdom for larvae resembling those of echinoderms, we find such a larva only in the phylum Enteropneusta. This is the tornaria larva of the worm-like *Balanoglossus* which is described in the article BALANOGLOSSUS. But the resemblance is so close that tornaria was actually regarded as an echinoderm larva until its life-history and metamorphosis were known. It has a longitudinal ciliated band with a pre-oral loop which resembles that of the auricularia. It has a long pre-oral lobe containing a single anterior coelom like the bipinnaria. Besides this coelomic sac, a pair of anterior sacs at the sides of the gullet represents the hydrocoele, and its missing fellow on the right side and a pair of posterior sacs represent the posterior sacs of the echinoderm larva. Most striking of all, it has above the gullet a small pericardial sac, the floor of which vibrates and acts as a heart, exactly as it does in the larvae of Asteroidea, Ophiuroidea and Echinoidea. The tornaria has some additional features. There is a posterior transverse ring of cilia behind the longitudinal ciliated band and an apical nervous plate with two eyes at the apex of the pre-oral lobe. Such a plate is not found in the bipinnaria but is found in the echinopluteus. The fate of the tornaria larva is different from that of the echinoderm larva because the adult habits are different, but there can be no serious doubt that it represents the same ancestral stock. An ally of *Balanoglossus*, *Cephalodiscus*, actually uses its pre-oral lobe for temporary fixation and has the middle section of the coelom on each side developed into long ciliated tentacles. As pointed out in the article BALANOGLOSSUS, this animal in its gill-sacs, and rudimentary nerve-tube and notochord, shows unmistakable affinities to the vertebrates, so that here the embryology of the Invertebrata merges into that of the Vertebrata.

In this article we have striven to give some idea of what has already been gleaned as to the past history of life by the study of invertebrate embryology. But what has been discovered is only a small fragment of what is still unknown and could be known if more life-histories were studied and compared.

INVERT SUGAR: *see* SUGAR.

INVERURIE, royal burgh and parish, Aberdeenshire, Scotland, situated at the confluence of the rivers Don and Ury, 16¼ m. N.W. of Aberdeen by rail, on the L.N.E. railway. Pop. (1931) 4,524. Paper-making and the making of mineral waters are the chief manufactures. It also contain? railway workshops and is a summer resort. At Harlaw, about 3 m. to the N.W., was fought in 1411 the great battle between Donald, lord of the Isles, and the royal forces under the earl of Mar. Not far from the scene of this conflict stands Balquhain Castle, a seat of the Leslies, now a mere shell, which was occupied by Queen Mary in September 1562 before the fight at Corrichie between her forces, led by the earl of Moray, and those of the earl of Huntly. Near Bennachie (1,619 ft) are stone circles and monoliths. There is a branch line from Inverurie to Old Meldrum.

INVESTIGATION, CRIMINAL. Criminal investigation is that branch of criminal jurisprudence which applies the principles and practices of philosophical analyses, science, art and

BY COURTESY OF (1, 1A) SCIENTIFIC CRIME DETECTION LABORATORY, NORTHWESTERN UNIVERSITY, (2, 4) SCOTLAND YARD, (3, 5, 6) G. F. GURRIN, F.R.M.S.

METHODS OF DETECTING CRIMINALS

1. The Lie Detector. (1, Blood-pressure cuff; 2, Pneumograph contact for measurement of breathing; 3, Electro-dermal electrodes; 4, Graph which records breathing, pulse, and blood Pressure: 5, Galvanometer unit which records abnormal sweating from emotion)

1a. Lie detector polygram of suspect who is lying

2. See description under picture

3. By means of specially prepared transmitted light photographs, it is possible to ascertain whether an envelope has been opened and resealed. The white patches inside the outline of the flaps indicate that the top flap has been disturbed

4. Photographs showing the identical coincidence of marks transferred from the breech shield of a revolver to the back of a cartridge case fired by that revolver

5. Detection of a forgery. A natural size photograph of the letters "h" and "a" from a disputed signature, with an enlarged photograph of the same letters showing imperfections pointing to a freehand forgery

6. The two illustrations on the right are instances of the letter "d" (enlarged) taken from specimens of an authentic handwriting. The two illustrations on the left are instances of the same letter (similarly enlarged) taken from a forgery of the same handwriting. In attempting to reproduce the characteristic finishing stroke of the "d," the copyist overlooked the less obvious characteristic of the direction of connecting strokes (see arrow)

technical skill in judicial proceedings, subject to legal rules and forms in which there must be elucidation of questions relating to crime. This covers the questions: who the victim was; the exact place at which the offence occurred; how the crime was committed, with what weapon it was committed, or what were the means employed in its commission; what was the time of attack, what was the motive or object of attack, and the identity of the offender or offenders. Criminal investigation is employed also in the search for and interrogation of material witnesses who are able and willing to give competent and relevant testimony against the suspect or offender, and in the reconstruction of all facts connected with the crime in order that, at the trial of a defendant, a true picture of what occurred may be presented in such manner as to leave no doubt in the minds of the jurors or judge regarding the guilt or innocence of the accused.

History.—Although the beginning of criminal investigation is unknown there is reason to believe that in a very rudimentary form it came into existence with the origin of legal trials. It is clearly laid down in the Code of Hammurabi (*c.* 2250 B.C.) that suspicion does not give ground for condemnation; receiving of testimony, and even elaborate examination of sites or circumstances by the court itself, were established rules of procedure. In Athens, by about 500 B.C., the examination of facts had become meticulous; a defendant, having lost his case, might bring suit against a witness for bearing false testimony and, if successful in his new suit, would go free of his earlier condemnation. In the Fuotinian legislation (6th century A.D.) evidence was so construed as to imply the co-operation of experts in certain cases. In the middle ages, whether in civil or in ecclesiastical courts, and generally in the commercial and customary tribunals, the weighing of evidence was as careful as it has ever been. The introduction, in that period, of courts of inquest whose object was avowedly to procure condemnations, such as those of heretics, and the survival of certain ancient uses of the ordeal have obscured the prevalence of careful taking of evidence in the middle ages.

In 1507 a penal code containing exact instructions as to evidence was issued by a bishop of Bamberg, and in 1532, the Caroline code of the German States contained provisions for the examination of criminals. In 1575, a French physician described the form in which judicial reports should be made in medico-legal cases, and at the close of the 16th century, outlines of the method of testifying in such cases were numerous, especially in Italy. Toward the end of the 18th century, legal medicine was recognized as a science. Orfila, who occupied the chair of chemistry and medical jurisprudence in the University of Paris, was employed as an expert in judicial proceedings; in 1814 he published a Traite' des Poisons. In 1689 Johannes Bohn, of Leipzig, published a work on the examination of wounds, the distinction between ante-mortem and post-mortem wounds, the different effects of death by injury, strangulation and drowning. In another of his works, published in 1704, he gives rules for the conduct of physicians during court testimony. During the latter part of the 18th century German scientists published numerous books on the subject. Lectures in medical jurisprudence were given at the University of Edinburgh in 1792, and in 1806 the university gave the title of "Professor of Medical Jurisprudence" to A. Duncan, Jr. Percival, with his Medical *Ethics* (1803), made himself one of the first noteworthy English contributors to medical jurisprudence, and was followed by John Gordon Smith. In 1823, Paris and Fonblanque published the first English work which associated the medical and legal professions. In 1836, Dr. Alfred Swaine Taylor published his Elements of Medical *Jurisprudence,* an authoritative work. The first Spanish treatise on legal medicine (1796–97) was written by Juan Fernández de Valles. In 1844, Prof. Pedro Mata of Madrid published the first edition of a work on legal medicine and toxicology, which, in the development of its subsequent editions, has become the most important Spanish treatise on the subject. The fathers of the modern school of scientific investigation are Dr. Hans Gross, formerly a professor of criminology; Dr R A. Reiss, of the University of Lausanne, and Dr. Alfred Niceforo Most procedure now follows their principles.

The old trial-and-error method in criminal investigation is being rapidly displaced by scientific methods, including the use of very highly specialized instruments. Philip Valois initiated the modern police system of criminal investigation. In Paris, in 1327, he appointed *commissaires,* or royal officers, who were not part of the judicial system and who conducted preliminary examinations in the enforcement of police regulations. The *Maréchaussée,* a military police, was organized in 1356, becoming the Gendarmerie in 1720. The first modern police organization, however, was founded in London in 1829. Twenty-five years later the Paris civil police were reorganized on the London model. In 1830 all ungarrisoned Prussian cities were authorized to establish a police force.

Police investigators of crime were originally spies. In England they entered the service to obtain rewards offered for the capture of criminals and in France for political prestige and pecuniary rewards. Later, members of the uniformed force were detailed to plain clothes police duty. These officials cultivated the acquaintance of criminals and of persons able to supply information for the apprehension and prosecution of offenders. The results justified the experiment and the plain-clothes man of yesterday is the police detective or criminal investigator of to-day, whose chief stock in trade is common sense, with coolness, courage, patience, perseverance, an analytical mind and a large acquaintanceship with criminals.

Since the majority of crimes reported to police departments are offences where property is obtained by theft, fraud or violence, police departments, drawing from their large experience in such investigation, have developed fairly effective technique; criminal investigation methods successful in one community have been adopted by others until there is now a certain uniformity in procedure. Existing differences in technique are of minor importance and are traceable either to local conditions or to the emphasis placed by police executives on one or another phase of general procedure.

Large police departments divide the detective force into small groups, members of each group devoting their attention to a particular type of crime or criminal. Investigators detailed for duty with the pickpocket squad have little interest in, or knowledge of, the practices of burglars. Men employed in combating the activities of hold-up men frequently know little or nothing of the passer of worthless checks, but seek to acquaint themselves with the name and address, associates, habits and haunts of every bandit at large in their community. A member of the burglary squad may know who is implicated in a complaint made to the police department as soon as he reads the details of the crime.

MODERN METHODS

Classification of Criminals by their methods of operation is now a permanent and invaluable feature. Some departments use the Atcherley *modus operandi* system for this purpose. Major-General L. W. Atcherley, originator of this system of classifying criminals according to their *modus operandi,* utilizes the following classes:—

(1) Classword—Kind of property attacked, whether dwelling house, lodging house, hotel, etc.
(2) Entry—The actual point of entry, front window, back window, etc.
(3) Means—Whether implements or tools used, such as a ladder, jimmy, etc.
(4) Object—Kind of property taken.
(5) Time—Not only time of day or night, but whether church time, rnarket day, during meal hours, etc.
(6) Style—Whether criminal describes himself as mechanic, canvasser, agent, etc., to obtain entrance.
(7) Tale—Any disclosure as to his alleged business or errand which the criminal may make.
(8) Pals—Whether crime was committed with confederates, etc.
(9) Transport—Whether bicycle or other vehicle was used in connection with crime.
(10) *Trademark*—Whether criminal committed any unusual act in connection with crime, such as poisoning a dog, changing his clothes leaving a note for the owner, etc.

Many departments use their own system for keeping a record

of the criminal's specialty. Race, age, sex, colour, class and occupation of the victim are noted. Whether the attack occurred in a dwelling place, office, public or semi-public building, store, shop, vehicle, vessel, public place or on a thoroughfare, is an important item in classifying the criminal. How a burglar entered an enclosure, particularly the actual point of entry, as for example, first floor, kitchen door or second storey, rear window, or how the bandit attacked his victim, whether by beating, drugging, or otherwise, are additional means of connecting the criminal with the crime. Tools, instruments, devices, or weapons used, or means employed in committing the offence, the actual time of day, as well as the particular day, the kind of article stolen and all individual characteristics associated with the offence are factors which assist in narrowing the scope of investigation.

The object clue is always important. Second-hand dealers and pawnbrokers are required to furnish a description of all articles sold or pledged. Although the laws regulating pawnbrokers and second-hand dealers vary somewhat, in the main they require that every person who carries on the business of pawnbroker or who purchases gold bars, gold quartz or gold bullion, or mineral containing gold, shall, at the time of the transaction, enter in a register kept by him for that purpose, the date, duration, amount and rate of interest of every loan made by him; an accurate description of the property pledged; the estimated value of the property purchased; the name, residence and description of the pledgor or seller. A written copy of such entry shall be delivered to the pledgor or seller and a written account shall be kept of all sales made by the pawnbroker or seller. Police investigators assigned to pawnshops visit these and second-hand stores regularly to inspect the records and view all articles sold or pledged.

Record-keeping. — In the written report which the criminal investigator makes of stolen property, he separates the identifiable from the non-identifiable articles. His report eventually reaches a police clerk who writes a description of each identifiable article on a 5 × 3 in. card. These cards are then filed in cabinet drawers behind appropriate guides. Unnumbered articles are filed according to an elaborate decimal system, or behind alphabetically arranged guides containing the names of the articles. Numbered articles such as watches, cameras, automobiles, etc., are filed behind numerical guides. The last two or three figures in the number are arbitrarily used as primary guide divisions. Cards are arranged in strictly numerical order within these divisions. Thus, in a two-number system, a card containing a description of a watch numbered 1,100 would be filed behind the guide **00** and would follow the card in this division numbered 1,000. A record of all articles pledged or sold is also filed in these cabinets. Pledged or sold articles are distinguished from stolen property by different coloured cards. Hence, when two cards containing the same description or numbers, but on different coloured cards, are brought together in the files, it means that property which has been stolen and reported to the police department has been located in a second-hand store or pawnshop. As previously stated, the pawnshop or second-hand store record contains a description and signature of the pledgor or vendor and this information frequently helps the police investigators in their search for the criminal.

Police investigators still believe in "fighting fire with fire" and retain a remnant of the old spy system. Criminals, prostitutes, gamblers and other underworld characters are employed as undercover agents and report regularly to one or more contact officials, whom the chief of the criminal investigation division designates. A safe-breaker lavishly spending money; a bandit or burglar suffering from gunshot wounds; an automobile thief possessing numerous licence plates; a pawnbroker or second-hand dealer buying "hot stuff" (stolen articles) and neglecting to enter the sale as required by law; robbery, burglary or theft being planned; criminals proposing to move from one community to another; — all these are types of instances reported to the contact official or officials by undercover agents. These may have important bearing upon a crime that has already been committed or may be committed in the future. Apart from the regularly employed undercover agents, individual investigators obtain information from criminals and other persons that they have befriended and thus clear up a baffling mystery that would otherwise be unsolved.

An old, successful investigator once said, "I spend most of my time cultivating the friendship of people who can help me to clear up crimes that are assigned to me for investigation; they often pay enormous dividends on a very small investment."

PRINCIPLES OF INVESTIGATION

General Rules. — Hans Gross's rules for guiding investigators are quite generally observed by police detectives assigned to investigate crimes. Briefly, they are: Take the simplest view at the outset and disregard all strange and extraordinary suppositions; omit the romantic features of fiction writers, remove exaggerations and confine the investigation to bare facts; never follow one idea exclusively; since women play either an indirect or direct part in many crimes and also aid in the concealment and escape of criminals, it is well to look for the woman in the case; search for causes; observe and report on all facts; make comparisons; examine localities with minute care; make measurements of places and things, and take photographs; check statements of witnesses as to time and distance, also memory of events and persons in order to determine whether their statements rest on false suppositions; remember there is usually one great blunder which a criminal nearly always commits, especially in big crimes; interview persons who have been employed in the district and know the inhabitants; endeavour to find the victim, relative or interested person from whom the preliminary information regarding the crime can be obtained; never alter the position of, pick up, or even touch an object before it has been minutely described in the report; note all points where traces of the crime or important details are to be found, *e.g.*, clothing, finger-prints, foot-prints, hair, marks caused by firearms or tools, impressions and stains of all kinds — in short, everything which may have been produced by the criminal and everything which may have been left behind by him. Absolutely everything must be carefully examined, for there is no place where important objects connected with the crime may not be found. Often the strongest proof is found in the smallest details. Foot-prints, traces of blood and forgotten or discarded objects must be protected until experts have had an opportunity to collect or preserve such evidence. The ultimate objective of the examination or interrogation is to give the investigator of the occurrence as much detail as if he had been present in person. The investigator must have a wide acquaintance with experts and their capabilities for they are indispensable assistants and their findings and conclusions enable the detective to obtain a broader perspective of the case.

The Expert. — Police photographers and finger-print experts are commonly employed by criminal investigators, and experts in special fields occasionally assist in clearing up crimes. Seemingly insoluble problems have been unravelled by workmen and artisans of every trade, occupation or profession.

Obviously, medico-psychologists are valuable aids of the police, and the types of cases in which they assist cover a very wide field: ante-mortem and post-mortem examinations of wounds; all fractures and contusions; blood examinations; determination of the cause of illness, death or abnormal behaviour; observation of mental conditions of victims and suspects; and the restoration of decomposed, discoloured, mutilated or mummified remains. In many cases they are able to give the exact race, stature, age and sex from a study of the teeth and skeletal remains. On one occasion, the mutilated and mummified remains of a murdered woman were soaked for three hours in a 1% solution of potassium-hydrate and then placed in a 2% solution for 18 hours. After the soaking process, the body was drained and dried, cuts in the cheek were sewed up, cavities in the head and face were stuffed with cotton and then filled with plaster of paris, the filled-in places were smoothed over with flesh coloured embalmer's wax, artificial eyes and hair were placed in position, a missing ear was worked up in wax, flesh tints were added, and eyebrows and lashes painted on A photograph of the reconstructed body was then taken and easy identification was made possible. Very slight traces oi blood may be readily distinguished with the aid

of the Dudley Roberts occult blood test. When a stain is definitely determined to be blood, the pathologist utilizes the well known precipitin test to discover whether it is human blood or not. A microscopic study of the size, shape and colour of the corpuscles often makes it possible to determine from which particular group of animals the blood has come.

The micro-analyst recognizes at a glance all the structures which may appear within the field of the compound microscope and interprets the findings with a reasonable degree of accuracy. Lower plants and animals, plant and animal tissues, vegetable, animal and inorganic fibres, starches, dextrins, sand, soil and minerals are readily identified and their connection with the case under investigation may be quickly established. Dust or stains found in or attached to clothing or weapons, also deposits found under finger-nails, have furnished the investigator with the only and occasionally the most important clue. A single hair from the head of a human being has pointed unerringly to the perpetrator of a felonious offence. The fact that it was human hair, also the age, sex, race, probable coiour of eyes, and probable weight of the person to whom the hair belonged, were ascertained by the micro-analyst after examining the four structural parts of the one strand that was left behind by the criminal. The hair of every fur-bearing animal has its own characteristics and these characteristics are so well defined that the expert experiences little difficulty in determining the type of mammal from which the single strand of fur came (see HAIR).

The chemical analyst is employed in all cases where the investigator believes that poison has been given, whether through the mouth or otherwise. He may also supplement the work of the micro-analyst. These experts are able to prove the nature of the substance that was administered and to determine also the nature of organic or inorganic substances that play an important part in any criminal investigation. Particles of dust may prove distinctly injurious to some persons and sometimes perfectly healthy people are affected fatally by doses of common drugs or by simple kinds of food. When this occurs, the chemical analyst will discover the true cause of death. Such information has occasionally cleared accused persons.

Firearms. — Forensic ballistics is that branch of criminal investigation which deals with the identification of firearms, bullets, cartridge cases and explosive materials used in guns. Experts in this field study also the effect and trajectory of bullets fired from guns; they can determine whether a bullet was fired from, or a cartridge case ejected from, a particular firearm. After examining a bullet they are able to state the make, calibre, type, approximate date of manufacture and the approximate serial number of the gun from which it came. This information is obtained by studying the following points on the bullet: — number of rifling lands, pitch or twist of rifling, width of grooves and lands, depth of grooves, calibre and weight of bullet, and the individual characteristics which are to be found in the barrel of every firearm, such as rough spots, gouges, imperfections and emery marks. These peculiarities are impressed upon the bullet when fired from the gun.

Identification of cartridge cases discharged from an automatic weapon is made possible by examining the scratches on the side of the case which are produced by the several mechanical operations connected with automatic loading and unloading, the marks made by the extractor hook, the firing pin imprint on the primer, the breech face imprint on the primer and shell base, and the imprint of the ejector blade or shoulder. When the cartridge case has been exploded in a revolver, the firing pin and breech face impressions on the primer and shell base furnish means for identification. Chemical composition of alloys used in the manufacture of bullets is easily ascertainable from slight traces of the metal, especially if the composition is unusual, while micro- and chemical analysis of powder found upon a bullet, even after it has entered a foreign body, has revealed the manufacturer's formula.

To the handwriting expert are referred questioned documents of every description. He studies erasures, obliterations, additions to writing, false seals, water marks, imitations of stains or marks of any character whatever on the paper, age and chemical nature of inks and papers, type of pen or pencil used.

Photography and the Deception Test. — Photography and photo-micrography play an important rôle in criminal investigation. Speaking of the value of the photograph to the criminal investigator, Reiss says: — "(I) It constitutes an indestructible document taken automatically which reproduces all the facts and acts as an artificial memory. (2) It is a help to all those called to discharge duties during the trial without knowing the place of the crime. (3) It is able to exercise a psychological effect, whether upon the jury or on the judge. (4) The little details photographically revealed upon the place of the crime, such as the foot impressions, the digital markings, or anything of that nature, aid in the conviction of a criminal or the finding of the one responsible for the crime."

Briefly, the camera is employed as a recording agent whenever it is desired to obtain absolute, objective, permanent and easily controlled proofs.

Recently one other tool has been added to the equipment of the investigator: *i.e.*, the psycho-physioiogical deception test, although it is better known to the public as the "lie-detector." With this technique it is possible to establish guilt or innocence in a comparatively short period, thus avoiding the long, wearisome hours given to the examination of persons who are under suspicion.

The technique of the deception test consists primarily in securing a blood pressure curve, taken synchronously with a respiratory and a time curve. In practice, the suspect is seated on a chair, a cuff is then strapped on the upper part of the arm for the purpose of recording the blood pressure and a rubber tube is hooked round the chest for recording the respiration. After adjusting the blood pressure device, the instrument is set in motion and permitted to run for a few minutes in order that the normal reaction for this individual may be obtained. The expert conducting the investigation then follows this by an introductory statement to the effect that the suspect is being subjected to a test to determine his guilt or innocence and, further, that taking the test is optional for him. A few questions are then asked which require an answer of "yes" or "no," the correct answers being known to the expert before they are given. The graph, which includes the brief run without questions and reactions to the preamble and indifferent questions, is used for comparison with the later record obtained when questions relating to the crime under investigation are asked of the suspect. Results obtained thus far indicate that the deception test (*q.v.*) affords a convenient and reliable method for detecting deception.

Identification. — Criminal investigation and criminal identification go hand in hand. The identification expert is the foremost ally of the investigator. Occasionally the identification expert furnishes information to the investigator regarding the identity of the person who committed the crime as well as supplies the evidence that serves to convict the offender after his apprehension. The duties of the identification expert are: —

(1) To ascertain identification of the perpetrator of the crime prior to his apprehension (a) by the use of the alphabetical index when the name of the offender is known; (b) by photograph when the criminal has been seen by his victim or by witnesses; (c) by the *modus operandi* of the criminal; (d) by the handwriting of the criminal; (e) by finger impressions left at the scene of the crime.

(2) To ascertain identification of offenders after arrest (a) by the alphabetical index; (b) by a photograph, where no finger-prints have been taken; (c) by the *modus operandi* system connecting the arrested criminal with numerous other crimes; (d) by comparison of the criminal's handwriting with documents connected with criminal offences; (e) by finger impressions of the criminal found at scenes of crimes committed by him, of which he was not suspected by the investigator; (f) by the ten-digit finger-print system when the offender has been previously recorded in the bureau.

Criminal identification may be said to have originated with the branding of criminals. In 1487, it was enacted in England that every person convicted of a felony in which benefit of clergy was admitted should be branded on the brawn of his thumb; with an M if his case was murder and with a T if it was theft. Tattooing was also used in marking criminals.

A name registry of convicted criminals marks the beginning of modern criminal identification methods. This registry has served officials effectively and is still used in an amplified form. Quite early, however, a name registry was found to be comparatively worthless for the purpose of identifying habitual and migratory criminals because they changed their names or residence with every arrest.

SCIENTIFIC ENQUIRY

The earliest scientific method used for the purpose of criminal identification was photography. In 1850 photography made rapid advances with the introduction of the collodion process, for then untrained persons could easily learn how to take and develop photographs. The result was that photographs of criminals were taken in various countries. When photography was introduced, it was believed that this means of identification would furnish a solution to the problem which confronted the law enforcement officials. In the course of a few years, however, the collection of criminal photographs grew so large that it became physically impossible to locate a previous record of the offender. Experts spent weeks in an effort to identify a person suspected of having a prior record. England then started a tattoo registry to supplement the photograph record. This, too, became unwieldy and yielded comparatively small results, considering the enormous amount of labour expended in maintaining and searching the registry.

Bertillon System.—Many unsuccessful methods were devised to break up and make serviceable the huge collection of photographs and finally Dr. Alphonse Bertillon, chief of the identification bureau in Paris, invented the signaletic system in 1882. This system is divided into three parts: (1) the anthropometric signalment, which consists in measuring some of the characteristic dimensions of the bony structure of the body, under prescribed conditions and with the utmost precision; (2) the descriptive signalment, which is the observation of the shape and movements of the body, and even the most characteristic mental and moral qualities; (3) the signalment by peculiar markings, which is the observation of peculiarities of the surface of the body resulting from disease, accident, deformity or artificial disfigurement, such as moles, warts, scars, tattoo marks, missing or deformed members. The following measurements are taken:

Measurements of the body: Height (height of man standing) Reach (length of the outstretched arms from finger-tip to finger-tip) Trunk (height of man sitting).

Measurements of the head: Length of the head. Width of the head. Length of the right ear. Width of the right ear.

Measurements of the limbs: Length of the left foot. Length of the left middle finger. Length of the left little finger. Length of the left forearm.

Bertillon's system has been discarded by most police departments, but his descriptive methods are used by investigators because no better scheme has yet been devised for furnishing a minutely descriptive, verbal portrait of an individual. Colour of eye, shades of hair and complexion, shape of the forehead, nose and ear, and build of the criminal are subjected to a rigorous but simple classification scheme. Other complementary features included in the verbal portrait are a description of the lips and chin, the general contour of the head, including profile and face, the various modes of implantation of the hair, the beard and the eyebrows, the shape of the eyelids, the form and size of the eyebrow and the orbit, the mouth, the wrinkles and furrows of the face, the expression of the physiognomy, also various kinds of information relative to the general aspect of the subject and the visible marks, scars, moles and missing or deformed parts of the anatomy.

Finger-prints.—Dactyloscopia, the science which deals with the identification of individuals through their finger-prints, was removed from the realm of theory and made practical by Juan Vucetich of Buenos Aires in July 1891. A finger-print registry was established by him at La Platte on Sept. 1 of the same year to supplement the Bertillon system, which at that time was found to be wanting in many respects. Later the Bertillon system was eliminated.

A theoretical classification of finger-prints was presented to the University of Breslau by Prof. John Purkinje in 1823. This classification was the foundation of all the theoretical and practical work that followed. Purkenje divided finger-prints into nine basic types. In 1888 Francis Galton made an additional and distinct contribution to the science of dactyloscopia by analysing and counting the papillary ridges in the bulbs of the fingers. His method has been followed by all later investigators. Application of one or two digital impressions as a substitute for signatures and as a means for identification, was made as early as 1858 by Sir William Herschel, head of the Indian Civil Service district of Hooghly, Bengal. The governor-general, in June 1897, directed that the E. R. Henry finger-print system of identification should be adopted in British India. In 1892 the first identification was made from bloody finger-prints left at the scene of a crime. In that year Francisca Rojas, an Argentinian, who had charged a neighbour with the murder of her sons, was found to be the assassin. The proof of her guilt was established by the bloody impressions left on the jamb of her door.

Vucetich divides all finger-prints into four primary groups. The first group consists of all those designs formed by curved ridges without angles or deltas, the ridges extending from one side of the finger to the other without recurving. They are called arches. The second group has the angle or delta situated at the right of the person observing it and the directive lines have their exit toward the left. They are called internal loops. The third group has the delta situated at the left of the person observing it and the direction of the lines runs toward the right. They are called the external loops. The fourth group has two deltas and the directive lines circumscribe circular figures. They are called whorls.

For classification purposes the arch, internal loop, external loop and whorl are denominated respectively A. I. E. W. for the thumbs; and 1. 2. 3. 4. for the fingers. Accordingly a hand containing internal loops in the ten fingers would classify $\frac{\text{I } 2222}{\text{I } 2222}$. The total possible primary combinations of the Vucetich system number 1,048,576.

Primary classification will suffice for the ordinary collection of finger-prints but Vucetich provides for subdivision of large groups in the following classification scheme. Arches: natural arch, 5; internal inclination, 6; external inclination, 7; tented arches, 8. Internal loops: natural, 5; converging ridges, 6; approximating central pockets, 7; irregular loops, 8. External loops: natural, 5; converging ridges, 6; approximating central pockets, 7; irregular loops, 8. Whorls: natural, 5; lateral pockets and twinned loops, 6; elliptical whorls, 7; accidental or irregular types, 8.

E. R. Henry divides all impressions into four types, namely: arches, loops, whorls, composites. (1) In arches, the ridges run from one side to the other without backward turn or twist and, ordinarily, have no delta. (2) Loops have at least one recurving ridge and at least one ridge between the delta and core. In ulnar loops the ridges recurve toward the little finger; in radial loops, the ridges recurve toward the thumb. (3) Whorls have at least one ridge making a complete circuit. (4) Composites are patterns having characteristics of two or more of the foregoing patterns.

The primary classification is arrived at by pairing off the fingers. Beginning with the right thumb they occur on the finger-print sheets thus: first pair, right thumb and index are given a value of 16; second pair, right middle and ring fingers, a value of 8; third pair, right little finger and left thumb, a value of 4; fourth pair, left index and middle fingers, a value of 2; fifth pair, left ring and little fingers, a value of 1; the first of each pair counting as the denominator and the second as the numerator. Only whorls or composites are given a valuation. One is added to the numerator and denominator, thus giving 1 over 1 where all patterns are arches or loops, and 32 over 32 where all patterns are whorls or composites.

Arches, tented arches, radial or ulnar loops occurring in either of the index fingers compose the sub-classification, the right index finger being the numerator and the left index the denominator.

A group classification is obtained by tracing the ridges in the whorls and counting the ridges in the loops of the index and middle fingers of both hands. Arches, tented arches and radial loops, being of relatively infrequent occurrence, are always noted in the formula.

Owing to the fact that it was difficult to discover the identity

of a person from a single finger impression left at the scene of the crime, even though the criminal's finger-prints were filed in the identification bureau, identification experts decided to give attention to the classification oi single finger-print impressions. Oloriz, in Spain, was a pioneer in this field, followed by Jorgensen in Denmark. Collins in England, and Crosskey and Larson in the United States. These investigators have succeeded in producing single finger-print systems that are operating in various countries. Their formulae make it possible to identify a criminal from a single digital impression which may be left behind by the criminal, provided that the offender's prints have been previously registered and are in the single finger-print file.

Larson System.—The following is a brief outline of the Larson system. The pattern to be identified is (1) classified according to the gross configurations of characteristic formations; arches are divided into seven types; loops, 9; whorls, 6; twinned loops and lateral pockets, 4; and accidentals, 13. (2) The inclination of the pattern—*i.e.*, the pattern slopes to the right or left, or has no inclination at all—divides all types into three sub-divisions. (3) The pattern is then classified according to the configuration of the ridges which constitute the core. (4) The ridge surrounding the core—called by Larson, the "envelope"—is classified according to its peculiarities or appendages. (5) The first ridge in front of the delta is classified according to its characteristics, such, for example, as abrupt terminations, tented, composite characteristics, dotted ridges, forked, natural or recurving. (6) The delta is then classified according to two basic types: open and closed. These two types are further divided into eight sub-types. (7) The final differentiation is reached by ridge counting and ridge characteristics. Larson says: "The pattern is split into natural divisions and each division may be treated independently. Thus a pattern may be searched for according to type; core; envelope; delta; ridge count; or ridge characteristics."

Factor	Class 1	Class 2	Class 3
I. *Form* If eyed forms are present classify as No. 3; otherwise according to whether angular or rounded.	Angular	Rounded	Eyed
II. *Skill* Legibility, symmetry and pictorial aspect considered.	Poor	Medium	Good
III. *Connections* If small letters show disconnection classify as No. 3; otherwise according to whether capitals are connected or disconnected.	Capitals connected	Capitals disconnected	Small letters disconnected
IV. *Shading* Determined by difference in width of the lightest and heaviest strokes.	Light	Medium	Heavy
V. *Movement* Finger movement lacks freedom, is slow and usually shaded; forearm shows speed, force, dash, freedom and little shading.	Finger	Compound	Forearm
VI. *Embellishment* Determined by degree of ornamentation.	Plain	Intermediate	Embellished
VII. *Terminals* Inclination of terminal strokes.	Upward	Horizontal	Downward
VIII. *Slant* Degree of slant above horizontal.	Less than 60 degrees	60 to 80 degrees	More than 80 degrees

Analysis of Handwriting.—Such a large amount of handwriting in the form of signatures on pawnshop and second-hand store books, hotel registers, writing found on worthless cheques, letters and documents of every character, is connected with criminal cases that it was necessary to find a means of classifying this valuable material. Dr. Hans Schneickert in Germany, several Austrian experts, and Lee and Abbey in the United States have contributed to this important method of identifying criminals.

The chart used by Lee and Abbey is in the adjoining column.

Modern identification bureaux, or divisions, maintain elaborate indexes giving the alphabetical arrangement of names according to the directory guide system; the *modus operandi*, arranged either by index guides or decimal system; a special marks file, in which are kept the anatomical peculiarities that assist in identifying individuals; and the ever-present "rogues' gallery."

In some cities the "rogues' gallery" photographs are pasted in books kept in numerical order; in others, they are kept in books but filed according to crime; and in still others they are placed in books and segregated according to crime, then according to hair colour, eye colour, height and weight. Some departments use the Rardex sysrem and file photographs according to the *modus operandi* of the criminal, and then by the English descriptive method. Others have large wall leafs on which are placed the photographs of active operators, and these are frequently arranged according to description of the individual and his *modus operandi*.

While it is true to-day that not many identifications are made by photographs, they are yet sufficient in number to warrant their continuance as a means of identification.

INVESTITURE, the formal installation into an office or estate, which constituted in the middle ages one of the acts that betokened the feudal relation between suzerain and vassal. The suzerain, after receiving the vassal's homage and oath of fealty, invested him with his land or office by presenting some symbol, such as a clod, a banner, a branch, or some other object according to the custom of the fief. The sword and sceptre, emblematic respectively of service and military command and of judicial prerogatives, became the usual emblems of investiture of laymen. The word investiture is later than the 9th century; the thing itself was an outcome of feudal society.

It is in connection with the Church that investiture has its greatest historical interest. The Church quite naturally shared in feudal land-holding; in addition to the tithes she possessed immense estates which had been given her by the faithful from early times, and for the defence of which she resorted to secular means. The bishops and abbots, by confiding their domains to laymen on condition of assistance with the sword in case of need, became temporal lords and suzerains with vassals to fight for them, with courts of justice, and in short with all the rights and privileges exercised by lay lords.

Investiture of ecclesiastics by laymen had certain serious effects which were bound to bring on a conflict between the temporal and spiritual authorities. In the first place the lay authorities often rendered elections uncanonical by interfering in behalf of

some favourite, thereby impairing the freedom of the electors. Again, benefices were kept vacant for long periods in order to ensure to the lord as long as possible the exercise of his regalian rights. And, finally, control by temporal princes of investiture, and indirectly of election, greatly increased simony. The main investiture struggle with the empire took place when Hildebrand became Pope Gregory VII. (*q.v.*). To Gregory it seemed intolerable that a layman should invest a churchman with the symbols of office. To the emperor Henry IV. it was highly undesirable that the advantages and revenues accruing from lay investiture should be surrendered; it was reasonable that ecclesiastics should receive investiture of temporalities from their temporal protectors and suzerains. Although the full text of the decrees of the famous Lenten synod of 1075 has not been preserved, it is known that Gregory on that occasion denounced the marriage of the clergy, excommunicated five of Henry IV.'s councillors on the ground that they had gained church offices through simony, and forbade the emperor and all laymen to grant investiture of bishopric or inferior dignity. The struggle was complicated throughout its course by political and other considerations; there were repeated rebellions of German nobles, constant strife between rival imperial and papal factions in the Lombard cities and at Rome, and creation of several anti-popes, of whom Guibert of Ravenna (Clement III.) and Gregory VIII. were the most important. Final settlement of the struggle was retarded, moreover, by the question of the succession to the lands of the great Countess Matilda, who had bequeathed all her property to the Holy See, Henry claiming the estates as suzerain of the fiefs and as heir of the allodial lands. The efforts of Gelasius II. to settle the strife by a general council were rendered fruitless by his death (1119). At length in 1122 the struggle was brought to an end by the concordat of Worms, the provisions of which were incorporated in the eighth and ninth canons of the general Lateran council of 1123.

In France the course of the struggle was somewhat different. As in the empire, the king and the nobles, each within his own sphere of influence, claimed the right of investing with ring and crozier and of exacting homage and oaths of fealty. The struggle, however, was less bitter chiefly because France was not a united country, and it was eventually terminated without formal treaty. The king voluntarily abandoned lay investiture and the claim to homage during the pontificate of Paschal II., but continued to interfere with elections, to appropriate the revenues of vacant benefices, and to exact an oath of fealty before admitting the elect to the enjoyment of his temporalities. Most of the great feudal lords followed the king's example, but their concessions varied considerably, and in the south of France some of the bishops were still doing homage for their sees until the closing years of the 13th century; but long before then the right of investing with ring and crozier had disappeared from every part of France.

England was the scene of an investiture contest in which the chief actors were Henry I. and Anselm. The archbishop, in obedience to the decrees of Gregory VII, and Urban II., not only refused to perform homage to the king (1100), but also refused to consecrate newly-chosen bishops who had received investiture from Henry. The dispute was bitter, but was carried on without any of the violence which characterized the conflict between papacy and empire; and it ended in a compromise which closely foreshadowed the provisions of the concordat of Worms and received the confirmation of Paschal II. in 1106. Freedom of election, somewhat similar in form to that which still exists, was formally conceded under Stephen, and confirmed by John in Magna Carta.

Many documents relating to the investiture struggle have been edited by E. Dümmler in *Monumenta Germaniae historica, Libelli de lite imperatorum et pontificum saeculis xi. et xii.* (3 vols., 1891–1897). *See* Ducange, *Glossarium,* s.v. "Investitura."

INVESTMENT. An investment may roughly be defined as the depository of savings. The term is usually applied to money, but strictly speaking it is equally applicable to all kinds of property, such as land, buildings and furniture. In short, the whole of an individual's property, including the debts due to him at any time, may be described as his investments.

In considering the question, a broad distinction must first be drawn, between "forced" or "unconscious" and "voluntary" or "conscious" investment. Forced investments arise in several ways. The chief is that every business man has to grant credit to his customers, and most workers receive their wages or salary "in arrears," that is after they have performed their week's or month's work. Money thus due is clearly part of each man's investments, and the amount thus "invested" is dependent not on his voluntary act, but on the customs of the trade or on his terms of employment. Before considering voluntary or conscious investment, it is necessary to examine the various motives which induce saving and govern the choice of investments. First and foremost comes the desire to provide for old age, sickness and other emergencies. Here safety is the paramount consideration, and the interest on the investment need not be taken into account. To illustrate this, £100 may be a godsend in case of an emergency, but until it is required, it makes little difference to the owner's annual income whether it is earning 25% on deposit in the bank, or 7% in some highly speculative mining shares. Next comes the question of interest, and this arises from the desire of the individual to use his savings to augment his income. In general, the rule is "the greater the yield, the greater the risk," and the application of this rule and the weighing-up of capital safety and income is one of the chief problems of the investor. Next comes the desire for that will o' the wisp, "capital appreciation," when the investor hopes that his property will rise in value. Here the distinction between investment and speculation becomes very thin. Finally come a whole host of motives. One man invests his money in his own business because it is expanding, and will gain for him fresh profits and fresh prestige; another in his business because it is going downhill, and he has still to learn not to throw good money after bad, and another in real and personal property of one kind and another, simply because of the satisfaction the possession of such property will give him. Every investor must bear in mind one general warning. Every investment demands eternal vigilance on the part of the holder. Consols, which, before the World War, were regarded as the soundest of stocks, are themselves a striking warning to the unwary. In 1896 they were quoted at 110½, by 1907 they had fallen to 84, and by 1913 to 73⅝. Then came the War, and the inflation period, and by 1920 they had fallen to a minimum of 43⅝. By the end of 1927 they had recovered to 56. It is true that the interest remained constant throughout this period at a steady 2½%, but £2 10– would buy much less in 1927 than in 1896, so that even this stability possesses a certain unreality.

General Rules.—There are certain general rules governing the course of trade and finance which should be known to every investor. The first has already been quoted, but is repeated again

so as to be presented in compact form with the remainder:—

(1) The greater the yield, the greater the risk.

(2) Where the rate of interest is fixed, a high yield means a low price; therefore, as the risk increases, the price falls.

(3) When money is scarce, interest rates rise, and prices fall.

(4) Rising commodity prices mean active trade and high profits, but ultimately scarce money; and falling prices the reverse.

(5) The capital value or yield on a share is not only its "money" value or yield, but depends also on the purchasing power of money. This and the preceding rule must be read together.

(6) When trade is active and money in demand to the point of scarcity and high interest rates, buy consols, war loan and similar gilt-edged fixed-interest stocks, for these will be cheap under rule **(2)** and will improve under the second part of rule (4).

(7) When trade is dull and money plentiful, buy ordinary shares whose value rises and falls with the course of business; these, provided the company is sound, will be cheap under rule (2), and will improve under the first part of rule (4).

(8) Last and most important of all, lay a solid foundation. Life insurance comes first, and see that insurance is added to if the cost of living rises or the assured's standard of life improves. A life policy for £500 taken out in **1896** when living was cheap, is only partial protection in **1928** when prices have approximately doubled. If prices rise, more insurance must be taken out to maintain the same degree of protection.

Next in turn for the British investor come savings certificates. Even at 16s./- these are an attractive investment; they are safe, realizable, independent of market fluctuations and free of income tax. These should be bought up to the limit. After that, the investor can consider other openings. These are discussed in detail below.

and there is always the risk of the property standing vacant for a time. Again rents can vary just as much as an "ordinary" dividend. Every time a lease expires, a fresh agreement has to be made, and it is not always the tenant that is the loser. Over and above this comes one important point. Land and house-room are a universal necessity, and the result is that so far as public opinion and legislation are articulate, they are more anxious that the tenant should have adequate housing at a rent he can afford, than that the landlord should earn on his property a net return commensurate with that to be obtained elsewhere. This particularly applies to the smaller class of houses, and the war and post-war Rent Restriction Acts in England are an example of this point. Those who before the War owned houses which were exempt from restriction, found they had an investment with all the advantages of an ordinary share, while those whose property came below the line, found it had many of the disadvantages of a fixed-interest stock. In short, when money depreciates violently and prices rise, the landlord of small property must expect to be debarred by law from raising rents accordingly. Provided that he can raise his rents enough to equal any increase in maintenance costs, so that his net rent remains unchanged, restriction is not inequitable. A landlord has no greater right to claim a larger net rent because of a rise in prices than the holder of $2\frac{1}{2}\%$ consols has to claim that in future the Government should pay him 4% or 5%. Sufficient has been said to show that house-property is a dangerous possession for the ignorant investor.

British Government and Corporation Stocks.—The first of the rules previously enunciated stated that "the greater the risk, the greater the yield." Here the risk is negligible, so all the investor has to watch is the general rise and fall in interest rates. Rules **(3)** to (7) inclusive, should be a sufficient guide, but the accompanying table of post-war prices will illustrate their incidence.

Variations in Certain *British Gilt-edged Securities* 1919–27*

Stock	Nominal interest	1919	**1920**	**1921**	**1922**	1923	1924	1925	**1926**	1927

*Redeemable 1930–50. †4th Series, redeemable 1929.

Land, House-property, **etc.**—Here is often an obvious case of forced investment, viz, that of the man who has to buy his own house or farm, or else clear out. He, too, often has to pay a forced price. If it is any consolation, he must realize that in post-war days, purchase is often the only means of getting a decent home. Two words of warning may be uttered in this connection. The first is contained in the explanation of a farmer for his action in warning off the local hunt: "I've changed my landlord, and the new one's far harder on me than the old. My new landlord is myself!" The other is that in buying, or making an offer to buy, he must count all the costs, including stamp duties and legal charges. If he buys through an estate agent, it is customary for the vendor to pay the agent's commission, which is considerable on a big transaction. The customary legal scale of charges for both buyer and seller is heavy, and it is always well to make a bargain in advance with the solicitor acting in the matter. As regards land and houses as a medium for voluntary investment, here the investor becomes the landlord. He must realize at once that property of this kind demands special care and knowledge from its owner. Repairs, maintenance, ground rents, rates, legal charges all levy a toll upon the gross rent,

Two short-dated securities have been included. These are both redeemable at 105, and so their market price gradually approximates towards this point. The level and trend of interest rates are also included in the table. The reader can trace for himself the connection between interest rates and prices. He can also see when it was "a good time" to buy or to sell. Finally, he can see that even gilt-edged stocks are subject to wide price fluctuations. The years 1921 and **1922** in particular are commended to his notice.

Foreign Stocks and Bonds.—"The greater the risk, the greater the yield," and here a special risk enters. The interest and principal on foreign stocks are often payable in foreign currency, and even when payable in sterling, the Government concerned has to buy the sterling needed for the service of the debt. In the first case, the interest received by the British holder varies with each fluctuation in exchange, for the interest on Frs. 1,000 5% French Rentes is 50 francs, whether a franc is worth tenpence, twopence or a penny. Exchange fluctuations govern the sterling interest, and also the market price. This is illustrated by the table which will be found on the next page relating to 5% Rentes:

The "risk" here was the collapse of the franc. This increased up till 1926, and then sharply receded. Hence the rise and fall in the yield. The London market price was determined jointly by the sterling interest and the yield required by the market to compensate for the risk.

Industrial Stocks.—These fall into three main categories: debentures, preference shares and ordinary shares. Each is subject to wide fluctuations, and the buyer should remember this and judge by their past record, whether the shares he is contemplating purchasing stand at a "top" or a "bottom" price. Debentures are governed both by the level of interest rates, and by the risk of loss or default, and this risk is judged usually by the fortunes of the company's shares. Thus the passing of the ordinary dividend will cause a slight fall, and the passing of the preference dividend a heavier fall in the company's debentures. The issue of further (and especially of prior debentures) may also weaken existing debentures, unless it is clear that the company is obtaining the fresh money to finance new and remunerative business. The price of ordinary shares reflects many things, such as current dividends, future dividends, the possibility of bonus share issues or the existence of accrued losses. These are dealt with later. The preference share comes half-way in between. In some ways it has the disadvantages of both. It also is dealt with later. Holders of all three classes of securities should watch price fluctuations, but not be unduly elated by a rise, or dismayed by a fall. A sound share is usually worth holding.

if things prosper, the gains go to the ordinary shareholder. The preference shareholder's measure of protection is clearly the size of the ordinary capital and ordinary dividend. If 100,000 £1 preference shares have 100,000 £1. ordinary shares behind them, and the usual ordinary dividend is 10%, the "capital" protection is £100,000, and the "dividend" protection is £10,000. If the ordinary shares are 100,000 of 1s. each, and the ordinary dividend is 50%, the "capital" protection falls to £5,000, and the "dividend" protection to £2,500, both of which figures are dangerously small. In other words, it will not take much of a loss to encroach upon preference dividends while the smaller ordinary capital will receive just as many plums as before.

Ordinary shareholders receive what is left out of profits, after debenture interest, preference dividend and allocations to reserve have been made. When times are bad, they get nothing, and when they are good they may receive much. Many companies try and maintain a constant ordinary dividend, and in good times declare a "cash bonus" which is really an extra dividend. One of the great merits of ordinary shares is that a proportion of the profits are every year "put back" into the business by the directors of the company. This is necessary if the business is to progress, but it also means that a proportion of the ordinary shareholder's income is forcibly saved for him and re-invested by his directors. Hence his shares are steadily appreciating in value all the time. The issue from time to time of bonus shares from reserves is simply the outward and visible sign of this continuous progress. A bonus issue in itself adds nothing to the value or earning power of the property, and the reason why the market hails it as a bull point is that it marks a definite stage in the company's progress, releases to the shareholder some of his forced savings, and is considered by the ignorant to be of the nature of "receiving something for nothing"

The fundamental principle of debentures, preference and ordinary shares, is that the holder of the last-named is first in line for both the "kicks" and "half-pence" distributed by fortune. He also exercises full control over the company, and the debenture and

Debentures represent money lent to a company, and principal and interest must alike be met, whether or not any profits are earned. Default is equivalent to an act of bankruptcy, so the way to regard them is whether or not the company possesses the required resources. Special points to remember are that as a rule trade creditors rank ahead of debenture-holders, and in many cases a company has the power to issue new debentures ranking ahead of the old ones. These points should be investigated by the prospective purchaser. Preference shareholders are part owners of the business. They only receive a fixed dividend, but in return have first claim to divisible profits, and first claim to repayment on the liquidation of the company Thus, if things go wrong, the ordinary shareholder has to bear the brunt of the attack, while preference shareholder can only intervene when surplus "kicks" start coming his way. It must be realized that this gives great scope for the unscrupulous ordinary shareholder to display his ingenuity. Thus, he can distribute two years' profits in advance to himself by a suitable manipulation of the accounts, and then explain to the others that the company is insolvent and all must make sacrifices. Conversely, he can by a fraudulent conservatism, write down some of the assets to vanishing point, report insolvency, buy up the preference shares cheap, and then restore the assets (and the preference shares) to their true value Nor need debenture and preference shareholders' rights count for much They can always surrender their right.; and when the voluntary surrender of tl eir rights is put before tl em as the only alternative

to bankruptcy, it is hard for the holder to resist.

There are too many cases where a company starts with, say, £10,000 in £1 preference and £10,000 in £1 ordinary shares. A good period ensues, and 10,000 more £1 ordinary shares are issued from reserve by way of bonus, the future being partially mortgaged in the process. Then comes a slump, a loss of £10,000 piled up, and eventually dealt with by writing the preference shares down to 15s. and the ordinary shares down to 12s. 6d. On the face of it, the ordinary shareholder has dropped 7s. 6d. to the preference shareholder's 5s. In reality, adding together the bonus issue and the reconstruction, the ordinary shareholder has taken 5s. from the preference shareholder.

A post-war development, which has nothing to commend it, is the splitting of a company's capital into £1 preferred and 1s. deferred shares. It has already been shown how this weakens the bulwark between the preferred shareholder and disaster. It is also a means of reserving the "half-pence" for the deferred shareholder, and sharing the "kicks" equally between the two classes. Take this case:

100,000	6% Preferred shares of £1 each	£100,000
100,000	Deferred „ „ 1s. „	5,000
	Total capital	£105,000

The following table shows how the "half-pence" are distributed:

Total dividends	£20,000	£15,000	£10,000	£6,000
Pref. dividend at 6%	£6,000	£6,000	£6,000	£6,000
Def. dividend (amount)	£14,000	£9,000	£4,000	Nil.
Def. dividend (rate	280%	180%	80%	Nil.

Say these were four years' consecutive results. The deferred shareholders have received £27,000 on their original holding of £5,000, that is, their capital back and £22,000 to boot. They can ask the preferred shareholder to be brave in facing bankruptcy with them with perfect equanimity. Nor is this the whole indictment against the shilling deferred share. In 1927 when it first appeared in Great Britain in obnoxious quantities, the vendors or promoters of a company would often keep half the deferred shares for themselves. The public would be graciously allowed to buy the other half, provided that they also bought all the preferred shares. This was a reincarnation of the founders' share with a vengeance. To show the market's appreciation of the relative worth of £1 preferred and 1s. deferred shares, the following examples may be quoted. The names are suppressed for obvious reasons:

	Share and issue price	Price	Rise or fall from issue price %
Company A	£1	18/–	– 10
„ „	1/–	9/–	+ 800
„ B	£1	12/6	– 37½
„ „	1/–	3/9	+ 275
„ C	£1	16/9	– 16¼
„ „	1/–	7/–	+ 600
„ D	£1	£1	..
„ „	1/–	12/6	+1,150

These figures speak for themselves.

Reading the Balance Sheet.—Every shareholder should be able to read the balance sheet of his company. He must remember that every figure in it represents only the estimates of the board and their advisers—thus, "plant £200,000" and "stocks £50,000" are obviously estimates, and as more intangible items, such as profits and reserves, are deduced from these first, they are equally only estimates. There are three rough tests a shareholder can apply to a balance sheet: (a) What are the liquid assets of the company—these equal cash plus any investments in "trustee" stocks plus debtors minus creditors and bank overdraft? If they are diminishing from year to year, the shareholder is put upon his guard. (b) What is the net value of the property, *i.e.*, assets (less accrued losses, preliminary expenses, etc.) less creditors? Again, is this increasing? (c) Are the directors putting at least £1 to reserves for every £3 distributed in capital? If not, why not, for this is a fundamental principle of sound company finance.

The first two points are illustrated by this balance sheet:—

	£		£
Preference shares	100,000	Plant and stocks	350,000
Ordinary shares	200,000	Debtors	25,000
Reserve fund	150,000	War loan	50,000
Creditors	20,000	Cash	45,000
	£470,000		£470,000

Liquid assets are, therefore, £25,000+£50,000+£45,000–£20,000=£100,000. The total value of the property is £470,000–£20,000=£450,000. Deducting preference shares, this is equivalent to 35s. per £1 ordinary share.

The rate of interest on debentures and preference shares is fixed; even if it falls into arrears, the arrears must be made up in the case of debentures and "cumulative" preference shares. So the potential investor must consider chiefly the risk of default. As regards ordinary shares, he must weigh the risk of no dividends against the chance of high dividends and cash bonuses. Capital appreciation and depreciation are dependent partly on the level of market interest rates, but mainly on the view taken as to the future of the company in particular and the industry in which it operates as a whole. The investor, therefore, must watch these points, accepting all rumours with a large grain of salt. Over and above the fluctuations of trade, ordinary shares in a company with a proper reserve policy should steadily appreciate in value. It is this that accounts for the new theory that ordinary shares are a "safer" investment than gilt-edged stocks. As regards wide changes in the purchasing power of money, to a large extent the ordinary share comes out best of all. When prices are rising, profits and dividends also rise, and the shares appreciate in money value to an amount roughly equivalent to the decline in money's purchasing power. The important point to watch is that the company uses this period to build up a good reserve fund. The reason for this is that a fall in prices operates so unevenly upon a trading company as to involve it temporarily in heavy loss. Once it survives this, the contraction in the money value of its shares is compensated for by the higher purchasing power of money, but this is no consolation to the shareholder if the company fails altogether.

Practical Hints.—One or two practical hints may be given in conclusion:—

(1) As already urged, the small investor should first insure his life for an adequate amount, and then buy (in Britain) savings certificates up to the limit of £100.

(2) The investor who wants to go further, should spread his money between gilt-edged stock, some sound debentures, and ordinary shares with a "good history."

(3) With the return on gilt-edged stock at 4½%, do not aim at more than 5½% on debentures or 7% on ordinaries.

(4) Avoid foreign and specialized shares and also new issues, unless you have personal knowledge of their peculiarities.

(5) Deal through a bank or member of a recognized stock exchange.

(6) Do not put too much into one company, or even one industry. To spread investments is to minimize losses.

(7) Watch your investments, and continue to watch. (*See* also STOCK EXCHANGE; MONEY; BALANCE SHEET.) (N. E. C.)

The United States.—American investment habits are conditioned by the newness of the country and the venturesomeness of the people. Securities which give a semblance of the safety of an investment and at the same time offer the prospect of profit of a speculation, have been in growing favour. Bonds which are convertible into stock, bonds with stock purchase warrants attached, preferred shares which are convertible into common stock and preferred or so-called A shares which participate in profits under specified conditions with the common shares, constitute the chief banking devices for combining investment with speculation. To an increasing extent, the American investor, desiring to have his cake and eat it too, has been indulging in speculative investments.

Before the World War, it was commonly conceded that shares were for speculation and bonds for investment. It is now held that well selected common shares are suitable for long term invest-

ment for individuals who are less concerned with getting back a particular number of dollars than with assuring themselves of given purchasing power or command over commodities in the future. In a steadily growing country, such as the United States, a good case can be made out for the equities—or stock interest—in well managed companies, which perpetually increase their stake in the nation's business.

The growing preference for common stocks for long-term holding was rationalized as a new investment philosophy by Edgar Lawrence Smith in his volume *Common Stocks as Long Term Investments* and by Kenneth Van Strum in *Investing in Purchasing Power.* As investors show a disposition to turn from conservative bonds to more speculative stocks, there has been a growing recognition of the need of timely statistical data and analytical skill. Accordingly, the new profession of investment management has been springing up. Between 1924 and 1928, the American investor, desiring to invest by proxy through experts, showed widespread appreciation of the investment trust idea, a novelty in the United States. According to recent estimates, there were 208 investment trusts in the country, with total resources exceeding $1,000,000,000. Such agencies, which differ widely among themselves, take the form of corporations more frequently than of common law trusts. Such agencies have for the most part built up portfolios consisting largely, if not entirely, of stocks instead of bonds. Moreover, investment counsellors, who sell only advice, have tended to favour a balanced investment list, consisting of stocks as well as bonds.

The amateur, or lay buyer, has become in the last decade an increasingly important factor in the American investment market. Before the war, it was estimated that there were only 400,000 bond buyers in the country. The Liberty Loan campaigns during the World War gave millions of Americans their first experience as security owners. There is no reliable record of the number of security owners in the United States, though estimates run upwards of 10,000,000. Not only have American governmental agencies and private corporations dipped deeply into the reservoir of savings, but an increasing array of foreign governments and foreign private business enterprises have borrowed funds in this market. New York city has accordingly become a world financial capital sharing honors with London. In 1928 New York city stood pre-eminent as a lender of long term capital, whereas London retained the primacy in financing short term foreign trade operations.

The New York money market has become increasingly cosmopolitan in character. The American investor, traditionally provincial in his tastes, gradually developed a wider outlook, and began to buy foreign issues, their higher rate being usually the attracting feature. Also outside of New York city investment banking facilities have been enormously expanded. The South and West, which before the war were virtually without local agencies for cosmopolitan investment, were covered with a network of local investment bankers and branches of nation-wide organizations. Individuals in the hinterland, who had formerly invested surplus funds almost exclusively in farm and urban real estate mortgages, began to diversify their risks. Financial advertising developed enormously in quality and quantity. Recent broadening of activity reflects, in part, the carrying of ticker facilities to parts of the country hitherto uncovered, particularly in the South, the Southwest, the Far West and in Canadian provinces. As recently as 1915, there were only 2,000 stock tickers in the country, compared with more than 7,000 in 1928. The expansion has been extremely rapid since the beginning of 1927.

In American practice, there is a sharp distinction between investing by individuals and investing by institutions. Although individuals are interested primarily in assuring purchasing power in the future, institutions, such as the savings banks and life insurance companies, with huge liabilities measured in dollars, rather than in purchasing power, are interested in assuring a specific number of dollars through their investment programmes. Accordingly, institutions for the most part favour bonds, which promise a given number of dollars at a specified date. The eligible investments for savings banks and life insurance companies are clearly set forth in State laws. In general, the life insurance companies have more freedom than the savings banks. In some States, as also in Canada, insurance companies may purchase common stocks. The New York law respecting life insurance companies has recently been liberalized, permitting the purchase of the highest grade of preferred stocks as well as bonds, though common shares are still ineligible for life insurance companies in that commonwealth. With the growth of the power and light industry in the last decade, numerous States have made public utility bonds eligible for investments for trustees, savings banks and other institutions. Life insurance companies have consistently increased the proportion of their total investable funds placed in public utility securities.

An important new outlet for the investable funds of individuals has come through the conversion of hitherto privately owned close corporations into companies whose securities have been widely distributed. Department stores, chain stores, and other merchandising agencies have been conspicuous in this group. Holding companies have been set up, which have expanded rapidly through taking over local enterprises through an exchange of stock. The absorption has been profitable in most instances, for the public has usually placed a higher value on earning power when taken over by a large company, whose shares are readily marketable, than when reported by an obscure company, whose securities were illiquid.

Before the war, conservative investors favoured railroad securities, shunning all others as too speculative. They have got away from this notion, partly because the railroads, with their rates fixed by public regulatory bodies, have been less spectacularly prosperous than certain unregulated industrial corporations whose profits have been limited only by competition and the capacity of management. Seemingly, no successful product is too trivial or too unessential to win an investment following. As is usually the case when security prices are showing a long term upward trend, the security buyer exaggerates the importance as a determinant of value of current earning power and minimizes the effect of asset worth. (M. S. R.)

INVESTMENT TRUSTS. Although stock exchange dealings as we know them to-day, originated with the Dutch, the investment trust is essentially a British invention. In the early part of the 19th century, following upon the emancipation from Spanish rule of many portions of South America, there was a flood of foreign government and municipal issues in London, offering rates of interest that were very attractive compared with those obtainable on British Government loans. Numerous defaults occurred and within ten years only one-third of this total was in receipt of interest, A few years later followed the great railway boom, which was succeeded by the panic of 1847. The result was that British investors of all types were heavily hit, and in numerous cases ruined; but a comparatively small number of people were conspicuous exceptions. These were persons of considerable wealth who were in a position to command information and expert knowledge, and who had invested largely abroad. The need for some combination of smaller investors who, by co-operation, could secure similar advantages, was evident, and in 1863 (just after an act had been passed limiting the liability on shares in joint stock companies) two investment trust companies were formed in London. Several other companies of the same description were formed, and by the year 1886 these were sufficiently numerous to cause them to be grouped under the heading of "financial trusts" in the official list of the London Stock Exchange. The investment trust is a form of company that appears to have made a strong appeal to Scottish investors, and from the early beginnings of the movement Edinburgh has been the home of many such companies, most of them having been conspicuously successful.

Although not immune from the vicissitudes of the stock, and share markets, investment trusts, as a whole, showed that they could pass satisfactorily through bad periods as well as good. It was not, however, until some years after the World War that a movement towards the creation of new investment trusts became apparent in Great Britain. This movement coincided

with one of much greater dimensions that started in the United States. A few new investment trusts were started in London, and older trusts began to form what might be termed sister investment trusts under the same management.

230 British Investment Trusts.—At the beginning of 1939 the number of investment trusts in Great Britain was about 230 with an aggregate capital of approximately £370,000,000. At the same period the number of investment trusts in the United States was over 200 with a paid-up capital in excess of $800,000,000 —a surprising total when it is borne in mind that the first of these was formed so recently as 1921. Switzerland, Holland, France, and Japan have all created investment trusts of recent years, but the tendency in these countries is more in the direction of what Americans aptly name, "specialty trusts," *viz.*, companies investing primarily in the stocks of one class of undertaking, e g., electric light, power and tramways, shipping, rubber and tea.

It is necessary to make a distinction between the investment trust and the finance company. The investment trust is an organization holding investments in common on behalf of its shareholders and distributing among the latter the income received. Emphasis requires to be placed upon the word "income," for the genuine investment trust never distributes profits made by the sale of its holdings; such profits, according to its statutes, must always be carried to reserve, and are, of course, invested to earn additional income available for distribution. This is the "acid test" of the investment trust. The title of a company is not a sure guide, for, unfortunately, there are some companies, British and others, incorporated under the name of investment trusts, which are ordinary finance or holding companies. In Britain the inland revenue authorities themselves make this distinction, exempting genuine investment trusts from payment of income tax on "profits" from sales of securities, regarding them as associations of investors pooling their capital for safety and distributing income, that is, investment revenue only. A company that distributes any portion of such profits as dividends is regarded as an ordinary trading concern and pays tax on the total of its net profits, whether it calls itself an investment trust or not.

The ordinary type of British investment trust starts with an issue of capital divided as to 50% (sometimes 60%) in preference stock, and 50% (or 40%) in ordinary stock. After it has been established some time it issues debenture stock to the extent of perhaps its total share capital, so that roughly its capitalization is 20% ordinary stock, 30% preference and one-half debentures. By this method it obtains cheap *permanent* capital, an advantage which cannot be enjoyed by the private investor. The assets behind the debentures of soundly established investment trusts are so considerable as to constitute them practically gilt-edged stocks.

As a result of the excellent method of capitalization adopted by the British investment trusts the ordinary (or deferred, where the ordinary has a fixed dividend) stocks are frequently quoted at a price which represents a market capitalization in excess of what would come to them in the event of a liquidation, based upon the book value of the assets. The reason is that all the advantage arising from the cheap capital provided by the debenture and preference stocks accrues to the ordinary, either in the shape of a steady increase of dividend or bonus shares—or both.

Some British Examples.—The following table summarizes the position of a few typical British investment trusts at the end of September, 1939:

About one-half of the British investment trusts publish with their annual reports full lists of their investments. Others state the percentage held of different groups, but without specifying the individual investments. It is recognized in Great Britain that an investment trust may legitimately distribute income even where the capital is not intact, owing to depreciation of investments. This view was confirmed by judgments in the English courts in 1894. As an investment trust is precluded from distributing profits on the sale of securities, these go to build up a reserve, which is invested and immediately becomes revenue-producing.

Fixed Trusts.—Fixed or unit trusts originated in America, and were introduced into Great Britain in 1931. The underlying idea is, while retaining the principle of spreading of risks, to take out of the hands of the management the unrestricted right to change investments. Some twenty or thirty investments, usually industrial ordinary shares, are selected, mixed in agreed proportions to form a "unit" to be locked away for fifteen or twenty years in the custody of some bank or other institution acting as trustee, after which the shares or their value are to be distributed. Dividends received meanwhile are paid out. Against these securities sub-unit certificates are issued at a price (to which is added a management charge for the period of the trust) within the means of the small investor, who thus obtains a fractional participation in a number of different securities.

Started when prices were low and favourable to investment, these trusts made great progress, and in 1939 numbered nearly one hundred, with a total capital of £80,000,000. In the light of experience the tendency has been to make the newer unit trusts less fixed, giving more latitude to the management to change investments, but always within a prescribed list of securities. By the Prevention of Fraud (Investments) Act of 1939, fixed trusts have been brought under a certain measure of legislative control.

(A. E. DA.)

The United States.—The investment trust idea, which has decades of experience behind it in England and Scotland, is relatively new in the United States, yet by the end of 1928 there were more than 200 investment trusts in operation with total resources exceeding one thousand million dollars. An investment trust is an instrument for meeting the needs of the great class of small investors, who began for the first time to buy securities in large aggregate amounts at the time of the World War loans. Moreover, with America now in a leading world creditor position, the investment trust forms a useful medium for expert selection and diversification in foreign investments with which the average American investor is himself inexperienced.

The well-managed investment trust offers the advantages of co-operation and of guidance by specialists. Each is of distinct value. By joining with other investors and thus creating a large reservoir of capital, each participates in a fund which can be widely diversified in scores or hundreds of securities. The man with a $1,000 surplus can get a participation in 400 securities, but, if he acted alone, he would have to be satisfied with one or, if he selected "baby" bonds, with ten.

Mere numbers are of distinct importance. Life insurance, for example, depends on them. If a group of six men were to insure themselves cooperatively against the hazard of death, their venture would be dangerously speculative and uncertain. However, if 60,000 men would insure themselves co-operatively the outcome would be certain. The risks would be so well diversified that the group would live in accordance with the established American tables on mortality. Similarly the investor who stakes his fortune in a handful of investment companies without sufficient diversification assumes needlessly grave hazards.

The classic American investment trust of the English type offers the actuarial benefits of heightened diversification through participation in a larger pool of capital than is available to the ordinary investor single-handed; second, the investment trust offers expert knowledge in the original choice of securities for the portfolio of the fund; and third, it assures continuous supervision by experts, in the light of changing conditions, of the investment portfolio. In addition to adapting the English type of investment

trust, American financiers have also created new patterns and variations. Even those trusts which are built on the English plan have set up far more restrictions on management.

In the United States, two schools of thought concerning the latitude that should be granted investment trust management have developed. One adheres to the British example and gives the management discretion, subject to the limiting clauses of the charter of the enterprise. The other virtually deprives management of all discretion after the initial selection of securities. In between, a compromise, semi-fixed type of trust has developed.

Most investment trusts take the legal form of corporations which are in a position to offer a variety of securities, including debentures and common and preferred stocks. The Second International Securities Corporation, which is of this type, discloses that it pays the American Founders Trust ½ of 1% of the value of the corporation's average resources, for management. The International Securities Corporation of America, which is closely allied, makes an annual management charge of 4% of income, which in practice has worked out to about the same. The Mutual Investment Trust, another company, gives holders of its A shares, which are sold to the public, a preferential return of 6%. The management company subscribes 10% in cash against every new certificate sold to an outsider. After the outside investor has received 6%, the company gets 6% on its investment. Then the residue of income is divided equally between the outside investor and the management company.

Competent observers have pointed out that investment trusts are springing up faster than experienced managers are being trained. In some instances the new issues are sold on the basis of high pressure selling ability, rather than because of capacity of investment management. In 1928 several investment trusts were in liquidation, and it is possible that others may undergo a similar fate, or else a process of consolidation, before the pioneer period of experiment, adjustment and competition is over. In 1924 the governing committee of the New York stock exchange passed a resolution that participation by members of the exchange in the formation or management of investment trust corporations was an act held to be detrimental to the interests of the exchange. This resolution did much to prevent at the start abuses and unsound developments of the investment trust idea. The New York State law department has also conducted investigations to determine unsound practices and means of combating them. Since the investment trust has had long trial in England and is founded at bottom on sound principles, namely expert management and diversification, it is expected that it will certainly survive and continue to grow as long as prosperity continues. It is very necessary that prospective investors assure themselves that (a) the people managing the trust are possessed of character, foresight, integrity and responsibility, (b) that the managers have sufficient faith to risk a substantial amount of their own capital in the enterprise, (c) that books and accounts are properly kept with accurate and reasonably frequent reports to investors, (d) and that the companies are true investment trusts and are not merely masquerading under the name in order to secure clients.

Numerous American trusts have been sponsored by houses of issue. This connection raises the possibility that management will not be entirely disinterested. In such cases the trust could be used as a repository for the undigested new securities of the house of issue. An investor should carefully check the character and experience of the management through independent sources, and should examine the conditions of the association. He should seek to learn whether securities have been placed in the trust at cost or whether the managers act as principals and make a profit. Furthermore, he should become fully aware of the ratio of earnings on his capital which will be credited to him. To ascertain this information, he should find out the exact schedule for deductions which the organizers will make for themselves. He should also look into the policy in respect to reserves, and should ascertain the policy in regard to publicity.

See L. T. Grayson, *Investment Trusts* (1928); L. R. Robinson, *Investment* Trust *Organization and Management* (1926), and *Survey* of *Investment Trusts* (1926), and *Supplemental Survey* (1928), Securities Bureau of the New York State Law Department. (M. S. R.)

INVISIBLE EXPORTS: see EXPORTS, INVISIBLE.

INVOICE, a statement giving full particulars of goods sent or shipped by a trader to a customer, with the quantity, quality and prices, and the charges upon them (originally a plural, *Invoyes* or *Invoys,* of *Invoy,* a variant of "envoy" from the French *envoyer,* to send). Consular invoices, *i.e.,* invoices signed at the port of shipment by a consul of the country to which the goods are being consigned, are generally demanded by those countries which impose ad valorem duties.

INVOLUCRE. The whorl of bracts at the base of the inflorescences or general umbel in umbelliferous plants is called a *general involucre;* the similar leafy whorl adjoining the smaller umbels or umbellules being termed an involcel or partial involucre. In Compositae the name is applied to the bracts surrounding the head of the flower characteristic of this family and Umbelliferae. See FLOWER, UMBELLIFERAE and COMPOSITAE.

INVOLUTION, in arithmetic is the operation of raising a number to any power, rolling it up, as it were, by continued multiplication. Before the invention of a satisfactory symbol like a^2 or a^3, the Greeks spoke of the second power as a "tetragon number" (*τετράγωνος ἀριθμός,* tetragonos *arithmos',* four-angled number) or a "power" (*δύναμις,* dy'namis, whence also "dynamo" and "dynamite"). Diophantus (c. 275) called the third power a cube (*κύβος,* cu'bos, see CUBE), the fourth power a "power-power" (*δυναμοδύναμις,* dynamody'namis), a fifth power a "power-cube" and so on, using the additive principle.

Involution is the converse of evolution (*q.v.*), which is the operation of finding a root. See ARITHMETIC. In geometry, an involution is a one-to-one correspondence between two ranges of points or between two pencils. See PROJECTIVE GEOMETRY. The "involute" of a curve is the locus of the end of a string when unwrapped from the curve itself.

IO, in Greek mythology, daughter of Inachus, the river-god of Argos and its first king. Under the name of Callithyia, Io was regarded as the first priestess of Hera. Zeus fell in love with her, and, to protect her from the wrath of Hera, changed her into a white heifer; according to Aeschylus (*Supplices,* 299) the metamorphosis was the work of Hera herself. Hera, having persuaded Zeus to give her the heifer, set Argus Panoptes to watch her. Zeus thereupon sent Hermes, who lulled Argus to sleep and cut off his head or killed him with a stone. But the wrath of Hera still pursued Io. Maddened by a gadfly sent by the goddess, she wandered all over the earth (Aesch. P.V., 561, et seq.), swain the strait known on this account as the Bosporus (Ox-ford), and crossed the Ionian sea (traditionally called after her) until at last she reached Egypt, where she was restored to her original form and became the mother of Epaphus. She was thus identified with Isis, and Epaphus with Apis. He was said to have been carried off by order of Hera to Byblus in Syria, where he was found again by Io. This fable connects Io with the Syrian Astarte. Both legends reflect intercourse with the East and identification of foreign with Greek gods. She was a favourite subject among Greek painters, and many representations are preserved on vases and wall paintings.

IODINE, a chemical element, belonging to the halogen group, was discovered in 1812 by B. Courtois when investigating the products obtained from the mother-liquors prepared by lixiviating kelp or burnt seaweed. It forms heavy, blackish scales with a violet lustre which gives it a metallic appearance. In 1815 L. J. Gay-Lussac showed it was an element. Iodine (symbol I, atomic number 53, atomic weight 126.92) is not in nature uncombined; it is found very widely but sparingly distributed, chiefly in the form of its sodium and potassium salts. It is also found in small quantities in seawater, in some seaweeds, and in various mineral and medicinal springs. Deep-sea weeds, as a rule, contain more iodine than those which are found in the shallow waters.

Iodine is obtained either from kelp (the ashes of burnt seaweed) or from the mother-liquors obtained in the purification of Chile saltpetre. In the former case the seaweed is burnt in large heaps at as low a temperature as possible, and the product is known either as *kelp* or *varec.* Another method is to heat the seaweed in large retorts, whereby tarry and ammoniacal liquors pass over and a very porous residue of kelp remains. A later method consists in boiling the weed with sodium carbonate; the liquid is filtered and hydrochloric acid added to the filtrate, when *alginic acid* is precipitated; this is also filtered off, the filtrate neutralized by caustic soda, and the whole evaporated to dryness and carbonized, the residue obtained being known as *kelp substitute.* The kelp obtained by any of these methods is then lixiviated with water, which extracts the soluble salts, and the liquid is concentrated, when the less soluble salts, which are chiefly alkaline chlorides, sulphates and carbonates, crystallize out and are removed. Sulphuric acid is now added to the liquid, whereby alkaline sulphides and sulphites present are decomposed and iodides and bromides are converted into sulphates, while hydriodic and hydrobromic acids are liberated and remain dissolved in the solution. The liquid is run into the iodine still and gently warmed, manganese dioxide in small quantities being added from time to time, when the iodine distils over and is collected. In the second method it is found that the mother-liquors obtained from Chile saltpetre contain small quantities of sodium iodate, $NaIO_3$; this liquor is mixed with the calculated quantity of sodium bisulphite in large vats, and iodine is precipitated:—

$$2NaIO_3+5NaHSO_3=3NaHSO_4+2Na_2SO_4+H_2O+I_2.$$

The precipitate is washed and then distilled from iron retorts. Iodine may also be prepared by the decomposition of an iodide with chlorine, or by heating a mixture of an iodide and manganese dioxide with concentrated sulphuric acid. Commercial iodine may be purified by mixing it with a little potassium iodide and then subliming the mixture; in this way any traces of bromine or chlorine are removed.

Iodine's specific gravity is 4.948 (17°/4°), melting at 114·2° C; it boils at 184·35° C under atmospheric pressure (W. Ramsay and S. Young). The specific heat of solid iodine is 0·0541 (H. Kopp), Its latent heat of fusion is 11·7 calories, and its latent heat of vaporization is 23·95 calories (P. A. Favre and J. T. Silbermann). It volatilizes slowly at ordinary temperatures, but rapidly on heating. Iodine vapour on heating passes from a violet colour to a deep indigo blue.

Iodine possesses a characteristic penetrating smell, not so pungent, however, as that of chlorine or bromine. It is only very sparingly soluble in water, but dissolves readily in solutions of the alkaline iodides and in alcohol, ether, carbon disulphide, chloroform and many liquid hydrocarbons. Its solutions in the alkaline iodides and in alcohol and ether are brown in colour, whilst in chloroform and carbon disulphide the solution is violet, and in the latter cases there is some indication of combination with the solvent. Its chemical properties resemble those of chlorine and bromine; its affinity for most other elements, however, is less than theirs. It will only combine with hydrogen in the presence of a catalyst, but combines with many other elements directly; for example, phosphorus melts and then inflames, antimony burns in the vapour, and mercury when heated with iodine combines with it rapidly. It is completely oxidized to iodic acid when boiled with fuming nitric acid. It is soluble in a solution of caustic potash, a dilute solution most probably containing the hypoiodite, which changes slowly into a mixture of iodide and iodate; change is rapid on warming. Iodine is readily detected by the characteristic blue coloration that it immediately gives with starch paste in the presence of soluble iodides; the colour is destroyed on heating, but returns on cooling provided the heating has not been too prolonged. Iodine in the presence of water frequently acts as an oxidizing agent; thus arsenious acid and the arsenites, on the addition of iodine solution, are converted into arsenic acid and arsenates.

Iodine finds application in organic chemistry, forming additional products with unsaturated compounds, the combination, however, being more slow than in the case of chlorine or bromine It rarely substitutes directly, because the hydriodic acid produced reverses the reaction; this can be avoided by the presence of precipitated mercuric oxide or iodic acid, which react with the hydriodic acid as fast as it is formed, and consequently remove it from the reacting system. As a rule it is preferable to use iodine in the presence of a carrier, such as amorphous phosphorus or ferrous iodide or to use it with a solvent. It is found that most organic compounds containing the grouping $CH_3{\cdot}CO{\cdot}C—$ or $CH_3{\cdot}CH(OH){\cdot}C—$ in the presence of iodine and alkali give iodoform, CHI_3 (*q.v.*).

Hydriodic Acid, HI, is formed by passing hydrogen and iodine vapour through a hot tube, but the reaction is reversible, $H_2+I_2\rightleftarrows 2HI$. On shaking iodine with a solution of sulphuretted hydrogen in water, a solution of hydriodic acid is obtained, sulphur being at the same time precipitated. The acid cannot be prepared by the action of concentrated sulphuric acid on an iodide on account of secondary reactions taking place, which result in the formation of free iodine and sulphur dioxide. The usual niethod is to make a mixture of amorphous phosphorus and a large excess of iodine and then to allow water to drop slowly upon it; the reaction starts readily, and the gas obtained can be freed from any admixed iodine vapour by passing it through a tube containing some amorphous phosphorus. It is a colourless sharp-smelling gas which fumes strongly on exposure to air. It readily liquefies at 0° C under a pressure of four atmospheres, the liquefied acid boiling at −34·14° C (730·4 mm.); it can also be obtained as a solid melting at −50·8° C. It is readily soluble in water, one volume of water at 10° C dissolving 425 volumes of the gas. The saturated aqueous solution is colourless and fumes strongly on exposure to air; after a time it darkens in colour owing to liberation of iodine. When boiled the solutions lose either acid or water until a solution containing 58% of HI is obtained, which distils unchanged at 127° C. This has a specific gravity of 1·7 and is used in the Zeisel method of determining methoxyl groups. The gas is readily decomposed by heat into its constituent elements. It is a powerful reducing agent, and is frequently employed for this purpose in organic chemistry; thus hydroxy-acids are readily reduced on heating with the concentrated acid, and nitro-compounds are reduced to amino-compounds, etc. It is preferable to use the acid in the presence of amorphous phosphorus, for the iodine liberated during the reduction is then utilized in forming more hydriodic acid, and consequently the original amount of acid goes much further. It forms addition compounds with unsaturated compounds.

It has all the characteristics of an acid, dissolving many metals with evolution of hydrogen and formation of salts, called *iodides.* The iodides can be prepared either by direct union of iodine with a metal, from hydriodic acid and a metal, oxide, hydroxide or carbonate, or by action of iodine on some metallic hydroxides or carbonates (such as those of potassium, sodium, barium, etc.; other products, however, are formed at the same time). The iodides as a class resemble the chlorides and bromides, but are less fusible and volatile. Silver, mercurous, mercuric and cuprous iodides are insoluble in water; lead iodide is sparingly soluble, whilst most of the other metallic iodides are soluble. Cupric iodide is unstable and breaks down to cuprous iodide and iodine. Strong heating decomposes the majority of the iodides. Nitrous acid and chlorine readily decompose them with liberation of iodine; the same effect is produced when they are heated with concentrated sulphuric acid and manganese dioxide. The soluble iodides, on the addition of silver nitrate to their nitric acid solution, give a yellow precipitate of silver iodide, which is insoluble in ammonia solution. Hydriodic acid and the iodides may be estimated by conversion into silver iodide.

Iodine combines with chlorine to form *iodine monochloride,* ICl, which may be obtained by passing dry chlorine over dry iodine until the iodine is completely liquefied. It is readily decomposed by water. The *trichloride,* ICl_3, results from the action of excess of chlorine on iodine, or from iodic acid and hydrochloric acid, or by heating iodine pentoxide with phosphorus

pentachloride. It crystallizes in long yellow needles and decomposes readily when heated into the monochloride and chlorine. It is readily soluble in water, but excess of water decomposes it. Iodine monochloride in glacial acetic acid solution is used for obtaining the "iodine value" of fats and oils in the Wijs method.

Iodine *pentoxide*, I_2O_5, the best known oxide, is obtained as a white crystalline solid when iodic acid is heated to 170° C; it is easily soluble in water, combining to regenerate iodic acid; and when heated to 300° C it breaks up into its constituent elements. It is used in the detection of carbon monoxide (see CARBON), which it oxidizes with liberation of iodine: $I_2O_5+5CO=I_2+5CO_2$. Iodine dioxide, IO_2 or I_2O_4, is a lemon-yellow solid obtained by acting on iodic acid with sulphuric acid, or by grinding iodine with cold fuming nitric acid.

Although *hypoiodous* acid is not known, it is extremely probable that on adding iodine or iodine monochloride to a dilute solution of a caustic alkali, hypoiodites are formed, the solution obtained having a characteristic smell of iodoform, and being of a pale yellow colour. It oxidizes arsenites, sulphites and thiosulphates immediately. The solution is readily decomposed on the addition of sodium or potassium bicarbonates with liberation of iodine. The hypoiodite disappears gradually on standing, and rapidly on warming, being converted into a mixture of iodide and iodate.

Iodic Acid, HIO_3, can be prepared by dissolving iodine pentoxide in water; by boiling iodine with fuming nitric acid, $6I+10HNO_3=6HIO_3+10NO+2H_2O$; by decomposing barium iodate with the calculated quantity of sulphuric acid, previously diluted with water; or by suspending iodine in water and passing in chlorine, $I_2+5Cl_2+6H_2O=2HIO_3+10HCl$. It is a white crystalline solid, dissolving readily in water to give an acidic solution. It is a most powerful oxidizing agent, readily changing phosphorus to phosphoric acid, arsenic to arsenic acid, silicon at 250° C to silica, and hydrochloric acid to chlorine and water. It is readily reduced, with separation of iodine, by sulphur dioxide, hydriodic acid or sulphuretted hydrogen, thus:—

$$HIO_3+5HI=3H_2O+3I_2;\quad 2HIO_3+5SO_2+4H_2O=5H_2SO_4+I_2;$$
$$2HIO_3+5H_2S=I_2+5S+6H_2O.$$

The salts, known as the iodates, can be prepared by the action of the acid on a base, or sometimes by the oxidation of iodine in the presence of a base. They are mostly insoluble or only very slightly soluble in water. The iodates of the alkali metals are, however, readily soluble in water (except potassium iodate). They are decomposed on heating, with liberation of oxygen, in some cases leaving a residue of iodide and in others a residue of oxide of the metal, with liberation of iodine as well as of oxygen. It is noteworthy that, although chlorine or bromine will displace iodine from an iodide, yet in these highly oxygenated acids the reverse obtains and iodine displaces chlorine (see the preparation of periodic acid).

Periodic acid, $HIO_4{\cdot}2H_2O$, is only known in the hydrated form. It can be prepared by the action of iodine on perchloric acid, or by boiling normal silver periodate with water: $2AgIO_4+4H_2O=Ag_2H_3IO_6+HIO_4{\cdot}2H_2O$. It is a colourless, crystalline, deliquescent solid which melts at 135° C, and at 140° C is completely decomposed into iodine pentoxide, water and oxygen. A remarkable feature of iodic and periodic acids is the ease with which they give complex salts, *e.g.*, $KH(IO_3)_2$, $KH_2(IO_3)_3$, K_5IO_6 (compare $HIO_4,2H_2O$), etc.

Iodine has extensive applications in volumetric analysis, being used more especially for the determination of copper in virtue of the reaction: $2CuSO_4+4KI=2K_2SO_4+Cu_2I_2+I_2$.

In medicine iodine is frequently applied externally as a counter-irritant, having powerful antiseptic properties. In the form of certain salts iodine is very widely used, for internal administration in medicine and in the treatment of many conditions usually classed as surgical, such as the bone manifestations of tertiary syphilis. The most commonly used salt is the iodide of potassium; the iodides of sodium and ammonium are almost as frequently employed, and those of calcium and strontium are in occasional use. The usual doses of these salts are from five to thirty grains or more. Their pharmacological action is as obscure as their effects in certain diseased conditions are consistently brilliant and unexampled. Our ignorance of their mode of action is cloaked by the term *deobstruent*, which implies that they possess the power of driving out impurities from the blood and tissues. Most notably is this the case with the poisonous products of syphilis. In its tertiary stages—and also earlier—this disease yields in the most rapid and unmistakable fashion to iodides; so much so that the administration of these salts is at present the best means of determining whether, for instance, a cranial tumour be syphilitic or not. No surgeon would think of operating on such a case until iodides had been freely administered and, by failing to cure, had proved the disease to be non-syphilitic. Another instance of this deobstruent power—"alterative," it was formerly termed—is seen in the case of chronic lead poisoning. The essential part of the medicinal treatment of this condition is the administration of iodides, which are able to decompose the insoluble albuminates of lead, which have become locked up in the tissues, rapidly causing their degeneration, and to cause the excretion of the poisonous metal by means of the intestine and the kidneys. The following is a list of the principal conditions in which iodides are recognized to be of definite value: metallic poisonings, as by lead and mercury, asthma, aneurism, arteriosclerosis, angina pectoris, gout, goitre, syphilis, haemophilia, Bright's disease (nephritis) and bronchitis.

A minute proportion of iodine in the diet appears to be essential for health. This was formerly supplied as an accidental impurity in table salt, but the highly purified article now used as a condiment is free from iodides, and in certain States (*e.g.*, some cantons of Switzerland) iodides are added to the drinking water. The deficiency is of greater significance in the case of small children, for the iodine is required for the synthesis of thyroxine, the active principle of the thyroid gland, which, however, has been artificially prepared by C. R. Harington and G. Barger (Biochem. J., 1927, 21, p. 169).

IODINE-BUSH or PICKLEWEED (Allenrolfea occidentalis), a North American plant of the goosefoot family (Chenopodiaceae), native to moist alkaline "cay soil from western Texas to central California. It is an erect, diffusely branched shrub, 2 ft. to 5 ft. high, with alternate, fleshy, green, apparently leafless, jointed branches, the leaves being reduced to minute pointed scales or wanting. The numerous small flowers are arranged spirally by threes in crowded cylindrical spikes, $\frac{1}{4}$ in. to $\frac{3}{4}$ in. long, borne in the axils of fleshy bracts near the ends of the branches. In appearance the plant is suggestive of a tall, much-branched form of the glasswort (*q.v.*) or samphire, to which it is closely allied.

IODINE VALUE, of an oil or fat, is the percentage of iodine it absorbs when dissolved in chloroform or carbon tetrachloride and treated with iodine chloride. This furnishes one of the most important methods of identifying an oil or fat; it gives a measure of the unsaturated fatty acids (*q.v.*) present, which gives a basis for the classification of oils, fats and waxes (*q.v.*).

IODOFORM, a valuable antiseptic discovered by G. S. Sérullas in 1822. Iodoform, CHI_3, is formed by the action of iodine and aqueous potassium hydroxide on ethyl alcohol, acetone, acetaldehyde, isopropyl alcohol and most compounds containing the group $CH_3{\cdot}CO{\cdot}C$—. It crystallizes in yellow hexagonal plates, melting at 119–120° C, and is readily soluble in alcohol or ether, but insoluble in water. It has a characteristic odour and is volatile in steam. On reduction with hydriodic acid, it yields methylene iodide, CH_2I_2.

Iodoform is also prepared by electrolysis of a solution of potassium iodide in the presence of alcohol or acetone. A solution of potassium iodide and sodium carbonate in water with the necessary alcohol is contained in a porous cell fitted with a lead anode, whilst the cathode compartment contains a solution of caustic soda and a nickel electrode. The electrolysis is carried out at a temperature of 70° C, with a current density of one ampère per square decimetre. After three hours the yield is 70% of the calculated quantity.

From its formula it can be seen to be strictly analogous with chloroform, $CHCl_3$, which is tnchloromethane, while iodoform is

tri-iodomethane.

IOLA, city, southeastern Kansas, U.S.A , on the Neosho river; the county seat of Allen county. It is on federal highways 54, 59 and 169 and is served by the Missouri-Kansas-Texas, the Missouri Pacific and the Santa Fe railways. The population in 1940 was 7,244. It is the trade centre of one of the leading dairy districts of the state. Its industries include a milk condensery with a capacity of 150,000 lb. daily, large creameries, a cement plant, ironworks and a dress factory. Iola was founded in 1859, by a company that was dissatisfied with the location of the county seat at Humboldt. It became the county seat in 1865, and was chartered as a city in 1870. Natural gas was discovered here on Christmas Day, 1893, and a period of rapid development followed. The city has a commission form of government.

IOLITE: see CORDIERITE.

ION, of Chios, Greek poet, lived in the age of Pericles. At an early age he went to Athens, where he made the acquaintance of Aeschylus. He was an admirer of Cimon and an opponent of Pericles. Later he met Sophocles in Chios at the time of the Samian war. Aristophanes' Peace, 830 ff., seems to show that he died before 421. His first tragedy was produced between 452–449 B.C.; and in 429 he was third to Euripides and Iophon. In a subsequent year when he gained both the tragic and dithyrambic prizes, he gave a jar of Chian wine to every Athenian citizen (Athanaeus p. 3). According to the scholiast on Aristophanes (*loc. cit.*) he composed comedies, dithyrambs, epigrams, paeans, hymns, scolia, encomia and elegies. He also wrote an account of the antiquities of Chios and ἐπιδημίαι, recollections of visitors to the island.

See C. Nieberding, *De Ionis Chii vita (1836,* containing the fragments); **F.** Allègre, *De Ione Chio* (1890), an exhaustive monograph; and Bentley, *Epistola* ad *Millium.*

IONA or **ICOLMKILL,** island, Inner Hebrides, Argyllshire, Scotland, 6½ m. S. of Staffa and 1¼ m. W. of the Ross of Mull, from which it is separated by the shallow Sound of Iona. Pop. (1931) 141. It is about 3½ m. long and 1½ m. broad; its area being some 2,200 acres, of which about one-third is under cultivation, oats, potatoes and barley being grown. In the rest of the island grassy hollows, yielding pasturage for a few hundred cattle and sheep and some horses, alternate with rocky elevations, which culminate on the northern coast in Duni (332 ft.), from the base of which a stretch of white shell sand, partly covered with grass, stretches to the sea. To the south-west the island is fringed with precipitous cliffs. There is a ferry to the Ross of Mull. The inhabitants depend partly on agriculture and partly on fishing. Near the S.E. point is a marble quarry.

The original form of the name Iona was Hy, Hii or I, the Irish for Island. By Adamnan in his Life of St. Columba it is called Ioua *insula,* and the present name Iona is said to have originated in some transcriber mistaking the *u* in Ioua for n. It also received the name of Hii-colum-kill (Icolmkill), that is, "the island of Columba of the Cell," while by the Highlanders it has been known as Innis nan Druidhneah ("the island of the Druids"). This last name seems to imply that Iona was a sacred spot before St. Columba landed there in 563 and laid the foundations of his monastery. After this date it developed into the most famous centre of Celtic Christianity, the mother community of numerous monastic houses, whence missionaries were despatched for the conversion of Scotland and northern England, and to which for centuries students flocked from all parts of the north. After St. Columba's death his relics rested here until they were removed to Ireland early in the 9th century. Pilgrims came to die in the island, in order that they might lie in its holy ground; and from all parts of northern Europe the bodies of the illustrious dead were brought here for burial. Several times the monastery was plundered and burnt and the monks massacred by the heathen Norse sea-rovers, attracted by the wealth of the foundation. Late in the 11th century the desecrated monastery was restored by Queen Margaret, wife of Malcolm Canmore, king of Scotland; and in 1203 a new monastery and a nunnery were founded by Benedictine monks who either expelled or absorbed the Celtic community. In 838 the Western Isles, then under the rule of the kings of Man, were erected into a bishopric of which Iona was the seat. When in 1098 Magnus III., "Barefoot," king of Norway, ousted the jarls of Orkney from the isles, he united the see of the Isles (Sudreyar, "the southern islands," Lat. Sodorenses *insulae*) with that of Man, and placed both under the jurisdiction of the archbishopric of Trondhjem. About 1507 the island again became the seat of the bishopric of the Isles; but with the victory of the Protestant party in Scotland its ancient religious glory was finally eclipsed, and in 1561 the monastic buildings were dismantled by order of the Convention of Estates. (For the political fortunes of Iona see HEBRIDES.)

The cathedral church of St. Mary dates from the 13th century; a great portion of the walls with the tower are still standing. The choir and nave have been roofed, and the cathedral has in other respects been restored, the ruins having been conveyed in 1899 to a body of trustees by the eighth duke of Argyll. The remains of the conventual buildings still extant, to judge by the portion of a Norman arcade, are of earlier date than the cathedral. The small chapel of St. Oran, or Odhrain, the oldest building on Iona, which was built by Queen Margaret on the supposed site of Columba's cell, was in process of restoration in 1927. Of the nunnery only the chancel and nave of the Norman chapel remain, the last prioress, Anna (d. 1543), being buried within its walls. The cemetery, called in Gaelic *Reilig* Oiran ("the burial-place of kings"), is said to contain the remains of forty-eight Scottish, four Irish and eight Danish and Norwegian monarchs, but most of the monumental stones were thrown into the sea at the time of the Reformation. Those that remain have been restored and enclosed. The finest, those of Maclean and St. Martin, are still almost perfect, and are richly carved.

IONIA, in ancient geography, the name given to a portion of the west coast of Asia Minor, adjoining the Aegean Sea and bounded on the east by Lydia. It consisted of a narrow strip of land near the coast, which together with the adjacent islands was occupied by immigrant Greeks (Ionians), and thus distinguished from the interior district, inhabited by the Lydians. According to the universal Greek tradition, the cities of Ionia were founded by emigrants from the other side of the Aegean (see IONIANS), and their settlement was connected with the legendary history of the Ionians in Attica, for the colonists were led by Neleus and Androclus, sons of Codrus, the last king of Athens. Modern thought tends to support the popular Greek idea that Ionia received its main Greek element rather late—after the descent of the Dorians, and, therefore, after the Aegean period. Herodotus tells us (i. 146) that the colonists comprised settlers from many different tribes and cities of Greece (a fact indicated also by the local traditions of the cities), and that they intermarried with the native people.

The cities called Ionian in historical times were twelve in number—an arrangement copied as it was supposed from the constitution of the Ionian cities in Greece which had originally occupied the territory in the north of the Peloponnese subsequently held by the Achaeans. These were (from south to north)—Miletus, Myus, Priene, Ephesus, Colophon, Lebedus, Teos, Erythrae, Clazomenae and Phocaea, together with Samos and Chios. Smyrna (*q.v.*), originally an Aeolic colony, was afterwards occupied by Ionians from Colophon, and became an Ionian city—an event which had taken place before the time of Herodotus. But at what period it was admitted as a member of the league is ndt known. Like the Amphictyonic league in Greece, the Ionic was rather of a sacred than a political character; every city enjoyed absolute autonomy, and, though common interests often united them for a common political object, they never formed a real confederacy like that of the Achaeans or Boeotians.

Ionia was a mountainous country, 90 m. long from north to south, with a breadth varying from 20 to 30 m.; to this area must be added that of the peninsula of Mimas, together with that of two large islands. Among the outstanding peaks were Mimas and Corycus, situated on the peninsula which stands out to the west. facing the island of Chios; Sipylus, to the north of Smyrna; Corax, extending to the south-west from the Gulf of Smyrna, and descending to the sea between Lebedus and Teos.

The strongly marked range of Mycale, a continuation of Messogis in the interior, forms the bold headland of Trogilium or Mycale, opposite Samos. None of these mountains attains a height of more than 4,000 feet. The district comprised three extremely fertile valleys; the Hermus in the north, flowing into the Gulf of Smyrna; the Cayster, which flowed under the walls of Ephesus; and the Maeander, which in ancient times discharged its waters into the deep gulf that once came up to the walls of Miletus, but which has been gradually silted up by deposits brought down by the river. In ancient times Ionia was considered the most fertile of all the provinces of Asia Minor. It still produces an abundance of fruit of all kinds.

The colonies naturally became prosperous. Miletus especially was at an early period one of the most important commercial cities of Greece; and in its turn became the parent of numerous other colonies, which extended all around the shores of the Euxine and the Propontis from Abydus and Cyzicus to Trapezus and Panticapaeum. The mariners of Phocaea extended their influence to the shores of the western Mediterranean. Ephesus, though it did not send out any colonies of importance, from an early period became a flourishing city.

History.— About the middle of the 7th century B.C., the Cimmerii (see SCYTHIA) ravaged a great part of Asia Minor, including Lydia, and sacked Magnesia on the Maeander, but failed to take Ephesus. About 700 B.C. Gyges, first Mermnad king of Lydia, invaded the territories of Smyrna and Miletus, and is said to have taken Colophon as his son Ardys did Priene. But it was not till the reign of Croesus (560–545 B.C.) that the cities of Ionia successively fell under Lydian rule. The defeat of Croesus by Cyrus was followed by the conquest of all the Ionian cities. They became subject to the Persian monarchy with the other Greek cities of Asia. They continued to enjoy a considerable amount of autonomy, but were subject to local despots. It was at the instigation of one of these, Histiaeus (*q.v.*) of Miletus, that in about 500 B.C. the principal cities broke out into insurrection against Persia. They were at first assisted by the Athenians, with whose aid they penetrated into the interior and burnt Sardis, an event which ultimately led to the Persian invasion of Greece. But the Ionian fleet was defeated off the island of Lade, and the destruction of Miletus after a protracted siege was followed by the reconquest of all the Asiatic Greeks.

The Greek victories during the Persian war had the effect of enfranchizing their kinsmen on the other side of the Aegean; and the battle of Mycale (479 B.C.), in which the defeat of the Persians was in great measure due to the Ionians, secured their emancipation. They henceforth became the dependent allies of Athens (see DELIAN LEAGUE), though still retaining their autonomy, which they preserved until the peace of Antalcidas in 387 B.C. once more placed them as well as the other Greek cities in Asia under the nominal dominion of Persia. They appear, however, to have retained a considerable amount of freedom until the invasion of Asia Minor by Alexander the Great. After the battle of the Granicus most of the Ionian cities submitted to the conqueror. Miletus, which alone held out, was reduced after a long siege (334 B.C.). From this time they passed under the dominion of the successive Macedonian rulers of Asia, but continued, with the exception of Miletus (*q.v.*), to prosper both under these Greek dynasties and after they became part of the Roman province of Asia.

Ionia was the home of the Ionian School of Philosophy (*q.v.*) and it led the way also for the brilliant artistic development of Athens in the 5th century. Ionian art flourished in the 8th, 7th and 6th centuries, and is distinguished by the fineness of workmanship and minuteness of detail with which it treated subjects, inspired to some extent by non-Greek models. (See GREEK ART.)

See D. G. Hogarth, *Ionia and the East* (1909).

IONIA, city, Michigan, U.S.A., on the Grand river, 34m. E. of Grand Rapids; the county seat of Ionia county. It is served by the Grand Trunk and the Pere Marquette railways. The population was 6,935 in 1920 (89% of native whites) and in 1940 by the federal census 6,392. Behind the city is an irregular semicircle of hills commanding extensive views of the valley. Ionia is the trade centre of a rich farming district, and the seat of the state reformatory and a state hospital for the insane. The manufactures include automobile fittings and trim, reed chairs, florists' pots, wire and furniture. Ionia was settled in 1833 by colonists from German Flats, near Herkimer, N.Y. It was incorporated as a village in 1857, and was chartered as a city in 1873.

IONIAN ISLANDS, the collective name for the Greek islands of Corfu, Cephalonia, Zante, Santa Maura, Ithaca, Cythera (Cerigo) and Paxo (*qq.v.*), with their minor dependencies. These islands, though often described as the *Heptanesus* ("Seven Islands"), have no geographical unity. The name "Ionian" is obscure, but is probably due to ancient Ionian colonies, for example in Corfu from Eretria. The political unity of the islands is comparatively modern; their independence lasted only seven years (1800–7). Pop. (1928, last census before World War II) 213,157.

The Ionian islands consist almost entirely of Cretaceous and Tertiary beds, but in Corfu Jurassic deposits have been found. The oldest beds which have yet been recognized are shales and hornstones with Liassic fossils. These are overlaid conformably by a thick series of platy Viglas limestone, representing the rest of the Jurassic and the lower Cretaceous. Then follow dolomites and unbedded *Hippurites* limestones evidently Upper Cretaceous age. The Eocene beds are folded with the Cretaceous. Both occasionally assume the form of Flysch. Miocene beds are found in Corfu and Zante, and Pliocene deposits cover much of the low ground. (X.)

HISTORY

Mediaeval and Venetian Periods.— The beginning of Heptanesian history dates from the 9th century. Leo the Philosopher (*c.* A.D. 890) formed all or most of the islands into a distinct province of the Eastern empire under the title of the Thema of Cephallenia. Robert Guiscard captured Corfu (1081) and Cephalonia, but his early death prevented the establishment of a Norman dynasty. When the Latin empire was established at Constantinople in 1204 the Venetians received Corfu. After defeating the Genoese corsair Leon Vetrano, the senate granted fiefs in Corfu to ten noble families in order that they might colonise it (1206). The Greek "Despot" of Epeiros, however, captured the first Venetian colony in 1214, and a long period of Epeirote, Sicilian and Neapolitan-Angevin rule followed till in 1386 the people of Corfu made voluntary submission to the Venetian republic.

Paxo, created a barony, was treated as part of Corfu. The County Palatine of Cephalonia (with Zante), seized by Matteo Orsini in 1194, owned the suzerainty first of Venice, then of Achaia, to which it was annexed in 1324. In 1357 it was bestowed upon the Tocco family of Benevento, and was united with Santa Maura and Ithaca (called Val di Conspare) in the Duchy of Leucadia. In 1479 the Turks annexed these four islands. But they gradually became Venetian; Cephalonia and Ithaca 1483–85, and from 1500 onwards; Zante 1482 and from 1485, and Santa Maura 1502–03 and from 1684. Cerigo, a Venetian Marquisate of the Venier family from 1207, became a Venetian colony in 1363, but was parcelled out between Venice and the Venier in 1393.

The Venetians, who exacted heavy contribution~sfrom the islands, won the adherence of the principal native families by the bestowal of titles and appointments; the Roman Catholic Church was established, and the Italian and Greek races were largely assimilated by intermarriage; Greek ceased to be spoken except by the lower classes, which remained faithful to the orthodox communion. On the fall of the Venetian republic in 1797 the Treaty of Campo Formio annexed the Ionian islands to France; but a Russo-Turkish force drove out the French at the close of 1798; and in the spring of 1799 Corfu capitulated. By treaty with the Porte in 1800, the Emperor Paul erected the "Septinsular Republic," but the Treaty of Tilsit (1807) declared the islands an integral part of the French empire. They were incorporated with the province of Illyria (*q.v.*); but British forces under General Oswald took Zante, Cephalonia and Cerigo in 1809, and Santa Maura in 1810; Colonel (afterwards Sir Richard) Church

(*q.v.*), reduced Paxo in 1814; and after the abdication of Napoleon, Corfu, which had been defended by General Donzelot, was, by order of Louis XVIII. surrendered to Sir James Campbell. By the Treaty of Paris (Nov. g, 1815) the contracting powers (Great Britain, Russia, Austria and Prussia) agreed to place the "United States of the Ionian Islands" under the exclusive protection of Great Britain.

British Protectorate. — The constitutions, voted by a constituent assembly in 1817 and applied in the following year, placed the administration in the hands of a senate of six members and a legislative assembly of 40 members; but the real authority was vested in the high commissioner, Sir Thomas Maitland ("King Tom") (1815). The successive British commissioners, General Sir Frederick Adam (1823), Lord Nugent (1832) and Sir Howard Douglas (1835–41) did much for the administration, justice, education and communications of the islands, but their firm, often despotic rule was resented by the natives, the principal exponent of the opposition being the historian Andreas Mustoxidi (d. 1861). A complete change of policy was inaugurated by Mr. Mackenzie (1841–43), and Lord Seaton (1843–49) was induced by the European disturbances of 1848 to initiate a number of important reforms. But the party in favour of union with Greece was rapidly growing. Serious insurrections of the peasantry, especially in Cephalonia, had to be put down by military force, and the parliament passed a resolution in favour of immediate union with Greece.

Cession to Greece. — Contrary to the expectations of the Greeks, Mr. Gladstone, who toured the islands as high commissioner extraordinary, did not propose the abolition of the protectorate, and his successor, Sir Henry Storks, seemed indifferent or blind to the popular feeling, but on the abdication of King Otho of Greece in 1862 the British Government declared to the provisional government of Greece that the selection of Prince William George of Gliicksberg would be followed by the cession of the Ionian islands. After the prince's election by the national assembly in 1863 the high commissioner laid before the Ionian Parliament the conditions of the cession. The rejection of one condition (the demolition of the fortifications of Corfu) led to a new prorogation, but on March 29, 1864, the plenipotentiaries of the five great Powers signed the treaty by which the protectorate was ended. Neutrality was confined to Corfu and Paxo. On May 3, 1864 Sir Henry Storks left Corfu with the British troops and men-of-war. King George made his entry into Corfu on June 6.

After their annexation to Greece the history of the Ionian islands was uneventful; their prosperity somewhat declined. Corfu with Paxo; Cephalonia; Santa Maura (Levkas) with Ithaca and Zante (Zacynthos) each formed separate monarchies or departments; Cerigo (Cýthera) formed part of the monarchy of Laconia. The islands retained the exemption from direct taxation which they enjoyed under the British protectorate; in lieu of this there was an *ad* valorem tax of 20½% on exported oil and a tax of 6% on wine exported to Greek ports; these commodities were further liable to an export duty of 1½% levied on all agricultural produce and articles of local manufacture. Axis troops occupied the islands in 1941.

IONIAN MODE: see HARMONY and PLAINSONG.

IONIANS. This name was used in classical times for one of the four divisions of the Greek world, the remaining three being Aeolic, Doric and Arcado-Cypriote or Achaean. This is strictly a linguistic division, and the Greeks did not recognize it in an exact sense. Aeolian, Dorian and Ionian were well-marked divisions socially as well as linguistically. There was also a strong race antipathy between Dorian and Ionian, manifested particularly in the Peloponnesian War, in which Athens and Sparta were the protagonists. Each was inclined to regard the other as not fully Hellenic. The Ionians claimed that the Dorians were the descendants of non-Greek northern invaders commingled with an earlier Greek population of the Peloponnese. The Dorians asserted that the Ionians were pre-Greek or Pelasgian, standing much in the same relationship to true Greeks as do the Welsh and other Britons to the Anglo-Saxons.

Attica was the centre of Ionic culture on the mainland. Euboea and the Cyclades were also regarded as Ionic with the exception of the Dorian islands of Melos and Thera, but the name Ionia itself in classical times was confined to the tract of land on the coast of Asia Minor that contained the Ionic cities. This lay between Aeolis on the north and Doris on the south, and extended from Smyrna to Miletus. The twelve cities, while retaining their independence in true Greek fashion, formed a league for social and religious purposes, their central cult being that of Poseidon carried on upon Mt. Mycale. The Ionians claimed that this worship derived from Achaia in the Peloponnese, but it at least contained elements that were Anatolian in origin. The Ionian cities were energetic, thriving and opulent. Their wealth made them luxurious and they had a name for effeminacy. They were subdued by Croesus, king of Lydia, in the middle of the sixth century and passed at his subjugation under the Persian empire. In 500 they revolted but were conquered by King Darius and a higher tribute was imposed upon them. After the successful termination of the Persian wars they were set free by the Greeks of the mainland under the leadership of Athens, but later fell again under Persia when that empire recovered its strength. They remained nominally subject to Persia till its overthrow by Alexander the Great. There were various Ionic colonies on the coast of the Euxine and in Sicily and Magna Graecia.

The chief characteristics of the Ionic dialect to which Attic was closely akin were: (i.) the representation of an original long ā by *ē*, for example in the word μήτηρ for Doric, etc., μᾶτηρ, Lat. *mater;* (ii.) the lengthening of the vowel before a nasal or liquid that preceded a lost digamma, *e.g.*, ξεῖνος, κούρη for Attic ξένος, κόρη; (iii.) the nom. plur. of the personal pronouns in -εις instead of -ες, *e.g.*, ἡμεῖς for Doric ἀμές; (iv.) the termination -ου for pronominal adverbs of place (ποῦ, etc.) for West Greek -ει; the third person plural of certain aorist forms in -σαν (ἔθεσαν, ἔδοσαν) by analogy from an s-aorist; (v.) the very early loss of digamma, etc. Ionic-Attic with Aeolic formed loosely an eastern group of dialects as opposed to Doric and North-West Greek. The turning of the original dialect of the Homeric poems, Aeolic or otherwise, into Ionic where possible, *i.e.*, where the exigencies of the metre, vocabulary, and other considerations permit, produced the artificial Epic dialect.

The name Ionians had probably a more extensive use in early times than in historical. In the Pentateuch, in the 15th or 16th century B.C. (Gen. x. 2), Javan appears as a son of Japheth. To the Hebrews the name represented the whole Greek race. To the Persians the Greeks were known as Yauna. It does not follow from this fact that the Greeks knew themselves by this same, for the case may be parallel to the Italians and Illyrians later applying to them the name of Graeci, that of the small Epirote tribe with whom they first came in contact. In view of the name of the

Ionian sea, which was ancient, it is possible that the mainland of Greece was once known as Ionia or its inhabitants as Ionians. No Ionian Greeks lived in historical times on the shores of the Ionian sea.

The Homeric Ionians were inhabitants of Attica (*Il.* xiii. 685). In the Hesiodic genealogies Ion was son of Xuthus and brother of Achaeus. According to Herodotus the original home of the Ionians was in north-east Peloponnese in the region around Troezen. Hence they were expelled by the Achaeans and occupied Attica, from which they later spread to the Cyclades and to Asia Minor. This traditional history of the Ionians is feasible and need not be dogmatically contradicted. We may perhaps regard the Ionians as pre-Achaean inhabitants of the Peloponnese disturbed by Achaean invaders from the eastern Aegean. This is the view of Kretschmer and of N. P. Nilsson, except that they bring the Achaeans as a second wave of Greek-speaking peoples from the north. Nilsson regards the Ionians as the foremost wave of Greek-speaking peoples to reach Greece and as the originators of the Mycenaean culture. Later came the Dorian invasion of the Peloponnese, consisting perhaps of two coincident elements, an irruption of Illyrian and Epirote tribes from the north-west and an invasion by sea from Crete. The Ionians when they emerge into history are a recognized integral part of the Greek world, distinguished like the Dorians by a well-marked dialect and a common cult. *(See* DORIANS; ACHAEANS: GREECE: *History.)*

IONIAN SCHOOL OF PHILOSOPHY. Under this name are included a number of philosophers of the 6th and 5th centuries B.C. Mainly Ionians by birth, they are united by a local tie and represent all that was best in the early Ionian intellect. It is a most interesting fact in the history of Greek thought that its birth took place not in Greece but in the colonies on the west coast of Asia Minor. But not only geographically do these philosophers form a school; they are one in method and aim. They all sought to explain the material universe as given in sensible perception; their explanation was in terms of matter, movement, force. In this they differed from the Eleatics and the Pythagoreans who thought in the abstract, and explained knowledge and existence in metaphysical terminology. In tracing the development of their ideas, two periods may be distinguished. The earliest thinkers down to Heraclitus endeavoured to find a material substance of which all things consist; Heraclitus, by his principle of universal flux, took a new line and explained everything in terms of force, movement, dynamic energy. The former asked the question, "What is the substratum of the things we see?"; the latter, "How did the sensible world become what it is; of what nature was the motive force?"

The first name in the list of the Ionian philosophers—and, indeed, in the history of European thought—is that of Thales (*q.v.*). He first, so far as we know, sought to go behind the infinite multiplicity of phenomena in the hope of finding an infinite unity from which all difference has been evolved. This unity he decided is Water. It is impossible to discover precisely what he conceived to be the relation of this unity to the plurality of phenomena. Later writers from whom we derive our knowledge of Thales attributed to him ideas which seem to have been conceived by subsequent thinkers. Thus the suggestion preserved by Stobaeus that he conceived water to be endowed with mind is discredited by the specific statement of Aristotle that the earlier physicists (physiologi) did not distinguish the material from the moving cause, and that before Anaxagoras no one postulated creative intelligence. Again in the *De anima* (i. 5) Aristotle quotes the statement that Thales attributed to water a divine intelligence, and criticizes it as an inference from later speculations. It is probably safest to credit Thales with the bare mechanical conception of a universal material cause, leaving pantheistic ideas to a later period of thought.

The successors of Thales were Anaximander and Anaximenes, who also sought for a primal substance of things. Anaximander postulated a corporeal substance unlike any of the known substances. This substance he called "the Indeterminate" (τὸ ἄπειρον). He felt that all determinate things have emerged from primal unity (first called ἄρχη by him) into which they must ultimately return. Change, growth and decay he explained on the principle of mechanical compensation.

Anaximenes, pupil of Anaximander, seems to have rebelled against the extreme materialism of his master. Perceiving that air is necessary to life, that the universe is surrounded by air, he was convinced that out of air all things have resulted. The process by which things grow is twofold, condensation (πύκνωσις) and rarefaction (ἀραίωσις), or, in other words, *heat* and cold. From the former process result cloud, water and stone; from the latter, fire and aether. This theory is closely allied to that of Thales, but it is superior in that it specifies the processes of change. Further, it is difficult not to accept Cicero's statement that Anaximenes made air a conscious deity; we are, at all events, justified in regarding Anaximenes as a link (perhaps an unconscious link) between crude Hylozoism (*q.v.*) and definitely metaphysical theories of existence.

We have seen that Thales recognized change, but attempted no explanation; that Anaximander spoke of change in two directions; that Anaximenes called these two directions by specific names. From this last, the transition to the doctrine of Heraclitus is easy. He felt that change is the essential fact of experience and pointed out that any merely physical explanation of plurality is inherently impossible. The Many is of Sense; Unity is of Thought. Being is intelligible only in terms of Becoming. That which is, is what it is in virtue of its perpetually changing relations (πάντα ῥεῖ καὶ οὐδὲν μένει). By this recognition of the necessary correlation of Being and Not-being, Heraclitus is in a very real sense the father of metaphysical and scientific speculation, and in him the Ionian school of philosophy reached its highest point. Yet there is reason to doubt the view of Hegel and Lassalle that Heraclitus recognized the fundamental distinction of subject and object and the relations of mind and matter. Like the early Ionians he postulated a primary substance, fire, out of which all things have emerged and into which all must return. This elemental fire is in itself a divine rational process, the harmony of which constitutes the law of the universe. Human knowledge consists in the comprehension of this all-pervading harmony as embodied in the manifold of perception; the senses are "bad witnesses" in that they report multiplicity as fixed and existent in itself rather than in its relation to the One. This theory gives birth to a sort of ethical by-product whose dominant note is Harmony, the subordination of the individual to the universal reason; moral failure is proportionate to the degree in which the individual declines to recognize his personal transience in relation to the eternal Unity. From the same principle there follows the doctrine of Immortality. The individual, like the phenomena of sense, comes out 'of the infinite and again is merged; hence on the one hand he is never a separate entity at all, while on the other hand he exists in the infinite and must continue to exist. Moreover, the soul approaches most nearly to perfection when it is least differentiated from elemental fire; it follows that "while we live our souls are dead within us, but when we die our souls are restored to life." This doctrine is at once the assertion and the denial of the self, and furnishes a striking parallel between European thought in its earliest stages and the fundamental principles of Buddhism. Knowledge of the self is one with knowledge of the Universal Logos (Reason); such knowledge is the basis not only of conduct but of existence itself in its only real sense.

Thus far the Ionian philosophers had held the field of thought. Each succeeding thinker had more or less assumed the methods of Thales, and had approached the problem of existence from the empirical side. About the time of Heraclitus, however, there sprang up a totally new philosophical spirit. Parmenides and Zeno *(see* ELEATIC SCHOOL) enunciated the principle that "Nothing is

born of nothing." Hence the problembecomes adialectical a priori speculation wherein the laws of thought transcend the sense-given data of experience. It was therefore left for the later Ionians to frame an eclectic system, a synthesis of Being and Not-being, a correlation of universal mobility and absolute permanence. This examination of diametrically opposed tendencies resulted in several different theories. It will be sufficient here to deal with Anaxagoras, Diogenes of Apollonia, Archelaus and Hippo, leaving Empedocles, Leucippus and Democritus to special articles (*q.v.*). The latter three do not belong strictly to the Ionian School.

Anaxagoras (*q.v.*) elaborated a quasi-dualistic theory according to which all things have existed from the beginning. Originally they existed in infinitesimal fragments, infinite in number and devoid of arrangement. Amongst these fragments were the seeds of all things which have since emerged by the process of aggregation and segregation, wherein homogeneous fragments came together. These processes are the work of Nous (νοῦς) which governs and arranges. But this *Nous* or Mind, is not incorporeal; it is the thinnest of all things; its action on the particle is conceived materially. It originated a rotatory movement, which arising in one point gradually extended till the whole was in motion, which motion continues and will continue infinitely. By this motion things are gradually constructed not entirely of homogeneous particles (the homoeomerê, ὁμοιομερῆ) but in each thing with a majority of a certain kind of particle. It is this aggregation which we describe variously as birth, death, maturity, decay, and of which the senses give inaccurate reports. His vague dualism works a very distinct advance upon the crude hylozoism of the early Ionians (*see* ATOM), and the criticisms of Plato and Aristotle show how highly his work was esteemed The great danger is that we should credit him with more than he actually thought. His *Nous* was not a spiritual force; it was no omnipotent deity; it is not a pantheistic world-soul. But by isolating Reason from all other growths, by representing it as the motor-energy of the cosmos, in popularizing a term which suggested personality and will, Anaxagoras gave an impetus to ideas which were the basis of Aristotelian philosophy in Greece and in Europe at large.

In Diogenes of Apollonia we find a return to Anaximenes. Diogenes (*q.v.*) began by insisting on the necessity of there being only one principle of things, herein contradicting the pluralism of Heraclitus. This principle is that of the universal homogeneity of nature; all things are at bottom the same, or interaction would be impossible. This universal substance is Air. But Diogenes went much farther than Anaximenes by attributing to air not only infinity and eternity but also intelligence.

Another pupil of Anaxagoras was Archelaus of Miletus (*q.v.*). His work was mainly the combination of previous views, except that he is said to have introduced an ethical side into the Ionian philosophy. "Justice and injustice," he said, "are not natural but legal." He endeavoured to overcome the dualism of Anaxagoras, and in so doing approached more nearly to the older Ionians.

The last of the Ionians whom we need mention is Hippo (*q.v.*), who, like Archelaus, is intellectually amongst the earlier members of the school. He thought that the source of all things was moisture, and is by Aristotle coupled with Thales (*Metaphysics*, A 3).

IONIC ORDER, one of the classic orders (*q.v.*), usually listed as the second Greek or the third Roman. It is characterized by the capital whose most important feature is a horizontal band terminating at either end in large spiral scrolls or volutes.

IONIC THEORY: see CHEMICAL ACTION and ELECTROLYSIS.

IONIZATION POTENTIAL: see RESONANCE POTENTIALS.

IONS, CATALYTIC ACTION OF. The fact that many reactions are accelerated by acids and bases has been generally associated with the idea that the hydrogen and hydroxyl ions are unique in the possession of catalytic qualities. The term hydrogen ion is here understood to refer to the hydrated form $H\cdot H_2O$ or oxonium ion OH_3^+. In the case of acid catalysis, the simple hydrogen ion theory met for a long time with almost universal acceptance for the reason that it served to correlate with a fair degree of precision a large body of experimental facts. More recent studies, in which new reactions have been subjected to minute examination indicate, however, that there is in general no simple proportionality between the catalytic activity of an acid and either the concentration or the thermodynamic activity of the hydrogen ion. On the other hand, the observations show clearly that catalytic activity is by no means peculiar to the hydrogen and hydroxyl ions, but that similar qualities must be attributed to other positive and negative ions and also to electrically neutral molecules. The catalytic effects produced by a weak acid HA,-when admixed with the corresponding salt for the purpose of reducing the preponderating influence of the hydrogen ion, require, indeed, for their representation an equation of the form

$$v=k_h[OH_3^+]+k_m[HA]+k_w[H_2O]+k_a[\bar{A}]+k_{OH}[O\bar{H}]$$

in which the total observed catalytic action is expressed as the sum of the joint effects due to the positive hydrogen ion, the neutral molecules HA and H_2O and the negative ions $\bar{A}$ and $O\bar{H}$. The relative magnitudes of the individual catalytic effects depend on the nature of the reaction and also on the solvent medium. As might have been anticipated, the values of k_m, k_w, and k_a are usually very small compared with the values of k_h and k_{OH}.

If for a given reaction, the values of k_m and k_a for a series of different acids are compared, it is found that with increasing ionisation constant of the acid, the magnitude of k_m increases whilst that of k_a diminishes. The high efficiency of the hydroxyl ion as a catalytic agent is thus connected with the fact that water is an acid with a very small ionisation constant.

If certain secondary effects which depend on variations in the reaction medium are ignored, the results of recent work indicate that the catalytic effects which are produced by the positive and negative ions resulting from the dissociation of the acid HA may be expressed in terms of the hydrogen ion concentration in the form of a general relation which is independent of the nature of the acid and of its concentration. The relation in question, which may be put in the form $r=\frac{1}{2}(n+\frac{1}{n})$ where r is a measure of the catalytic effect of the ions, and n a measure of the hydrogen ion concentration, is also independent of the temperature, of the nature of the solvent medium and even of the nature of the catalysed reaction. The catalytic effects associated with the hydrogen and hydroxyl ions conform closely to the requirements of this generalisation.

As the result of catalytic observations, it is now recognised that the traditional conception of the relations between acids and bases is inadequate and requires modification. The modern view assigns to the free hydrogen ion or proton the rôle of the connecting link between the acids and bases as represented by the formula: acid $\rightleftarrows$ base$+H^+$. In accordance with this view OH_3^+, NH_4^+, HCl and CH_3CO_2H are acids, and NH_3, $\overline{Cl}$, $CH_3\overline{CO_2}$ are bases. The water molecule affords an example of an amphoteric substance in that it may act as a proton donator (acid) or as a proton acceptor (base) in accordance with $H_2O \rightarrow H^+ + O\bar{H}$ and $OH_3^+ \rightarrow H_2O + H^+$ respectively. (H. M. D.)

IOPHON, Greek tragic poet, son of Sophocles. He gained the second prize in 428 B.C., Euripides being first, and Ion third. In the *Frogs* of Aristophanes (405) he is spoken of as the only good Athenian tragic poet. He wrote 50 plays, of which only a few fragments remain. It is said that Iophon accused his father of being incapable of managing his affairs and that Sophocles was

triumphantly acquitted, on reading the famous chorus of the *Oedipus at Colonus* (688 ff.).

See Aristophanes, *Frogs*, 73, 78, with scholia; Cicero, *De senectute*, vii. 22; Plutarch, *Moralia*, 785, B; O. Wolff, *De Iophonte poëta* (Leipzig, 1884); *A.* Nauck, *Tragicorum Graecorunz fragmenta* (1889).

IOTA, the ninth letter of the Greek alphabet corresponding to the ninth letter of the English alphabet. *See* I.

I.O.U. ("I owe you"), a written acknowledgment of a debt. It usually runs thus:

To——. I. O. U.——

(Signed) ——. Date ——.

An I.O.U., if worded as above, or even if the words "for value received" are added, needs no stamp in Britain, as it contains no term of agreement. If any such words as "to be paid on such a day" are added it requires a stamp. An I.O.U. should be addressed to the creditor by name, though its validity is not impaired by such omission. Being a distinct admission of a sum due, it is *prima facie* evidence of an account stated, but where it is the only item of evidence of account it may be rebutted by showing there was no debt and no demand which could be enforced by virtue of it. An I.O.U. is not negotiable in the technical sense. *(See* NEGOTIABLE INSTRUMENT.)

IOVILAE or JOVILAE, a latinized form of *iŭvilas*, the name given by the Oscan-speaking Campanians in the 5th, 4th and 3rd centuries B.C. to an interesting class of monuments, not yet fully understood. They all bear crests or heraldic emblems proper to some family or group of families, and inscriptions directing the annual performance of certain ceremonies on fixed days. While some of them are dedicated to Jupiter (in a special capacity, which our present knowledge of Oscan is insufficient to determine), others were certainly found attached to graves

See the articles OSCA LINGUA, CAPUA, CUMAE and MESSAPII. The text of all those yet discovered (at Capua and Cumae), with particulars of similar usages elsewhere in Italy and other historical-and archaeological detail, is given by R. S. Conway in *The Italic Dialects* (Cambridge, 1897, pp. 101 ff.). (R. S. Co.)

IOWA (Ī′ǫ-wą), known as the "Hawkeye State," is a north central state of the United States of America, situated between 40° 36' and 43° 30' N. and 89° 5′ and 96° 31' W. It is bounded north by Minnesota, east by the Mississippi river, which separates it from Wisconsin and Illinois, south by Missouri, and west by the Missouri and Big Sioux rivers, which separate it from Nebraska and South Dakota. The state's total area is 56,280 sq mi., of which 294 sq.mi. are water surface.

Physical Features.—Iowa lies wholly in the prairie plains region, all its surface having been overrun by one or more of the great ice sheets of the glacial epoch. For the most part the surface is that of a prairie tableland, moderately rolling, and with a general but scarcely perceptible slope, which in the eastern two-thirds is from northwest to southeast, and in the western third from northeast to southwest. Elevations above the sea range from between 1,200 to 1,600 ft. in the northwest to 500 ft. and less in the southeast, the highest point being in Osceola county, the lowest at Keokuk. In the southern half of the state the height of the crests of the divides is very uniform. The northern half, because of glaciation, is more broken and irregular. Elevations, usually. rounded, mingle with depressions, some of which are occupied by small shallow lakes or ponds. But the most marked departures from the prairie surface are in the northeast and southwest. In the northeast the whole of Allamakee and parts of Winneshiek, Fayette, Clayton, Delaware, Dubuque and Jackson counties form the so-called driftless area of the state. In that region cliffs frequently rise almost vertically from the banks of a river to a height of from 300 to 400 ft.; and from the summit of the cliff to the crest of the divide, a few miles distant, there is another ascent of 300 ft. or more, terminating occasionally in knob-topped hills crowned with small cedar. Moreover, the largest streams have numerous tributaries flowing circuitously between steep if not vertical cliffs or in deep craggy ravines overlooked by distant hills. In the west, southward from the mouth of the Big Sioux river, extends a line of moundlike bluffs, usually free from rocks, rising abruptly from the flood plain of the Missouri to a height varying from 100 to 300 feet. A broad water-parting extending from Spirit lake, on the northern border, nearly south to within 60 mi. of the southern border, and thence southeast to Wayne county in the south central part of Iowa, divides the state into two drainage systems. That to the east, comprising about two-thirds of the whole area, is drained by tributaries of the Mississippi, of which the Des Moines, the Skunk, the Iowa with its tributary the Cedar, and the Wapsipinicon are the largest.

These streams have long courses and moderate slopes.

The region to the west of the divide is drained by tributaries of the Missouri, such as the Big Sioux, the Little Sioux, the Boyer and the Nishnabotna. In the bluff belt along the Missouri, steep but grassy banks 200 or more ft. in height are sometimes found.

Climate.—The climate is one of great extremes of heat and cold, with a dry winter and a usually wet summer, the prevailing wind of winter being northwest, while in summer it not infrequently blows from the southwest. Both the midwinter isotherm of Montreal and the midsummer one of Washington, D.C., pass through the state.

The mean annual temperature of the state is 48° F; the average range of extremes per year is about 135° F; while the greatest extremes recorded are from −47° F in 1912 to 118° F in 1934, a diiference of 165°. The average mean annual temperature at Sibley in Osceola county, near the northwest corner of the state, is 44°, while at Keokuk in the southeast corner it is 52·4°. As the isotherms cross the state, their tendency, especially in the north, is to move southwest. The rainfall is also very unequal in distribution throughout the year, as between the same periods of different years, and as between the different parts of the state. While the mean annual precipitation is 31·44 in., about 71% of this falls during the six months from April 1 to Oct. 1, or 11% in winter, 24% in autumn, 27% in spring and 38% in summer. May, June and September are the wettest months. At the same time extremes during the four most critical crop months, from May 1 to Sept. 1, have ranged from 6.75 in. to 27.8 inches. Within any one year the precipitation is in general usually less in the western part of the state than in the eastern; the western part also is marked by having a still greater percentage of its rain in spring and summer than has the eastern. The unequal distribution throughout the state is in large measure caused by local showers. Though the average frost-free growing season is from May 2 until Oct. 7, killing frosts may occur later or earlier. Injury to crops from drought and hot winds has occurred about two or three times in a decade, but liability to injury of the crops from excessive rainfall, hailstorms and prolonged excessive heat is greater than that from a deficiency of moisture.

Soil.—Its depth, together with its porous nature, makes the fertile soil of Iowa capable of withstanding the extremes of wetness and dryness remarkably well, and it is perhaps true that, taken as a whole, no other state in the union has a superior soil for agriculture. Certainly no other has so many acres of grade A land, or so large a proportion—from 85% to 90%—of its land subject to cultivation. The soil is of four kinds: till or drift, alluvial, loess or bluff, and geest. The dark drift, composed chiefly of clay, sand, gravel, boulders and lime, is both the soil and subsoil of the greater part (about 66%) of the state, being especially predominant in the north and northwest. The alluvial soil, composed of what has been washed from other soils, together with decayed vegetable matter, covers about 6% of the surface of the state, and is found in the river bottoms, particularly in the Missouri; it varies much in fertility. The loess soil, chiefly a mixture of porous clay and carbonate of lime, forms the bluffs bordering the bottom lands of the Missouri and is common in the northeast. Its fertility is not inferior to that of the better drift. Geest is found particularly in the northeastern part of the state; it covers less than 1% of the area of the state.

ADMINISTRATION

Constitution.—There is comparatively little in the political institutions of Iowa dissimilar to those of other states of the union; they show in recent years a tendency towards greater centralization—in boards, however, rather than in individual officers.

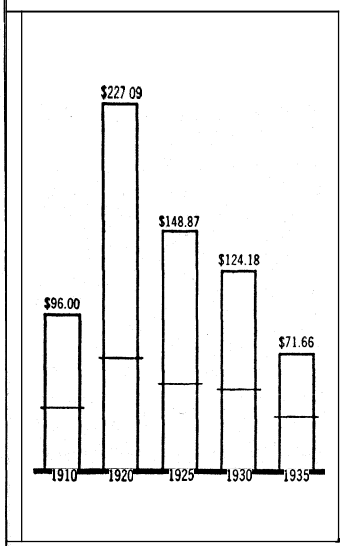
The state's constitution was adopted in 1857, the constitution of 1846 having been superseded chiefly on account of its prohibition of banking corporations. The constitution may be amended by an affirmative vote of both houses of two successive legislatures, followed by a majority vote of the electors in the state voting on the amendment; and by this process it was amended in 1868, 1880, 1884, 1904, 1908, 1916, 1926 and 1928. The Iowa constitution also provides that the question, "Shall there be a convention to revise the constitution and amend the same?" shall be submitted to the people once every ten years (beginning with 1870); but the vote in accordance with this provision has never been in the affirmative except in 1920, when it was—yes: 279,652; no: 221,763. The 39th general assembly, however, failed to provide for a constitutional convention. The suffrage belongs to all citizens of the United States at least 21 years of age who shall have resided in the state for six months, and in some one county 60 days preceding an election, except idiots and persons insane or convicted of some infamous crime. The franchise was conferred on Negroes by an amendment adopted in 1858, and on women by the federal amendment adopted in 1920. Prior to 1904 elections were held annually, but by an amendment of that year they became biennial.

The supreme executive authority in Iowa is vested in the governor. The constitution also provides for a lieutenant governor, secretary of state, treasurer, auditor, and attorney-general. The legislature has provided by statute for other elective state officers, including a superintendent of public instruction (since 1864) and a secretary of agriculture (since 1923). All officers must be citizens of the United States and have the age and residence qualifications of voters. The governor and lieutenant governor must, in addition, be at least 30 years of age and must have resided in Iowa at least two years preceding the election. All are elected for two years except the superintendent of public instruction, whose term is four years. The governor has extensive appointive power, oversees the making of the budget, and may veto acts of the general assembly, although such acts may be passed over his veto by a two-thirds majority of both houses. His annual salary is $7,500. The lieutenant governor is ex-officio president of the senate and takes the office of governor in case of the death, resignation or removal from office of the chief executive.

In addition to these elective offices a number of subordinate administrative offices have been created by the legislature. In almost all cases such officials are appointed by the governor, usually with the proviso that a majority or two-thirds of the senators must approve the appointments. Among these officers are the adjutant general (since 1839), a commissioner of banking (since 1917), a commissioner of public health (dating back to 1913), a commissioner of insurance (since 1913), an industrial commissioner (since 1913), a labour commissioner (since 1884), and a commissioner of public safety (since 1939). The governor also appoints a state comptroller who prepares the state budget and has general supervision of expenditures. The comptroller represents the governor and serves at his pleasure. A state printer is appointed by the state printing board made up of the auditor, secretary of state and attorney-general and two members appointed by the governor.

The governor. secretary of state, auditor of state, treasurer of state, and secretary of agriculture make up the executive council. This ex-officio board canvasses state election returns, supervises* the incorporation of building and loan associations, appoints the board of mine inspectors, allocates space in the capitol and other buildings used by the state government to the various offices and departments, and has other supervisory duties. It formerly had certain authority in dispensing funds. This duty has been largely taken over by the legislative interim committee, officially designated as the committee on retrenchment and reform, which is made up of the chairmen of the senate and house committees on ways and means, judiciary and appropriations and tao additional members from each house appointed by the presiding officer from the minority parties. In case there are two of these committees, the presiding officer decides which one is to be represented.

Much of the administrative work of the state government is performed by boards or commissions, usually bi-partisan. The members of these boards are appointed by the governor with the approval of the senate, except the three members of the commerce commission, which was created in 1937 to take the place of the board of railroad coinmissioners (1878–1937). They are elected by the voters for four-year terms. The commerce commission appoints the commerce counsel. Among the other administrative boards are: the board of education (1909), with nine members; the state highway commission (1904), with five members; the board of parole (1907), with three members; the conservation commission (1935), with seven members; the board of control of state institutions (1898), with three members; the liquor control commission (1934), with three members; the employment security commission (the unemployment compensation commiss ~1937–41), with three members; the state tax commission (the board of assessment and review, 1929–39), with three members; and the state board of social welfare (1937), with three members.



FARM VALUES (LAND AND BUILDINGS) PER ACRE OF LAND IN FARMS. THE LINE ACROSS EACH COLUMN SHOWS THE AVERAGE VALUE FOR THE UNITED STATES

The state legislature, or general assembly, composed of a senate and a house of representatives, meets in regular session the second Monday in January in odd numbered years at Des Moines. Senators are elected for a term of four years, one from each of 50 senatorial districts, the term of one-half expiring every two years. Representatives are elected for a term of two years, one from each of the 99 counties, with an additional one from each of the counties (not exceeding nine) having the largest population; the ratio of representation and the apportionment of the additional representatives from the larger counties are fixed by the general assembly. Senators must be at least 2j years old.

Judiciary.— The judiciary consists of a supreme court of nine judges, and a district court of 70 judges, from one to six in each of 21 districts. The supreme court has three sessions a year, and each district court judge is directed to hold at least one session a year in each county of his district. No two district court judges may sit together on the same case. The supreme court has original jurisdiction in certiorari and mandamus cases, and appellate jurisdiction in cases sent up from the lower courts. It also has the power to pass on the constitutionality of state laws. The district court has general, original and exclusive jurisdiction in all matters civil, criminal and probate not expressly conferred on an inferior court, and may hear appeals from inferior courts, boards or officers.

For purposes of administration and local government the state is divided into 99 counties, each of which is itself divided into townships that are usually 6 mi. square. The township may be divided into school districts and highway districts, but in these matters option has resulted in irregularity. Each county has its own administrative boards and officers. The board of supervisors, consisting of not more than seven members, elected for a term of three years, has the care of county property and the management of county business, including highways and bridges; it fixes the rate of county taxes within prescribed limits and levies the taxes for state and county purposes. Other officers of the county are: auditor, treasurer, clerk, recorder, sheriff, attorney. engineer, coroner and superintendent of schools. All are elected for a term of two years, except the engineer and superintendent of schools, who are appointed. The officers of the township are three trustees, a

clerk, an assessor, two justices of the peace and two constables. The trustees are elected for a term of three years, the other officials for two years. All taxable property of the state, that of corporations for the most part excepted, is assessed by the township

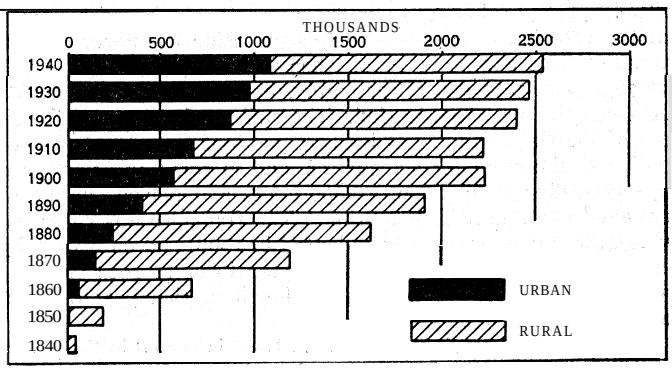
The municipal corporations are civil divisions quite independent of the county and township system. They are divided into cities of the first class, cities of the second class and towns, besides a few cities with special charters. Cities of the first class are those having a population of 15,000 or more; cities of the second class, a population of at least 2,000 but less than 15,000; all other municipal corporations, except cities with special charters, are known as incorporated towns. The commission plan of government, authorized in 1907 for cities of 25,000 or more inhabitants, was extended to cities of 2,000 or more inhabitants. According to the *Report on Municipal Finances, 1940,* seven cities were organized under the commission plan: Burlington, Cedar Rapids, Des Moines, Fort Dodge, Keokuk, Ottumwa and Sioux City. Commissioners are elected on a non-partisan ticket for a term of two years. In 1915 the general assembly passed acts allowing cities not exceeding 25,000 to adopt the commission-manager plan, the city manager being appointed by the commissioners. Twelve cities—Ames, Clarinda, Dubuque, Fredericksburg, Iowa Falls, Manchester, Maquoketa, Mason City, Mount Pleasant, Villisca, Webster City and West Liberty—have adopted this form. Camanche, Davenport, Muscatine and Wapello are governed under special charters, granted before the adoption of the constitution which forbids such acts of incorporation. All other municipalities are governed under the mayor-city council plan.

In Iowa a wife enjoys property rights equal to those of her husband. The expenses of the family, including the education of children, are chargeable upon the property of either or both, but neither is liable for what are clearly the debts of the other. In case of the death of either, one-third of the property owned by the deceased during the marriage and not sold on execution is set aside for the surviving spouse unless the right to this share has been relinquished. A homestead cannot be conveyed or encumbered without the consent of both husband and wife; and a homestead, to the value of $500, is exempt from liability for debts post-dating the purchase, unless for property improvements.

Population. — The population of Iowa in 1840 was 43,112; in 1860, 674,913; in 1880, 1,624,615; in 1910, 2,224,771; and in 1940, 2,538,268. This last figure represents an increase of 2·7% over the population in 1930. The population per square mile was 45.3, as compared with 44·2 for the United States as a whole. Of the 1940 population, 1,084,231, or 42·7%, lived in urban places; that is, in cities of 2,500 or more. The number of occupied dwelling units returned in the housing census of 1940 was 701,920, which is approximately the same as the number of families. The average population per family (occupied dwelling unit) declined from 3.9 in 1930 to 3.6 in 1940. The white population of Iowa formed 99·3% of the total in 1940 as well as in 1930. The number of males per 100 females in the entire population of the state was 101, though there was a marked excess of females in the urban population, the sex ratio being 93·2 for the urban and 107·3 for the rural population. The population of the state and of its principal cities is summarized in the following table:

Finances. — The tax system of Iowa includes a general property tax (with provision for a limited homestead exemption), taxes on incomes, inheritances, insurance companies, corporations, chain stores, beer and cigarettes, a two per cent tax on retail sales and a tax of three cents a gallon on motor vehicle fuel. For the year beginning July 1, 1939, and ending June 30, 1940, the receipts in the general fund of the state were $24,734,425, while trust and special funds received $64,431,817, a total of $89,166,242. The federal government added $8,312,399.

The net cash balance in the general fund on June 30, 1940, was $10,648,166, with a balance in the trust funds of $6,202,360.



BY COURTESY OF THE U S. BUREAU OF THE CENSUS

URBAN AND RURAL POPULATION OF IOWA, 1840–1940

The amount represented by outstanding bonds issued in 1921 for the soldiers' bonus is $2,200,000. This is the only state debt, but on Jan. 1, 1940, the total indebtedness of Iowa counties was $106,770,985, approximately two-thirds of which was in the form of primary road bonds issued by the counties and paid from the special taxes on motor vehicles and gasoline. In June 1941, the amount of outstanding road bonds was $62,153,000.

The adjusted valuation of Iowa real estate as assessed for 1940 was $2,498,967,871, personal property $258,615,253, moneys and credits $326,110,821 and public utilities $246,807,266.

Education. — The first step toward establishing a system of public schools dates from the first session of the territorial legislature in 1838, but the system was not established until after 1850.

At the head of the whole system is the state superintendent of public instruction, assisted by a board of educational examiners. The county administration is in the hands of a board of education and a superintendent. The county superintendent is elected for a term of three years by a convention of representatives of each school township, consolidated independent and city independent school districts. The county board of education consists of six members, elected by the convention for six years, and the county superintendent. Each school district has its separate board of education or trustees. School revenue is derived from the state's permanent school fund, which grew out of land granted to the state by the federal government and from local or district taxation. School attendance was first made compulsory by legislative action in 1902. Subsequent acts have extended the period of school attendance to 24 consecutive weeks every year for children between the ages of seven and sixteen unless they have completed the eighth grade or are over fourteen and employed. In 1911 the legislature authorized large centrally located, consolidated schools, which replaced small scattered ones. At the close of 1938 there were 408 consolidated districts, including about 25% of the area of the state and taking care of approximately 82,000 pupils. In 1911 state aid was granted by law to high schools organizing normal training of rural teachers. In 1917 a state board for vocational education was established to take advantage of the provisions of the Smith-Hughes law offering federal aid for vocational education. A law, enacted in 1919, provided for part-time schools for the benefit of children between the ages of 14 and 16 working on employment certificates. The establishment of these schools was required where there were 15 eligible pupils in the district, and attendance became compulsory.

In 1939–40 the total population between five and twenty-one years, inclusive, was 681,297, of whom 509,200 were enrolled in public and 46,368 were in private and parochial schools. In the public schools 364,071 were enrolled in the kindergarten and ele-

mentary schools; and 139,410 in secondary schools. The total number of teachers employed was 24,952. The average number of days attended per pupil enrolled had increased from 121·4 in 1910 to 153·2 in 1940. The total expenditure for public school education for the year ending June 30, 1940 was $49,517,347.

Iowa has 23 universities and colleges, 27 public junior colleges and 6 private junior colleges. The state-supported institutions of higher education are the State University of Iowa at Iowa City (1847), the Iowa State College of Agriculture and Mechanic Arts at Ames (opened in 1869) and the Iowa State Teachers' college at Cedar Falls (1876). The state also maintains a school for the deaf at Council Bluffs and a school for the blind at Vinton. The enrolment for the year 1939–40 was as follows: state university, 10,778; Iowa state college, 7.963; state teachers' college, 3,610 All the state-supported educational institutions are under the management of the state board of education. The nine members of the board are appointed by the governor for six-year terms, subject to approval by the senate. The board chooses from outside its own members a finance committee of three members. The committee selects its chairman and secretary.

Educational institutions not supported by the state include: Iowa Wesleyan college (Methodist, 1842) at Mount Pleasant; Grinnell college (opened in 1846 as Iowa college, Congregational) at Grinnell; Coe college (1880) at Cedar Rapids; Drake university (1881) at Des Moines; Cornell college (Methodist. 1853) at Mount Vernon; Upper Iowa university (Methodist, 1857) at Fayette; Luther college (Norwegian Evangelical Lutheran, 1861) at Decorah; Penn college (Friends, established 1873) at Oskaloosa; Parsons college (Presbyterian, established 1875) at Fairfield; Loras college (Catholic, begun in 1866 to take the place of a seminary which closed in 1860) at Dubuque; St. Ambrose college (Catholic, 1882) at Davenport.

Charities and Corrections. — The charitable, penal and reformatory institutions of the state are all under a board of control of state institutions. composed of three members appointed by the governor and approved by two-thirds of the senators, careful provision being made also to make the board non-political.

The institutions under its charge include a soldiers' home at Marshalltown; an institution for feeble-minded children at Glenwood; an industrial school for boys at Eldora; an industrial school for girls at Mitchellville; a state sanatorium for the treatment of tuberculosis at Oakdale; state hospitals for the insane and inebriates at Mount Pleasant. Independence, Clarinda and Cherokee; a state penitentiary at Fort Madison; men's reformatory at Anamosa; women's reformatory at Rockwell City; hospital for epileptics and school for feeble-minded at Woodward; soldiers' orphans' home at Davenport; and a juvenile home at Toledo. The board of control of state institutions has supervisory and inquisitorial powers over county and private institutions in the state in which the insane are kept, and over homes for friendless children maintained by societies or institutions. In the year 1907 the general assembly passed a law under which the indeterminate sentence was established in the state, and the governor appoints a board of parole of three members, of whom one must be an attorney, and not more than two are to belong to the same political party. In connection with the passage in 1929 of a bill for the sterilization of certain mental defectives, there was created an ex-officio state board of eugenics. In 1937 a state department of social welfare was created. This board has charge of old-age assistance, aid to the needy blind, child welfare and care of dependent children, and general relief by the state. It supervises county boards of social welfare.

THE STATE'S PRODUCTS

Industry, Trade and Transportation. — The superior qualities of the soil, together with the usually warm and moist months of spring and summer, make Iowa one of the foremost states in the union in agriculture and stock raising, especially in the production of Indian corn. oats, hay and eggs, and in the raising of hogs, horses, dairy cows and poultry. Of the state's 912,835 persons engaged in profit-earning occupations in 1930, 330,881 were engaged in agriculture, 173,149 in the manufacturing and mechanical industries and 77,015 in trade and transportation. Of the total farm acreage of 34,148,673 in 1940, 20,358,588 were under actual cultivation. The average size of Iowa farms was 160 1 ac. in 1940. The tenure distribution for the state's 213,318 farms on April 1, 1940 was as follows: full owners, 88,206; part owners, 22,410; managers, 1,218; tenants, 101,484. According to estimates the total value of farm products in the year 1939 was $589,915,000, the distribution being $132,647,000 for crops of all kinds, and $457,268,000 for livestock and livestock products. Government payments added $69,444,000.

Indian corn is the chief crop, approximately half of the cultivated area being devoted to its culture. In 1939 the 9,688,000 ac. planted in Indian corn had an average yield of 52 bu. per acre, the total yield being 503,776,000 bu. valued at $267,001,000. The grain second in importance was oats, which, from 5,076,000 ac., and an average yield of 30·5 bu. per acre, produced 154,818,000 bu. valued at $41,801,000. Both winter and spring wheat are raised, but wheat is a minor crop, its total value in 1939 being about $4,218,500. As a producer of cultivated hay Iowa ranks among the leading states. The yield from 3,498,000 ac. of all varieties of cultivated hay was 4,814,000 short tons in 1939, valued at $26,958,000. Other crops that had a value in excess of $1,000,000 in 1939 were: soybeans, $7,670,000; barley, $5,242,000; Irish potatoes, $4,200,000; and flaxseed, $1,342,000. Iowa is not only a great feeding state for livestock shipped into the state, but ranks high as a breeding state. In the year 1939 Iowa led the other states in the total number of swine and horses raised. There were reported on Jan. 1, 1940, 9,651,000 swine valued at $88,070,000; 4,688,000 cattle valued at $208,438,000; 1,844,000 sheep valued at $12,523,000; and 752,000 horses valued at $57,492,000. The pig crop for 1939 was 14,358,000.

Iowa's first settlement was a mining camp, but this event proved to be no index to her future importance as a mineral producing state. The early worked lead and zinc mines about Dubuque are little worked at present, and these products are of small significance in comparison with the state's total mineral output.

The value of mine products in 1938 was $24,794,058. Coal, mined in 20 counties extending from the southeast along the Des Moines river and three counties in the southwest, was the chief mineral product. The total production for the state in 1938 was 3,103,187 short tons, valued at $7,963,000 The product second in importance was cement, 4,759,390 bbl. being produced in 1938, valued at $7,327,048. Clay products were manufactured to the value of $2,913,992. The production of gypsum in 1938 was 364,920 short tons. The producing area is confined to about 50 square miles in the vicinity of Fort Dodge in Webster county. Other products of commercial value in 1938 were sand and gravel valued at $2,299,682, and building stone valued at $3,782,480.

The manufactures of Iowa deal chiefly with the products of the farm. Meat packing is the most important, the product of this industry amounting in 1939 to $257,315,000. Next in importance is the manufacture of dairy products, the value of which in 1939 was $68,618,000. Dressed poultry was the product third in importance, its value in 1939 having been $23,879,000. Corn products were valued at $21,668,000 and flour and grainmill products at $10,021,000.

Other industries which had a product in excess of $5,000,000 in 1939, in the order of their importance, were: printing and publishing, $23,404,000; bakery products, $22,415,000; machinery, $18,615,000; planing mills, $18,080,000; laundry equipment, $16,147,000; prepared feeds, $9,043,000; cement products, $8,529,000; and non-alcoholic beverages, $5,534,000.

The state ranked first in the production of pearl buttons, with Muscatine the centre of the industry. The chief shell supply came from the Mississippi and tributary Iowa rivers. In 1939 the industry gave employment to 1,717 persons working at 31 plants. and had a value of $3,063,000. In 1939 the 2,670 manufacturing establishments in Iowa engaged 67,878 wage earners and had a product value of $718,532,000.

Transportation is afforded chiefly by steam railways, of which the state had 9,017 mi, in 1940. Scarcely a farm is more than 6 or

8 miles from a railway station; and only three other states have a greater mileage—Texas, Illinois and Pennsylvania. The great period of railway building in Iowa came during the 25 years immediately following the close of the Civil War, the railway mileage being only 655 in 1860. The several roads are under the management of twenty-two companies, but the chief systems are the Chicago, Burlington and Quincy railroad; the Chicago and North Western railroad; the Chicago, Milwaukee, St. Paul and Pacific railroad; the Chicago, Rock Island and Pacific railroad; the Minneapolis and St. Louis railroad; and the Illinois Central, operating the Dubuque and Sioux City railway.

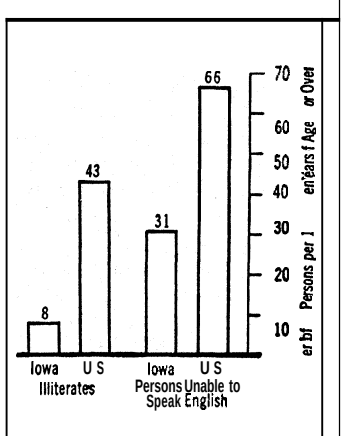
Electric interurban railways were of importance for freight and passenger service until paved roads brought buses and trucks into competition. In 1908 about 225 mi. of such railways were in operation; in 1932 the mileage was 891; and in 1940, only 467. Transportation facilities by water are afforded by the Mississippi river. With the canal constructed by the U.S. government between Keokuk and Montrose and the channel improvements at Clinton, there has been a revival of river traffic. Iowa has long had a state highway system, but it was not until 1919 that the highways were classified as primary and secondary. At the end of 1939 the highway commission controlled 8,497 mi. of road, of which 5,208 mi. were paved and 3,263 mi. otherwise surfaced. Of the secondary roads, 38,890 mi. were gravelled or paved. Four paved roads cross the state east and west. Bus service is offered on most paved roads. A transcontinental air line crosses Iowa, with airports at Iowa City and Des Moines.

HISTORY

Iowa, as a part of the Mississippi valley, was taken into the formal possession of France in the year 1682; in 1762 as a part of the western half of that valley it was ceded to Spain; in 1800 it was retroceded to France; in 1803 it was ceded to the United States. From 1804–05, as a part of the District of Louisiana, it was under the government of Indiana Territory; from 1805 to 1812 it was a part of Louisiana Territory; from 1812–21 it was a part of Missouri Territory; from 1821–34 a part of the unorganized territory of the U.S.; from 1834–36 a part of Michigan Territory; from 1836–38 a part of Wisconsin Territory. In 1838 Wisconsin Territory was divided, the western portion being named Iowa, and out of this the state with its present bounds was carved in 1846.

The name Iowa mas taken from a tribe of Siouan Indians (probably of Winnebago stock) which had dwelt in that part of the country for some time and were still there when the first white men came—the Frenchmen, Fathers Marquette and Joliet, in 1673, and Father Hennepin in 1680. Father Hennepin left an account of his early travels in Iowa and its neighbouring districts entitled *Description de la Louisiane*. In the century following, the territory of Iowa was left to its Indian inhabitants by the explorers and missionaries. The tribe of Iowa was forced to the westward and largely supplanted by the tribes of Sacs and Foxes who had in turn been driven from Michigan by the French.

Not until after 1785 did the 'next white man, Julien Dubuque, cross to the Iowa side of the Mississippi River. He was a French Canadian who came to trade and made friends with the Fox Indians. Discovering the valuable lead mines of the district, he negotiated for their sole ownership with Kettle Chief and his people. In 1788 he obtained an Indian grant of about 21 sq.mi. and formed a settlement at these mines. He received a verification of his grant from the later governor, Carondolet, and continued his mining operations, together with a trade in furs, until his death in 1810. Dubuque's story is the rare one of a white man who was respected by the Indians with whom he lived and his Indian friends gave him the honours of a chief at his burial, which took place in the city which bore his name and which was the outgrowth of his first discovery of the lead mines in Iowa. The Indians would not allow any outsiders to work the mines and were upheld in this by the United States troops, especially from 1830 to 1832.



RELATIVE PROPORTION OF ILLITERATES AND OF PERSONS UNABLE TO SPEAK ENGLISH IN 1930

But the war which Black Hawk instigated ended in 1832 with a cession to the United States of nearly 9,000 sq.mi., embracing much of this region.

In spite of the act of congress of 1807 prohibiting such settlements, the frontiersmen rushed in to mine and to farm, and often established voluntary associations. Proceedings of these associations which related to claims to land were later recognized by the United States authorities. Iowa was separated from Wisconsin in 1838 and the question of applying for admission into the union as a state was voted on as early as 1840, the territory in that year having a population of 43,112. The measure was defeated then, as it was again in 1842, by those who most wished to avoid an increase of taxes. In 1844, however, a convention was called, a constitution framed and application for admission made. The question of boundaries caused delay, but the territory became a state in 1846.

The Whigs had steadily opposed applying for admission, but the Democrats carried it through, and remained in power until 1854. Since 1857 the state has been preponderantly Republican in all national campaigns except in 1912, when a split in the party gave the electoral vote to Woodrow Wilson, the Democratic candidate, and in 1932 and 1936 when Franklin D. Roosevelt caused a complete reversal of the Republican tradition. With four exceptions, in 1889 and 1891, when liquor and railroad legislation were the leading issues, and in the Democratic landslides of 1932 and 1936, Iowa has elected a Republican state administration. Within the dominant party, however, there has been a tendency towards the formation of two opposing elements, the more radical seeking the promotion of the "Iowa Idea," which in substance was to further the expansion of the trade of the United States with the rest of the world through the more extended application of tariff reciprocity, and at the same time to revise the tariff so as to prevent it from "affording a shelter to monopoly."

In 1882 an amendment to the constitution was passed prohibiting the manufacture and sale of intoxicating liquors within the state. The supreme court, in April 1883, pronounced this amendment invalid on the ground of irregularity in its adoption, whereupon the legislature provided for a like prohibition in an ordinary statute. Attempts to execute this were, however, so unsuccessful that it was succeeded by a law imposing the "mulct tax," which required the consent of a majority of the voters and payment of a $600 mulct tax annually, and placed a lien for the whole amount on the real property in use for the business. The vital portions of the "mulct tax" law were repealed by the general assembly in 1915, thus restoring statutory prohibition in Iowa, but a prohibitory amendment to the state constitution was voted down at the election in Oct. 1917. The 18th (prohibition) federal amendment was, however, ratified by Iowa Jan. 15, 1919. After repeal of this amendment in 1933, measures were passed to legalize the sale of beer with 3.2% of alcoholic content and to establish a state monopoly in liquor traffic, The sale of intoxicating liquor was placed under a state-liquor control commission. In 1916 a constitutional amendment extending suffrage to women was submitted to the electors, but was defeated. The federal suffrage amendment ,,, ratified by the legislature in 1920, and in 1926 a constitutional amendment allowed women to be elected to the general assembly.

Other offices were open to them when they became voters.

The general assembly in 1913 passed an employers' liability and workmen's compensation act, and a mothers' pension act, providing for the granting to widowed and indigent mothers of sums not to exceed $2 per week for each child under 14. In 1915 the Perkins law was passed, providing free treatment for crippled children of poor parents. In 1917 an appropriation was made by the general assembly for the erection and equipment of a hospital at Iowa City for such children. In 1917 the general assembly established at Iowa City a child-welfare station. The cost of an old-age pension system, created in 1935, whereby persons 65 years of age, if without support, were to receive up to $25 a month, was at first met by a tax of $2 each year on every person of voting age. Both the old-age assistance program and aid to the blind were then financed by the "three-point" tax system—a tax on incomes, a 2% retail sales tax, and a tax on corporation incomes.

For 1941–43 the appropriation for old-age pensions and state relief was $10,000,000 annually.

The farm bureau movement in Iowa was an important development. By 1917 organizations among farmers were numerous, and in that year the general assembly passed an act providing that where a farm-improvement association in any county had among its members 200 farmers or farm owners and had raised $500 in annual subscriptions, the county board of supervisors could contribute $2,500 for the employment of a county agent. A law in 1919 modified the amount and terms of payment by the county, and made the contribution mandatory.

The movement gained rapid headway, county associations being established for the betterment of both social and economic conditions and the improvement of agricultural methods.

IOWA, STATE UNIVERSITY OF, an institution of higher learning, situated in Iowa City, Ia. It was organized by an act of the legislature in **1847.** Instruction was begun in the spring of 1855, but the first regular collegiate session did not open until the autumn of 1856. Because of financial reasons, the university maintained only a normal department during the two years 1858–60. Since that time new departments, schools and colleges have been added to the original college of liberal arts. The law department was established in **1868,** the medical department in 1870, the dental department in **1882** and the department of pharmacy in 1885. All these are now colleges. The graduate college was added in 1900 and the college of engineering in 1905. The school of education, created in 1907, became the college of education in 1913; and a school of commerce, established in 1914, became the college of commerce in **1921.** In addition to these nine colleges now functioning, a preparatory department was maintained from the organization of the university until 1879; a homeopathic medical department, later a college, from 1876 to 1919; and a college of fine arts from 1911 to 1915. Within the college of liberal arts is the school of fine arts, the school of letters and the school of journalism. Within the college of medicine is the school of nursing. A summer session, begun in 1900, has become an important part of the university. The extension division was organized in 1913; the Iowa Child Welfare Research Station in 1917; the division of physical education in 1924 and the Institute of Hydraulic Research in 1931.

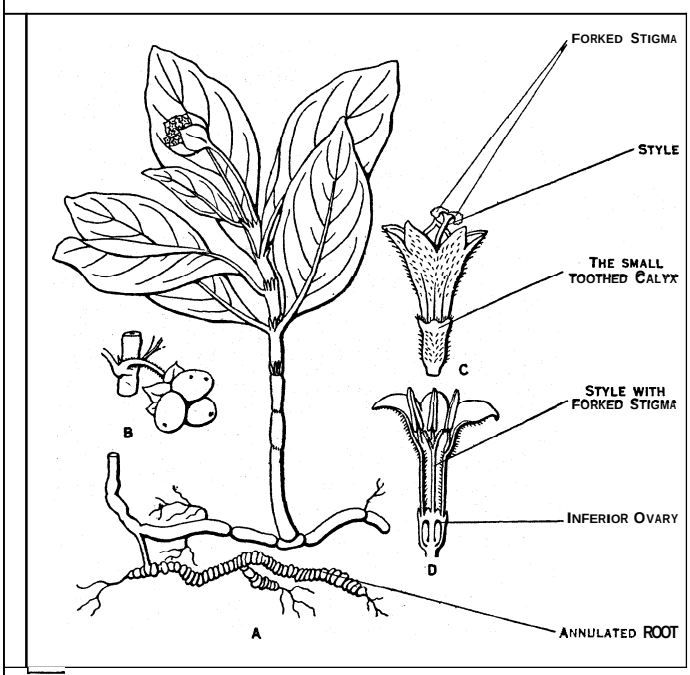
The university is the capstone of the public school system of the State. It is under the direction of a State board of education of nine members appointed by the governor, with the approval of the senate, for a period of six years. The faculty contains more than 500 men and women and the student enrolment for 1935–36 was **10,208.** Funds are derived to some extent from the sale of lands originally donated for its support by the U.S. Government, but the greater part of its support comes from the appropriations made biennially by the general assembly. For the biennium 1935–37, the amount set aside for the university was $3,924,000.

The central building of the university campus is the beautiful Old Capitol, which was begun in **1839** and served as the capitol of Iowa from **1841** until 1857, when Des Moines became the capital of Iowa and the capitol building was turned over to the university. Around this building are grouped more than 85 buildings on a campus of over 385 ac. lying on both sides of the Iowa river. The latest additions to the material equipment of the university are the fine arts and dramatic arts buildings and the botanical laboratories at a cost of approximately $11,500,000. Iowa Union is the centre of university social activities. The university libraries contain more than 430,000 volumes. Closely associated with the work of the university is the State Historical Society of Iowa, with a library of over **84,970** titles. (E. A. G.)

IOWA CITY, a city of south-eastern Iowa, U.S.A., on the Iowa river, 12 om. E. of Des Moines; the county seat of Johnson county. It is on federal highways **6** and **218;** is served by the Cedar Rapids and Iowa City (electric) and the Rock Island railways, and is a station on the transcontinental air-mail route from east to west, with an airport that is brilliantly illuminated at night. The population in 1940 (federal census) was **17,182,** The city lies in a natural amphitheatre, almost surrounded by hills and bluffs. It has various manufacturing industries, and is the seat of the University of Iowa (*q.v.*), of the library of the State Historical Society. The State sanatorium for tuberculosis is at Oakdale about 4 miles away. In **1839** Iowa City was chosen the seat of government of the newly created Territory of Iowa, and it remained the capital until 1857, when Des Moines was chosen in its stead, because of its more central position. The old State capitol is now the headquarters of the administration of the university.

IPECACUANHA. The root used in medicine under this name is obtained from *Psychotria* (or *Uragoga*) Ipecacuanha, a rather small shrubby plant of the family Rubiaceae. It is a native of Brazil, growing in clumps or patches in moist shady forests from 8° to 22° S., and is also found in Colombia and probably in Bolivia. The great value of the drug in dysentery led to attempts to acclimatize the plant in India. Like other dimorphic plants, ipecacuanha ripens seeds best when cross-fertilized, and presents various forms.

Ipecacuanha root occurs in pieces about two or three lines in thickness, of a greyish-brown or reddish-brown tint externally, having a ringed or annulated surface (*see* illustration), and exhibiting a white or greyish interior and a hard wiry centre. It has a faint rather musty odour and a bitterish taste. The variety imported from Colombia and known as Cartagena ipecacuanha differs only in its larger size and in being less conspicuously annulated. Ipecacuanha owes its properties to the presence of rather more than 1% of the alkaloid emetine, which occurs only in the cortical portion of the root. It is a white amorphous substance, with the formula $C_{20}H_{30}NO_5$. It has a bitter taste, no odour, and turns yellow when exposed to air and light. There are also present a volatile oil, starch, gum and a glucoside, which is a modification of tannin and is known as ipecacuanhic acid. The dose of the powdered root is $\frac{1}{4}$ to 2 grains when an expectorant action is desired, and from 1j to **30** grains when it is given as an emetic, which is one of its most valuable functions.



IPECACUANHA (PSYCHOTRIA IPECACUANHA)
A. Plant showing annulated root
B. Fruits
C. Long-styled flower
D. Longitudinal section through a short-styled flower

Ipecacuanha powder is a powerful cutaneous irritant, even causing pustulation. When inhaled it causes violent sneezing and a mild inflammation of the nasal mucous membrane, resembling a common cold in the head. Small doses stimulate the secretions of the mouth, stomach, intestine and liver. The drug, therefore, increases appetite and aids digestion, Toxic doses cause gastro-

enteritis, cardiac failure, dilatation of the blood-vessels, severe bronchitis and pulmonary inflammation closely resembling that seen in ordinary lobar pneumonia. In this respect and in its action on the skin, the drug resembles tartar emetic. Ipecacuanha is very frequently used as an expectorant in cases in which the bronchial secretion is deficient. Its diaphoretic properties are employed in the *pulvis ipecacuanhae compositus* or Dover's powder, which contains one part of ipecacuanha powder and one part of opium in ten.

Other plants to which the name of ipecacuanha has been popularly applied are American ipecacuanha (Gillenia *stipulacea*), wild ipecacuanha (*Euphorbia Ipecacuanha*), bastard ipecacuanha (Asclepias *curassavica*), Guiana ipecacuanha (*Boerhavia dècumbens*), Venezuela ipecacuanha (Sarcostemma *glaucum*), and ipecacuanha des Allemands (*Vincetoxicum officinale*). All these possess emetic properties to a greater or less degree.

IPEK or PEE, a town in the Zetska banovina of Yugoslavia, occupied by Italy in 1941. Pop. (1931) 13,194. The town lies in a fertile plain on which tobacco is cultivated. Ipek is surrounded by trees and gardens, while a pleasant stream runs through it. Nearly every house is provided with a watch-tower. It is situated on the road from Jakova to Prizren, and from its position, it is destined to form a connecting link for trade with Serbia. Ipek was formerly the centre of the Serbian Church, the archbishop having been raised to the patriarchate by Stephen Dushan (1331–55). It was suppressed in 1459, restored in 1557 and finally abolished by the Turks in 1767. On the heights above the town stands the 13th century monastery, the seat of the patriarchs until 1690, and the church, which dates from the 16th and 17th centuries. Here are the marble tombs of many church dignitaries, and the marble throne of the patriarchs. After the fall of Belgrade in 1521 many of the iahabitants migrated to Hungary, and in 1690 there was a second migration there led by the patriarchs. The town was captured by the Montenegrins in the Balkan Wars (1912–13) and ceded to Montenegro by the Treaty of Bucharest (1913). In World War I, thousands of refugees fled here. It was here too, that on the long march to Scutari, the broken Serbian army called a halt to destroy their guns, which they rolled over a precipice.

IPHICRATES, Athenian general, son of a shoemaker, flourished in the earlier half of the 4th century B.C. He is chiefly known for the use he made of lightly armed troops (peltasts); he increased the length of their weapons, and improved their mobility by reducing their defensive armour. He also paid special attention to discipline, drill and manoeuvres. With his peltasts Iphicrates seriously injured the allies of the Lacedaemonians in the Corinthian War, and in 392 (or 390) dealt the Spartans a heavy blow by almost annihilating a battalion of hoplites (Diod. Sic. xiv. 91; Plutarch, Agesilaus, 22). He was later transferred from Corinth to the Hellespont, where he was equally successful. After the peace of Antalcidas (387) he assisted Seuthes, king of the Thracian Odrysae, to recover his kingdom. About 378 he was sent with a force of mercenaries to assist the Persians to reconquer Egypt; but a dispute with Pharnabazus led to the failure of the expedition (Diod. Sic. xv. 29–43). On his return to Athens he commanded an expedition in 373 for the relief of Corcyra, which was besieged by the Lacedaemonians (Xenophon, Hellenica, vi. 2). On the peace of 371, Iphicrates returned to Thrace, and fought for Cotys in a war against Athens for the possession of the Chersonese. The Athenians, however, soon pardoned him and gave him a joint command in the Social War. He and two of his colleagues were impeached by Chares, the fourth commander, because they had refused to give battle during a violent storm. Iphicrates was heavily fined. He died about 353.

There is a short sketch of his life by Cornelius Nepos; see also C. Rehdantz, Vitae *Iphicratis*, Chabriae et Timothei (1854); Bauer, *Griech. Kriegsaltert.* in Müller's Handbuclz, 4, § 49; and histories of Greece, *e.g.*, Holm, Eng. trans., vol. iii.

IPHIGENEIA, daughter of Agamemnon (*q.v.*); not mentioned in Homer, but by some absurdly identified with the Iphianassa of Il. ix, 145, who was alive and well some ten years after Iphigeneia's supposed death. As she is constantly represented as connected in some way with Artemis, and as Iphigeneia ("mightily born," *i.e.*, "great princess") is a title of the goddess; as, moreover, she has substituted for her one of Artemis' beasts (see below), it is in no way impossible that originally she was a by-form of the goddess herself; but the question is obscure. Agamemnon had vowed to sacrifice to Artemis the fairest thing that should be born in a certain year, meaning the handsomest beast; but in that year Iphigeneia was born. Another story is that he or Menelaus had offended Artemis in some way. As a result, Artemis stayed the Greek fleet at Aulis on its way to Troy, by calm or contrary winds, and Calchas discovered that only the sacrifice of Iphigeneia would appease the goddess. Iphigeneia therefore was sent for on pretence of marrying her to Achilles; at the last moment the goddess relented and substituted a hind, bear, or bull for the victim, whom she spirited away to the land of the Tauri (Crimea). Here she became priestess of Artemis and as such had to sacrifice all strangers. At last Orestes (*q.v.*) and Pylades arrived; by a stratagem, she fled with them taking the image of Artemis, which Orestes had been sent to fetch. They left it somewhere in Greece; among places claiming to have the true statue and some remnant of the old rites of human sacrifice were Brauron in Attica, where a pretence was made of cutting a man's throat before the goddess, and Sparta, where boys were beaten till the blood came, in the ritual of Artemis Orthia.

Iphigeneia was variously said to have died and been buried at Brauron or Megara, and to have been transported to Leuce, where she was wedded to Achilles, or even to have been transformed into the goddess Hecate (*q.v.*).

See Stoll in Roscher's Lexikon (bibl.); L. R. Farnell Greek Hero-Cults (1921); H. J. Rose Handbook of Greek Mythology (1928).

IPOMOEA, a large genus of mainly climbing herbs or shrubs of the convolvulus family (Convolvulaceae, *q.v.*), containing about 400 species. It includes the sweet potato (*I. Batatas*), the cultivated morning glory (I. *purpurea*) and the manroot (I. *pandurata*).

IPSUS, BATTLE OF, 301 B.C. This, named "the battle of the kings," was the great clash in the wars of Alexander the Great's "Successors," which shattered Antigonus's attempt to reconsolidate the Macedonian empire. Hard-pressed in Thessaly by Demetrius, the son of Antigonus, Cassander turned the tables by a stroke of true genius. Keeping only a minimum of force, he despatched his ally, Lysimachus, to invade Asia Minor and arranged with Seleucus to advance from Babylon on Antigonus's rear. The combination and concentration against the heart of the opposing power succeeded, and forced Demetrius to evacuate Greece and sail home to his father's aid. The armies of Antigonus and Demetrius on the one hand, and of Lysimachus and Seleucus on the other met at Ipsus in Phrygia. Antigonus had 70,000 foot, 10,000 horse and 75 elephants; the allies only 64,000 foot, 10,500 horse, but 480 elephants. At the outset of the battle Demetrius with the cavalry charged and dispersed the opposing cavalry, but, pressing the pursuit too far, found himself cut off by the enemy's elephants. But instead of assaulting Antigonus's army, thus stripped of his cavalry, Lysimachus demoralized it by threat of attack and by fire until it began to melt—part going over to the allies. Then only did Seleucus launch a strong body at the position occupied by the enemy's command. Borne down by this charge, Antigonus died, crying vainly "Demetrius will come and save me." If the victory is memorable in military history as one of the outstanding triumphs of the war elephant, its greater political consequence was to ensure the disappearance of any central power and the dismemberment of the Graeco-Macedonian world. (See DIADOCHI, WARS OF.)

IPSWICH, a town of Stanley county, Queensland, Australia, on the river Bremer, 23½ m. by rail W. by S. of Brisbane. Pop. (1933) 22,499. It is the centre of a rich and populous agricultural mining and manufacturing district. Coal outcrops on the surface and is worked on the banks of the river. There are woollen factories, saw-mills, and foundries and large railway workshops at North Ipswich. The first settlement was made here in 1829; the town was incorporated in 1860. It has

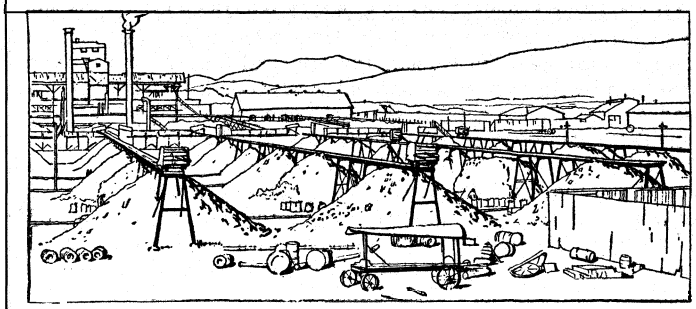
grown immensely during the first quarter of the 20th century.

IPSWICH, municipal, county and parliamentary borough and county town of Suffolk, England, 69 mi. from London by L.N.E.R. Pop. (est. 1938) 95,070. Area 13.7 sq.mi. The borough was considerably extended in 1934. It is on the river Gipping. Antiquarian remains are Sparrowe's house (1567), and Archdeacon's Place (1471), two old gabled houses, while Wolsey's Gateway (1528), a Tudor brick building, is the only remnant of the Cardinal's foundation to supply scholars to his great college (Cardinal's College, now Christ Church) at Oxford. The older churches are all towered flint-work structures, wholly or mainly Perpendicular in style, with the exception of St. Peter's, which is principally Decorated, with a Norman font of marble. They include St. Margaret's with a beautiful oak Tudor roof, elaborately painted *temp.* William and Mary; St. Mary-at-Key (or Quay), with a similar roof, St. Lawrence and St. Clement's. The museum is of some importance. The grammar school, dating at latest from 1477, was refounded by Queen Elizabeth in 1565. There is a picture gallery in the Tudor mansion (1549) in Christchurch Park. Industries include engineering and agricultural implement works. railway plant works. electrical apparatus, paper, furniture and the making of artificial manures, and clothing. Imports are principally grain, timber, petroleum and coal; exports agricultural machinery, railway plant, artificial manures and oil cake. There is an Anglican bishopric of St. Edmundsbury and Ipswich. The parliamentary borough returns one member.

Prehistoric finds include a Roman villa, and a Saxon settlement. In 991 the town (*Gipeswic, Gipeswich*) was sacked by Vikings. It owes its prosperity to its situation on a harbour admirably suited for trade with the Continent. In 1200 King John granted the burgesses their first charter, the town to be held at fee-farm, with a gild-merchant. The burgesses were definitely incorporated in 1464 and re-incorporated in 1665 under a charter which remained in force up to its modification by the Municipal Act of 1835. The cattle market and provision market are the prescriptive right of the corporation. A September fair, still held in 1792, was in the hands of the corporation in the 17th century. Large ironworks were established late in the 18th century. The wool and cloth trade of the 14th and 15th centuries was superseded by the manufacture of sailcloth, now, represented by the sacking industry.

IPSWICH, a town of Essex county, Massachusetts, U.S.A., 28m. N.N.E. of Boston, on both sides of the Ipswich river and fronting on Ipswich bay; served by the Boston and Maine railroad. The population was 6,348 in 1940 and is increased *in* the summer by some 2,000 seasonal residents. The town was settled under the name of Aggawam in 1633 and was incorporated in 1634 as Ipswich. During the early days of the colony it was little inferior to Boston in wealth and influence, and frequently took an opposing position on public questions. Ipswich was the home of several of the leading writers of the colonial period, including the Rev. Nathaniel Ward (1578–1652). A number of houses date from the 17th and 18th centuries. In the oldest, the John Whipple House, is the interesting collection of the Historical society. The Choate bridge, built in 1764, is the oldest arched bridge in America.

IQUIQUE, a city and port of Chile, capital of the province of Tarapacá, 820 mi. N. of Valparaiso, in 20° 12′ 15″ S., 70° 11′ 1j″ W. Population (1940) 37,713. The coast here runs due north and south and the city is built on a narrow level plain between the sea and bluffs, the latter rising steeply 2,000 ft. to the level of the great desert plain of Tarapaca, celebrated for its rich deposits of nitrate of soda. Facing the city is the low barren island of Serrano, or Iquique, which is connected with the mainland by a stone causeway 1,500 ft. long, and shelters the anchorage from southerly storms. **A** mole extending from the north-eastern end of the island affords further protection. The city is laid out on the rectangular plan, with broad streets and large squares. Water is brought by pipes from Pica, 50 mi. inland. Iquique is a city of much commercial importance and is provided with banks, substantial business houses, newspapers, clubs, schools, railways, tramnays, electric lights, telephone lines, and steamship, air and cable communication with the outside world. It exports iodine and immense quantities of nitrate of soda obtained from the desert region of the province. A large number of vessels are engaged in the nitrate trade, and Iquique ranks as one of the two leading ports of Chile in the aggregate value of its foreign commerce. It is connected by rail with the inland town of Tarapacá and various mining centres, and through them with the ports of Pisagua on the north, and Patillos on the south. Iquique was an insignificant Peruvian fishing settlement until 1830 when the



BY COURTESY Of W. R GRACE & CO.

LARGE NITRATE FACTORY OF W. R. GRACE & CO. NEAR IQUIQUE

export of nitrate began. In 1868, the town was nearly destroyed by an earthquake, in 1875 by fire, and again, in 1877, by earthquakes, a fire and a tidal wave. It was occupied by the Chileans in 1879 in the war between Chile and Peru, and was ceded to Chile by the treaty of Oct. 20, 1883.

IQUITOS, a tribe of South American Indians. It is divided into many branches, some on the river Tigre, others on the Nanay. Missionary efforts have failed and they remain savages, worshipping figures carved in the shape of birds and beasts. They brew the Indian fermented liquor *chicha* better than any of the neighbouring tribes, flavouring it with the shoots of some plant which has the effect of an opiate.

IQUITOS, a city and river port of Peru, and capital of the great department of Loreto, on the left bank of the upper Amazon near the mouth of the Rio Nanay, 2,330 mi. from the Atlantic, 73° 11′ 25″ W., 3° 45′ 23″ S. During the height of the rubber boom (1906–1912) the population reached 15,000; its population in 1940 was 34,231. Iquitos is about 400 ft. above sea level, on the low wooded banks of the river. The climate is hot and damp. As a Peruvian, not Indian town, it dates from 1863 when the first government buildings were erected. The chief buildings are the prefecture, custom house, municipal palace, churches, schools, clubs and barracks; Iquitos is the centre of a military region. Houses are mostly adobe roofed with thatch or tile, streets wide, but with few exceptions badly paved.

The city has regular service from the Atlantic by the Amazon River Steamship Co., Ltd., controlled by the Booth line, and is the distributing point for all up-stream tributaries navigated from Iquitos by smaller craft. The city is in direct radio communication with Lima and other stations, and is provided with regular air service by the Peruvian National and Condor lines. Rubber is the basis of the city's prosperity (see LORETO). Other exports include tobacco, cotton, wax, tortoise-oil, sarsaparilla, vanilla, gold and Panama hats. Tile and brick are manufactured, and there are a few other small industries. The city has electric lights, steam tram, cinemas, telephones which connect with the wireless station at Itaya, a suburb, and water and sewage systems. Iquitos dates officially from 1863, when it had a population of 431, though there had been a white settlement there for more than half a century. The opening of the Amazon to navigation added immensely to the importance of the city and made it the commercial entrepôt of eastern Peru.

IRAN, the great plateau between the plain of the Tigris in the west and the valley of the Indus in the east, the Caspian Sea and the Turanian desert in the north, and the Persian Gulf and the Indian Ocean in the south, surrounded on all sides by high mountain ranges with a great salt desert in the centre. The modern name Iran (in middle-Persian, Eran) is derived from the ancient *Aryāna*, "the country of the Aryans." Eratosthenes limited the name of Ariana to the south-eastern part of Iran, and excluded Persia, Media and Bactria, and therein he is followed by Strabo

(ii. 78, 130, xv. 720 ff.; Pomp. Mela i. 3.)

The term Iran, having always been used by native Persians to designate their indefinitely bounded country, became current in western usage after 1927 as the name of the kingdom proper in recognition of its reinvigorated life and newly asserted independence.

For the ethnography and history of Iran see PERSIA.

IRANIAN LANGUAGES AND PERSIAN. Three successive stages in the history of the Iranian languages, viz., ancient, middle and modern, in Persian, the principal branch of the group, correspond with epochs of national vicissitudes. Old Persian was used on the monuments of the Achaemenian dynasty (558–339 B.C.) destroyed by Alexander the Great. Middle Persian is known from the Parthian, or Arsacid period (250 B.C.–A.D. 225), even more from the Sassanian times (A.D. 225–651), terminated by the Arab conquest and domination. With the Persian Renaissance (ninth century AD.) modern Persian, with some unsubstantial changes, appears again as still a living language. Other Iranian idioms passed through stages similar to those of Persian.

Ancient **Iranian Languages.**—Of the Median language we know only one word (*σπάκα*, "dog") preserved by Herodotus (I., 110) and several personal names. This material suffices to place Median among Iranian (northern Persian) idioms. Of the Old Scythic group of languages (Scythic and Sarmatian) only personal names in Greek inscriptions, found in South Russia, have come down to us. The only ancient Iranian languages really known to us are Avestic and Old Persian.

The former is the language of the Zoroastrian sacred books. By earlier European scholars it was improperly called Zend, which term designates only the commentary to the Avesta, written in Middle Persian (*see* below). The age of the Avesta is dubious. Two parts of it are clearly distinct: the so-called Gāthās are more or less at the same linguistic stage as the most ancient Vedic hymns of Old Indian. These archaic fragments, though perhaps not directly or not wholly emanating from Zoroaster (*q.v.*), are authentic documents of the religious reform brought about by the Prophet of Iran. The greater part of the Avesta, the so-called "recent or younger Avesta," is a collection of texts of varying antiquity and is characterised by a gradual simplification and a lax use of the grammatical forms. The Avesta when codified (towards A.D. 379) had long been a dead language known to the priests alone. its present state the Avesta has the size of the *Iliad* and *Odyssey* put together. The original home of Avestic is doubtful. Some scholars regarded it as the old Bactrian language but no decisive arguments can be drawn from the text itself. Others (Darmesteter, and recently, on linguistic evidence, Tedesco) place the home of Avestic in north-western Persia (Media), though, even in this case, Avestic could not be simply identified with Old Medic. The alphabet of the Avesta has no claim to antiquity, being the late Pahlavi script (*see* below) reformed by the addition of the missing signs. For linguistic purposes these late characters are in some cases definitely misleading.

Old Persian was used in the cuneiform inscriptions of the Achaemenian kings. The text is usually accompanied by translations into Elamitic and Akkadian (Assyro-Babylonian). The most important document is the famous inscription of Darius the Great (522–486 B.C.) on the rock of Bīhistūn, near Kermanshah, which was first read and published by Sir H. Rawlinson in 1846–47.

Aryan Languages.—Within the Indo-European family of languages, Old Iranian and Sanskrit form the division of "Aryan" languages (The terms Aryan and Īrān have a common origin.) How near Old Iranian is to Sanskrit is seen from the comparison of a phrase translated from Avestic into Sanskrit:

Avestic:	yō	vō	āpō	vanguhiš	yazāitē	ahurāniš ahurahe
Sanskrit:	yō	vō	āpō	vasvīs	yajātē	asurāṇīṣ asurasya
Avestic:	vahištābyō			zaoθrābyō		sraēštābyō...
Sanskrit:	vasiṣṭhābhyō			hōtrābhyō		srēṣṭhābhyo...

The original Avestic words, undisguised by the alphabet, would be still nearer to Sanskrit.

The principal phonetic distinctions of Iranian from Indian are: 1. original s becomes *h* in Iranian; 2. to Indian voiced and voiceless aspirates correspond respectively Iranian voiced stops or spirants; 3. Iranian has *z*, absent in Indian; 4. Iranian diphthongs *ai*, au are found in Indian as *ē*, *ō*, etc. See above and the following examples:

Sanskrit	Avesta	Old Persian	Modern Persian
Sindhu (Indus)	*Hindu*	*Hindu*	*Hind*
Asura Medhās	*Ahura Mazdāh*	*Ahuramazdā*	*Hurmuzd*
bhūmī (earth)	*būmī*	*būmī*	*būm*
kratu (insight)	*xratu*	..	*xivad*
hasta- (hand)	*zasta-*	*dasta-*	*dast*
açva- (horse)	*aspa-*	*asa-*	*asp*

Later on the two branches, Indian and Iranian, have diverged

Middle Persian.—Until the beginning of the 20th century only "Pahlavi," among the Iranian languages, was known at the stage of linguistic development, where the original wealth of forms had disappeared but the language had not finally simplified its characteristics. This Sassanian Middle Persian was chiefly known under two aspects: a. as scarce rock-inscriptions, and b. as a written language.

a. The former are cut in an uncouth but sufficiently clear script. The earliest of them (before +A.D. 300) gives usually two versions of the same text: the one is identical with the "book-Pahlavi"; the other, considerably different, was surnamed "Chaldaeo-Pahlavi," an ill chosen term which was vaguely supposed to cover the surviving dialect of Parthian times.

b. The written Pahlavi ("book-Pahlavi") is the language of the later Zoroastrian literature coming down to the ninth century A.D., when the language was certainly dead. Pahlavi literature consists mainly of commentaries on the Avesta and treatises on religious subjects (in all some 587,000 words), and only to a much smaller degree (41,000 words) treats of historic and other lay matters. This literature is written in an exceptionally ambiguous and unsuitable alphabet in which many characters are confused (one sign for *g*, *d*, *y*; one sign for *v*, *n*, *r*, etc.). Owing to such complications the name of the Supreme Deity Ōhrmazd was long read by error Anhōmā. Further difficulties are created by the use of numerous Semitic ideograms: it has long been discussed, whether *yōm* ("day" in Semitic) was to be read as it stood, or replaced by its Persian equivalent *rōzh* (as the Latin *viz.*, is read in English namely). This latter opinion was accorded universal recognition only after 1900. The defects of the Pahlavi alphabet caused the Zoroastrians to transcribe some of their texts in later Avestic characters, in which case these writings are called Pāzand.

Discoveries After 1900.—Of exceptional importance have been the Middle-Persian documents (Christian and Manichaean) found, chiefly by the German expeditions in Turfan (Chinese Turkestan) and deciphered by Prof. F. W. K. Müller. All these fragments are written in a special alphabet, derived, as usual, from Semitic (Aramean), but clearly distinguishing single characters. The words formerly known only in Semitic disguise are here written in plain Persian. Besides many additions to vocabulary and grammar, the new texts have fully confirmed the existence in Middle Persian of two parallel dialects. The one, the descendant of Old Persian, was spoken in the south (Fars) and the other probably in the north-west (or north and west) of Persia. This latter has some special traits in common with Avestic but is not its lineal offspring. The southern dialect must have been originally called Pārsīk, while the term Pahlavik (another form of the name Parthian) belonged specially to the north-western dialect. The divergence of the dialects can then be traced down to modern days. Some differences will appear from the table on page 587.

1924 Professor Herzfeld published an entirely revised text of the largest of all Sassanian inscriptions, that of the ruins of Pai-Kuli, near Sulaimaniya. Meanwhile, an original Middle Persian document of the earlier Arsacid times was found in Avroman (Persian Kurdistan), together with some important Greek parchments of that epoch (published by E. H. Minns in 1915). The Persian document was finally deciphered by H. S. Nyberg (1923).

Middle Persian		Modern languages	
North-Western	Southern	N.-W. dialects	Persian
zān- (know)	*dān*	*zān* (Kurdish)	*dān-*
zhan (woman)	*zan*	*zhin* (Kurdish)	*zan*
das (ten)	*dah*	*das* (Simnani)	*dah*
puhr (son)	*pus*	*par* (Persian doublet)	*pus-ar*
zizd (heart)	*dil*	*purd* (Kurdish)	*dil*
		zir (Kurdish)	

The existence of a different branch of the Middle Iranian languages has now been demonstrated. To it belongs the Sogdian language of which the documents were chiefly discovered and deciphered by the French scholars, and another called by some German scholars (Leumann) "nordarisch," but now supposed to be Sacian, *i.e.*, the language of the people Sacae. These two languages possess some traits in common; moreover, Sogdian has particularly close affinities with the "Scythic" group of the Iranian languages (see above).

Modern Languages.—All present Iranian languages display in different degrees a tendency towards an analytic stage (simplification of the sounds and in morphology, to the use of new auxiliary tenses, etc.).

Of these languages by far the most important is the literary Persian, as found in the extensive Persian literature and in the present day speech of the more educated classes of the Persian-speaking countries. Modern Persian is a direct descendant of the southern middle Persian, but it has borrowed many words in the north-western form, and numerous Arabic and Turkish elements. It is written in Arabic characters. Though Modern Persian is one and the same language, local variations, spoken in Persia, Afghanistan, India and Russian Turkistan (Tājīkī), are considerable.

Parallel to literary Persian, in most Persian towns, and especially villages, special dialects are in use. The dialects of Fars, Luristan, Khurasan and perhaps Kerman, belong to the same southern (south-western?) group as the literary Persian. On the other hand, very numerous and different vernaculars represent the remains of former north-western idioms. Such are the local dialects of the Caspian provinces, the language of the Kurds (spread over a vast area and sporadically found in northern Syria and even close to Angora in Asia Minor), the language of the Baluches and of isolated groups (as those of Kashan, Simnan, etc.).

Among modern Iranian languages of the "eastern" and "northern" group are the Afghan language (Pushtu [*q.v.*]), Ōrmurī, the various dialects of the Pamir group (Shughni, Wakhi, Munjani, etc.), Yaghnobi (a modern descendant of the Middle Sogdian), Ossetic (spoken in the heart of the Caucasian mountains south of Vladikavkaz, survivor of the once powerful "Sarmatian" group [*see* above] spoken in South Russia). In 1927 some new written material was found in the Khvārizmian language which seems to have been in use in the oasis of Khiva as late as the 14th century AD. This Khvārizmian must be a survival, or a descendant, of a sister-language of the Middle Sogdian.

BIBLIOGRAPHY.—Detailed monographs on the Iranian languages with complete bibliography will be found in vol. i. of *Grundriss d. Iran. Philologie*, edited by Geiger and Kuhn, Strassburg (part I., 1895–1901) (part II., 1898-I~OI), supplement on Ossetic (1903). Later important works are: Bartholomae, *Altiranisches Worterbuch* (Strassburg 1904); Bartholomae, *Zum altiranischen Worterbuch, Indogerm. Forschungen*, Beiheft to vol. xix. (Strassburg 1906); Meillet, *Granzmaire du vieux perse* (1915). For the discovery of Middle-Persian texts *see* F. W. K. Miiller, *Handschriften-Reste aus Turfan*, I.–II., *Sitzungsber. Berl. Akad.*, 1904 (the texts have been re-edited by Salemann, *Manichaeische Studien*, I., *Mtmoires de l'Académie de St. Pttersbourg*, VIII., No. 10 [1908], pp. 1–172; *see* also Salemann's further articles); texts in "nord-arisch" (Sacian) have been published chiefly by Leumann in 1912, 1919 and 1920; Gauthiot, *Essai de Grammaire sogdienne, I.* (1914–23, second volume to be published in 1929); P. Tedesco, *Dialektologie d. westiranischen Turfantexte, Le Monde Oriental*, Uppsala, *XV.* (1921) fasc. 1–3 (a general survey of western dialects); Grierson, *Linguistic survey of India*, vol. x., *Specimens of languages of the Eranian family* (Calcutta, 1921); also vol. i. pg. 27; Herzfeld, *Paikuli, Monument and inscription of the early history of the Sasanian Empire* (1924).

The best theoretical grammar of Modern Persian is Salemann and Zhukovski's *Persische Grammatik* (1889). In the Otto-Gaspey-Sauer series (Heidelberg) have appeared two detailed practical grammars by St. Clair Tisdall (in English) and S. Beck (in German). Philott, *Higher Persian Grammar* (Calcutta 1919), 935 pp.; F. Rosen, *Shumā fārsī harf mizanīd?* [Do you speak Persian?] (Leipzig 1890), several German and English editions. European dictionaries: Vullers, *Lexicon Persico-latinum* (Bonn, 1855), 2 vols. and an annex (complete and important for scientific work); Desmaisons, *Dictionnaire persan-français*, 4 vols. (Rome 1908–14); Steingass, *A comprehensive Persian-English Dictionary* (1892), 1,539 pp.; Abdullāh Ghaffārov, *Persidsko-russki slovar* (Moscow, 1914–27), 2 vols. (important phraseology).

(V. F. M.).

IRANIAN RELIGION: *see* ZOROASTER and ZEND-AVESTA.

'IRAQ. The modern independent Arab Kingdom of 'Iraq was formed after the World War out of the former Turkish vilayets of Mosul, Baghdad and Basra. It includes an area of over 140,000 sq.m. with a population according to the census of 1920 of 2,849,282. Of this number 1,146,685 were Sunni Mohammedans, 1,494,015 Shi'ah Mohammedans, 87,488 Jews, 78,792 Christians and 43,302 of other religions. The capital is Baghdad, pop. 1920, 145,000. Basra, the chief port, 70 m. up the Shatt el' Arab from the Persian Gulf, has about 50,000 inhabitants. The region embraces not only the valley of Mesopotamia but also an important desert corridor stretching westwards to the boundaries of Transjordan. 'Iraq is bounded on the north by Turkey, on the west by Syria and Transjordan, on the south-west and south by Nejd and Kuweit and on the east by Persia. Owing to the nature of the country, the difficulties of water rights and raiding proclivities of the desert tribes the western and southern boundaries are by no means clearly defined. Cotton here is an irrigation crop. Before 1921 none was exported. No spectacular development has taken place, but a steady, healthy progress is shown. The whole of the cotton passes through the hands of the British Cotton Growing Association, who possess the only ginnery. The 1926 crop was 3,500 bales, of the value of £77,000. (For physical and economic geography *see* MESOPOTAMIA.) Until she acquired full sovereignty on Oct. 4, 1932, 'Iraq was mandated to the British Empire.

The terms of the mandate were never formally laid down by the League of Nations, but the relations between Great Britain and 'Iraq were defined in terms of a treaty concluded on Oct. 10, 1922, originally for a period of 20 years. This, however, was modified by a protocol dated April 30, 1923, in which it was agreed that the treaty should terminate upon 'Iraq being admitted to membership of the League of Nations and in any case not later than four years from the date of the ratification of peace with Turkey, when it was contemplated that the parties would conclude a fresh treaty for the regulation of their future relations. On Sept. 24, 1924, the League of Nations accepted this instrument as properly fulfilling the provisions of Art. 22 of the Covenant. By a further treaty ratified on March 30, 1926, and resulting from the decision of the League on the Mosul question, the period was again altered to 25 years (from Dec. 16, 1925), unless 'Iraq should previously be admitted to the League of Nations. She was, in fact, admitted on Oct. 4, 1932.

The 'Iraq Government is a limited monarchy on the Egyptian model, with a king, a senate of 20 nominated members and a lower house of 88 deputies. The country is divided into three vilayets (provinces) comprising in all 14 liwas (divisions), the administration being represented in each liwa by a Mutessarif, who is assisted by a British official with advisory powers. The liwas are: Mosul Vilayet: Mosul, Arbil, Kirkuk and Sulaimaniyah; Baghdad Vilayet: Baghdad, Karbala, Diyala, Kut, Diwaniyah, Hillah and Dulaim; Basrah Vilayet: Basrah, Amara and Muntafik.

HISTORY

Nationalist Movement.—During the years from 1911 to the outbreak of the World War the Ottoman regime in the distant vilayets of Turkish Arabia showed marked deterioration. The last hope that any efficient administrative system might be established in Mesopotamia vanished with the fall in 1911 of Nazim Pasha, an energetic man of singular integrity, who had set himself to the intricate task before him with all the rude strength of a Turkish soldier of the old order. The Italian and

Balkan wars had weakened the central Government, while in the Arab provinces in particular the disappointment of hopes born of the constitution of 1908 was leading to a recrudescence of racial aspirations. Damascus and Beirut had long been centres of nationalist movements, and by the end of 1913, the secret society called the Ahd (the League) had extended its activities also to the three Mesopotamian vilayets.

The Mesopotamian Campaign. — The declaration of war was followed on Oct. 31, 1914, by a proclamation by the Political Resident in the Persian Gulf to local Arab rulers explaining that Turkey had entered the war only at the instigation of Germany and promising the chiefs who had enjoyed the protection of Great Britain that no act of that country should threaten their liberty or their religion. With these assurances they were satisfied. Before military operations had begun, Sir Percy Cox, whose efforts as British Resident during the previous decade had consolidated the British position on the Gulf, joined the force concentrated at Bahrein as chief political officer and on Nov. 6 when the British took Fao Fort and made their first landing on Turkish soil, he issued a proclamation in similar terms to the Arabs of Turkish Arabia. At this stage a determined attempt was made by the Ottoman Government to arouse Muslim fanaticism by the preaching of a Jihad, but it met with no response from the tribesmen and by Nov. 21 the Turks had abandoned Basrah, the British position on the Shatt-el-Arab was established and the valuable refinery of the Anglo-Persian Oil Company at Abadan rendered secure. On Nov. 22 British troops entered Basrah and, in the name of the general officer commanding in chief, Sir Percy Cox published a third proclamation assuring the inhabitants that Turkish rule was dead and that Great Britain came as their good friend and protector. The British arrival in Basrah was in fact greeted with acclamation by the terror-stricken populace and civil administration was at once inaugurated by the chief political officer under the orders of the G.O.C. In the same way, as success followed success, a large measure of civil law and order was gradually established close in the wake of the army.

The advance from Basrah to Baghdad is described under MESOPOTAMIA. A period of grave anxiety preceded the victory of Shu'aiba, on April 12, 1915, when a reverse would in all probability have involved the evacuation of 'Iraq by the British expeditionary force. After the retreat from Ctesiphon (Nov. 25, 1915) and the fall of Kut (April 29, 1916), the fate of 'Iraq again hung in the balance, but the vigorous re-organization of the force, now under the command of General Sir Stanley Maude, restored the foundations of victory, and Baghdad was occupied on March 11, 1917.

In the proclamation which General Maude issued on the occupation of Baghdad a definite promise was given that alien institutions should not be imposed, that Arab aspirations should be realized and that on those grounds the collaboration of Arab nobles, elders, and representatives, with British political officials, was essential. A further development of civil administration was made when in July 1917, Sir Percy Cox was appointed civil commissioner. The army and his country suffered great loss in the death from cholera on Nov. 19, 1917, of General Maude, whose distinguished powers as a military leader had earned the respect and admiration of 'Iraqis, but under Lieut.-general Sir W. R. Marshall, the success of British arms continued. Late in Nov. 1917 the northern Euphrates was occupied up to Ramadi, and in March 1918 up to Ana. In the same month, however, a serious incident occurred on the middle Euphrates. The holy towns of Karbala and Najaf were not only racked by internal feuds but both they and the adjacent tribesmen owned the sway of Persian divines to whom the secular interest of 'Iraq counted nothing. The Holy Places thus presented a fertile field for intrigue and when the Government of Occupation showed a determination to check the rapacity of the local headmen at Najaf, a plot, engineered from without, came to a sudden head with the murder of the newly appointed political officer. Sir Percy Cox was on his way home at the time to attend a conference in London but the situation was handled successfully by his locum tenens Colonel (later Sir Arnold) Wilson and the G.O.C. in chief. Though Najaf was blockaded not a shot was fired, but the pressure exerted resulted in the handing over of the guilty by May 19. **A** court of specially qualified members condemned 13 of the accused to death, while over 100 were sentenced to transportation for life or shorter periods, but all of these latter were ultimately amnestied.

North-east of Baghdad, progress was hindered by the Russian débâcle, but when, at the end of June 1917, the upheaval which was taking place in Russia obliged the Russians to retire, the British force gradually drove the Turks from the vacated positions, occupying Khanaqin in Dec. 1917 and Kifri in April 1918. Kirkuk was reached in May and immediately a provisional Government under a local magnate, Shaikh Mahmud-al-Barzanji, was set up voluntarily in Sulaimaniyah in friendly co-operation with the British. But the exigencies of the Persian situation made it impossible for the general staff to maintain the position effectively and it was not until the final advance took place in Oct. 1918 that the occupation of the whole of the Mosul vilayet was effected.

THE ANGLO-FRENCH DECLARATION

Liberation of 'Iraq. — On Nov. 7, 1918, ten days after the signature of the Turkish armistice at Mudros, the British and French Governments issued a joint declaration of vital importance to the occupied Arab territories, stating their aims in the East to be: —

To complete the final enfranchisement of the peoples so long oppressed by the Turks, and the establishment of national governments and administrations, drawing their authority from the initiative and free choice of native populations.

The proclamation went on to promise encouragement and help in the establishment of native governments and administrations, alike in Syria and Mesopotamia. In the case of General Maude's earlier pronouncement made on the occupation of Baghdad, when the upshot of the war was still doubtful, the flamboyant sentiments expressed therein had been to a great extent discounted by the public as a natural form of propaganda, but the Anglo-French declaration, published after victory had been achieved, was taken in all seriousness. Had an early peace made it possible to give early effect to the policy therein enunciated all would have gone well. Unfortunately the inordinate delay which ensued over the peace negotiations and the wide promulgation of President Wilson's 14 points, with the potent element of self-determination, gave unbridled play to political speculation and stimulus to nationalist feeling. This was further encouraged by enquiries which the civil commissioner set on foot under instructions from H.M. Government, whether: —

(i.) The people of 'Iraq were in favour of a united Arab State from the northern boundary of the Mosul vilayet to the Persian Gulf.
(ii.) It should be under British tutelage.
(iii.) It should be under an Arab amir.
(iv.) In the latter case, whom would they suggest?

On the first point their replies were unanimously in the affirmative. In regard to the other three every variety of opinion was given. Unfortunately the conflicting character of the response had the effectof delaying a definite pronouncement of policy, and meanwhile other factors came into play. All this time the administration had remained patently alien; British forces had been cut down to a minimum and when in May 1920 the British Government announced their acceptance from the League of Nations of a Mandate over 'Iraq, the Damascus Government had already, in the absence of the Amir Feisul and contrary to his orders, begun encroachments. In answer to objections raised against the Mandate by a self-chosen committee in Baghdad, it was announced (June 20) that Sir Percy Cox would return in the autumn to establish a provisional Arab Government and call an Assembly, freely elected by the people, in consultation with which he would prepare an Organic Law. But nothing would then have satisfied the claims of the nationalist leaders, and on June 2, 1920, the turbulent Shiah tribes, encouraged by their religious leaders, broke into open revolt.

To restore peace and order was the first necessity. Troops were drafted in from India, and when Sir P. Cox reached Basrah on his return as High Commissioner (Oct. 1) the rebellion in its

main centres, the middle Euphrates, the Diyala and the adjacent part of Kirkuk district was already doomed to failure. By Nov. 10 it was found possible to establish. as a first step towards national government, a Council of State under the presidency of the venerable Naqib of Baghdad. This body represented all classes and sects of society. It gave immediate attention to the repatriation of 'Iraqi officers from Syria and the Hejaz; to the re-organization of civil government under 'Iraqi officials, greatly facilitated by the return of many experienced men from Turkey; and to the preparations of an electoral law and the formation of an army. It was the arrival of 'Iraqi officers who had served under the Amir Feisul which set on foot a specific movement in his favour in 'Iraq. He had been expelled from Syria by the French authorities in July 1920 and had since resided in England.

In March 1921 Mr. Winston Churchill, who had now become secretary of State for the Colonies, convened a conference at Cairo to which all British representatives in the Middle East were summoned. The first result of the conference was the publication of a general amnesty in May and at the same time an attempt was made to ascertain the wishes of the Kurdish provinces about their inclusion or non-inclusion in the 'Iraq State. The net result was that Sulaimaniyah elected to remain under the control of the High Commission, but the rest of the Kurdish population was content to look to the 'Iraq Government, subject to the promise of Kurdish officials and the local use of the Kurdish language.

Choice of King.—It was not until June that H.M. Government were in a position to make any clear announcement of policy as the result of the Cairo deliberations and towards the end of that month the Amir Feisul arrived in 'Iraq to offer himself to the inhabitants as a candidate for the throne. He was received with acclamation, and on July 11, the Council of Ministers passed a resolution declaring him king of 'Iraq, on condition that his government should be constitutional, representative, and democratic. But Sir Percy Cox thought it necessary to fortify himself by consulting the people and a referendum was carried out through the Ministry of the Interior, throughout the country, with the exception of Sulaimaniyah, with the result that 96% of the votes were cast in favour of the Amir Feisul, most of the townships and districts stipulating for the continuance of the British Mandate. The Amir Feisul was crowned king on Aug, 23, 1921, and entrusted the Naqib with the formation of his first cabinet.

TURKISH HOSTILITY

Troubles on Turkish and Arabian Frontiers.—The early years of King Feisul's reign were troubled without and within. To the north Turkish nationalism adopted an attitude distinctly hostile to 'Iraq. Turkish garrisons on the frontier were increased, the tribes flooded with propaganda, and the whole of Southern Kurdistan was kept in a ferment until finally in the spring of 1923 the Turks were ejected.

On the Arabian frontier, since the beginning of 1921, the operations of Ibn Sa'ud against Ibn Rashid had profoundly disturbed the nomad tribes. As early as April 1921 the Shammar of Jbn Rashid began to seek safety in 'Iraq, where a large section of the tribe resides. Their presence embittered relations between 'Iraq and Nejd, and after the fall of Ibn Rashid's capital, Hail, in Nov. 1921, Ibn Sa'ud's pretensions increased, and he claimed the allegiance of the Anizah on the eastern side of the Syrian desert, who had always been attached to 'Iraq. In March 1922, he permitted the leaders of his Akhwan, or Brethren, to attack the 'Iraq desert camel corps and the shepherd tribes grazing under its protection about 30m. south of the railway between Baghdad and Basrah. Heavy loss was inflicted.

Anti-Mandate Agitation: the Preliminaries of the 'Iraq Treaty.—These dangers on the frontier coincided with a serious divergence of views between the British and 'Iraq Governments as to the nature of their relations with one another. King Feisul and his prime minister asked for the complete abrogation of the unpopular "mandatory" relation and its substitution by a treaty of alliance, whereas the British Government were contemplating a treaty within the scope of the Mandate. The difference was largely technical, but it gave rise to great misunderstanding and embittered controversy. It was even suggested that the attack by Ibn Sa'ud, who at the time was in receipt of a subsidy from Great Britain, had been instigated by the latter in order to expose the weakness of the 'Iraq Government. At this point the Shi'ah divines took a hand in the matter and summoned a conference at Karbala; nominally to consider measures of defence against the Akhwan, but really with the object of protesting against the British Mandate. The conference assembled, but the Sunni shaikhs held aloof, the wiser among the Shi'ahs nipped any subsidiary intentions in the bud, and the meeting confined itself to petitioning King Feisul to take steps against the Akhwan. But the heat engendered was not extinguished, and the anti-Mandate agitation continued throughout the summer, though in June the Council of Ministers accepted the treaty with Great Britain, subject to its acceptance in due course by the Constituent Assembly. On Aug. 16 the cabinet resigned, and Sir Percy Cox when paying an official visit to the king on the anniversary of his accession was greeted by an anti-Mandate demonstration. He demanded and received an instant apology, but at the same moment it was announced that the king was struck down with a dangerous attack of appendicitis and an immediate operation was necessary. Thus by a singular combination of circumstances, the country was left with no authority but that of the High Commissioner, who proceeded to use it. He issued a proclamation explaining the situation, arrested and deported certain agitators, and induced two of the Shi'ah divines to leave voluntarily for Persia. By Sept. 10, 1922, all agitation had died out and on Oct. 10 Sir Percy Cox and the Naqib signed a treaty of alliance between Great Britain and 'Iraq for a period of 20 years (British Treaty Series No. 2). Ratification, however, was delayed and negotiations over the subsidiary agreements dragged on until 1924.

No sooner was the internal situation stabilized than the north-eastern frontier again demanded attention. With Shaikh Mahmud in Sulaimaniyah and the Turks in Ruwandiz and its neighbourhood, effective administration had ceased east of Erbil, Kirkuk, and Kifri. In Oct. 1922 a measure decided on at the Cairo Conference was put into force and the air marshal, Sir John Salmond, assumed charge of all imperial forces in 'Iraq, ground troops, levies and air force. By his vigorous action he forced the Turks to retire to Ruwandiz. But the autumn of 1922 was the period of Mustafa Kemal's great triumph over the Greeks. It influenced both the Shi'ahs of the Euphrates and the tribes of the North. On Oct. 21, 1922, the king issued an Iradah ordering elections for the Constituent Assembly to begin; it was countered by a fatwah, signed by the Shi'ah divines of Karbala and Kadhimain forbidding participation in elections. In Nov. the Naqib resigned, and Abdul Muhsin Beg al Sa'dun formed a new cabinet. In the same month elections were held in Great Britain, during which a campaign was conducted against the fulfilment of British pledges to 'Iraq. Mr. Bonar Law's cabinet came in under obligation to consider the question, and Sir Percy Cox was summoned to London in Jan. 1923 to take part in the discussion. He left in charge Sir Henry Dobbs, who had come out as Counsellor to the High Commission in the previous December. The position of the British Government was extremely difficult, but a solution was found in the reduction of the term of the yet unratified treaty from 20 to a maximum of four years after the ratification of peace with Turkey (which took place on Aug. 6, 1924), with the prospect of renewal at the end of that period. The treaty would lapse in the event of 'Iraq becoming a member of the League of Nations. The protocol embodying this agreement was brought back by Sir Percy Cox on March 31, 1923, and signed on April 30.

Operations in Mosul.—Meantime, in March 1923, it had again become necessary to take vigorous steps against the Turkish threat in the north. The strong stand taken by Lord Curzon at Lausanne reacted on 'Iraq. Shaikh Mahmud, who was in league with the Turkish band at Ruwandiz, was dealt with, and in April, by a brilliant movement supported by air action, the Turks were ejected from Ruwandiz, and-a Kurdish chief put in as Kaimmakam under the Mutasarrif of Erbil. As it was not considered feasible for the time being to set up a local administration in Sulaimaniyah it was decided to give Shaikh Mahmud another chance of

rehabilitating himself, but in 1924 his intrigues made his expulsion again necessary. The Sulaimaniyah liwa became included in 'Iraq in March 1924 and sent representatives to the Constituent Assembly.

Settlement **with Nejd.**—In the winter of 1923–24 an attempt was made to settle the growing differences between 'Iraq and Nejd by a conference of representatives held at Kuwait under Colonel Knox. The main point of difference was the repatriation of Nejd tribes which had taken refuge in 'Iraq. The 'Iraq representatives rightly pointed out that apart from the violation of tribal custom involved, they had not the requisite force to constrain these unwelcome guests to return to their own country but they agreed to abide by stipulations considered satisfactory by the British Government. Though on lesser matters agreement was reached Ibn Sa'ud proved obdurate on the major issue, and just as the conference was about to reassemble, in March 1924, his followers carried out a brutal raid on the 'Iraq shepherd tribes. The conference thereupon broke up. Other raids occurred during 1924–25, and as a result, the 'Iraq Government made a determined effort to remove the tribes from the vicinity of the frontier.

Ibn Sa'ud likewise gave orders to his Akhwan leaders to desist from their raids. Finally, at the conference held at Bahra in the Hejaz between the Sultan and Sir Gilbert Clayton in Kov. 1925, a treaty was drawn up between 'Iraq and Nejd on the lines proposed by H.M. Government and the 'Iraq Government, at Kuwait.

Ratification of Treaty.—Sir Henry Dobbs and the 'Iraq Government had been engaged during the winter of 1923 in discussing the details of the agreements subsidiary to the treaty. These agreements were signed on March 25, 1924, and the instrument of alliance being thus complete, the Constituent Assembly was opened by the king on March 27.

THE TREATY ACCEPTED

The debates on the treaty and agreements continued until June 10. There was much misrepresentation but undoubtedly some solid ground for dissatisfaction at the heavy burdens imposed on 'Iraq by the obligation simultaneously to expand the army, redeem the capital cost of the railways, and shoulder a large share of the Ottoman debt. H.M. Government gave an undertaking that after the ratification of the treaty they would be prepared to reconsider certain of the financial obligations of 'Iraq towards Great Britain, and the debates were brought to a close by the announcement of the determination of the British Government to raise, at the June session of the League of Nations, the whole question of the continuance of their Mandate, and by the warning that failure to pass the treaty through the 'Iraq Assembly by June 10 would be regarded as a rejection. King Feisul and his Government clearly discerned the attendant risks, the cabinet called on its followers for support, and the treaty and agreements were accepted before midnight on the appointed date. The instrument was accepted by the League on Sept. 27, 1924, and was ratified by King George and King Feisul in the winter of 1924. The Constituent Assembly then passed the Organic and Electoral Laws, and was dissolved on Aug. 2, 1924. The question which now overshadowed all others was the settlement of the northern frontier with Turkey (see LEAGUE OF NATIONS; MOSUL).

It had not been considered advisable to disturb the proceedings of the Frontier Commission sent by the League of Nations to Mosul in the spring of 1925 by the holding of elections; on March 21, 1925, however, the Organic Law was promulgated and elections for the first parliament began. Yasin Pasha's cabinet had previously passed four notable measures, vital for the further prosperity and stability of 'Iraq. The first was the signature with the Anglo-Persian Oil Company of an agreement for the dredging of the Shatt-el-Arab. The second was a trade transit-agreement with Syria. The third was the granting to an international group, known as the Turkish Petroleum Company, of a concession for the development of oil in the Baghdad and Mosul vilayets; while the fourth was the signature of long term contracts with over a hundred experienced British advisers and technical officials.

The visit in April 1925 of the secretaries of State for the Colonies and Air gave opportunities for frank and valuable exchange of views, and also resulted in the adoption of a scheme which would provide for the speedier training of the 'Iraq army so that it may eventually assume responsibility for internal security and external defence.

Elections were completed by June 23, 1925, and Parliament met on July 16 in extraordinary session to consider the budget and certain necessary amendments to the Organic Law.

(G. BE.; P. Z. C.)

Second Treaty, Jan. 1926.—The award of the Council of the League on the Turco-'Iraq frontier question (see LEAGUE OF NATIONS) was accepted by 'Iraq with considerable relief, and in response to the Council's invitation to the British Government, negotiations for the conclusion of a new treaty were initiated towards the end of 1925. This instrument was to endure for a period of 25 years, or until such time as 'Iraq should become a member of the League. It was signed by the representatives of the two Governments on Jan. 13, 1926; accepted by the 'Iraq parliament on Jan. 18, by the British parliament on Feb. 18; and recognized by the Turkish Government in the preamble to a tripartite treaty concluded at Angora on June 5, 1926, between the representatives of Great Britain, 'Iraq and Turkey (Cmd. 2679). This latter treaty records the acceptance by the parties of the boundary-line adopted by the Council of the League; provides for the despatch of a boundary commission to trace it on the ground; lays down procedure for the amicable settlement of boundary disputes and the maintenance of tranquillity on the frontier; and finally provides for the payment to Turkey by the 'Iraq Government, for a period of 25 years, of 10% on all royalties received by the latter from the Turkish Petroleum Company and its subsidiaries. It may be mentioned that this important company reported its first successful boring experiment in the neighbourhood of Kirkuk in Oct. 1927 and promises to have a prosperous future.

Third Treaty, Dec. 1927.—The boundary commission provided for in the above instrument having successfully completed its labours by the autumn of 1927, the 'Iraq Government were encouraged to hope that the conditions necessary for admission to membership of the League of Nations, under Art. 1 of the Covenant, would now be considered fulfilled. King Feisul and his prime minister, Jaafar Pasha, accordingly journeyed to London in Nov. 1927 for the purpose of approaching the British Government as to the possibility of their supporting an application from the State of 'Iraq for admission, at the meeting of the League in Sept. 1928. The questions involved in this proposition were fraught with no little difficulty, relating mainly to the problem of national defence; King Feisul's Government considering that full military responsibility could only be met at the present juncture by the adoption of some form of conscription, a measure to which the British Government found it difficult to promise their support. On the whole, the British Government considered that it would not be possible for them to support 'Iraq's application for admission at such an early stage with the least chance of success. Short of that, however, some readjustment of the relations between 'Iraq and her Mandatory was adjudged to be possible, having regard to the undoubted progress made by the 'Iraq administration during the past two years, and this took the form of yet another treaty to replace that of Jan. 1926. While the main principles of the second treaty underwent little change therein, another step was taken towards the satisfaction of 'Iraqi aspirations by the formal recognition of 'Iraq as an independent State (Art. 1), and Great Britain further agreed, provided that the present rate of progress be maintained, to support the candidature of 'Iraq for admission to the League in 1932 (Art. 8). At the same time it was recognised that the existing military and financial agreements admitted of some revision of the progress made, and negotiations were accordingly opened for that purpose. Unfortunately, as they progressed, considerable divergence became apparent between the modifications pressed for by the more advanced nationalists in 'Iraq and the views of H.M. Government as to what would be safe and feasible. The main difficulty arose in connection with the fundamental question of national defence. Was the state of 'Iraq already capable, as her government claimed,

of taking full responsibility for national defence? If not, should she be called upon to bear the extra cost involved to H.M. Government by the necessity for keeping forces in 'Iraq?

A new treaty for 25 years between Great Britain and 'Iraq as equal and independent states was signed on June 30, 1930, and took effect from 'Iraq's admittance to the League of Nations on Oct. 3, 1932. Ghazi I succeeded his father, Feisal, as king in 1933 but was killed in a motor accident in 1939. His 4 year old son succeeded him as King Feisal II.

Defence.—The military history of 'Iraq is bound up with that of Turkey (*q.v.*). British responsibility for the defence of the country is a legacy of the World War and the Covenant of the League of Nations under which a mandate for the well-being of the people formerly under the Turkish yoke was allotted to Great Britain on the conclusion of peace. The close of the World War found a British army, mostly of Indian troops, of a ration strength of over 204,000 in the country, pitted against about 29,500 Turks. The British troops were hastily withdrawn, and at the same time (1919) a frontier force of 'Iraq levies was raised with headquarters at Mosul. These levies were reorganized and redistributed in 1921, March 1922 and again in 1924. The cavalry were disbanded in 1927, and most of the infantry have already followed, leaving only 2 battalions, both of Assyrians, and a depot (March 1928). The 'Iraq levies number about 3,000 in all.

The present-day problem of the military defence of 'Iraq under treaties with Great Britain is of unique interest, in that defence has been entrusted mainly to British aircraft, thus minimizing the number of troops, and the whole placed under the control of the air force commander. The British garrison has been reduced to 2 battalions of Indian infantry. In addition to the 'Iraq levies, an 'Iraq army is in process of formation under British officers. The strength (1928) may be taken at about 10,300, organized in 3 cavalry regiments, 2 field and 3 pack batteries, and 7 battalions of infantry, with the usual military departments and details. There is a ministry of defence with an army headquarters working therewith, and the troops are distributed in 3 military areas, northern, eastern and southern. The Royal Air Force has 8 sections of armoured cars.

See also the British *Army list* and *Royal Air Force list*.

(G. G. A.)

'IRAQ, a province of Persia, situated south of Hamadan and west of Qum. The district is an agricultural one—producing much grain, and grapes and raisins are of particularly good quality. The revenue in 1926–27 amounted to 1,450,876 krans (£ St.=45 krans). Sultanabad, the administrative centre, is situated 34° 6′ N. and 49° 42′ E., at an elevation of nearly 6,000 ft. on the Tehran-Qum-Khurramabad road, which is suitable for motor traffic, and it is also connected by a similar road with Hamadan.

IRBIT, a town of the Uralsk Area of the R.S.F.S.R. in lat. 57° 38′ N., long. 63° 6′ E., at the junction of the Irbit and Niza rivers which drain into the Tura, a tributary of the Irtish. The Niza is navigable as far as Irbit in spring. It is famous for its fair held since 1643 from Feb. 8 to March 10, the clearing house for Siberian furs, wools and hides, and for tea from the east. A large proportion of the fur comes from west of Lake Baikal and of the wool from the Kirghiz steppe: what is not sold is sent on to the fair at Nizhni-Novgorod. The skins include squirrel, rabbit, sable, ermine, brown bear, kolonok, grey wolf, fox, badger, black cat, Orenburg marmot, Petchora, Yenisei and Obdorsk white fox, reindeer, mink and marten, and sales amount to £730,000 to £830,000 per annum. Until Jan. 1917 the town was 80 m. from the railway, but in that year a branch from Sverdlovsk (Ekaterinburg) to the Tavda river was opened, which will ultimately link up with Tobolsk. The Irbit fair was the first to be reopened (1922) after the 1914–21 war and civil war. The population was 20,064 in 1897, dropped to 9,647 in 1920, was 11,719 in 1926.

IRELAND, JOHN (1838–1918), American Roman Catholic prelate, was born at Burnchurch, County Kilkenny, Ireland, on Sept. 11, 1838, In 1849 he was taken to the United States by his parents, who settled at St. Paul, Minnesota Territory. After being educated in France for the priesthood, he returned to the United States in 1861; he was ordained at St. Paul and in the following year he accompanied the 5th Minnesota Volunteer Infantry south as chaplain. Subsequently he became rector of the cathedral at St. Paul. His appointment in 1875 as bishop of Nebraska was changed at the urgent request of Bishop Grace so that he might remain at St. Paul as bishop-coadjutor with the right of succession; at the same time he was made titular bishop of Maronea.

His liberal views gave him a wide influence and reputation both within and without the church, and he came to be looked upon as a leader of the "American" as distinguished from the "Roman" party in the clergy. Several of his administrative acts, notably his plan for the partial taking over of control of the parochial schools by the local authorities, were strenuously attacked. He was prominently identified with the planting of Catholic communities or colonies in the North-west, with the establishment of the Catholic university at Washington, and with the Catholic total abstinence movement. He published *The Church and Modern Society* (1896). He died at St. Paul on Sept. 25, 1918.

IRELAND, JOHN (1879–), English composer, was born at Bowdon, Cheshire, on Aug. 13, 1879, the son of Alexander Ireland, editor and proprietor of the *Manchester Examiner*. He studied at the Royal College of Music. His pianoforte trio (1908) was followed by the sonatas in D minor and A minor for violin and piano and a second trio in one movement. In 1913 appeared an orchestral work, *The Forgotten Rite*. His other works include *Decorations* (1914), and *Rhapsody* (1915), for piano; Four Preludes for pianoforte (1915); a trio in E minor (1917); a piano sonata in E (1919) and a series entitled *London Pieces* (1917–20) together with songs and church music.

IRELAND, WILLIAM HENRY (1777–1835), forger of Shakespearian manuscripts, born in London, was the son of Samuel Ireland, an engraver and author, and dealer in rare books and curios. In 1794 young Ireland, with his father, visited Stratford, where he met John Jordan, a local poet who had forged the will of Shakespeare's father. Seeing his own father's credulous interest, Ireland copied, in ink which had all the signs of age, Shakespeare's style and handwriting, and produced leases, contracts with actors, notes, receipts, a profession of faith and even a love letter to Anne Hathaway with an enclosed lock of hair, to the delight of his unsuspecting father, and the deception of many scholars. Ireland invented an ancestor "William Henrye Irelaunde," to whom the documents had been bequeathed by Shakespeare in gratitude for rescue from drowning. At last the discovery of a whole new play named *Vortigern* was announced. Sheridan purchased it for Drury Lane theatre, and an overflowing house assembled on April 2, 1796, to sit in judgment upon it. But its one representation was greeted with shouts of daughter. Samuel Ireland the elder had published in 1795 the *Miscellaneous Papers and Legal Instruments under the Hand and Seal of William Shakespeare; including the Tragedy of King Lear and a small fragment of Hamlet* (dated 1796). He had the fullest belief in their authenticity, but the hostile criticism of Malone and others, and the unsatisfactory account of the source of the papers, made him demand a full disclosure from his son. Ireland at last confessed his fraud, and published (1796) an *Authentic Account of the Shakespearian MSS.*, and in 1805, a more elaborate *Confession*, entirely exculpating his father and making a full admission. The disgrace seems to have hastened the elder Ireland's death (July 1800). Ireland died on April 17, 1835.

The more interesting publications on the Ireland forgeries are: *Inquiry into the autlzenticity of certain Papers, etc., attributed to Shakespeare*, by Edmond Malone (1796); the elder Ireland's *Vindication of his Conduct* (1796); *An Apology for the Believers in the Shakespeare Papers* (1797), and a *Supplemental Apology* (1799), both

by George Chalmers. Vortigern was republished in 1832. The elder Ireland's correspondence with regard to the forgeries is preserved in the British Museum, with numerous specimens of his son's talent.

IRELAND, an island to the west of Great Britain, extending from 51° 26' to 55° 21' N., and from 5° 25' to 10° 30' W. The 100 fathom line lies a short distance beyond its western coast and leaves it in structural affinity with western Europe. The north channel between the Mull of Kintyre (Scotland) and Torr head has a width of only 13½ m.; in the south, St. George's channel has a width of 69 m. between Dublin and Holyhead (Wales), and of 47 m. at its southern extremity; in the centre the Irish sea attains a width of 130 miles. The area of Northern Ireland is 3,352,250 ac. and its population (1937) was 1,279,745. Eire's area is 17,024,485 ac. and its population (1936) was 2,968,420.

GEOLOGY

Ireland, rising from shallow seas on the margin of the submarine plateau of western Europe, records in its structure the successive changes that the continent itself has undergone. The first broad view of the country shows us a basin-shaped island consisting of a central limestone plain surrounded by mountains; but the diverse modes of origin of these mountains, and the differences in their trend, suggest at once that they represent successive epochs of disturbance. The north-west highlands of Donegal and the Ox Mountains, with their axes of folding running north-east and south-west, invite comparison with the great chain of Leinster, but also with the Grampians and the backbone of Scandinavia. The ranges from Kerry to Waterford, on the other hand, are clearly parts of an east and west system, the continuation of which may be looked for in South Wales and Belgium. The hills of the north-east are mainly the remnants of lava-plateaux, which carry the mind towards Skye and the volcanic province of the Faeroe Islands. The two most important points of contrast between the geology of Ireland and that of England are, firstly, the great exposure of Carboniferous rocks in Ireland, Mesozoic strata being almost absent; and, secondly, the presence of volcanic rocks in place of the marine Eocene of England.

The fact that no Cambrian strata have been established by palaeontological evidence in the north and west of Ireland has made it equally difficult to establish any pre-Cambrian system. The great difference in character, however, between the Silurian strata at Pomeroy in county Tyrone and the adjacent metamorphic series makes it highly probable that the latter masses are truly pre-Cambrian. The other metamorphic areas of the north and west present even greater difficulties, owing to the absence of any overlying strata older than the Old Red Sandstone. They are generally referred to as "Dalradian," a convenient term invented by Sir A. Geikie for the metamorphic series of the old kingdom of Dalriada. The oldest rocks in this large area are a stratified series of mica-schists, limestones and quartzites, with numerous intrusive sheets of diorite, the whole having been metamorphosed by pressure, with frequent overfolding along axes with a north-easterly or Caledonian trend.

Following on these rocks of unknown but obviously high antiquity, we find fossiliferous Ordovician (Lower Silurian) strata near Killary harbour on the west, graduating upwards into a complete Gotlandian (Upper Silurian) system. Massive conglomerates occur in these series, which are unconformable on the Dalradian rocks of Connemara. In the Wenlock beds of the west of the Dingle promontory there are contemporaneous tuffs and lavas. Here the Ludlow strata are followed in apparent conformity by a thick series of barren beds (the Dingle Beds), which have been variously claimed as Upper Silurian and Lower Devonian. No certain representative of the Dingle Beds has been traced elsewhere throughout the south of Ireland, where the Old Red Sandstone succeeds the uptilted Silurian strata with striking unconformity. The folds which distort these Silurian rocks, including the Dingle Beds, have a north-easterly trend parallel to those which affect strata of the same age in the southern uplands of Scotland and thus belong to the Caledonian system. The best example of these folds is the axis of Leinster, its core being occupied by granite which is now exposed continuously for 70 m., iorming a moorland from Dublin to New Ross. On either flank the Silurian shales, slates and sandstones, which are very rarely fossiliferous, rise with steep dips. They are often contorted, and near the granite pass into mica-schists and quartzites.

In south-eastern Wexford, in northern Wicklow (from Ashford to Bray), and in the promontory of Howth on Dublin Bay, an apparently earlier series of green and red slates and quartzites forms an important feature. The quartzites, like those of the Dalradian series, weather out in cones, such as the two Sugarloaves south of Bray, or in knob-set ridges, such as the crest of Howth or Carrick Mt. in county Wicklow. The radial or fan-shaped markings known as *Oldhamia* were first detected in this series, but are now known from Cambrian beds in other countries; in default of other satisfactory fossils, the series of Bray and Howth has long been held to be Cambrian.

Extensive denudation followed the Caledonian folding and on the land-surface thus formed the Devonian lakes gathered, while the rivers poured into them enormous deposits of sand and conglomerate. Large areas of Old Red Sandstone have been brought up from beneath the denuded Carboniferous along the Hercynian folds of the south. The conglomerates, moreover, appear at intervals through the limestone covering of central Ireland, and usually weather out as conspicuous scarps or "hogs'-backs." The Slieve Bloom mountains are thus formed of a dome of Old Red Sandstone folded on a core of unconformable Silurian strata; while in several cases the domes are worn through, leaving rings of Old Red Sandstone hills, scarping inwards towards broad exposures of Silurian shales. Further north an extensive area of Old Red Sandstone is preserved within the rift valley, which is continued from central Scotland, beneath the North Channel and the basalt plateau, and comes to light again south-west of Lough Neagh. The Old Red Sandstone shows local evidence of contemporaneous volcanic activity.

The highest beds of Old Red Sandstone type pass up conformably in the south of Ireland into the Lower Carboniferous, through the "Yellow Sandstone Series" and the "Coomhola Grits" above it. The Yellow Sandstone contains *Archanodon*, the oldest known fresh-water mollusc, and plant-remains; the Coomhola Grits are marine, and are sometimes regarded as Carboniferous, sometimes as uppermost Devonian. In the south, the Carboniferous deposits open with the Carboniferous Slate, in the base of which the Coomhola Grits occur. Its lower part represents the Lower Carboniferous Shales and Sandstones of the central and northern areas, while its upper part corresponds with a portion of the Carboniferous Limestone of the central plain.

The Lower Carboniferous Sandstones are conspicuous in the region from Milltown near Inver Bay in southern Donegal to Ballycastle in county Antrim. In the latter place they contain workable coal-seams. The Carboniferous Limestone often contains black flint (chert), and at some horizons conglomerates occur, the pebbles being derived from the pre-existing ridges of the "Caledonian" land. A black and often shaly type called "calp" contains much clay derived from the same land-surface. While the limestone has been mainly worn down to a lowland, it forms fine scarps and tablelands in county Sligo and other western regions. Contemporaneous volcanic action is recorded by tuffs and lavas south-east of Limerick and north of Philipstown. The beds above the limestone are shales and sandstones. the true stratigraphical horizon of which is as yet ill defined, but which certainly range in places into the Middle Coal Measures. No beds equivalent to the Upper Coal Measures of England have yet been proved South of the line between Galway and Dublin the coal is anthracitic, while north of this line it is bituminous.

The "Hercynian" earth-movements, which so profoundly affected north-west and north-central Europe at the close of Carboniferous times, gave rise in the south of Ireland to a series of east and west folds and in the centre to a series of lesser folds deflected along Caledonian trend lines. The uplift which followed upon this folding led as in England to extensive denudation. It is however only in the north-east of Ireland that the subsequent history can be traced. Here the succeeding Permo-Triassic beds lie unconformably across the Carboniferous and older strata.

The Permian sea has left traces at Holywood on Belfast Lough

and near Stewartstown in county Tyrone. Certain conglomeratic beds on which Armagh is built are also believed to be of Permian age. The Triassic sandstones and marls, with marine Rhaetic beds above, are preserved mainly round the basaltic plateaux of the north-east and extend for some distance into county Down.

The Jurassic system is represented in Ireland by the Lower Lias alone, and it is probable that no marine beds higher than the Upper Lias were deposited during this period, From Permian times onward, in fact, the Irish area lay on the western margin of the epicontinental seas that played so large a part in determining the geology of Europe. Denudation, consequent on the renewed uplift of the country, affected the Jurassic beds until the middle of Cretaceous times. The sea then returned, in the north-east at any rate, and the first Cretaceous deposits indicate the nearness of a shore-line. Dark "green-sands," very rich in glauconite, are followed by yellow sandstones with some flint. These two stages represent the Upper Greensand, or the sandy type of the English Gault. Further sands represent the Cenomanian. The Turonian is also sandy, but in most areas was not deposited, or has been denuded away during a local uplift that preceded Senonian times. Even the succeeding Senonian chalk, where it rests in the extreme north on Trias or even on the schists, is often conglomeratic and glauconitic at the base, the pebbles being derived from the old metamorphic series. This chalk appears to underlie nearly the whole basaltic plateaux, appearing as a fringe round them, and also in an inlier at Templepatrick.

No records of late-glacial submergence such as characterize Scotland and Fennoscandia are known in Ireland. The earliest post-glacial deposits are the submerged forests and the marls at the base of the peat bogs. In Early Neolithic (Campignian) times a slight submergence with a maximum of some 20 ft. affected the north-east of Ireland, and the fauna of the deposits dating from this period shows a temperature several degrees higher than that of the present day. Wide-spread growth of mountain peat has occurred since the bronze age.

After the Irish chalk had been elevated and worn into gently rolling downs, on which flint-gravels gathered, the great epoch of volcanic activity opened, which was destined to change the character of the whole north-west European area. Fissure after fissure, running with remarkable constancy north-west, broke through the region now occupied by the British Isles, and basalt was pressed up along these cracks, forming thousands of dikes, from the coast of Down to the Dalradian ridges of Donegal. One of these on the north side of Lough Erne is 15 m. long, Most of the igneous region became covered with sheets of basaltic lava, which filled up the hollows of the downs, baked the gravels into a layer of red flints, and built up, pile upon pile, the great plateaux of the north. There was little explosive action, and few volcanic vents can now be traced, so that it is thought that the lavas originated in fissure eruptions like those of Iceland. After a time, a quiet interval allowed of the formation of a deep zone of lateritic weathering represented by 50 to go ft. of lithomarge capped by pisolitic iron ore and bauxite. The plant-remains associated with these beds form the only clue to the post-Cretaceous period in which the volcanic epoch opened, and they have been placed by Mr. Starkie Gardner in recent years as early Eocene. During this time of comparative rest, rhyolites were extruded locally in county Antrim. A renewal of the basaltic eruptions produced the Upper Series of plateau lavas, beneath which this old subtropical land surface is preserved. There was then a second long period of weathering which produced a soil comparable in thickness with that of the Interbasaltic zone. Warping led to the denudation of this soil, and its concentration in the centre of the basin now occupied by Lough Neagh. Thus were formed the Lough Neagh Clays, the plant remains of which are identical with those of the Interbasaltic Zone, and which must therefore be regarded as also of Eocene age. The whole plateau was subsequently greatly modified by faulting during the diastrophism of the Miocene period, but no further volcanic activity supervened, and no deposits of this period or of the later Pliocene are preserved to us. A well developed peneplain and still later deep cut fjords are all that remain as records of the history of Ireland between the end of the Eocene and the beginning of the Glacial periods.

Along the whole south coast of Ireland occurs a preglacial shoreline buried beneath the glacial drifts and lying some 10 ft. above present sea-level. This runs up the sides of the fjords and proves their submergence in preglacial times. Overlying scree deposits from the degradation of the sea-cliff, descend below sea-level and prove emergence before the advent of the land ice.

During the Glacial period Ireland was covered by ice-sheets, which extended from sea to sea and with the exception of some of the higher hills, which no doubt had their own snow-fields there was no actually unglaciated area. The Newer Drift probably does not cover as wide an area as the older, but its limits are not yet known. Boulder clay and glacial gravels cover large regions in tbe central plain and moraines occur around the mountains. The main centres pf snow accumulation lay in the hill areas of the north-west and west but the whole eastern coast was at one time invaded by ice, which came south from Scotland along the basin of the Irish sea and carried with it the highly characteristic riebec kite-eurite of Ailsa Craig in the Firth of Clyde. Wide-spread moraines and esker ridges mark the stages of retreat of the ice, and systems of marginal drainage are developed round the hills.

PHYSICAL GEOGRAPHY

The central plain which reaches the east coast between Dundalk bay and Dublin bay and extends westward to the highlands of Connaught, separates the mountains of the north with their Caledonian trend-lines from the ranges of the south, where remnants of Wercynian folds predominate. The Leinster chain belongs structurally to the north. Lough Neagh occupies a depression in a region of warped basaltic rocks. To the north-east is the Antrim plateau, capped with lava and with no height exceeding 2,000 feet. The Sperrin mountains, to the north-west, attain a height of 2,240 ft. in Sawel mountain, whilst to the south-east several peaks exceed 2,000 ft. in the mountains of Mourne. This rim is pierced by the river Bann, which drains Lough Neagh to the north by the river Lagan, which enters Belfast lough to the east; by tributaries of the Upper Bann and by the river Newry to the south, and to the west by the gap partly occupied by the river Blackwater and the Ulster canal.

The highlands of the rim, favoured by settlers in late Neolithic times, but abandoned for the fertile land which replaced the lowland swamps and forests in later periods, are now given over to pasturage. Villages seek the shelter of the valleys. The shores of Lough Neagh and the valleys of the Bann and the Lagan, sheltered from excessive rains, provide good agricultural land and rich meadows for the fattening of cattle. Corn and root crops, flax and potatoes predominate. The Congested Districts Board from 1891 onwards did a great deal to help the small-holder. Co-operative creameries and agricultural credit societies have also been important economic influences. Coleraine is a small port on the Bann; Ballymena, Antrim and Portadown are market towns with rural industries and secondary railway centres. In the sheltered bays of the north-east coast are fishing villages, frequented by tourists in summer. Larne is a packet station and has aluminium works. Belfast dominates the industrial activity of the region. It has brought to an area rich in flax, and to a people born to the making of linen, coal and iron from Scotland, and thus has made possible the development of large-scale industries. Along Belfast lough are large residential areas.

To the west of the river Foyle are the mountains of Donegal, rising in Mt. Errigal to a height of 2,466 ft., and in Slieve Snaght to 2,240 feet. Blocks of hills running from north-east to south-west, separated and cut across by many deep, narrow valleys,

some of which are occupied by elongated lakes, isolate the coastal lowlands of the north-west, where habitation has persisted at least since the end of Neolithic times. Villages nestle along the creeks. Agriculture is hindered by exposure to strong rain-bearing winds from the west and away from the coast, by the height of the land and by the thin soil. Unification under a central authority has been a difficult process. Settlement has been largely confined to the valley of the Foyle and Donegal bay. Lifford, although but a suburb of Strabane (in Tyrone), acts as the county town of Donegal. Londonderry, near the head of Lough Foyle, is a port with a small ship-building industry.

Beyond Loughs Conn, Mask and Corrib are the ice-worn masses of Mayo and Galway, exceeding 2,000 ft. in height at several points. Submergence and marine erosion help to account for the much-indented and island-studded coast. Agriculture is limited, as along the Donegal coast, and fishing in the sheltered waters is an important occupation. Hardy ponies are reared on the mountains of Connemara. Descendants of early types and groups survive in the hills, and the influence of the organization of the eastern plains has penetrated slowly. Between Galway bay and the mouth of the Shannon is the promontory which comprises Co. Clare. Here the mountains are lower and more rounded, exceeding 1,000 ft. only in a few isolated peaks. The coast is more regular and the percentage of low land is higher. Kilkee, Kilrush and Miltown Malbay are seaside resorts.

To the south of the Shannon estuary lies the remarkable country of Co. Kerry and south-west Co. Cork. Parallel ribs of high land form steep-sided promontories separating the long, narrow rias which characterize this coast. Slieve Mish (Baurtregaum, 2,796 ft.), Dingle bay, Macgillycuddy's Reeks (Carrantuohill, 3,414 ft.), Kenmare river, Slieve Miskish and the Caha mountains (Knockowen, 2,169 ft.), Bantry bay, Sheep's head and Dunmanus bay illustrate well the rapid alternation of land form. Isolated groups cling to the narrow shores of the rias and earn a precarious living by fishing and sheep-rearing. Modern communications show the forced seclusion of the area. A line runs from Castlemaine along the south side of Dingle bay. Kenmare, on Kenmare river, and Bantry, at the head of Bantry bay, both have connections with towns to the east, but have not easy communication with one another. A line following a gap to the north-east of Macgillycuddy's Reeks serves Killarney and adjacent places. Castlemaine is in touch with Kenmare.

Between the mountains of the south-west and the Leinster chain lies a region of broken country which deserves special attention. Greatly influenced by Armorican fold movements, the area is composed largely of east to west lines of sandstone hills separated by limestone synclines. A general slope towards the south led to consequent drainage across rocks of varying hardpess. "Subsequent" tributaries limited their valleys to the softer limestone and captured the headwaters of many of the "consequent" streams. The present drainage pattern, therefore, presents long east-to-west lines connected by short north-to-south corridors. The sea has invaded the lower reaches of the Bandon, the Lee, the Blackwater and the Suir, and their estuaries provide good harbours. Between the Suir and the Blackwater are the Ballyhoura hills (Glenosheen 1,696 ft.), the Galty mountains (Galtymore 3,015 ft.) and, slightly to the south of these ranges, the Knockmealdown mountains (2,609 ft.), and the Comeragh mountains (Knockanaffrin 2,478 ft.). The Boggeragh mountains (Musheramore 2,118 ft.), continued by lower ranges to the east, separate the Blackwater from the Lee. Agriculture in the lowlands and sheep-rearing on the hills are the chief occupations in this diversified country. The structural pattern facilitates communication for some distance to the west, and also provides routes to the north. Cork and Waterford are packet stations which have benefited by these advantages, and Cork, on its fine natural harbour with Cobh (Queenstown) on an island, is the effective capital of the south.

Caledonian trend-lines prevail in the Leinster range which, rising steeply to the south of Dublin, runs south-westward and overlooks the lower valley of the Barrow. Several heights exceed 2,000 ft. and Mt. Lugnaquilla reaches 3,039 feet, Rain-soaked basins favour the formation of peat bogs, and give rise to sluggish streams which later cut rocky gorges down the steep sides. The windward slopes of the west are less steep than the eastern edge, and provide good pasturage. The coastal plain facing the Irish sea is sheltered from excessive rains, but is too narrow to be employed extensively for agriculture. It widens considerably, however, to the south, where the foothills of the Wicklow mass die away; arable land is estimated at 33% in Co. Wexford, whereas it only comprises 18% of Co. Wicklow. The Wicklow valleys were once exploited for their gold.

The Central Plain. — Enclosed by this girdle of highlands lies the central plain, consisting largely of limestone and covered, particularly towards the east, by drifts of sands and gravels deposited during the retreat of the ice-sheets. Between the Shannon and Loughs Mask and Corrib are extensive exposures of limestone, providing, in a region of abundant rainfall, good pasturage for cattle. Rising at the foot of Cuilcagh mountain, the Shannon flows in a general southerly and south-westerly direction. It winds through a marshy, rain-soaked area, and swells out into many broad, shallow lakes (Lough Ree, Lough Derg). At Killaloe, on the southern extremity of Lough Derg, it has a gorge between Slieve Bernagh and the Arra mountains, and from this point to Limerick, at the head of its estuary, its flow is more rapid. In this section it was proposed (1928) to harness the Shannon for the generating of electricity. (See SHANNON.) The Siemens-Schiickert scheme aimed at keeping the waters of Lough Derg at winter level, and diverting the river via O'Briensbridge to the generating station at Ardnacrusha, where the river would return to its natural course. The success of the Shannon scheme led to its further development. It provided electrical power to street railways and factories as well as to villages and municipalities. As managed by the Electricity Supply board it increased the number of units sold and reduced their price.

The marshy line of the Shannon has long been a barrier to communication. Athlone developed as a ford town where firm land approached the river banks, and has continued as a railway centre. Banagher and Shannon Bridge functioned similarly, but have lost much of their importance in recent times. To the east of the Shannon is an area of limestone and boulder clay studded with shallow lakes and peat-bogs. It has provided many obstacles to movement and settlement throughout history, and despite natural desiccation and drainage many of its disadvantages continue. Early roads follow the dry ridges of the eskers above the marsh, and one starting from Tyrrellspass undoubtedly added greatly to the early importance of Athlone. The wet lowlands of Meath, Westmeath, Kildare and Dublin provide pasture.

The extension of the plain to the eastern coast between Dundalk and Dublin provided one of the historic entries into Ireland. Control of this coastal strip has always been recognized as of great strategic importance, and Dublin (*q.v.*), in which this power has been vested, has developed as the administrative centre of central and southern Ireland. The Royal canal and the Grand canal connect it with the Shannon, and a branch from the latter links it with Waterford and the river Suir. The Great Northern railway runs northwards along the coast to Drogheda and Dundalk, and lines of the Great Southern system run westward and southward. Kingstown is a packet station in communication with Holyhead, Wales. Dublin imports grain, timber and general merchandise, and exports grain, whisky, beer and linen, but its function as a government centre is most important.

Climate. — Its girdle of high land and its insular position in the track of south-westerly winds are factors governing the climate of Ireland. The south-western and western coasts are comparatively warm in winter, Valencia having a January temperature of 44·6°. Numerous inlets increase the maritime influence. The central plain and the east coast, in the lee of the mountains, are more continental. Birr has a January temperature of 39·7°, and Dublin one of 41·7° F. Maritime influences delay the summer maximum temperatures in the south-west. Valencia records 59° in July and 59·3° in August, the corresponding figures for Birr and Dublin being 59·1° and 58·6° and 60·5° and 59·7° respectively. The autumn temperatures also are much more evenly graded in the west than in the centre and east. The distribution

of rainfall may be closely correlated with the orographical features. The heaviest falls occur on the mountains of Galway and Kerry, where considerable areas receive over 80 inches. Most of the mountainous areas around the coasts receive over 40 in., but averages for various localities on the central plain run between 30 in. and 40 in., whilst the east coast around Dublin receives under 30 inches. Maximum rainfall occurs at Valencia in winter (October and November 5·5 in., December 6.5 in., and January 5.6 in.); but the fall is steady throughout the year, May, the driest month, recording 3·1 inches. The mean annual rainfall at this station is 56.0 inches. Dublin (mean annual rainfall 27·7 in.) has its maximum in late summer and in autumn. The average fall in August is 3·1 in. and in October 2.9 in.; February, with 1·9 in., is the driest month.

Flora and Fauna. — Insularity retarded the recovery of Ireland's flora and fauna after the Ice age. Whereas Germany has 90 species of land mammals, Britain has 40 and Ireland 22. In western Ireland are some plant species, including members of the heath family, not found in other parts of the island. South-eastern Ireland has many species in common with south-west England. A few plants are found only in Ireland and America, and have been classed as an American group. Similar distributions can be traced in the fauna. Some fresh-water sponges in western Ireland are connected with American types. The arbutus, or strawberry tree, is now confined to the south-west corner of Ireland and to the Mediterranean. This is one illustration of a Lusitanian element in the flora, probably persisting from a time before Ireland was separated from Europe, and when an Atlantic coastal flora lived along the shores of the ocean from the Iberian peninsula to Ireland. There are aiso connections with the north, the mountain or Arctic hare being common to Ireland and Scotland. Remains of reindeer, Arctic fox, and Arctic lemming are found in Irish caves.

People and Settlement. — The retreat of the ice sheets left the central plain a marshy waste, with thick forest growth on drier patches. The moorlands and some coastal strips alone seem to have remained to early man. A limestone shore, rich in flints, and protected from excessive erosion by a capping of basalt, favoured early settlement in Antrim and Down. At Larne flints showing human workmanship have been found, with sea-shells, at from 20 to 25 ft. above the present sea-level. Similar evidence has been obtained from other sites in the north-east and in the south. The arrival of new peoples from the south-west marks the closing phase of the Neolithic period.

With these newcomers are associated large stone monuments, the distribution of which may help to define the chief centres of population at that time. Dolmens, generally consisting of several upright stones capped by large stone slabs, occur frequently in western Ireland. The eastern half of Co. Clare, the upper basin of the Lee in the south-west, and the shores of Donegal bay and Lough Swilly in the north-west, appear to have been important centres. At Carrowmore, in Co. Sligo, occurs a group of 65 dolmens. In the north-east, the numbers decrease from the coasts towards the interior, but no district here appears to have had the importance of the centres already mentioned. In the east, a few occur to the south of Dublin.

Rich deposits of copper in the counties of Wicklow, Waterford, Cork and Kerry added greatly to the importance of Ireland in the Bronze age; southern Wicklow was also rich in gold. Thus the coasts retained their importance, and the lowlands of the interior were still avoided. The finding of gold lunulae of Irish origin in western France, southern Scotland and central Europe suggests that there was commercial intercourse with the Baltic as well as with south-west Europe. The chambered tumulus of New Grange, near Drogheda, with its fine corbelled roof, resembles Maes Howe in Orkney, as well as graves in Brittany and the south of the Iberian peninsula. Many amber beads of Baltic origin have been found in Ireland, whilst the distribution of objects showing a spiral ornamentation has also been cited by some as evidence of contacts with the Baltic, and by others as evidence of southern links. Types of copper weapons and some contemporary pottery are related to Iberian types.

The very early peoples were, no doubt, long-headed (dolichocephalic) and dark and of short stature, resembling the people who inhabited Britain at the same period. Dark, strongly-built, broad-headed men have been located on coastal patches in Wales, Cornwall, Brittany, Spain and southern France, and it has been suggested that they may indicate an anthropological type which spread around the western coast of Europe during the period of commercial expansion in the Bronze age. These elements have been noted in the people around the coasts of Co. Wicklow, and with further investigations may be found in other parts of Ireland. The Rhenish beaker-peoples who are thought to have introduced a broad-headed element into Britain, seem to have had little influence in Ireland. Specimens of the pottery associated with them have been found only at Moytura, Co. Sligo, and at Mount Stewart, Co. Down, and they may be otherwise interpreted. We cannot estimate what may have been the effects on the population of contacts with the Baltic in the Megalithic and Early Bronze period. In the Early Iron age intruders from the Continent gained a footing.

Scandinavian Raiders. — Ireland, untouched by Roman organization, fell a prey to Scandinavian raiders. Norsemen, followed by Danes, raided the coasts and penetrated along the rivers. At the beginning of the 9th century they ascended the Shannon, and later had strongholds around the shores of Lough Ree. Another group progressed along the river Bann and established themselves around Lough Neagh, whence they devastated the neighbouring territory. About the middle of the 9th century Dublin, Limerick and Cork were founded. All three are at the head of estuaries and command good water-ways into the interior. The end of the 10th century and the beginning of the 11th saw a revival of the native tribes, which culminated in the overthrow of the Norse forces by the men of Munster and Connaught at the battle of Clontarf in 1014. During their régime the value of the coast lands and the valley-ways for settlement had again been accentuated. They doubtless strengthened the fair, long-headed element in the population, and their raids tended to drive the darker elements to the shelter of the hills.

The Anglo-Norman invasion accentuated divisions of long standing in Ireland. Strongbow landed near Wexford in 1169, and took advantage of inter-tribal struggles to extend his own power. Later, the Anglo-Normans obtained a firm hold around the coasts and gradually took possession of the fertile lowlands. The mountains became more and more the strongholds of the Irish, whence they periodically raided the intruders on the plain. In the reign of James I. an attempt to make the English land system universal aroused the chiefs of the north-west and north-east to revolt. They were defeated and their land confiscated. English and Scottish colonists received grants in Tyrone, Donegal, Armagh, Cavan, Fermanagh and Derry. The citizens of London were granted the site of Derry, which they garrisoned and fortified, Londonderry becoming the stronghold of the new settlers. In the time of Cromwell, a ruthless policy of extermination was followed, and the native peoples beyond the Shannon were evicted from their holdings. The land was parcelled out among adyenturers; many of the original holders remained as serfs, others preferred a precarious independence in the mountains.

The potato, introduced early in the 17th century, provided a large crop which needed little attention and encouraged a rapid increase of population. In 1845 its dependents numbered over 8,000,000; then came the terrible famine of 1846–48, from which the country has not yet recovered. In 1851 the population had fallen to 6,500,000 and, as a result of wholesale emigration, largely to the United States of America, the figure continued to fall. Between 1847 and 1852 over 1,200,000 people emigrated, and of these more than 1,000,000 went to the United States of America. Between 1851 and 1905 over 4,000,000 left the country. The loss of population was borne chiefly by the agricultural districts. In 1841 the rural population was returned as 7,052,923, and the urban as 1,143,674, while the corresponding figures in 1901 were respectively 3,073,846 and 1,384,929. The increase in the urban population has been accentuated by the development of certain large centres. The population of Belfast was, in 1891,

273,079; in 1901, 349,180; in 1926, 415,007; and, in 1937, 438,086; the corresponding figures for Dublin were 268,587; 289,108; 316,471, and in 1936, 468,103.

The areas and populations of the counties and county-boroughs of Northern Ireland (1937 census):

county boroughs	Area in statute acres (exclusive of water)	Population in 1937		
		Males	Females	Total
Antrim	702,890	96,003	101,263	197,266
Armagh	312,767	54,271	54,544	108,815
Belfast C. B.	15,289	205,538	232,548	438,086
Down	609,057	102,535	108,152	210,687
Fermanagh	417,912	28,856	25,713	54,569
Londonderry	512,580	47,929	46,994	94,923
Londonderry C. B.	2,198	22,344	25,469	47,813
Tyrone	779,548	65,678	61,908	127,586
Total for Northern Ireland	3,352,250	623,154	656,591	1,279,745

For Eire the census of 1936 gave the following:

Counties and county boroughs	Area in statute acres*	Population in 1936		
		Males	Females	Total
Province of Leinster:				
Carlow	221,485	18,066	16,386	34,452
Dublin County	227,724	277,098	309,827	586,925
Dublin C. B.	18,740	219,967	248,136	468,103
Kildare	418,644	31,956	25,936	57,892
Kilkenny	509,470	36,489	32,125	68,614
Leix (Queen's)	424,892	27,149	22,960	50,109
Longford	257,935	20,152	17,695	37,847
Louth	202,814	32,829	31,510	64,339
Meath	577,824	32,501	28,904	61,405
Offaly (King's)	493,636	27,555	23,753	51,308
Westmeath	435,605	29,039	25,667	54,706
Wexford	581,061	48,577	45,668	94,245
Wicklow	500,250	29,868	28,701	58,569
Total of Leinster	4,851,340	611,279	609,132	1,220,411
Province of Munster:				
Clare	787,756	47,957	41,922	89,879
Cork County	1,843,593	179,620	176,337	355,957
Cork C. B.	2,685	38,285	42,480	80,765
Kerry	1,161,705	73,503	66,331	139,834
Limerick County	663,971	72,407	68,746	141,153
Limerick C. B.	2,386	19,569	21,492	41,061
Tipperary	1,051,292	72,397	65,438	137,835
Waterford County	454,278	39,528	38,086	77,614
Waterford C. B.	1,438	13,229	14,739	27,968
Total of Munster	5,962,595	485,412	456,860	942,272
Province of Ulster (part of):				
Cavan	467,162	41,446	35,224	76,670
Donegal	1,193,581	73,924	68,386	142,310
Monaghan	318,985	31,994	29,295	61,289
Total of Ulster (part of)	1,979,728	147,364	132,905	280,269
Province of Connaught				
Galway	376,764	89,170	79,028	168,198
Leitrim	1,333,941	27,337	23,571	50,908
Mayo	608,540	83,213	78,136	161,349
Roscommon	443,917	41,308	36,258	77,566
Sligo		35,371	32,076	67,447
Total of Connaught	4,230,822	276,399	249,069	525,468
Total of Eire	17,024,485	1,520,454	1,447,966	2,968,420

*Exclusive of larger rivers, lakes and tideways.

Vital Statistics. *Northern* Ireland.—The following table gives the number of marriages, births and deaths for four years:—

Year	Marriages	Births	Deaths
1937	8,623	25,412	19,282
1938	8,617	25,742	17,649
1939	9,185	25,240	17,542
1940	9,195	25,363	18,941

The number of births per 1,000 of the population in 1939 was 19.5, and the number of deaths per 1,000 of the population, 13.6. A relatively high birth rate, a continual decline in emigration figures, and industrial developments were important factors in the increase of the population as compared with the decline of Eire's population. World War II produced many changes in this picture, for there were many Northern Irish serving throughout the world in the British army, and American troops were in Northern Ireland in large numbers.

Eire.—The number of marriages, births and deaths:

Year	Marriages	Births	Deaths
1937	14,780	56,488	45,086
1938	14,934	56,753	40,066
1939	15,192	56,097	41,730
1940	15,323	56,510	42,033

The number of births per 1,000 of the population in 1939 was 19.1, and the number of deaths per 1,000 of the population was 14.2. In 1936 the corresponding figures were 19.6 and 14.4. The Irish birth rate had not fluctuated widely for 20 years. It suffered no such decline as the English birth rate. Nonetheless Ireland's population is declining. Limited opportunities in industry and the inability of many children of farmers to find an adequate living on a limited amount of land account for some emigration to England and the other dominions. The figures of the 1936 census which showed a decline in the population came as a surprise to many as it was thought that the population would increase after the practical stop of emigration to the U.S. The age of marriage in Eire is quite late. But families are large.

Religions.—(See IRELAND: Mediaeval *History*, and IRELAND, CHURCH OF.) In Northern Ireland, the principal religious professions, as recorded at the census of 1937, were: Roman Catholics, 428,290; Presbyterians, 390,931; Protestant Episcopalians, 345,474; Methodists, 55,135; others, 59,915; giving a total of 1,279,745. For Eire the figures (1936) were: Roman Catholics, 2,773,920; Protestant Episcopalians, 145,030; Presbyterians, 28,067; Methodists, 9,649; others, 11,754.

(O. J. R. H.; F. E. MN.)

AGRICULTURAL CO-OPERATION TO 1928

The main interest and importance of the co-operative movement in Ireland since the beginning of the World War consists in the struggle of its promoters to preserve and develop it as the chief agency for implementing a certain philosophy of rural life and evolving an agricultural policy consonant therewith. The movement had been initiated a quarter of a century before the War by men who were not themselves farmers, and its inspiration has ever since come from practical idealists. These men realized that in a country dependent upon a sound agricultural economy for the well-being of every section of the population, a technically educated and efficiently organized rural community was of the first importance.

In countries highly industrialized, agriculture could be neglected without disaster; in a country predominantly agricultural the efficient production and economical distribution of food was what mattered most. Yet those who saw that these ends could best be obtained by the application of the co-operative principle and system to the occupation of farming were chiefly concerned for the building of a rural civilization which would provide intellectual interests and social amenities calculated to counteract "the lure of the city." For the solution of the modern rural problem as they saw it, they invented the formula: "Better Farming, Better Business, Better Living."

Agricultural Organization Society.—The post-war civil disturbances in Ireland might well have wrecked the movement.

War prices and a demand which ignored quality had considerably demoralized the dairy societies. The movement was in no condition to meet the sudden decline in prices which set in in 1920–21. It became clear that its future success—perhaps even its survival—would depend upon the ability of the Irish Agricultural Organization Society to continue its service as guide, philosopher and friend of the societies. This central body had always derived from the farmers it served and from philanthropic individuals a large part of its funds. In the circumstances of the country, these subscriptions were bound to fall off. While the Development Commission, which was authorized by its act to treat "the organization of co-operation" as one of the ways of "aiding and developing agriculture," functioned in Ireland it subsidized the I.A.O.S. for this purpose. Under the Anglo-Irish Treaty, the Commission transferred its functions and a proper proportion of its funds to the two Irish Governments. The I.A.O.S. had to be partitioned, an Ulster A.O.S. being formed to operate in the six north-eastern counties.

The Government of the Irish Free State from year to year continued the grants to the I.A.O.S and for its first year the Government of Northern Ireland continued it to that part of the organization movement which came within its territory. This, however, was not renewed, except for a grant of £200 in 1927, increased to £700 in 1928, and in Northern Ireland the movement consequently had greatly to restrict its work. But that the farmers there have come to realize its value is evident from the fact that most of its funds come from the societies' contributions and the movement is thus able, through its own practical public spirit, supplemented by that of a few friends, to carry on without incurring a deficit.

The Free State Government, from the start, made every effort to reconstitute the agricultural policy of the country. This was to be expected in a land which, itself purely agricultural, had just obtained independence from a union of countries mainly industrial. The department was merged in a new Ministry of Lands and Agriculture, and a commission on Agriculture was set up which made many far-reaching recommendations, especially emphasizing the importance of agricultural education and commending the development of co-operation as well as an increased subvention to the I.A.O.S. A grant of £10.000 was voted by Dail Eireann for the year 1926–27, and £8,500 p.a. for the four following years.

Position **of** the Societies.—A movement, started in the autumn of 1926, to market the butter of the co-operative creameries in common, under a new trade organization (Irish Associated Creameries, Ltd.) proceeded *pari passu* with the decision of the State to enable bodies of farmers (organized into registered co-operative societies by the I.A.O.S.) to take over, by the utilization of Government credit, the machinery, buildings and trading interests of the principal creamery proprietors in Southern Ireland. A "holding body," consisting of civil servants, was registered under the Industrial and Provident Societies Act to serve as a temporary "bridge" between existing proprietors willing to sell and prospective co-operative farmers organizing to purchase. More than three-fourths of the existing co-operative dairying societies had already (1928) voluntarily signed agreements to market their butter through Irish Associated Creameries Ltd., and it was anticipated that, with the additional trade passing into co-operative hands through the scheme for purchasing new premises and plant, and acquiring existing business, the creamery industry of the Irish Free State would be virtually run for the future by and in the interests of the organized dairy farmers. In Irish Co-operative Meat Ltd. (Waterford), another co-operative enterprise was successfully launched.

Credit societies had largely developed (up to 1928). The Commission on Agriculture had recommended that this aspect of co-operative business be specially endowed; and in 1925 the Dail, at the instance of the Minister for Agriculture, passed a vote for loans not to exceed £100,000, for restocking of lands, to be advanced to credit societies approved by the I.A.O S., to whom the administration of the scheme was entrusted. The Agricultural Credit Act 1927 also makes provision for similar loans and for loans to co-operative societies of agricultural producers. Thus were re-established satisfactory relations between the State aid and the self-help parts of a movement which may encourage other countries to adopt the device of an "organization society," working in close co-ordination with the governmental Departments of Agriculture.

The urganization of about 150,000 farmers, mostly heads of families and, therefore, representing over 600,000 persons (in a country containing about 4,250,000 people), into a movement whose aggregate business for the decade 1914–23 (inclusive) was well over £80,000,000—to which creameries contributed about one-half—was an important factor in Irish economics.

Education.—The need of all co-operative movements is always education, and the higher the development the greater is that need. The hampered condition of the Central Organization society is probably the true cause of the halt of the movement as a whole. Up to 1928 the I.A.O.S had to render many services, notably technical advice to creameries and other societies, which the Government, through the Ministry, are now rendering under the Dairy Produce Act and the Agricultural Produce (Eggs) Act. To ensure the future of co-operation, technical instruction in itself is not the chief desideratum. When it can leave that to the Ministry, the Organization society will concentrate on educating the farmers not only in credit and the technique of co-operation, but in the co-operative spirit.

The Government of Northern Ireland, like that of the Free State through its Department of Agriculture, enforces egg-grading; but the Ulster Organization society, with its small staff, cannot do the work necessary to educate the farmer up to a standard which the Government can only punish him for failing to reach. The work, therefore, cannot be expected to show immediate spectacular results, but that, it must be understood, is as much due to the width of the aim as to the narrowness of the resources. And these two have another connection. In 1928 the central society's funds were largely drawn from the fees the farmers willingly paid it for technical instruction, which is not a co-operative but a manufacturing technique. When that function is transferred to Government and the Organization society is restricted to its educational but less remunerative purposes, the farmers' financial support will for some time be considerably lessened.

Nevertheless, the founders of the movement were convinced that nothing less than a continual extension of the study of the rural problem—the regarding of agriculture as an *industry*, as a *business* and as a life—could bring the country population to a standard of efficiency demanded by modern economic conditions. The next step, therefore, in this concerted advance was to gather and distribute knowledge of every side of agricultural co-operative evolution the world over, and to provide a centre at which students and organizers could study and compare the progress of local developments. To provide this, the Co-operative Reference library had been founded in Dublin in 1913. One of the founders of the Irish movement has endowed a trust (which the trustees christened the Horace Plunkett Foundation) for the purpose of extending the Irish philosophy of rural life throughout the British Commonwealth.

Under its auspices there was convened at Wembley in July 1924 a conference on agricultural co-operation in the British empire. The delegates, who were thoroughly representative of agriculture in this vast area, approved the Irish policy, and called upon the Foundation to establish an office in London to act as a clearing-house for the exchange of experiences and opinions of all organizations which were putting the co-operative principle into practice. This has been begun by opening a London centre which, when the Carnegie United Kingdom Trust promised to defray the cost of maintenance, naturally offered hospitality to the Co-operative Reference Library, an offer which the Carnegie United Kingdom Trust approved. Thus the Foundation is in a favourable position to see that Ireland is kept fully informed of the progress of similar movements in other countries.

HISTORY

Earliest Inhabitants. — The earliest known remains of human habitation in Ireland are assigned by archaeologists to the period of the transition between the early and the late stone age. This period, it is held, was preceded by intense glacial conditions, covering the whole island and extending also over Britain as far south as the estuaries of the Severn and the Thames. The Neolithic and Copper periods which follow are well represented in Ireland, but their data belong rather to archaeology than to history. The bronze age in Ireland, though it has no documents, native or extraneous, has left evidences sufficiently abundant and vivid to be considered historical. To it belong numerous tombs of massive structure, surmounted by great tumuli of earth or stones, the stone slabs in some of them being carved with a great variety of designs, symbolic or ornamental — evidence of a settled population under opulent rulers. Bronze was abundant. There were rich copper mines, but no tin mines, and the tin which was needed to make bronze must have been an article of import, no doubt from Cornwall, during the whole of the bronze age and later. The distinctive feature of this period in Ireland was the production of native gold, of which it is certain that there were comparatively rich deposits in the Wicklow mountain region. Irish gold ornaments of the bronze age have been found in various parts of Britain, in northern France, in Luxembourg, Hanover and Denmark. In Ireland, the principal finds have been in districts far away from the gold-producing region. Finds of the ancient apparatus of bronze-founding are likewise recorded in places far away from copper mines and from seaports through which tin could be obtained. The facts point to a development of commerce, internal and external.

To the Celts of Gaul, and through them to the Greeks, the ancient inhabitants of Britain and Ireland appear to have been known by the common name of Pretani. The two islands, Albion and Iverna, are called in Greek the Pretanic islands. In Latin and first, so far as is known, by Julius Caesar, the name *Brittani* (becoming later *Britanni* and *Brittones)* is substituted for *Pretani* and used distinctively of the people of the larger island, to which the name Brittania (Britannia) was given. *Pretani*, represented in early Irish by *Cruithin*, was the name of the people who in later times are known as *Picti*, Picts. Hence it may be inferred that during the bronze age the Picts were the chief people of Ireland as well as of Britain, and this inference is amply confirmed by ancient Irish traditions.

Celtic Colonization. — The earliest Celtic migrations to Ireland cannot be dated earlier than 400 B.C. The Celts were a people of Nordic type, fair haired and tall, physically akin to the Germanic peoples, and speaking a language closely related to the Germanic and Italic languages. At the time of their first immigration, they were in what is known as the "La Tène" stage of material culture. By them iron was introduced into general use in Ireland. They are likely to have arrived in small colonies, settling first in maritime districts and along the larger rivers. The later Celto-Germanic or Belgic migratory movement also extended to Ireland. Ptolemy, about A.D. 150, shows the Manapii and the Cauci settled on the eastern coast, and these are to be identified with the Menapii, a Belgic people, and the Chauci, a Germanic people, on the coast of the North Sea. This later phase of immigration is reflected in various ancient Irish traditions.

The Early Celtic Regime. — The Celts established small states, the nucleus of each state *(tuath)* being a convenient place of assembly to which the freemen could resort, like country people to a local market, without having to lodge away from home. The chief who presided over such an assembly was entitled king. He also performed the functions of judge and leader in war. Besides the common assembly of freemen *(oinach)*, there was a curia or senate *(aireacht)* of nobles, which met in the king's house. The nobles who composed it were known as the companions *(celi)* of the king — we may compare them with the king's *hetairoi* in Homer. In ancient theory, a *tuath* provided an armed levy of 3,000 men, but in the period of contemporary documents much smaller states are indicated. Each *tuath* formed a separate jurisdiction. A freeman was a citizen *(urrad)* in his own *tuath*, but a non-citizen *(deorad)* in any other *tuath*, having, however, a legal status which did not belong to a foreigner *(allmurach, muirchuirtke)*. Common jurisdiction *(cairde)* for legal proceedings could be made operative by agreement between states. It was the tendency of these small states to group together under hegemonies, the king of one state of the group having a certain authority over the kings of the other states. Such groupings could become permanent. The chief salient feature of the early Celtic régime is the division into five major groups of states, "the Five Fifths of Ireland," so firmly fixed in tradition that in later times, when the country was divided into four "provinces," these were called and are called at present by the Irish word meaning "fifths." The five fifths were:—

Ulster *(Coiced Uloth*, "the fifth of the Uluti"), extending on the west as far south as Loch Boderg on the Shannon, on the east as far south as Drogheda; much larger thus than the later province. Its capital, *i.e.*, the seat of the chief king, was Emain, "the Navan," close to the city of Armagh.

North Leinster *(Coiced Lagan Tuad-Gabair*, "the fifth of the Lageni north of Gabair"). Capital: Temuir, "Tara."

South Leinster *(Coiced Lagan Des-Gabair*, "the fifth of the Lageni south of Gabair"). Capital: Dinn Rig, on the Barrow.

Munster *(Coiced Muman*, "the fifth of Muma") nearly coextensive with the counties of Limerick, Cork and Kerry, with part of Waterford. Capital: Temuir Erann, near Ardpatrick, Co. Limerick.

Connacht *(Coiced Connacht*, "the fifth of the Connachta"), including the present Clare but not extending east of the Shannon. Capital: Cruachain, "Rathcroghan" in Co. Roscommon.

Social Order. — The population consisted of free, unfree and slaves. The freemen in the main were the freeholders of land, but their franchise extended also to the men of certain professions and skilled crafts. In the early Christian period, all ecclesiastics and all who received education in the schools of Latin were free. From this and from Caesar's statement of the immunities of the Gallic Druids and their pupils, it may be inferred that the Irish Druids and their pupils were freemen. The unfree were tenants of land, labourers and craftsmen of inferior kinds. Among the landed freemen, the nobles were distinguished by a higher measure of wealth and by having a sufficient number of clients *(celi*, "companions"). The nexus between chief and client was formed by a personal contract which was terminable by either and was terminated by the death of either, differing thus from the hereditary connection of feudal lord and vassal. The clients were freeholders and retained their ownership of land. The chief advanced capital, usually in the form of cattle, to the client, protected his interests in court or assembly, was his leader in war. The client repaid the capital with large interest, attended on the chief at the assembly, and followed him to war, supplied him with labourers for certain works, and rendered him certain reliefs and fixed dues of hospitality. There were two classes of clients, free *(soercheli)* and subject *(doerclzeli)*. A subject client received from the chief, in addition to an advance of capital, his own "honour-price," that is, the legal valuation of his franchise or status, and so ceased temporarily to be a freeman; he paid a tribute in meat, vegetables and malt for the support of the chief's house.

Normally, each freeman was a member of a *fine* or joint family, consisting of descendants of the same great-grandfather — in other words, extending to second cousins. For some purposes, a wider extension of the joint family, as far as fourth cousins, was recognized. If a man died without issue, his property was divided in regulated shares among the members of his *fine*. In case of homicide, the compensation fixed by law was divided in like manner.

A fine could be made liable for the undischarged liabilities of any of its members. When a kingship became vacant, any man whose father, grandfather or great-grandfather had been king was eligible to succeed. The power of election belonged to the freemen in assembly, but it seems to have been usual for them to accept a choice made first by a meeting of the nobles.

The Druids. — Druidism, known only in Transalpine Gaul, Britain and Ireland, but not recorded in Britain outside of Anglesea

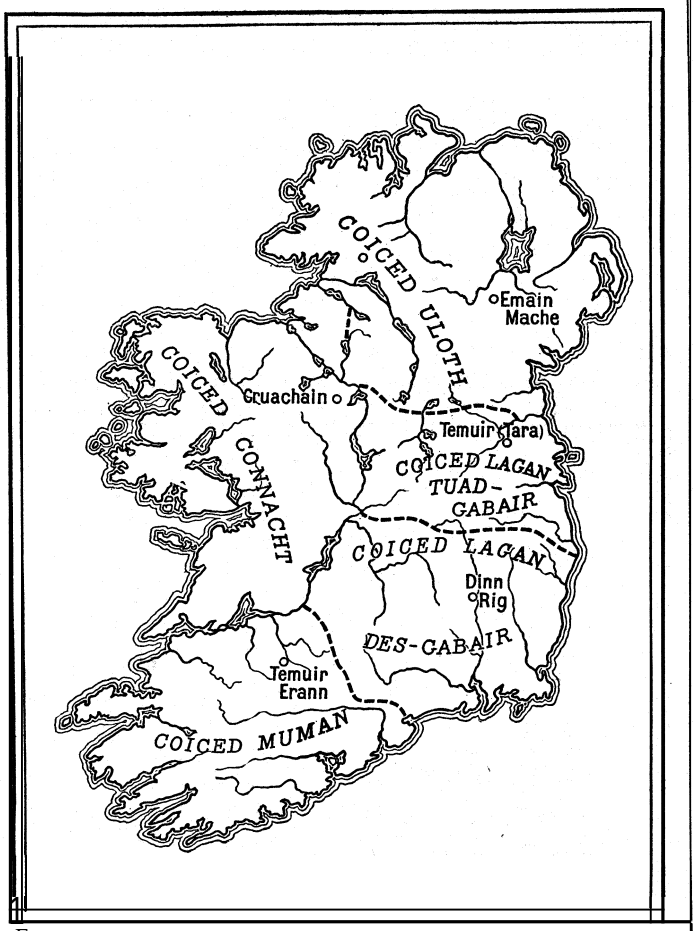

FIG. I.— ANCIENT IRISH HISTORY. THE "FIVE FIFTHS" OF IRELAND ABOUT THE BEGINNING OF THE CHRISTIAN ERA

Ancient Ireland was divided into fifths, each ruled by its own king; Coiced Uloth (Ulster), with Emain Mache as capital; Coiced Connacht (Connaught), with Cruachain as capital; Coiced Lagan Tuad-Gabair (North Leinster), with Temuir (Tara) as capital; Cciced Lagan Des-Gabair (South Leinster), with Dinn Rig; and Coiced Muman (Munster), with Temuir Erann as capital

and the northern Pictland, is likely to have originated in Ireland. Pokorny's view seems reasonable and is supported by Irish tradition — that among the pre-Celtic inhabitants there existed a class of seers and sorcerers from which, under the Celtic régime, the Druids were developed. The Druids may be described as an association of professional wise men, philosophers in the early Greek sense, claiming to be experts in all the higher branches of knowledge. They professed special knowledge of the gods, the other world, the future life, the form and measurement of the earth, the movements of the heavenly bodies, the history of men; and they were accepted as authorities in matters of religion and law. They also claimed occult and prophetic powers. In the Roman world, after their suppression by the State, and in Ireland, after its conversion to Christianity, they were chiefly remembered as prophets and magicians. The notion that they were the priests of a particular religion is of modern growth. In Christian Ireland the Druids continued to exist, but with a change of name and with limited scope. They were called *jlid,* a name which in time became restricted to the meaning of "poets" hut which originally, signifying "seers," denoted one of the functions of the Druids. They no longer had authority in matters of religion but they long continued to practise occult rites of divination. In matters of learning they were displaced from the ground covered by the Latin teaching of the ecclesiastical schools. They remained the authoritative exponents of the national history, literature and law. In Gaul, notwithstanding the division of the country into so many independent states, the Druids formed a single society, with annual conventions and an elected president. In Ireland, the filid do not present this organized form, but they maintain an effective unity through a long course of centuries. They provide a single code of law for the whole country. They follow a common literary usage in writing, and in minutely regulated rules of prosody which they all accept. What Caesar tells of the long course of education of the Gallic Druids and of the instruction given orally and in verse is paralleled in the filid. Like the Druids, they enjoy civil immunities. Their persons are sacred. The influence of Druidism remains operative and distinctive in Irish history throughout mediaeval times. It can be traced in the conversion of the Irish to Christianity, in the development of the monastic schools, in Irish law, in the form and content of Irish literature, in lasting pedantic tendencies, but chiefly in a sense of national unity not dependent on political coherence.

Origin **of** the Monarchy. — The sagas of the "Ulster Cycle" point to a rivalry for the hegemony of Ireland between the Ulster and the Connacht kings. In time the Connacht dynasty gains ground. Its kings cross the Shannon and occupy Cisnech, dominating the fertile midland plain, probably in the 2nd century. In the 3rd century they annex the Boyne valley and make Tara their capital. These conquests break up the pentarchy and give a decided headship to the kings of Tara. Of them the most celebrated in tradition is Cormac, perhaps the first clearly historical personal figure in Irish history, reigning between the years 250 and 300. About this time, taking advantage of the disorder of the Roman empire, the Irish undertake plundering incursions into Roman Britain. A panegyric of the emperor Constantius in 290 speaks of the Britons already "accustomed" to Irish raids. Contact with the Roman military power has effects in Ireland. In imitation of the Roman walls in northern Britain, the Ulster kings protect their diminished territory by a massive earthwork, of which the remains are traced extending, with intervals of lake and forest, across the island from Dundalk bay to Donegal bay. A great quadrangular earthwork called the Dorsey, anciently *Doirse Emna,* "the Gates of Emain," built no doubt in imitation of a Roman legionary camp, guarded the main road leading from Tara to the Ulster capital. The Roman military organization seems to have led to the formation of the *Fiana,* permanent bodies of professional soldiers, peculiar in Ireland to this period. In the earlier heroic tradition there is no military organization. Later. the Irish law does not recognize at all the military profession, and no permanently formed Irish military forces are seen until the introduction of the "galloglasses" from western Scotland in the 13th century. About A.D. 350, the Connacht-Tara dynasty captured Emain and annexed the greater part of Ulster. It reached the height of its power under Niall of the Nine Hostages at the beginning of the 5th century. His sons took possession of the western part of Ulster, and their kindred now ruled all the northern half of Ireland except the eastern strip from the mouth of the Bann to the mouth of the Boyne. The chief kings of this kindred Dall Cuinn, were recognized as kings of Ireland until 1002.

The high-kingship or monarchy was an acknowledged primacy, symbolic of the sense of national unity, rather than a politically operative institution. Its powers are nowhere found defined. It claimed no tributes from the suffragan kings except from the kings of Leinster, who denied the legality of the claim and yielded the tribute only to superior force. The assembly over which the high-kings presided was held annually at Taillte, in the Boyne valley, and was regarded in a sense as national, but there is no instance recorded of its acting as legislative or administrative authority for all Ireland, in the manner in which the assembly of Carman, for example, acted for all Leinster.

In Munster, the 4th century sees the rise of a strong dynasty, of the Eoganacht sept, whose traditions indicate a relatively late immigration from Gaul. Under its rule, the bounds of the older fifth are pushed out and rtach in the 5th century an extent

approximately the same as the modern province of Munster.

From the 5th century onward, the five major kingdoms of earlier tradition are replaced by seven. Of these, the older Ulster forms three, the kingdom of Ailech on the west, the kingdom of Airgialla ("Oriel") in the middle, the kingdom of the Ulaid ("Ulidia" or "Ultonia") on the east. The others are Connacht and Munster, both nearly co-extensive with the modern provinces, Mide ("Midia," "Meath"), comprising the greater part of older North Leinster and a small part of Ulster, and Leinster, consisting of the remainder of the two ancient Lagenian fifths. This division subsists with little change down to the 11th century, and is described in detail in the "Book of Rights" (10th century). The grouping, however, is in some particulars theoretical rather than actual. Eastern Ulster is to be regarded as containing three kingdoms of equal status, Dalriada, of which the kings ruled also in Scotland; Ulaid, the successor of the ancient Uluti; and Dal Araidi, a kingdom of the Picts. Osraige ("Ossory"), nominally in Leinster, does not appear subject to the king of Leinster. In each major kingdom or group-kingdom, the component states or petty kingdoms are of two kinds, tributary and non-tributary. The non-tributary states are those whose kings are of the same sept as the superior king, though their pedigrees may have branched apart for centuries. In Munster, for example, about half the number of component states were ruled by kings of Eoganacht lineage, and these were not tributary to the king of Munster, who was also of that lineage. Distributed all over the country were remnants of ancient subjugated tribes, the *Aithech-thuatha*, made tributary and held in political subjection.

Oversea Raids and Migrations.— From about the middle of the 3rd century, Latin writings bear constant evidence of Irish raiding expeditions, and the older Latin name *Hiberni* or *Iverni* is almost wholly replaced by a new name, *Scotti*, which appears to be a Celtic word meaning "raiders." Linked with the Scotti are found the *Atecotti*, also a Celtic word meaning "the very ancient folk," and probably distinguishing the Irish of pre-Celtic origin from the dominant Celts. Towards the end of the 4th century, large bodies of Atecotti were enlisted in the Roman service under the emperor Honorius. Irish tradition fully reflects the evidence of Latin writers. As the Roman power weakened in Britain, Irish raids were followed by migratory settlements. There is abundant evidence of Irish settlers all along the western seaboard of Britain from Argyle to Devon. Irish dynasties sprang up in Wales and lasted there for centuries. In the 5th century, the kings of Dalriada, a small kingdom in the north-eastern angle of Ulster, extended their power over the Irish settlers in Argyle and the neighbouring islands, their descendants ultimately, in the 9th century, becoming kings of Scotland. Crimthann, king of Munster, is said to have held a fortress in Britain. Branches of his sept settled in Wales and Cornwall. Niall of the Nine Hostages is identified by Ridgeway with "the Scot" who, in Claudian's poem, "mobilized all Ireland" against Roman Britain. In this reign, St. Patrick was carried to Ireland a captive and with him in the same raid, as his confession says and his epistle repeats, "so many thousands of men." At the head of a later expedition, Niall was killed at sea by a Leinster prince. His successor, Nath-i, heading another raid, died on the Continent.

Introduction of Christianity.— There is evidence of Irish Christians, apart from the thousands of enslaved Christian captives, before the first Christian mission to Ireland. In 429, at the instance of Palladius, deacon of the Roman church, St. Germanus, bishop of Auxerre, was sent by the pope, St. Celestine, to combat the Pelagian heresy in Britain. It was doubtless in answer to an appeal made through Germanus that, in 431, "Palladius was sent, their first bishop, to the Scots believing in Christ." After a short stay in Ireland, Palladius passed over to northern Britain, where he died soon after his arrival. In 432, Patrick, a disciple of Germanus, was sent as bishop to Ireland. He was a Briton, son of a decurion under the Roman government, and probably a native of Gwent in Monmouthshire. He was carried off a captive in the reign of Niall and became a slave in north-eastern Ulster. After six years he escaped. His birth may be dated in 385, his capture in 401, his escape in 407. His mission in Ireland succeeded rapidly. In 438 he was favourably received at the court of the high-king, Loiguire, son of Niall. In 439, doubtless in answer to a request sent to his patron Germanus, three bishops were sent to his assistance, Secundinus, Auxilius and Iserninus, the last also a disciple of Germanus. Patrick chose for his own see Armagh, beside the ancient Ulster capital. Secundinus had his church near Tara, the seat of the high-king; Auxilius, near Naas, also a royal seat in Leinster; Iserninus, driven out at first by Enda, king of Leinster, was restored later by Enda's son Crimthann, a Christian convert, and fixed his see at Aghade, near Rathvilly, where Crimthann lived. There is evidence that Patrick chose Baislex (Basilica Sanctorum), near Cruachain, the capital of the kings of Connacht, as the see of a bishop for that kingdom.

In the story of St. Patrick's reform of Irish law we may perhaps see an influence transformed by tradition into an event. A druid foretold to Loiguire: "He shall free slaves, he shall raise up men of lowly kin." In the written laws, two centuries later, a slave class no longer exists. St. Patrick's epistle condemns the enslavement of Christians. The earlier racial distinctions between conquerors and conquered, between Pict and Celt, survive only in antiquarian tradition, and all become known by the common name Goidil, "Gaels," or Fir Erenn, "Men of Ireland."

Political Events, **A.D. 450–1000.**—The descendants of Niall, Ui Neill, acquired territories in the regions annexed by conquest

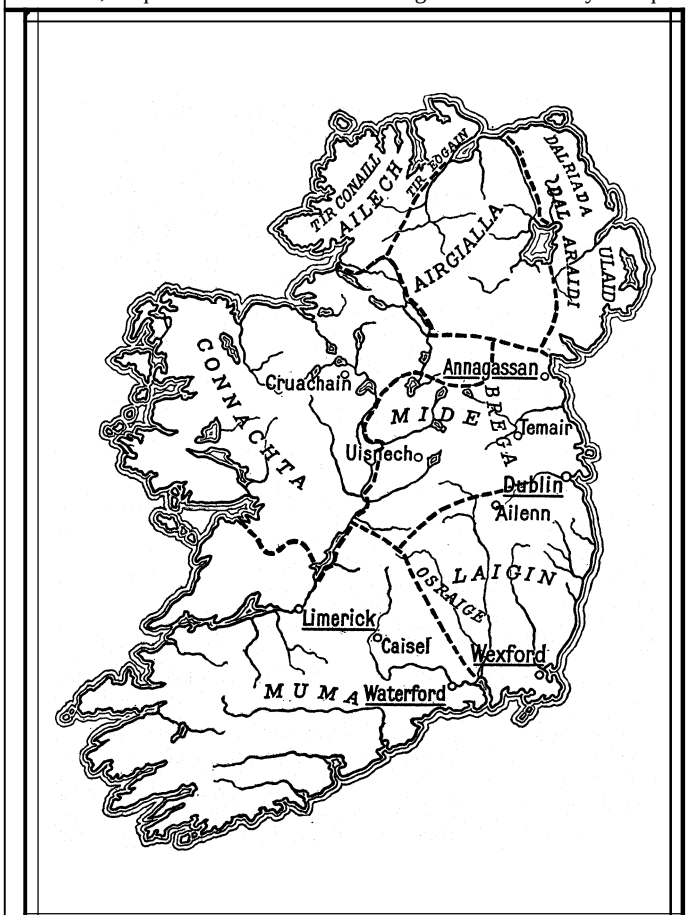

FIG. 2.—MAP OF THE SEVEN MAJOR KINGDOMS OF IRELAND. A.D. 500–900

These were Tir Conaill (Donegal); Airgialla (Londonderry, Armagh and Monaghan); Ulaid (Antrim and Down); Connachta (Connaught); Muma (Munster); Mide and Brega (Meath); and Laigin (Leinster)

to their ancestral kingdom, Connacht. The other branches of their kin remained in Connacht. Loiguire was succeeded as high-king by Aillill Molt of a Connacht branch. Niall's descendants combined against Aillill, who was defeated and killed in the battle of Acha, A.D. 483. Thenceforward, until 1002, the high-kingship was held exclusively by the line of Niall. One group of his descendants, the "northern Ui Neill," held western Ulster. Another group, the "southern Ui Neill," dominated Mide, the main part of the old

north Leinster fifth. In 563, the Pictish territory west of the river Bann was annexed by the northern Ui Neill. In 575, the high-king, Aed, son of Ainmeri, held an assembly at Druim Ceta, on the border of that territory, and decisions were adopted limiting the privileges of the *filid* and regulating the relations of the kingdom of Dalriada in Ireland to the kings of Dalriada in Scotland and to the kings of Ireland, In 637, Domnall, king of Dalriada, invaded Ireland from Scotland. He was defeated in the battle of Mag Roth ("Moira") by Domnall, king of Ireland.

After the battle of Octa, the high-kingship passed without any regularity from one branch to another of the Ui Neill, being held by descendants of five of his sons. In 734, Flaithbertuch, of the line of Conall, son of Niall, was deposed by Aed Allan, of the line of Eogan, son of Niall. Thenceforward the succession was confined to two branches, the kings of Ailech, descendants of Eogan, and the kings of Mide, descendants of Colman, these being respectively chief kings of the northern and southern Ui Neill, and the high-kingship was held by the kings of Ailech and Mide in a regular alternation, interrupted twice only, by the reigns of Congalach, king of Brega, 944–956, and of Brian Boroma, 1002–14.

ECONOMIC AND CULTURAL DEVELOPMENT

Development of Monastic and National Culture. — The great development of Latin learning and of the monastic schools takes its origin from St. David's school of Menevia in Wales about A.D. 500. The kingdom of Dyfed ("Demetia"), in which this school was situated, had originated as an Irish colony, and remained in close intercourse with Ireland. St. David was of partly Irish ancestry and his school attracted many from Ireland. Among its earliest pupils was St. Finnian, who founded the monastery and school of Clonard, about 520. Clonard became the parent of other noted monasteries, notably Clonmacnoise and Bangor, and, through its most famous pupil, St. Columba, of Derry, Durrow, Kells and other foundations in Ireland, as well as of Iona.

The language of these schools was Latin. The Latin classics were held in high esteem, and in some instances their survival is due to Irish zeal. When Theodore set up the teaching of Greek in Canterbury, he was beset by students from Ireland "like a wild boar surrounded by a troop of furious wolves." Scribes were continually at work providing copies of books. In the decoration of the more precious books, the art of illumination was highly developed. On the humanistic side, monastic learning was influenced by the traditions of Druidism. In the 7th century a fusion of the two cultures came about. In its early years a monastic chronicler introduced a framework of Irish history into his redaction of the Chronicle of Eusebius. A young noble, Cennfaelad, of the line of Niall, wounded in the battle of Moire (637), became a student in Tuaim Regon, where schools of the monks and the *filid* existed side by side. He broke away from the old druidical tradition by writing down the mnemonic formulae of Irish law. Cennfaelad, who died in 679, wrote also a number of poems on historical events and a short tract on the grammar of Irish. During the 7th century, an Irish written literature in prose and verse was extensive.

The Irish Missionaries. — In 563, Columba, then in his 43rd year, a descendant of Niall and a pupil of Clonard, having already founded the monastery of Derry on the site of the present city, led a colony of monks to the island of I ("Iona"), granted to him by the king of Dalriada. This was the beginning of the Irish missions oversea, the "surplus product" of the monastic schools. The work of Irish missionaries among the Picts, Angles and Saxons, belongs to the history of Britain. The continental missions began with Columba of the monastery of Bangor in Ulster, who, with a few companions, arrived in France about the year 574. Their range extended in time over a large part of France, the Netherlands, Germany, Austria, Switzerland and Italy.

The early missionary movement had its natural sequel in the sphere of learning. The part taken by Irishmen in the Carolingian revival of learning belongs to Irish history inasmuch as it exhibits the mental training given in Irish monastic schools and the scope and character of their studies. Clement the grammarian had a knowledge of Greek. Dicuil wrote a geography of the world in which he shows that his countrymen had travelled as far as Egypt and had discovered Iceland. Dungal, theologian and grammarian, wrote for Charlemagne an explanation of the solar eclipse of 810. Virgilius taught the existence of the Antipodes. Eriugena, for his knowledge of Greek and the boldness of his philosophical speculation, is the most prominent intellectual figure of his time. At Glastonbury, under Irish masters, St. Dunstan studied arithmetic, geometry, astronomy and music, Irish monasteries, in Ireland and abroad, were prominent in the cultivation of music.

Rural Economic Development. — The Irish laws point to a large development of rural industry in the period in which they were first written, preceding the Norse incursions. They deal minutely with the enclosure, subdivision and fencing of lands for tillage, the measurement and valuation of land, the management of crops and domestic animals, and innumerable details of husbandry, including milling, dyeing, spinning and weaving, dairying, malting, meat-curing, etc. The principal crops were wheat, barley, oats, flax and hay. Dye-stuffs were grown. Irish hounds were in high repute. St. Patrick, in his escape from captivity, joined a company of Irish traders whose chief merchandise was hounds. Watermills were owned and worked jointly by landholders.

The Paschal Controversy. — The Irish Church, in the dating of the Easter festival, followed a method introduced by its founders. Irish missionaries abroad found a different method under papal authority. About 631, the Roman computation was introduced in the southern parts, in northern Ireland somewhat later. Iona held out longest for the Irish tradition, even in opposition to its abbot, the celebrated Adamnan, and did not adopt the Roman Easter until 716, 12 years after his death.

Norse Invasions and Settlements. — The first appearance of the Norsemen on the Irish coast is recorded in 795, their first inroad in 807. Thenceforward there are frequent plundering raids, sometimes far inland. By degrees the Norsemen took possession of all the islands of Scotland, of Caithness, Argyle, Galloway, and the Isle of Man. In 841 they seized and fortified two ports, at Annagassan, between Dundalk and Drogheda, and Dublin. About the same time a fleet under Thorgest passed up the Bann to Lough Neagh. He afterwards sailed round to the Shannon and took possession of Lough Ree in like manner. Thorgest was captured in 845 and put to death by Mael-Sechnaill, king of Mide, who in 846 became king of Ireland. Large invading forces were defeated in 847. The turning point of these invasions was reached in the reign of Aed Findliath, high-king from 862 to 879, who forced the Norsemen to abandon all their stations in the northern parts of Ireland. At the same time the Norse kings of Dublin reached the height of their power, waging war in England and Scotland, and so nearly dominating Ireland that in the years 873, 876 and 878 the high-king was unable to hold the assembly of Tailtiu. Waterford in 914 and Limerick in 920 were occupied by the Norsemen without opposition. In 917, Niall Glundub, high-king, endeavoured to dislodge them from Waterford but they defeated a Leinster army coming to his assistance and forced him to withdraw. In 919, Niall led an army against Dublin, and in a battle where the Phoenix park is now he was defeated and killed. The permanence of the Norse settlements in Dublin, Waterford and Limerick became assured. Landed colonies spread out from Dublin and Waterford. Without quite abandoning piracy, the Vikings became traders in close intercourse with the Irish, and their commercial towns form a new element in the life of the country, typified in Wexford, which does not appear in warfare until the siege of 1169. The combination of war and commerce led to a recrudescence of slavery, and imported slaves are mentioned in the "Book of Rights" (about A.D. 900).

About 964, Mathgamain, king of Dal Cais, one of the petty kingdoms of Munster, became king of Munster, displacing the ancient Eoghanacht line. In 968 he defeated the Norse of Limerick and captured their city. In 976, he was captured and put to death by two Eoghanacht princes, one of whom, Mael Muaid, became then king of Munster. In 978, Mael Muaid was defeated and put to death by Brian, brother of Mathgamain. Brian, having gained the kingdom of Munster, kept steadily increasing his power. His claim to suzerainty over Leinster forced the Leinster king into close alliance with the Norse of Dublin. In 999 their

united forces were defeated by Brian at Glen Mama, near Dublin, and they agreed to become his allies and supporters. In 1002, Brian became king of Ireland by the submission of the high-king Mael Sechnaill II. The Irish and Norse accounts agree in bearing witness to the high character and good government of Brian. The kings of Dublin and Leinster, however, chafed under his suzerainty. In 1013, Sigurd, earl of the Orkneys, had for a Christmas guest the Norse king of Dublin, Sigtrygg, and a compact was made between them. Sigurd was to gather from all parts the greatest possible host of Norsemen and to bring them before Easter to Dublin, where they were to be joined by the forces of Dublin and Leinster to give battle to Brian and, if they were victorious, Sigurd was to have the kingdom of Ireland. Brian learned of these preparations, met the Norse army at Clontarf, near Dublin, on Good Friday, 1014. He was joined by the deposed high-king, Mael Sechnaill. The Norsemen and their Leinster allies were defeated and Earl Sigurd was slain, but a Viking chief, who had taken refuge in a wood, sallied out in the rear of the Irish army and killed Brian in his tent.

Though the battle of Clontarf removed the prospect of a Norse conquest it brought a period of unsettlement. All the chief dynasties had lost their prestige, and, except in Connacht, new rivalries and fresh pretensions to power, based on force and careless of tradition, arose everywhere. Brian's son, Murchad, who had already gained a reputation hardly less than his father's, had fallen in the battle. Of the sons who survived, none was able to sustain Brian's power. Mael Sechnaill was restored to the high-kingship and held it until his death in 1022. After him, for half a century there was no acknowledged king of Ireland.

Then followed the period of the high-kings "with opposition," *i.e.*, not acknowledged by a minority of the provincial kings: Toirdelbach, grandson of Brian, 1073–86; his son Muirchertach, 1086–1114; these were kings of Munster; in opposition to Muirchertach, Domnall Ua Locklainn, king of Ailech, who died in 1121; Toirdelbach Ua Conchubair, 1118–56, king of Connacht; Muirchertach Ua Lochlainn, 1156–60, king of Ailech; Ruaidri Ua Conchubair, 1166–74, king of Connacht. The centralized feudalism established in England by William the Conqueror had an apparent influence on the policy of these kings. One after another they sought, for the most part without success, to set aside the ancient tradition of local autonomy and to exercise direct authority outside of their hereditary jurisdictions. Thus Toirdelbach Ua Briain about 1075, appointed a kinsman of his own to be king of Tulach-Og in Ulster. Toirdelbach Ua Conchubair, in 1118, divided Munster into two coequal kingdoms; in 1124, deposed the king of Mide and appointed three kings in his stead; in 1126, made one of his sons king of Dublin and Leinster; in 1129, built the first castle in Ireland, commanding the passage of the Shannon at Athlone.

The last effort to establish Norse domination was made by Magnus, king of Norway, who in 1098 came with a strong fleet and restored the Norwegian sovereignty over the Scottish islands, Cantire, and the Isle of Man. In 1102, Magnus, then in Man, threatened an invasion of Ireland but agreed to a year's truce. In 1103 he landed on the Ulster coast where he was killed.

The period of political ferment which followed the success of Brian over the ancient chief dynasties was also a period of new growth in religion, literature and the arts. The movement for religious reform, mainly in the direction of a Catholic uniformity and the removal of abuses in matters of ecclesiastical discipline and observance, was led by Gillebert, bishop of Limerick, and Cellach (Celsus), bishop of Armagh and primate, in the beginning of the 12th century, and by the successor of Cellach, Maelmaedoc Ua Morgair, better known as St. Malachy. The outstanding feature of the abundant literary output of this time is enthusiasm for ancient national tradition. It became customary to compile tomes, each forming a kind of library of traditional lore, comprising sagas, poems, genealogies, etc. A number are still extant.

BIBLIOGRAPHY.—Macalister's *The Archaeology of Ireland (1928)* summarizes and explains the archaeological data. The data from Greek and Latin writers are given under appropriate headings in Holder's *Altceltische Sprachschatz*. For ancient Irish traditions bearing on the predocumentary period, the chief book of reference is Best's *Bibliography of Irish Philology and of Printed Irish Literature* (1913), which also gives particulars of the published chronicles. Irish contemporary chronicling begins towards the end of the 6th century and continues thenceforward until modern times. (E. MACN.)

HISTORY FROM 1166 TO 1485

The Anglo-Norman Invasion, 1166–1175.—Early in his reign, 1155, Henry II. of England had, through his envoy, John of Salisbury, received from Adrian IV. the grant of Ireland "as an inheritance," on condition that he should reduce to order the Irish Church and State. The so-called "Bull," Laudabiliter, which defines this grant, rests on the sole authority of Giraldus Cambrensis; how far it is genuine is one of the puzzles of history, but the general submission of the Irish to Henry later would imply that some such papal privilege was in the air.

Henry had to put his project aside for the time, and when the invasion came, it was a feudal one and directed from south Wales which was full of Norman adventurers. The first invaders, Maurice Fitzgerald, Robert FitzStephen, Raymond "le Gros" de Carew and others were sons or grandsons of the famous Welsh princess Nesta, and vassals of Richard FitzGilbert de Clare, called "Strongbow" in Irish tradition, earl of Pembroke.

Their opportunity came when Dermot MacMurrough, king of Leinster, expelled by his enemies, decided to seek aid in England and arrived in Bristol with his beautiful daughter Eva (Aoife) in Aug. 1166. He was there referred to Henry, found the king in France, was graciously received and given permission to raise forces in Britain. Returning to Wales, he won FitzGilbert over by the offer of his daughter's hand with apparently the succession to Leinster. He also enlisted "the sons of Nesta" in his cause and they found volunteers among the Welsh and Flemings of South Wales and Pembroke. Returning to Leinster, where his son Donal Kavanagh, whom Giraldus calls illegitimate, was holding out for him, he held his ground until successively Fitzgerald, FitzStephen, Raymond and finally Earl Richard himself arrived, the latter landing at Waterford in Aug, 1170 with 200 knights and 1,000 men-at-arms.

The successes of Dermot, backed by these professional fighters, were rapid; Danish Waterford was taken; the marriage of Eva and the earl celebrated; and by a rapid march Dublin also was captured and a relieving force under the high-king scattered, late in 1170. Leinster and Ossory were reduced, but the death of Dermot the following May made the situation difficult. The Irish regarded his son Donal as the true heir, but FitzGilbert considered himself king of Leinster, and anyway in feudal theory was, in virtue of his wife, lord of the province. But he was hemmed up in Dublin in mid-summer by a national levy raised by Rory O'Connor, king of Connacht, and though this attack was repelled, it was uncertain whether he could hold his own. Therefore when Henry, fearful lest a new Norman State should arise across the Irish channel, resolved to come to Ireland, Strongbow placed his conquests at his suzerain's feet.

Henry landed near Waterford on Oct. 17, 1171, with an imposing army, but a conquest in arms was not necessary, and in fact the peaceful submission of the Irish leaders was prompt and widespread. The king marched to Lismore and Cashel and finally to Dublin, where he spent the winter, leaving Ireland on April 27, 1172. Into this short period he packed the rough essentials of a government. At Dublin and elsewhere he received the homage of all the kings of Ireland except those of Connacht and Ulster To Strongbow he granted the "Land of Leinster," confirmed the Geraldines and others in their fiefs, and annexed to the Crown the Danish kingdom of Dublin. He gave the capital to "the men of Bristol," took the Ostmen under his protection, and appointed Hugh de Lacy governor of the colony. He did not scruple to confer on De Lacy the whole of Meath, though its native king, O'Melaghlin, had recently submitted, and the grant illustrates the inevitable clash of feudal and Irish law. Meanwhile during the winter the Irish bishops met at the Council of Cashel and, after enacting various reforms, declared (according to Giraldus): "Divine offices shall be celebrated according to the forms of the **Church** of England, for it is just and right **that** as **Ire-**

land has received her lord and king from England, she should accept reformation from the same source." This of course was an inspired assurance of the task with which the papacy had commissioned Henry. The submission of the Church was complete, nor was it a packed assembly, for though Christian, bishop of Lismore and papal legate, seems to have been on Henry's side, Laurence, archbishop of Dublin, and the native prelates of Cashel and Tuam were present. Thus was Ireland presented to the English Crown as a papal fief; such was the basis of its authority till 1541, and the Irish themselves accepted the fact.

Meanwhile the adventurers were attacking Desmond, though its king had submitted to Henry; De Lacy was organizing Meath; and John de Courci conquered in Antrim and Down a principality for which he could show no royal patent. Strongbow enfeoffed Leinster deeply with Normans, giving for instance the barony of Naas to Maurice Fitzgerald. Strongbow died in 1176, leaving only a daughter, who later married William the Earl Marshal and brought to him "the land of Leinster." Ulster and Connacht were still unconquered, and in 1175 by the Treaty of Windsor, Henry acknowledged Rory O'Connor as king of Connacht under him.

John as Lord of Ireland, 1175–1216.—At the Council of Oxford in 1177 Henry created his son John *Dominus* Hibernie and granted Desmond to FitzStephen and Milo de Cogan. Eight years later (1185) John himself visited Ireland. A fresh series of grants were made, and William de Burgh and Theobald Walter "le Botiller" got wide lands in north Munster, and Theobald de Verdun about Dundalk. The resentment of the Irish was shown in the assassination of Hugh de Lacy, and the lesson was taken to heart later in John's reign when Cathal Crovderg O'Connor, brother of Rory, was confirmed in the kingdom of Connacht and Donnchad O'Brien in that of Thomond west of the Shannon.

With John the lordship of Ireland was united with the English Crown, and to this king belongs the credit of first establishing a civil government at the expense of the conquistadors. He dispossessed De Courci, and gave the earldom of Ulster to Hugh, brother of Walter de Lacy, earl of Meath, but soon repented of making this family too great, and in a personal campaign in Ireland in 1210 expelled them both. During his short stay in Dublin he organized a permanent government under a justiciar, and "with the common consent of all men of Ireland ordained that the laws and customs of the realm of England should be kept therein."

After his defeat over Magna Carta, John had to restore the Lacys, and the feudal caste under Henry III. bent its energies upon the subjection of Ireland. When Richard de Burgh got a grant of all Connacht in despite of the claims of Felim O'Connor, conquered it and divided it among his followers (1235), and Maurice Fitzgerald acquired a claim to Tyrconnell, a complete conquest seemed probable. But during this period two great native dynasties arose in Ulster, the O'Neills and O'Donnells, and they repelled the Norman attacks, finding a new and potent weapon in those professional fighters, the "Galloglaigh" or "galloglass" (a word meaning "foreign soldiers"), Hebrideans of mixed Gaelic-Norse blood who now began to flock into the north. On Connacht, however, the De Burghs kept firm hold, leaving to the O'Connors only a few cantreds of Roscommon. The power of this family was increased when in 1264, after the extinction of the Lacys, Walter de Burgh was created earl of Ulster. The native race, though only partly successful, now broke the spell of Norman victory. Brian O'Neill was elected high-king and raised a Gaelic confederacy, but was defeated and slain at Downpatrick in 1260. But the next year the MacCarthys overthrew a colonial army at Callan, and henceforth ruled undisturbed over south-west Munster, their chief taking the name MacCarthy More. So when Edward I., in 1276, granted to Thomas de Clare the "Land of Thomond," Turloch O'Brien took up arms, and the De Clares were finally expelled in the war which ended in 1318.

In the early years of Henry III. the central Government was steadily built up. Magna Carta was sent over, the whole framework of English law was introduced, and Ireland had an administration under the justiciar and a parliament of peers and prelates, while the county organization was extended over the planted areas.

Great numbers of the Gaels had fallen under Norman lords, and while some were already villeins ("betaghs") under the old system, and remained so on the new manors, many of the colonists tried to reduce all Irishmen to the same level. Those living among the English and suffering from a denial of English law strove to procure it, but though the Government was not unwilling, the colonists opposed emancipation. The Irish who lived under Brehon law had less desire to exchange it for English law, but under the pressure of the new domination they naturally aspired to have its legal advantages. The chiefs especially sought to have their tenures legally established under the Crown, a benefit which, except in a few minor cases, had been denied them. The royal Government was to blame for not embracing the Irish within the law by edicts rigidly enforced, but, indeed, to reconcile and blend two races so far apart in language and tradition was a huge task which only a resident monarchy could have achieved.

English Lordship at its Height, 1272–1307.—Under Edward I. a second attempt was made to create a real central authority, and a series of justiciars, of whom John Wogan, viceroy from 1295 to 1307, was the abiest, extended the area of common law and did something to reduce the feudal liberties. The baronial interest, however, was too strongly entrenched, and Edward had to placate it, so he added to the ranks of the magnates by giving "the land of Decies and Desmond" to Thomas, head of the Munster Fitzgeralds. Wogan's greatest achievement was to summon a parliament in 1297 in which knights and the common clergy were included, and nine shires and five liberties sent representatives. In 1310 the towns also sent deputies, and thus Ireland received a legislative body which lasted till 1800. It mas an Anglo-Irish assembly in which the native race had no spokesmen.

A series of disasters now shook the ill-founded State to its very base. Fresh from his victory at Bannockburn, Robert Bruce despatched his brother Edward to win the Crown of Ireland, which a league of Irish chiefs under Donal O'Neill, Rex *Ultonie,* offered to him. When Edward Bruce landed with an army of veterans near Larne in May 1315, almost all the native race rose in arms, and not a few of the older stock of the Englishry joined Bruce. He defeated Richard the "Red Earl" of Ulster at Connor. On May day, 1316, he was crowned king of Ireland on a hill near Dundalk, "the Gaels of Erin proclaiming him king of Ireland," says the annals of Loch CC.

The English cause was at last saved: Bruce failed to take Dublin, Felim O'Connor, at the head of a great Irish confederacy, was defeated and slain by a colonial levy at Athenry in Aug. 1316, and a new viceroy, Roger Mortimer, put spirit and energy into the Government. Bruce himself was overwhelmed at Faughart, near Dundalk, by an army under John de Bermingham and fell in the battle (Oct. 1318). The Scottish fire was thus quenched and Edward II. recovered a kingdom he deserved on every count to lose. Little or no vengeance was taken, and Mortimer was instructed to admit the aggrieved Irish to English law and liberty, an edict again without much effect.

The Irish Revival.—For a time all seemed fair and the peerage between 1316 and 1329 was strengthened by the creation of new earldoms, that of Kildare, given to John, head of the Leinster Geraldines, that of Desmond, given to Maurice, head of the Munster Geraldines, and that of Ormond, given to James Butler. In Ulster, the true key of the colony, the power of the earls now covered the whole coast from Carlingford to Derry. But an element of discord was found in the older colonists who resented the dominance of the great lords, claimed that succession should go to heirs male instead of heiresses who conveyed lands to English absentees, and began to form clans of their own (*naciones* et *cognomina*). In 1333 the young earl of Ulster, William, was murdered by his own tenants, the Mandevilles, near Belfast, leaving only a daughter who later was married to Lionel, duke of Clarence. The O'Neills became supreme in mid-Ulster and the greater part of Antrim and Down, where they founded a new State, Clandeboy.

Connacht was at the same time lost to the English interest. Two cousins of the murdered earl, Ulick and Edmund de Burgh,

seized on the family lands and founded respectively the Burkes of Clanrickard and Mayo, known to the Irish as MacWilliam Uachtair, "the upper MacWilliam," and MacWilliam lochtair, "the lower MacWilliam." Though they maintained a certain English tradition of law and land-tenure, spoke French, and boasted their Continental descent, they were obliged amid so Irish a population to speak Gaelic and marry Irish wives.

As a result of such events an Irish revival alike in arms, language, law and civilization, displayed itself in every part of the island, and the Gaelic race recovered large parts of Ulster, the midlands, Connacht and Leinster. Even in the latter province the MacMurroughs became the terror of the lowland English and the descendants of Donal Kavanagh resumed the title "king of Leinster." Absenteeism here had left the lordships of Carlow and Wexford open to Irish attack.

Efforts to Restore English Lordship, 1333–1399.--Only a great army led by the king in person could have reconquered Ireland, and the young Edward III. had thoughts of coming over, but soon abandoned it for Scotland and France. The colony dwindled, and an Anglo-Irish parliament at Kilkenny in 1341, summoned without leave by the earl of Desmond, expressed its resentment against "the English by birth" who misgoverned Ireland, and complained of the decay of the revenue and the loss of

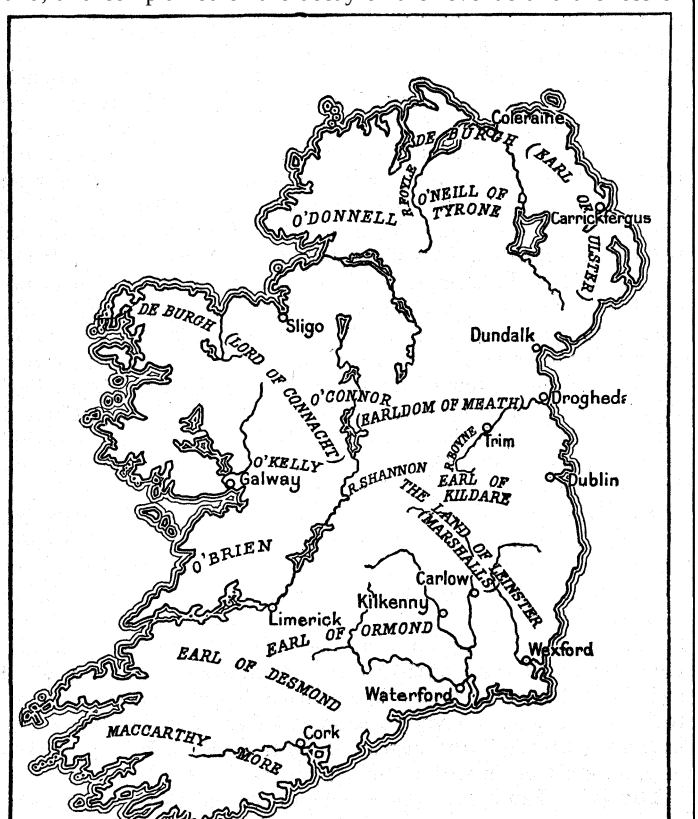

FIG. 3.— MAP OF MEDIAEVAL IRELAND. SHOWING THE LANDS OF THE RULING FAMILIES WHEN THE ENGLISH POWER WAS AT ITS HEIGHT, *c.* 1330

In addition to the counties governed directly from Dublin, several great earldoms had been created at this date; but that of Meath, belonging to the Lacys, had, owing to the extinction of this family, fallen into two portions, that of W. Meath (De Verdun) and that of Trim (Mortimer)

a third of the land to the Irish. The capacity of this "middle nation," "Irish to the English and English to the Irish." to turn into temporary rebels was often to puzzle England.

Finally at last a royal prince was sent, and Lionel, duke of Clarence, ruled as viceroy for six years (1361–67). The Statutes of Kilkenny are the one memorial of his rule. These enactments defined the "English" or "obedient" land as the counties and liberties of Louth, Meath, Trim, Dublin, Carlow, Kildare, Kilkenny, Wexford, Waterford and Tipperary. The decay of the colony was attributed to a general lapse into Irish language, law and habit, intermarriage and fostering, and the maintenance of Irish bards. Therefore the English were forbidden to make such alliances with the Irish or to use Brehon or "March" law, and along with the Irish who dwelt peaceably among them, were ordered to take English surnames, speak English, and follow English law and custom.

The purpose of these statutes was to preserve as large an area as possible for England at the cost of abandoning the rest. The king's sovereignty over the whole island was not renounced, but the independent Irish were henceforth treated as "Irish enemies," outside the pale of English law and loyalty, and unable to plead in or profit by the civil courts, to marry, purchase, possess or inherit land among the English. Up to the end of the 16th century the chiefs were held to have no right to their lands except by prescription and usurpation.

But nothing could recall the "degenerate English" from friendly intercourse with the *meri Hibernici.* The old Gaelic civilization, badly shattered in the 13th, recovered much of its strength in the 14th century, and with its music and poetry, the charm of its language and its women, and the aptness of its law, laid an irresistible spell on the older Englishry.

Lionel's only daughter marrying Edmund Mortimer, earl of March and lord of Trim, carried to him the earldom of Ulster, and this great lord came over as viceroy in 1380, but died prematurely. To buy off the Irish chiefs with Black-rents was now the poor device of the colonists, whose most dreaded foe was Art MacMurrough, king of Leinster. More than anything else, this chief's activities brought about the first royal visit since 1210. Richard II. arrived at Waterford in Oct. 1394 with a large army, attended by Roger Mortimer and other peers, and stayed in Ireland till May 15, 1395. His general policy for the "Irish enemies" was to secure their homage and confirm them in such lands as they had not "usurped," but with one exception; Art and his Leinster "urraghts" or vassals were to be induced to evacuate Leinster for other parts of Ireland and leave the province open to a new English plantation. This was achieved in both cases as far as paper went; almost all the ruling chiefs, headed by Niall O'Neill, *Princeps Hibernicorum Ultonie,* came in and did liege homage and entered into indentures with the king.

But on Richard's departure MacMurrough refused to fulfil his extraordinary bargain. Roger Mortimer, left behind as viceroy, was slain by the Wicklow Irish in 1398, and Richard in fury hurried over to Ireland again in 1399. His armies could do nothing against the light-armed Irish in their forests, and the unfortunate king returned to England only to meet his own doom.

The Great Earls, **1399–1452.**—There is little of importance to record of the dwindling "English land" during the Lancastrian age. An occasional strong viceroy, such as John Talbot, afterwards the famous earl of Shrewsbury, could do little against the "Irish enemy," the "degenerate English," and the "English by blood," who resented government from Westminster. A hope of uniting the Celts and Englishry was found in Edmund Mortimer, now earl of Ulster, who came over as viceroy and received the homage of O'Neill and other chiefs, but died of the plague in 1425. The old English and the Gaels transferred their affections to his nephew, Richard, duke of York, and in the wars of succession in England were almost to a man for the White Rose.

In reality three great earls now ruled Ireland. James of Desmond brought the greater part of counties Limerick, Cork, Kerry and Waterford with their towns under his absolute rule, James "the White," earl of Ormond, was equally dominant in Tipperary and Kilkenny, and Kildare in Leinster. The three worked together, dominated the Dublin Government in spite of an "English interest" headed by Talbot, took the lead of an Anglo-Irish "Home Rule" party and built up a rampart of feudal independence which it took the Tudors later almost a century to break down.

Ireland and the **Wars of** the Roses.—"Aristocratic Home Rule" may till 1495, and indeed till 1532, be written over Anglo-Irish history. The Wars of the Roses were to the Old English an occasion to secure colonial independence. Richard, duke of York,

who came over as lord lieutenant in 1449, played up to the enthusiasm that was at once displayed for his person and name. All Ireland believed him to be the true heir to the English Crown and greeted with enthusiasm the hereditary claimant, who in return was expected to rule Ireland by Irish ideas. Hence, when he arrived as a defeated refugee in 1459, the Irish parliament greeted him almost as a king, but proceeded to declare that the land of Ireland was bound only by the statutes of her own estates. When his son Edward ascended the English throne Ireland seemed to have the king of her choice, and the earldom of Ulster was merged in the Crown.

James, earl of Ormond, taking the Lancastrian side, was executed after Towton, and his house attainted. His two brothers, successively earls, spent their lives in England, and a junior branch of the Butlers took practical possession of the Ormond lands.

King Edward had little love for an oligarchy which ruled Ireland under the guise of Yorkist loyalty, and all Ireland was appalled when a new viceroy, John Tiptoft, earl of Worcester, got Thomas, earl of Desmond, attainted "for treasons, alliances and fosterages with the Irish enemies," and had him beheaded (1468). But Edward was not in a position to go further, and after this exhibition of blood-letting, the government had to be left to the Anglo-Irish, and Thomas, earl of Kildare, ruled till his death in 1477.

Under his son, Gerald, called by the Irish "Garret More," the Kildare supremacy reached an almost royal height. Although only deputy for English princes who bore the empty titles of lords lieutenant, Gerald was, in effect, actual ruler of Ireland. The Old English were for him, his sister was wife to O'Neill, various daughters of his married Irish chiefs, and the Dublin parliament was at his beck and call. He had the revenues of Ireland and the appointment to offices; these went to his supporters and Irishmen ruled Ireland. So things stood when Richard III. fell at Bosworth.

FROM 1485 TO 1800

The Kildare Supremacy, 1485–1534.—To the Ireland of 1485 the victor of Bosworth seemed a pure usurper, and a Plantagenet restoration was long hoped for. But by the year 1499 Henry was strong enough to attack the Anglo-Irish oligarchy. He removed Kildare and sent as deputy, in Oct. 1494, Sir Edward Poynings, who had Kildare attainted in a parliament at Drogheda and then proceeded to the task of restoring the royal power. The Acts of the Irish Estates of 1460, which proclaimed the legislative autonomy of Ireland, were annulled, and in their stead was passed the famous measure known to history as "Poynings' law," enacting that no parliament might meet in Ireland till the king, notified by the Irish Council of the necessity and the measures proposed, gate his approval under the Great Seal of England.

Among other acts of the parliament of Drogheda, one directed a ditch to be made around the nearer parts of Meath, Dublin,

FROM CURTIS "HISTORY OF MEDIAEVAL IRELAND"

Kildare and Louth. Within this "Pale" alone, and in the towns and a few strips of coast elsewhere, were English law, speech and loyalty regarded as secure. Outside were the great earldoms, the "degenerate English" and the "Irish enemy." To break the power of the first, to recall the second to their allegiance. and to Conquer or conciliate the third was to be the threefold task of the Tudors in Ireland. But it could not be undertaken yet. When Poynings departed in 1496, Kildare was restored and a general pardon was issued.

"This people of Ireland," said a later observer, "did ever, both English and Irish, love to be ruled by great persons." Garret More, who ruled Ireland till his death, in 1513, was such a personage. As deputy he controlled Dublin and the Pale, his earldom made him supreme in Leinster, and by vassalage, fee or marriage, he attached numbers of Irish chiefs to him, of whom the greatest were Conn O'Neill and Hugh O'Donnell. But his loyalty was dubious, and in his later years he was intriguing with Scotland against the young Henry VIII. His son Gerald, called "Garret Oge" ("the younger"), succeeded to this hereditary power, but to maintain it became an ever harder task. To the hostility of the Butlers was added that of Wolsey, who urged Henry against so overgrown a subject as "the king of Kildare." Gerald was again set aside, and the earl of Surrey came over as lord-lieutenant, for two years, in 1520–22. His reports, backed by such tracts as D'Arcy's *Decay* of *Ireland,* told the same tale; Kildare, "using the sword the king had committed to him to extinguish the fame and honour of any other nobleman within the land"; the Irish speech and habit universal, even in the Pale; the "March English" everywhere imposing on their tenants coyne and livery, quarterings of kern and galloglass and other such "Irish exactions"; the Irish, independent under their chiefs. Though Gerald was restored once again, the Butler-Wolsey alliance grew more dangerous, and when the divorce question began and Henry conferred the vacant earldom of Ormond on Sir Thomas Boleyn, grandson of the last earl, and made Sir Piers Butler earl of Ossory, it seemed impossible for him to escape. Yet so astute a man might have weathered through even yet but for a young and foolish son. Recalled to London in 1534, Gerald instructed his heir, Thomas, Lord Offaly (called "Silken Thomas"), to be ruled by the wise heads of the council. The Butler faction spread the rumour that Kildare had been done to death, and Offaly at once flew to arms. His father did, indeed, die in the Tower, but with mortification and dismay; a new deputy, Skeffington, arrived, and Thomas, while barring himself from pardon by offering Ireland to the emperor and declaring himself of the pope's sect against the heretic Henry, had finally to surrender at discretion, and in 1535 was executed at Tyburn with five uncles.

The Reformation of the Irish Church. — The new policy in Church and State could now be carried through, and henceforth English viceroys and obsequious Anglo-Irish officials directed the Government. Grey summoned a parliament in 1536–37, which declared Henry supreme head of the Church and voted the dissolution of the abbeys. It is certain that almost no desire for such "reformation" existed in Ireland; lords and chiefs might accept bribes of monastic lands, but even at the end of the reign scarcely any abbeys had been dissolved outside Leinster, and not till 1607 could those of Ulster be confiscated. Within the region of the Pale the abbeys were centres of English education, speech and civility; outside, they were the home of Gaelic culture, and civilization in general suffered by their extinction. George Browne, an Englishman, was sent over as archbishop of Dublin, to preach the royal supremacy and, before the end of the reign, some 14 or 15 of the older bishops temporized and accepted it, in the belief that the Church was still Catholic.

On its civil side the new policy had much support, not only in Piers Rua, who was at last created earl of Ormond, but in great numbers of the rural tenantry, desirous of being released from the exactions of the great lords. To recall the Old English to their natural allegiance was no insuperable task, and had the Tudors never abandoned the old faith it is probable that they would have commanded the entire loyalty of the "first conquerors." When, however, the Reformation began in earnest the Old English grew steadily alienated, and the introduction of new colonies became the royal policy.

Towards the Gaelic chiefs Henry adopted the plan of surrender and re-grant, by which they could surrender the lands they held and receive them back on tenure of knight-service to the Crown. To the great ones he offered to grant titles, but in return they must accept him as supreme in Church and State. St. Leger, who came as deputy in 1540, pointed out that a new title must be found for the Crown in Ireland, "for of long continuance Irishmen have supposed the regal estate of this land to consist in the bishop of Rome and the lordship of the kings of England here to be but a governance under the obedience of the same." Accordingly a parliament was summoned in June 1541, and six Gaelic chiefs approved the act that made Henry king of Ireland.

By the skilful handling of St. Leger, Manus O'Donnell accepted Henry as his lord and king, renounced the pope's authority, consented to serve the deputy with an agreed number of horse and foot, and to accept whatever title the king should give him. Conn O'Neill surrendered his ancestral claims, accepted Henry as king, and in 1542 was made earl of Tyrone; Murrough O'Brien became earl of Thomond, and Ulick Burke, earl of Clanrickard.

Ireland Under Edward VI. and Mary.—Under the two Protectors the Reformation mas pushed on apace, and the anger of the common people at the destruction of monasteries and the plunder of the Church was now shared by the great. Dowdall of Armagh, though one of Henry's bishops, defended the mass, and only five Protestant bishops held their ground, of whom most active was the Englishman, John Bale of Ossory, a Genevan reformer.

On her accession, the Catholic Mary retained the title of queen of Ireland, but had to leave the abbey lands to the grantees. St. Leger became deputy again, Dowdall returned, and, as a part of the general reconciliation, the exiled Gerald was restored to the earldom of Kildare. But in spite of religious unity, there was little peace. Henry had begun the policy of trying to rule the further provinces through the new earls, but these were opposed by the vested interests of those who preferred the old order, in which the O'Brien or MacWilliam was but an elected captain of his "nation," holding for life, not an hereditary official landlord. This was especially seen in the North, where Shane O'Neill, claiming to be Conn's eldest legitimate son, came out as champion of the old Gaelic order, preferred being "the O'Neill" to any English title, and opposed his brother Matthew, baron of Dungannon, whom he declared to be a bastard. The conflict of State feudalism and Gaelicism became general. In Leix and Offaly, where O'More and O'Connor Faly were sovereign, a determined stand was made against the extension of English law, and after a long border war the Government decided to annex and partly plant these areas. Lord FitzWalter, afterwards earl of Sussex, replaced St. Leger in 1556, and with him a policy of confiscation and plantation was adopted. The two lands were shired as King's and Queen's counties and divided into an eastern more fertile area, in which Englishmen were to be planted, and a western area, which was to be left to the natives holding by common law tenure.

The Elizabethan Reformation. — Elizabeth succeeded to the throne in Nov. 1558, and under the earl of Sussex the State religion was finally established. In a parliament of 1560, which represented ten counties and 28 towns, the Acts of Supremacy and Uniformity were passed and recusancy fines were imposed. Outside Dublin the supporters of the Established Church were a handful, and it soon became clear that the Old English were even more determinedly Catholic than the Irish. As loyal subjects their position was strong, and a constitutional resistance was successfully waged by the lawyer class, who were strong in the Commons, the town corporations and even the Government.

Ireland, with its feudal and Gaelic lordships, was a standing offence to a centralizing monarchy, and to extend the shireland and introduce sheriffs, garrisons and English law became the avowed object of the Tudor Government. But every such extension, which had to proceed piecemeal, met the opposition, alike of the chiefs and the Old English lords; and the resistance of the Gaelic population was the more deadly of the two, for their military resources were greater, their native civilization was dearly cherished, and their hatred of the Saxon was deeply rooted. The greatest of these captains, Shane O'Neill, was, in native eyes and, almost, in fact, king of Ulster. From the four counties, Tyrone, Derry, Armagh and Antrim, where he was overlord, his ambition was to rule the whole province, and after Matthew, baron of Dungannon, had fallen in an affray, and his son Hugh was taken to be educated with the earl of Leicester

and in Elizabeth's court, Shane had the field to himself. He proceeded to subject O'Donnell on one hand and the Scots of Antrim on the other, and having been invited over to court in 1562, he so flattered the queen with his Irish tongue that he returned in triumph as "The Lord O'Neill." When Sir Henry Sidney arrived as deputy in 1565 the power and influence of Shane overshadowed all Ireland, but in a rash attack on Hugh Duv ("the Black"), chief of Tyrconnell, he was routed at Farsetmore, and, flying to his enemies, the MacDonnells, was by them murdered in 1567.

The Desmond Wars.—Desmond was an "Old English" regality as Tyrone was a Gaelic State. The new earl, Gerald, was deeply suspicious of the "forward policy" which menaced his palatine authority. He and Thomas, earl of Ormond, were hereditary enemies, and after a pitched battle at Affane, in 1564, they were summoned to London, where Desmond spent many years of semi-captivity till 1573. The Geraldines, therefore, took as captain the earl's cousin, James "FitzMaurice" FitzGerald, who planned a league which should defend at once the earl's "liberties" and the Catholic faith. Exclusion from office under the Oath of Supremacy mas now alienating the "English of the Pale," and religious discontent was fanned by the Jesuit missions, which, from 1561, were many and determined. Catholic Ireland had its colleges at Douai, Salamanca and Louvain, and if rebellion needed the highest sanction it was found in the papal bull of 1569, which excommunicated Elizabeth and released her subjects from obedience. It was unfortunate that at such a time the Government allowed Sir Peter Carew, a Devon gentleman, to get legal possession of wide lands in Carlow and Cork in virtue of very musty pedigrees. With him began the age of the adventurers and land-speculators, the Raleighs and the rest, and Old English and Irish now felt that even their property was insecure. FitzMaurice was accordingly able, in 1569, to kindle a widespread revolt in Munster and Leinster, which Sidney, Carew and Gilbert stamped out with a severity that set the note for future "pacifications," and FitzMaurice submitted in 1573.

Six years later he was the leader of a new war in Munster. The Continental side of it was organized by the Spaniard, Oviedo, later "titular" archbishop of Dublin, but though the pope offered spiritual assistance, Philip gave little or no material aid, and FitzMaurice had but a small band with him when he landed in Rerry in 1579. With him was the English Jesuit, Sanders, who proclaimed a plenary indulgence for all who would fight against "Elizabeth, pretended queen of England." There was a widespread rising, but the only man who could have made it formidable disappeared when FitzMaurice fell in a petty affair at Castleconnell. The earl himself was driven into rebellion, and 800 Italians, sent by the pope, were besieged at Smerwick by the deputy and, after surrender, pitilessly massacred. Desmond was hunted down and killed and the South was pacified by the usual methods. Confiscation was henceforth to follow the horrors of war, and while the earl and his chief followers were attainted, some 600,000 acres were declared forfeit. In the end only some 200,000 were granted to newcomers like Raleigh.

Ireland was now so "pacified" that even in the year of the Armada she scarcely moved. Sir John Perrot, deputy from 1584 to 1588, encountered in the parliament of 1585 a strong and well-led "Recusant" party, but though Archbishop Loftus urged enforcement of the penal laws, the gallant and tolerant viceroy refused to force men's consciences. He was empowered by this parliament to make, with the chiefs and gentry of the West, "the composition of Connacht," by which they were confirmed in their immediate demesnes with rents from the rest of their "countries" in lieu of feudal and Irish regalities, and to serve the deputy in arms, pay rent to the Crown and hold by English tenure. The result was that Connacht, under its Gaelic and Norman proprietors, remained, on the whole, loyal up to 1640.

The Tyrone War, 1594-1603.—One of the last acts of Perrot was to have the young Red Hugh (Aodh Ruadh) O'Donnell kidnapped and sent to Dublin Castle as a hostage for the loyalty of his father, Hugh "Duv." The results were disastrous, for, up to now, the O'Donnells had been allies of the State, but the alliance was now shattered. After five years Red Hugh escaped to become "the O'Donnell" and the hero of Gaelic Ireland. Ulster was the last stronghold of the Celtic order which the State had determined to extirpate, and the northerners had always been the proudest and most warlike of the Irish, and when, therefore, under the new shiring order, a sheriff was set over Fermanagh it was not long before his "firm" methods drove Maguire into revolt, whereupon this chief was proclaimed traitor.

Red Hugh was naturally for Maguire, but it was uncertain what part Hugh O'Neill, now earl of Tyrone, would take. He, too, had to fear the extension of "English order," which would menace his hereditary lordship; he resented the religious and civil oppression of his country, and when, finally, he threw in his lot with O'Donnell, in 1594, the Government had to face the greatest opponent and the most formidable rising it had yet met. Tyrone and O'Donnell talked mainly of their ancestral rights and of religious tolerance, but at the same time they wrote to Philip asking for 6,000 men, and begging that an archduke might be sent as king.

Finally, the victory of the Blackwater, in Aug. 1598, over Marshal Bagenal, made O'Neill a hero of the Counter-Reformation. While Red Hugh overran Connacht, Tyrone descended into Munster, the new colony vanished like a dream, and a league of Irish and Old English, under James Fitzgerald, the so-called *sugan* (straw-rope) earl of Desmond, took the field. In 1600 the insurgents throughout all Ireland were reckoned at nearly 20,000, but O'Neill knew they could not take cities or hold the sea without Spanish aid.

After the failure of Essex in 1599, Charles Blount, Lord Mountjoy, proved the Scipio to the Irish Hannibal, and the tide was turned less by battles than by devastation and massacre. At last Don Juan d'Aguila arrived with 4,000 men, the Ulster chiefs marched to meet him, and the issue was decided at Kinsale. A rash attack by O'Donnell ended in the rout of the Irish, D'Aguila surrendered, O'Donnell sailing to Spain for more aid, died there, and O'Neill cut his way back to the North. Finally, he submitted to Mountjoy in April 1603, and going over to court was pardoned and restored by the new monarch, James, while Rory O'Donnell, brother of Hugh, was created earl of Tyrconnell.

With this fight Celtic and Norman Ireland passed. A new Irish nationality had emerged, Catholic by conviction, a blend of English and Irish in race, and in the upper ranks, English-speaking. How to reconcile this with a Protestant Government was the problem.

James I., 1603–25.—On the religious question the policy of James was a guarded toleration in the spirit of *"quieta non movere."* The royal prerogative was still supreme, especially in Ireland, and a series of viceroys, such as Chichester (1605–IS), exercised it in the interests of that large majority which it seemed now almost hopeless to convert. The opposition of the Catholic party, led by "the lords of the Pale," and the lawyers, was constitutional and loyal; it was impossible to debar "Recusants" from parliament, even if the oath of supremacy barred them from government, and in the older towns this party was so strong that up to 1624 every one had a Catholic mayor. Could James and this moderate element have had their way all might have been well, but the ultramontane spirit on one hand and the Puritan on the other made plain sailing difficult. The Established Church in Ireland was for "strong measures," and, on the other hand, when James proposed a simple oath of allegiance for Recusants, by which they should repudiate the supposed right of the papacy to depose heretic kings, two papal briefs in 1606 declared the proposed oath unlawful for Catholics.

Roman opposition also made the success of the new university at Dublin, founded by Elizabeth in 1591, but a partial one. A centre of disinterested learning would have been a force for reconciliation; but that it was not so intended became the general belief, and it was spoken of as "the college of the heretics near Dublin," and though at first there were no tests, Catholics preferred to seek education abroad. The statutes of Archbishop Laud confined its advantages to members of the Established Church, and though a few Catholics frequented it, disabling tests till 1793 barred them

from fellowships and degrees. As an active centre of learning, however, Trinity college could not fail to illuminate the country which it belonged to and from which it was richly endowed.

The Plantation of Ulster.—Though the earls of Tyrone and Tyrconnell had been restored in 1603, their new position was full of difficulties, for Ulster was now shireland, subject to sheriffs and garrisons hateful to its ancient lords, and Tyrone, involved in disputes with bishops, officials, grantees and his former vassals, complained that strong forces at Dublin were against him. At last the aged chieftain resolved to quit the field. Whether he and O'Donnell were guilty of plots to raise a new rebellion cannot be proved. In Sept. 1607, along with Tyrconnell and nearly 100 more chiefs of the North, he left Ireland for ever. The "flight of the earls" was a mortal blow to the Catholic interest and the old Gaelic tradition. Celtic Ulster was now to become the most British of the provinces, and the lament of the Four Masters over the passing of the earls is indeed the swan-song of the Gaelic world. With these devoted scholars, who laid down their pens in 1616, were silenced also the voices of the Gaelic brehons, poets and historians, and by 1700 only the Irish language, which the gentry were then forsaking, remained a visible memorial of a world that went back 2,000 years.

A plantation of Ireland was now urged on the ground that, without a strong Protestant population, neither would the State be safe nor the State Church have congregations. The earls and their adherents were found guilty of treason, and by legal processes six counties were declared "escheated." By the final plan (1609) the escheated lands were divided between undertakers, servitors, and "natives." Undertakers, mainly English, were to lease only to English and Scottish tenants, and take the oath of supremacy. Servitors, mainly Scots, might take Irish tenants, but if so their rents to the Crown were increased. Native Irish grantees were to pay quit-rents twice as large as the undertakers, but need not take the oath. Of these a good number received grants of thousands of acres, and several junior branches of the O'Neills and Magennises, etc., survived as large landlords, though no longer as '(Irish chiefs." But the colonists entered upon the best lands, and the lesser ranks of Irish were reduced to the position of tenants-at-will, for Sir John Davies, the solicitor-general, found, by a most iniquitous decision, that they had had no freehold rights under their attainted lords. The town of Derry was given to the City of London, and the London companies received grants which gave them practically all that county.

The practical success of the plantation was great, and for the first time a large part of Ireland was not merely owned by Saxon landlords, but was tilled and farmed by Scottish and Protestant farmers. The Irish population were numerous in the mountainous parts, and their natural disaffection was kept alive by hopes that Tyrone or another would return, but on the surface, at least, they seemed no longer a danger. (*See* also PLANTATION.)

The success of the Ulster scheme led to plantations in North Wexford, Longford, Leitrim and elsewhere, where, though the natives were treated with more equity, again the object of the Crown lawyers was to find that most of the Irish were not freeholders but tenants-at-will. The new English were dominant; adventurers and speculators such as Boyle, earl of Cork, and other moneyed men, displaced the old aristocracy; 39 new boroughs, carefully rigged, could be counted to offset the old towns, and several of the Old Irish, such as the earl of Thomond, had become Protestant.

In the parliament of 1613–15, summoned by Chichester to ratify the Ulster plantation, the Government engineered a small majority. partly through the new close boroughs, but the minority could claim that they spoke for 21 counties and 28 ancient boroughs in this first general representation of the kingdom. After failing to get their choice as speaker, the Opposition petitioned the Crown, and James saw a deputation of Old English peers and commoners, who complained of religion, the new boroughs, and the rigging of elections. James thoroughly enjoyed himself and declared "What if I had created 40 noblemen and 400 boroughs?—the more the merrier," and, as regards religion, "the pope is your father in *spiritualibus* and I *in temporalibus* only; you are but half-subjects and therefore only entitled to half privileges." The upshot was that 11 boroughs were disfranchised; James spoke some fair words and continued the *laissez faire* policy on religion, and parliament voted a large subsidy. The Recusants, though called "Old English Irelandized," were, in fact, loyalists with a religious grievance, but they had their left wing, and this veered steadily towards armed protest. The Continent was full of Irish exiles, soldiers and priests, and among these both the Old English and the Old Irish had their heroes. In spite of her troubles, economically Ireland benefited from a period of peace. Agriculture recovered; the settlers brought in their skill and enterprise; and the manufactures started by men like the earl of Cork made Ireland something of an industrial country.

Charles I., 1625–49.—With the second Stuart, came the idea of raising men and money in return for religious concessions. The deputy, Falkland, was allowed by "the Graces" to promise various concessions, such as that Catholics might practise at the bar, and that where land-titles, like those of the Connacht gentry under the Composition of Connacht, were lacking in legal confirmation 60 years' possession was to be held good against the Crown. From agents of the Catholic party Falkland secured a pledge of subsidies amounting to £120,000. But when the agents reached London they found a strong anti-papist spirit there, under pressure of which Charles gave way. He dropped the "Graces" but exacted the subsidies, though no parliament was called to ratify them.

To make Ireland first prosperous and then to use her in the royal interest against Puritan opposition was the idea of Wentworth, later earl of Strafford, viceroy from 1633 to 1640. He set himself to break the power of the great and the monopolists, making the Court of Castle Chamber into a Star Chamber for Ireland. While he wrested power from the anti-Irish clique in Dublin, he had no sympathy with Irish or Catholic complaints, and looked on religious concessions merely as policy. Similarly, his aim in making Ireland rich and prosperous was that out of a surplus revenue he might enrich his royal master, and the first-rate army that he raised largely from Catholics and natives was destined, if need be, to serve in Britain. Among the strongest measures of this satrap were the extracting subsidies of £50,000 from parliament, and then denying all but the least important of the "Graces," forcing the juries of Connacht to find a title there for the king, with a view to a fresh plantation, and attacking the London companies. But the policy of "Thorough" ultimately failed, and when Strafford was assailed in England all the interests he had offended in Ireland joined in the general impeachment that brought him to the scaffold in May 1641. His army was disbanded and the control of the Government passed under Puritan lords justices.

The War in Ireland, 1641–49.—A rising in Ulster was inevitable. The Irish there had local leaders of the old stock, such as Sir Phelim O'Neill, and still more abroad, where Owen Roe O'Neill, nephew of Tyrone, was in Spanish service. In the South the native party found a leader in Rory O'More, who planned a union of Old English with their religious grievances, and the Irish who had lost vast estates. A plot to seize Dublin Castle failed, but the rising in Ulster was general (Oct. 1641) and thousands of colonists were murdered, died of ill-treatment, or fled.

For the suppression of "the Irish war," the English parliament at once voted an army, but in order to find the money offered to the adventurers or subscribers of £1,000,000 the pledge of two and a half million acres of profitable lands which were to be confiscated. Naturally, the dread of confiscation, coupled with a belief that the Puritans meant to extirpate their religion, drove more and more Irish into arms. A Catholic confederacy was formed at Kilkrenny in May 1642 "to defend religion and the king against sectaries, and establish the Catholic religion as fully as at any time since Henry VII.," and soon after Preston and Owen Roe arrived from abroad, the first to lead the confederates, and the second the Ulster forces.

The history of the next seven years is a complicated one. There were forces for the parliament in Ulster and the south, Scots under Monroe in the north-east, an Ulster army under O'Neill, the confederates in Leinster, and Protestant loyalists under Charles lieutenant-general, James, marquess of Ormonde. As Charles'

cause declined, he offered the confederates terms hardly meant to be kept, and while a moderate party at Kilkenny favoured him, an ultramontane party, backed strongly from abroad, preferred foreign aid, and brought in Rinuccini, bishop of Fermo and papal nuncio, in 1645. This Italian priest's intervention stung English opinion into pitiless fury, but for a time his was the stronger party, especially after O'Neill, whom he favoured, defeated Monroe at Benburb in June 1646. The "Ormonde peace" of that year offered the confederates wide concessions, but Charles' cause was already lost and the nuncio's party denounced the peace, so Ormonde, who preferred "to surrender Dublin to English rebels than Irish ones," finally handed the capital over to Col. Jones, commander for the parliament, and left Ireland in 1647. The nuncio departed in Feb. 1643, and, on the execution of the king, Ormonde returned in the hope to rally all Ireland for the young Charles. But in an attempt to recover Dublin he was defeated by Jones, and when Cromwell himself landed as lord-lieutenant for the parliament his victorious campaign broke the back of the Irish resistance, though it lingered on tili 1652. O'Neill died in November, and part of the Ulster army, under his nephew, Hugh, gallantly repulsed Oliver at Clonmel, but other armies won little credit and Ormonde left Ireland finally in Dec. 1650.

The **Cromwellian Régime.**—Ireland had been conquered by an English faction to whom Irish papists were odious, both in race and religion, and she had now to pay for her own conquest. Not only the "adventurers," but the conquering army also were to be paid in Irish land. Under the rule of Fleetwood and by an Act of Settlement at first ten counties were appropriated to soldiers and adventurers and later others were added. The English parliament, which disavowed any intention to "extirpate that whole nation," divided the population into ten classes, of which the first five were excepted from pardon for life or estate and even "Innocents" found it hard to retain more than a portion of their estates. But such a plan involved a removal of the occupiers and by a scheme of transplantation the former landowners with their families and retainers were ordered to move into Connacht, where land was provided for them, generally though not always of inferior quality. The chief effect of the Cromwellian plantation was to impose a new English and Puritan landlordry on Ireland.

Charles **II.** and James 11.—The monarchy was restored in Ireland by the Cromwellians Broghill and Coote, and this gave the keynote to the resettlement. The Irish had lost all at the hands of sectaries and republicans and supposed that theirs would be the favoured side, but the real division was now between English and Irish, and Charles had to say to them "my justice I must afford to you all, but my favour must be placed upon my Protestant subjects." Ormonde as lord-lieutenant made a great fight for his fellow-countrymen, and finally by the English Act of Settlement the Cromwellian party consented to surrender one-third of the lands in dispute, but 5,000 claims were left unheard. Roughly the old proprietors now held one-third of Ireland; in population the Catholics were about 800,000 to 150,000, but in the corporations, parliament and Government they scarcely counted at this time. Much, however, was done to restore Catholics to the corporations, and their numbers and influence steadily grew. The "popish plot" of 1678 brought on a terrorism to which Archbishop Plunkett fell a victim, but on the return of reason toleration was resumed and the Irish later looked back an Charles' reign as a golden age.

In James II. Ireland found a king who tould be trusted to restore the faith and might be induced to repeal the detested Act of Settlement. For over a year the earl of Clarendon acted as viceroy, but his royal brother-in-law balanced him by Richard Talbot, whom he created earl of Tyrconnell, an Irishman and Catholic who first as lieutenant-general and then as sole lord deputy increased and remodelled the Irish army, officered it with Catholics, secured the garrisons and admitted his co-religionists into the Council, the corporations, the shrievalty and the highest legal offices. Ireland for a time was truly a Catholic kingdom and Tyrconnell planned an independent parliament to repeal at once the penal laws and the Act of Settlement. From the military point of view his mistake was in not securing Ulster, and so when James" cause collapsed at the end of 1688, though a great Irish army was in the field, Derry, Enniskillen and other places became cities of refuge for a Protestant population ready to fight for William.

William 111.—In March 1689 James himself landed from France, with officers, money and arms from Louis XIV., but no men. Catholic Ireland could provide these in plenty, but only on terms. When James, in May 1689, summoned what was practically a Catholic parliament to Dublin he announced liberty of conscience for all and some relief for sufferers by the Act of Settlement, but parliament totally repealed the hated act and so restored the heirs of those dispossessed since 1641. An act of attainder was passed which included some 2,400 persons supposed to be supporters of the prince of Orange. As for religion, Catholics and Protestants were to pay their tithes to their own clergy.

The successful stand and relief of Derry was a prelude to the wider operations in which first Marshal Schomberg and then William himself landed at the head of professional armies. On the other hand, a French force arrived to help the Irish. The battle of the Boyne was won and lost on July 1, 1690, and James returned to France, leaving the Irish to ruin themselves in his cause. At least the gallantry of Sarsfield and the heroic stand of Limerick illuminated the last fight of Catholic Ireland as a nation in arms. At Aughrim in July 1691 the issue long hung in the balance until the French commander, St. Ruth, fell, and Ginkel carried the hill. Tyrconnell died, and Sarsfield finally capitulated on terms at Limerick on Oct. 13. By "the Articles of Limerick" the Irish Catholics were guaranteed the religious liberty they had enjoyed under Charles II. and all officers in arms and those under their protection in the five western counties covered by the terms were to retain their estates and professions under a simple oath of allegiance "and no other." William was to have the terms ratified by parliament and do his best to get those who had been attainted restored to their estates; this latter clause was omitted in the signed articles but restored by William. Officers and men who would not take the allegiance oath might depart for France; 7,000 did so, and among the flower of the Irish aristocracy who sailed away was Sarsfield. William was a tolerant man and, after all, the Irish had but served the king de *jure;* but he had now to divide his prerogative with parliament, and while he strove to keep the spirit of the treaty, the parliaments of both islands ratified it in less than the letter: Irish opinion has always called it "the violated treaty." The English Whigs meant to keep the Irish Protestants in the saddle and a Test Act of 1691 was extended to Ireland which excluded Catholics from the Dublin parliament. In 1697 this body ratified what remained of the treaty, but William had to drop the "omitted" clause and abandon the stand he had made for justice. Finally, in 1699, the English Houses confirmed the settlement by which some three-quarters of a million acres passed to new owners. Thus the third conquest of Ireland within a century was zchieved. The most illustrious names of the Irish nation diszppeared from their country by attainder, death or voluntary exile. Those that remained owned only about a seventh of the soil. The middle classes suffered exclusion from the corporations, trades and professions and the penal laws began with acts of the Dublin parliament in 1695 and 1698, which debarred conscientious papists from wearing arms, teaching publicly, and practising the law.

English arms and statutes had given the Protestant ascendancy the title-deeds of Ireland but at the cost of their own political and economic subjection. Under Charles II. English acts had debarred Ireland from the colonial trade and prohibited the import of Irish cattle into England. Now an act of 1699 ruined the export trade in Irish woollens; Ireland retained the provision trade with Europe and America, and William encouraged the linen industry.

The Penal Laws.—The new ascendancy, full of memories of '41 and '89, was bent on treating the Jacobites like a beaten enemy. The land settlement as made under Charles II. and William was final, and Catholic landowners must keep what little they had and no more. The penal code, by which the majority was rendered powerless to rise again, was mainly passed in the years 1702–15. The acts that concerned the landowners forbade them to acquire freehold other than by inheritance or to take leases of more than 31 years at a crushing rent. By the "Gavelling Act" if the eldest son conformed he succeeded to the whole estate, other-

wise it was equally divided, and this, more than anything else, served to extinguish this class, who either conformed or were impoverished by subdivision. The Catholics in general were barred from trades and professions, education, office (great or small), juries, the electoral vote, the right to arms and a horse.

Feeling against the Presbyterians of the North was hardly less strong in the Episcopalian ascendancy. A Test Act was passed against them in 1703, but after the accession of George I. the "Regium Donum" was restored to their ministers and a Toleration Act allowed them to worship freely and hold petty offices. Though this Protestant democracy was debarred from parliament and from the government of the country, their lot could not be compared in severity to that of the papists, with whom, however, they shared the grievance of riches paid to a Church they both detested.

George I. and II.—With the Hanoverian succession the last hopes of the Jacobites faded away. For the old Irish nation the next half century was a time of oppression, despair and decay: the great exodus of the gentry and the more adventurous spirits to join the Continental armies was balanced by emigration of the poorer Protestants ruined by heavy rents and the commercial acts. The penal laws steadily crushed the upper classes and by 1780 some 4,000 of them had conformed. The old landlords had been the protectors of the Gaelic poets and scholars and naturally as they decayed or joined the ascendancy the old native culture declined, but a new race of poets took the place of the old aristocratic literati, using popular language and sharing the lives of the peasantry. Such histories as Lecky's, however excellent on Anglo-Ireland, fail to discern the strong current that ran, half underground, among the Gaelic-speaking people of poetic memories and hopes for a future in which now the Stuarts, now the French, would come over to restore "the Dark Rosaleen." Such feelings were not merely poetic; they were kept alive by unjust laws and what was perhaps the worst land-system anywhere in Europe. Hence those embittered agrarian movements of the "Whiteboys" and the like, which were not all confined to the Catholic peasantry.

The Protestant ascendancy of Ireland now began to resent their political and economic subjection to English interests. The constitutional and legal benefits of "the glorious revolution" had not been extended to Ireland, and while in England the sovereignty of parliament had been established, that of Ireland was shackled by Poynings' law; ministers were responsible only to England, and in 1719 by the Declaratory Act the imperial parliament affirmed its right to legislate for the sister island. The Dublin legislature became a mere dependency, hardly representative even of the Anglican minority.

How to keep Ireland at once dependent and secure was a question the Imperial Government solved for 50 years by putting power successively into the hands of such men as Archbishops Boulter and Stone, both Englishmen, who "managed" the country in the "English interest." The régime had its merits; government was cheaply run, the national debt kept low, and the surplus revenue used to beautify Dublin and develop the country. Economic progress made itself visible, an influential class of rich Catholic merchants appeared, and the wane of Protestant bigotry on the one hand and the ultramontane spirit on the other made toleration possible.

The "Patriot" Movement, 1760–82.—A political party now appeared among the Protestants, inspired by Locke, Molyneux, Swift and Berkeley, which found its leaders in Flood and Grattan. On the other hand, the British Government was ready to make concessions. The viceroy Townshend (1767–72) was instructed to offer an Octennial bill limiting the duration of parliament, and Harcourt continued the policy with the purpose of procuring troops from Ireland for the American War. After Saratoga, the "restrictive acts" had to go; at the same time the Imperial Government encouraged the Irish Protestants to relax the penal code and in 1778 the Catholics were allowed on a simple form of oath drawn up by the Catholic Association to inherit land and take leases like Protestants, while the "Gavelling Act" was repealed. The events of the American War put Ireland for the first time into Irish hands, but now it was a "Protestant nation," and 80,000 volunteers raised under Charlemont boasted themselves "the armed property of the nation." Free trade with the colonies was won by Flood, and Grattan moved the famous declaration: "no power on earth but the king, lords and commons of Ireland is competent to bind Ireland." The volunteer convention at Dungannon emphasized these demands and the view was general that without legislative autonomy there was no security for Irish rights. The Imperial Government gave way and an act of the Irish parliament was confirmed, amending Poynings' law and providing that bills duly enacted and sent to England should be returned without alteration under the great seal and receive the viceroy's assent. At the same time the Test Act for Protestant Dissenters was repealed and by Gardiner's Relief bill of 1782 Catholics were allowed to purchase lands freely and have their own schools.

The Irish Constitution 1782–1800.—The "Constitution of 1782" was completed by the Renunciation Act of the next year, by which England admitted the claim of the people of Ireland to be bound only by their own laws and courts. But Irish ministers were still appointed by and were responsible to the imperial authority; they could not be turned out by vote of the majority, and though Fitzgibbon and the rest were Irishmen, Grattan, Flood and their party remained a mere Opposition, and legislative autonomy without responsible government and electoral reform proved vain.

Popular support was needed for the new constitution and Flood and Charlemont sought it in a reform bill which would have created a Protestant democracy, while Grattan aimed at an extension of the franchise to Catholics and the admission of their gentry to parliament. But both were thwarted by the narrow clique which under Fitzgibbon (Lord Clare) controlled the Government and resisted pressure alike from Ireland and England. Pitt's attempt to carry a commercial treaty and the Regency dispute emphasized the difficulties created by the constitution, but it might have survived long (for Ireland as a result of commercial freedom, bounties and Foster's corn law was progressing rapidly in wealth, manufactures and agriculture), had not the war with France brought on a situation which grew ever tenser. "French principles" spread among the Presbyterians, the Catholic Association passed into the hands of bold politicians and agrarian discontent vented itself in the "Defenders." Clare held that either the Protestant ascendancy must remain intact or give way to a union, for general enfranchisement would fill parliament with disloyal Dissenters and Catholics and imperil the imperial connection. The British Government preferred Catholic relief to reform, but finally, faced with the question of how to hold Ireland against the French menace, Pitt chose to buttress up the unreformed Irish House which Clare and Beresford could "manage," and after 1798 decided on a union. The approaching crisis was accentuated in 1795 when, after British pressure had compelled the Irish Government in 1793 to admit Catholics to the electoral franchise, the viceroy, Fitzwilliam, failed to carry final emancipation and to break the Clare-Beresford junta. The "Society of United Irishmen," formed originally by Wolfe Tone on constitutional lines, now became revolutionary and entered into negotiations with France for an Irish republic, while the founding of the Orange Society intensified the religious feud. Insurrection acts and the suspension of habeas corpus bridled a country which was becoming an armed camp and the peril of a French invasion had to be faced. The Brest expedition of 1796–97 had failed to land troops at Bantry bay, but Tone still hoped for foreign aid, and a determined French invasion would undoubtedly have set Ireland ablaze. The Ulster Presbyterians were more feared by the authorities than was the Catholic south, and when in 1797 Gen. Lake "disarmed the North" by the most savage methods the back of a national rising was broken. The military forces were small, but 30,000 yeomanry led by the gentry sufficed to break the rebellion when it came. It was but a partial one, for the Government had seized the leaders, and though June 1798 witnessed a Presbyterian rising in Down and Antrim and a far more dangerous one of the Catholic peasantry in Wexford, both failed, and Tone, surrendering with the "Hoche," ended his life by his own hand in prison.

After "ninety-eight" the Union was inevitable. Many of the ascendancy became convinced that only such a measure could save them from the Catholic-Jacobin majority; the Presbyterians were disillusioned by the events of the rebellion and the Catholic population had been cowed into submission. Pitt and his Irish agents, Clare, Castlereagh and Cornwallis, had effective arguments for all—the Catholics could only be sure of emancipation from the Imperial Assembly, only union could save the Protestant establishment, and free trade would compensate the commercial classes. Several Catholic bishops declared for union in the inspired belief that emancipation would follow it, but it is very doubtful how far they spoke for their whole people. There was little to fear from the Irish parliament, where the majority was corrupt and unrepresentative, where the ministry could survive defeat after defeat and where patronage and bribery were at the Government's disposal. Grattan and the poor remnant of "the patriots" made a brave fight, but the Union became law by acts of both parliaments in May 1800.

Thus ended the experiment of a "Protestant Irish nation." The ascendancy created by the revolutions of the 17th century had ruled their fellow-countrymen firmly rather than generously, but in their later stages at least they contributed noble names to the annals of literature, thought, political idealism and religious freedom. They made Dublin a city of noble buildings, and modern Irish civilization is almost entirely their memorial.

THE UNION, 1800–1921

The fiscal fusion of the two islands was not complete until (1) the two exchequers were united in 1817 and (2) a tariff of 10% in favour of Irish industries disappeared in 1821 and (3) the two currencies were amalgamated in 1821. From 1817 the taxation in the two countries was the same, subject to certain exemptions and abatements in favour of Ireland which at one time were not inconsiderable but which had almost ceased in 1921, when the Union was dissolved.

The allegation that Ireland was overtaxed under the Union is not true. The terms of the agreement embodied in the Act of Union were strictly kept. It may be noted that from 1800 to 1817 Ireland paid nothing for Imperial services; that from 1817 to 1877, according to the estimate of a competent authority (J. G. Mulhall, writing in the *Contemporary* ***Review*** in 1882) the yield from Ireland did not exceed the cost of Irish services by more than £500,000 a year; and that in the opinion of the late John E. Redmond, speaking in parliament in 1912, Ireland was run at a loss from 1886 onwards. Taking the whole period from 1800 to 1914, the surplus of Ireland's revenue over Irish expenditure was small, probably much less than £1,000,000 a year on an average. For this sum Ireland was defended and had all the advantages, consular and otherwise, of the British empire. From 1914 to 1921 war taxation brought a considerable surplus which in its peak year came to £25 millions.

Condition of Ireland in 1800.—In 1800 the population was 4,500,000. It was composed of several elements, whose violent discords are at least intelligible:—the Catholic Irish, numbering 3,150,000; the Protestant Anglo-Irish, numbering 450,000; the Presbyterian Scoto-Irish, numbering nearly 900,000, with a small sprinkling of Methodists and other dissenters. The Anglo-Irish were at the top of the social ladder. They comprised the landlords, the official classes, the bishops and the clergy of the Protestant State Church, the few large farmers and the retinue of an aristocratic establishment. The Scoto-Irish were the business men and farmers of the north-east corner. With few exceptions, the Irish Catholics were the peasants and labourers of the country.

The few industries that existed were of no considerable character. The chief of these were the brewing industry, the output of which was about 500,000 barrels a year; the distilling industry, with an output of 4,000,000 gallons; and the cotton industry, which employed some 13,500 hands.

The condition of the land workers, who formed the great bulk of the population, was in general deplorable. When the population was more scanty, the land was mostly parcelled out in large grazing farms, occupied by Anglo-Irish Protestant farmers. The pressure of population and the stimulus given to tillage by an Irish corn law of 1784 led to the breaking up of the old ranches and to the conversion of the grazier into a middle landlord. The small tillage farmer thus created had little capital or knowledge, and his standard of living was not much higher than that of the cottiers whom he employed. The rent roll of the country was about

ten millions, which was about the average until 1881, when the first great Land Act started the process of reducing rents. The relations between landlord and tenant were of a most unhappy kind. The Protestants had a monopoly of every office. A Catholic could not be a member of parliament; or a king's counsel or a judge—not to mention other positions. Tithes, amounting to about £500,000 a year, were exacted for the upkeep of a State Church for a small minority of the people. The burden of the tithes fell upon the tillagers, who were almost all Catholics.

Catholic Emancipation.— Pitt gained the support of most—and perhaps all—of the Catholic bishops and of many responsible Catholic laymen by promising to do his best to reinove Catholic disabilities. The king was bitterly hostile, and Pitt resigned in 1801, to take office, however, again in 1804. Irish Catholics conceived they had been tricked, and the situation was much worsened. The Robert Emmet rebellion of 1803, though of no consequence in itself—for it was little more than a Dublin street riot—indicated the growth of popular resentment. It is not without interest that Grattan severely condemned this rebellion and that Daniel O'Connell armed himself to help to put it down. Henry Grattan, who in the Irish parliament had been the foremost advocate of the Catholic claims, became a member for an English constituency in 1805 and devoted himself till his death (1821) to the championship of the Catholic claims at Westminster. Also in 1805, a Catholic Association was formed in Dublin and was joined by Daniel O'Connell, a young barrister who believed in mass agitation in the country. In parliament, Grattan's eloquence made considerable way. In the five parliaments from 1807 to 1829—1807, 1812, 1818, 1820 and 1826—with one exception, the House of Commons showed a majority for the Catholic cause. But it was a great movement inaugurated by O'Connell in 1823 that carried the day. The country was brought to the verge of a revolution, and in face of this demonstration of popular feeling, an act was passed in 1829 which removed the main Catholic disabilities.

O'Connell, who entered the British parliament as member for Clare, then turned his attention to the repeal of the Act of Union. He attempted the same methods as were successful in the Catholic Emancipation campaign. A vast organization was established; great meetings were called, at one of which, held at Tara, the seat of the Ard-Righ, the Irish newspapers put the numbers present at 500,000. But O'Connell misjudged the forces against him. A later meeting called in 1843 at Clontarf, the site of the battle in which Brian Boru defeated the Danes, was proclaimed. O'Connell was prosecuted for sedition, convicted and sent to prison, but was released through an appeal to the House of Lords. He died in 1847.

Growth of Population and the Famine.— While these agitations were being conducted with such vigour, Ireland in many respects was making progress. Her exports and imports increased from £10,000,000 in 1800 to £40,000,000 in 1840; the excise revenue from £475,000 in 1800 to more than £2,000,000 in 1840. Commerce had increased, agriculture had improved, and the value of land had risen. Grinding, malting, brewing and distilling had greatly increased, while there was a thriving linen manufacture and linen trade. These signs of manufacturing and commercial growth more than outbalanced the disappearance of some small industries which, in Ireland as well as elsewhere, found it impossible to stand the competition of the large scale concerns.

The real troubles of Ireland, however, arose from an increase of population which far outstripped production. The population in 1700 was only 1,250,000. It was 4,500,000 in 1800, and this rapid rate of increase continued for nearly the first half of the 19th century. Early marriage was encouraged, and emigration was denounced. Irish political leaders favoured the subdivision of holdings, contrary to the policy of all British Governments, which sought, by various pieces of legislation, to keep the process within reasonable bounds. The corn laws which, until 1846, put a heavy bounty upon the production of corn tended to increase tillage and to stimulate population increase The population grew to 8,175,124 in 1841. In that year, the population density of Ireland per sq.m. was 251; England and Wales, 272. There were 685,000 farms in all. Of these, 300,000 were under 3 ac. in extent; and 250,000 were from 3 to 15 ac. As might be expected, the conditions of the vast majority of land workers was miserable.

The potato blight appeared in North America in 1844; it reached Europe in 1845, attacking Belgium, Hungary, Germany, Holland, and the United Kingdom. The United Kingdom felt its worst effects, scarcely a district escaping. 1846 and 1847—especially the latter—were its worst years. In a few weeks the abundant potato harvests in Ireland became a waste of putrifying vegetation. The British Government took active measures to relieve the distress. Relief works were instituted on a large scale, and great doles of maize were given out. In 1846, as many as 285,000 hands were employed on relief works and in 1847, 734,000. The Government imported in the first six months of 1847, 2,849,508 quarters of maize worth, at then current prices, nearly £9,000,000, a great part of which was distributed gratis. The United States sent substantial supplies across the Atlantic. Nevertheless, there were many deaths from sheer starvation, totalling from 1841 to 1851, 21,770. The total Irish mortality for the five years that ended in 1851 was close upon a million. In the decade that followed 1847 more than 1,500,000 persons emigrated.

The famine was followed by the Young Ireland rebellion of 1848. The chiefs of the Young Ireland movement were men of lofty idealism and considerable intellectual attainments. But they were not practical men of affairs and, with little or no previous preparation, they started an insurrection in Tipperary in the hopes that an unorganized peasantry would rise to support it. In the result, some 30 rebels were fired on by a squad of constabulary and fled, leaving some dead and wounded behind. A remarkable temperance movement in 1849 is an interesting study in national psychology. Inaugurated by Father Mathew, it brought down the consumption of spirits from 12,000,000 to 5,000,000 gallons. The movement collapsed with Father Mathew's death in 1856.

The tithe was a burning question until 1838 and many bloody conflicts had taken place in the collection of it. In 1838 the tithes were converted into a rent charge payable by the landlords, and in 1868 the Irish State Church was disestablished.

Land Reform.—An agitation which commenced with the formation in 1850 of an association demanding "the three F's"—Fair rent, Free sale, Fixity of tenure—pursued its inevitable course until it finally extinguished landlordism altogether. An act of 1870 gave a tenant a right to compensation for disturbance and for improvements if, without fault on his part, he was evicted. A world wide depression in agriculture combined with three wretched harvests (1877–8–9) brought about the great Land Act of 1881 which conceded "the three F's." This law and amending statutes of 1887, 1891, and 1896 had the effect of lopping upwards of £2,000,000 a year off the landlords' rental. The real solution, however, was begun in 1885, when the first great Land Purchase Act was passed. Under that act when a landlord and a tenant agreed upon the purchase price of the landlord's interest, the State would advance the money to finance the transaction and would be re-paid by annuities for a period of years. Thus, on a farm rented at £50, if the landlord agreed to sell at 18 years' purchase (which was in general the normal figure), that is at £900, the State would pay the landlord that amount; the tenant would repay the State by annual instalments of 4% or £36 a year; these instalments would cease in 49 years. Other laws were passed, under one of which the State undertook to provide a bonus to help the transaction—this bonus in certain cases amounting to 12% of the purchase money. In 1921, when the Irish treaty was signed, about two-thirds of tbe land in Ireland had passed to the tenants under voluntary transactions of this sort. The remainder has since been transferred by one great compulsory statute.

This great reform was not achieved without much agitation in parliament and outside it, and much crime. In the worst years, 1877–80, to use the words of a historian of the period, "it rained outrages." It is however, usually forgotten that the real land problem was not the landlord and tenant problem, but the multiplication of small farms and the congestion of the people upon them. In 1881, there were about 600,000 farmers, giving an average of about 30 ac. of cultivable land.

The Home Rule Movement. — The misery of the people gave great strength to the movement for secession from England. Propagandists in the '50s announced that under a home Government with power to impose tariffs, Ireland instead of having a population of 8,000,000, as the figure then was, of destitute people, would support a very much larger population (put by some at 25,000,000) in comfort if not affluence. Similar arguments were used by the leaders in the Home Rule movement (1870–1916) and the Sinn Fein movement (about 1900 to 1921). Arthur Griffith, the founder of the latter movement, put Ireland's true population at 20,000,000. The contrast between their actual position and their potential position under a Dublin parliament inflamed the people, instilled in them a hatred of Westminster rule, and kept them steady in the struggle for political independence.

That struggle took two forms. From the formation by Isaac Butt of the Home Rule party in 1870 down to the rebellion of 1916, it was mainly constitutional. But side by side with the constitutional movement, the physical force men kept up their secret associations for the establishment of an Irish republic, and now and then broke cover in violence of one sort or another. The most extreme Irish revolutionaries were in the United States of America, where the Fenian association was formed in 1863. (See FENIANS.) Irish-American newspapers founded a skirmishing fund in 1880, one of the objects of which was openly stated to be the burning down of London on a windy night. This extreme section were responsible for a petty attempt at a rebellion in Dublin and Kerry in 1867, and for the Phoenix Park murder in 1882 of Cavendish and Burke, the chief secretary and under secretary for Ireland. In the main, however, the physical force men were content, while advocating violence if opportunity should permit, to give adherence to the constitutional Home Rule movement which aimed at legislative and administrative control of Ireland by Irishmen themselves, without entirely severing the imperial link.

Butt's Home Rule Association for a time made little headway, and a Home Rule bill introduced by its leader in 1874 found only eight supporters in the House of Commons. The driving force of the movement came with the establishment of the Land League by Michael Davitt in 1879, which became a secession-cum-agrarian movement, under the leadership of an impoverished Irish squire, Charles Stewart Parnell. The Land League dominated the country and boycotting of farmers and shopkeepers who were not prepared to obey it proceeded on an extensive scale. Strong counter measures were adopted by the Government, under one of which the executive were empowered to put and keep in jail as "suspects" any person at their discretion. Parnell and many of his followers were imprisoned under this drastic code.

Ultimately Gladstone sought to solve the Irish problem by his Home Rule bill of 1886. It was a very modest measure, which transferred Irish administration to an executive appointed by an Irish parliament, but left most of the taxing power at Westminster. It was, however, accepted by Parnell as a settlement; though he fully recognized, to use his own language, that it set up a "subordinate parliament." Such as it was, it met with a furious opposition both in England and in Ulster. Many of Gladstone's followers seceded from him. Ulster threatened violent resistance. The bill was rejected in the House of Commons by 343 to 313. The situation was further complicated by the law case of O'Shea v. O'Shea and Parnell a divorce petition in which Captain O'Shea, an Irish member of parliament, alleged adultery between his wife and Parnell. The facts were clear and a divorce was granted (Nov. 15, 1890). The heads of the Catholic Church in Ireland called for Parnell's retirement. He refused, and his hitherto united party was split into two factions. The breach was not healed by Parnell's death (Oct. 7, 1891).

In 1893 Gladstone, again in office, introduced a Home Rule bill which passed the Commons (301 to 267) but was rejected in the Lords by an overwhelming majority (419 to 41). Another attempt to settle the question was made by the Irish Council bill of 1907, which was intended to establish a purely Irish body to spend in Ireland the proceeds of Irish taxation. This bill, however, was unacceptable to the Irish people and was withdrawn. H. H. Asquith introduced his Home Rule bill in 1912. It passed the House of Commons in Jan. 1913 (367 to 267) and was rejected by the Lords. The bill included Ulster and if passed again in three successive sessions by the House of Commons, would automatically, pursuant to the provisions of the Parliament Act 1911, become law without the assent of the House of Lords. Ulster prepared to resist it, and the Ulster Volunteers, headed by Sir Edward (Lord) Carson, aided and abetted by many prominent men in both countries, armed themselves and undertook to set up a separate Government in Belfast should the bill become law. The bill passed the House of Commons in May, 1914; the Lords excluded Ulster; an attempt at accommodation by the king at a conference held in July failed. The outbreak of war altered the whole situation. The bill, without resistance, passed and became law for all Ireland in Sept., 1914, but a contemporaneous act was passed which provided that it should not come into force until after the war, the Government giving an undertaking to bring in a bill dealing with the Ulster situation. The bill never came into operation.

Ireland in 1914. — When the World War came, the position of Ireland was in most respects very satisfactory. The landlord and tenant question, for all practical purposes, had disappeared. The country was free from serious crime. Emigration had brought the population within reasonable limits. The process of *morcellement* that had been the real economic curse of the country, had ceased. Imports in 1913 were valued at £74,000,000; exports at £73,000,000. Comparing the periods 1895–1899 with the year 1913, the average increase in yield per acre was not less than 25%, the additional money value to the country being £15,000,000 per year, and the money value increase in stock on the land was not less than £20,000,000. In 1913 the money on deposit in the Irish banks was £60,000,000 in addition to which the Irish people had large sums of money invested in England.

One of the most important and beneficial statutes ever passed for any country, was the Labourers (Ireland) Act 1883, which enabled comfortable cottages to be built at local expense (aided by a small State subsidy) for agricultural labourers, who received in addition from half an acre to an acre of land as well. The schemes under this act worked so well that Ireland was provided with 50,000 well built cottages which, with the half acre or acre patch adjoining, were let to a labourer at from 8d. to 1/6 a week.

The population was divided according to religious creed as follows: — Catholics 3,242,670; Protestants 576,611; Presbyterians 440,525; Methodists 62,382; Jews 5,148; other persuasions 60,504; indeterminate 2,379. The population of Dublin had increased from 172,000 in 1800 to 304,000 in 1911; that of Belfast in the same period from 25,000 to 386,000.

The position of the Catholics had enormously improved. The primary school system established in 1831, had from the first been a success. An Intermediate Education Act of 1879 which indirectly subsidized intermediate education, was of great and lasting benefit. The national university was founded in 1908 and became substantially a Catholic university. The Local Government Act of 1898 transferred all county power and patronage from the landlord classes, represented by the grand jury, to elected county councils. A strong Catholic middle class had grown up.

Ireland was well equipped with railways, having a mileage of 2,940 miles; in addition to 15 light railways established by State subsidy. There was an admirable judicial system in the country modelled upon the British, but containing features specially adapted to Irish requirements. In the British legislature, Ireland had 103 members while England, Scotland and Wales had 567 all told. The population ratio of Ireland to Great Britain was 1 to 10; while in 1914, taxation was £2. 10. 0 per head of the Irish population and £4. 8. 3. per head of the British population, A Congested Districts Board, set up in 1891 endeavoured to solve the small holding problem by migration and was slowly succeeding. The Department of Agriculture established in 1900, was so admirable that a commission sent over by the Canadian Government to study European agricultural conditions, specially recommended that the Irish model should be followed. The best feature of all was the success of the Irish Agricultural Organization Society,

established by Sir Horace Plunkett in 1889, to organize and educate the farmers in the methods best calculated to increase the production and facilitate the sale of agricultural products and to cheapen the cost of articles used by the farmers.

Rebellion of 1916.—The enrolment of the Ulster Volunteers to resist home rule angered the south of Ireland; the impunity accorded to an unconstitutional and illegal movement emboldened and stimulated the young Home Rulers. A body of "Irish Volunteers" was established in Oct. 1913 under the auspices of John MacNeill, a cultured Gaelic scholar and professor. It attracted to its ranks a number of constitutionalists and such residue of physical force men as were left in the country, and arms were smuggled in. Bad housing and labour conditions in 1913 led to much intimidation, strikes and some violence, and produced the Citizen Army, composed of Dublin workers, men and boys, under the leadership of James Larkin and James Connolly.

When the war broke out, Redmond and his parliamentary followers declared unequivocally in favour of the allies, and for a time it seemed as if the whole country was with them. A meeting at the Mansion House, Dublin, on Sept. 25, 1914, at which the prime minister (Asquith), and Redmond, Dillon and other leaders spoke, was packed, and there was much enthusiasm. But the war did not go well; conscription soon had to be introduced in England; and it was put about that Ireland would also be put under the yoke; no Irishman would submit to compulsion to fight; if Germany won, no land purchase annuities would have to be paid; there was land enough for everybody; Sinn Fein pamphlets and newspapers multiplied. Still, Ireland raised 134,000 recruits for the war, and the rebellion came as a surprise.

About this time the Sinn Fein party began to get a little prominence. Founded by Arthur Griffith, a Dublin journalist, in 1900, it bore pretty much the same relation to the Home Rule party under John Redmond as the Young Irelanders bore to the Old Irelanders under O'Connell. Sinn Fein (the best equivalent of which is the French *nous-même*) was not content with the home rule which Redmond was willing to accept and which left the taxing power, for all practical purposes, at Westminster. Sinn Fein wanted a self-contained Ireland, with full taxing power and advocated the building up of a great manufacturing country by a system of tariffs. Culturally, it resented the "anglicization" of Ireland and favoured the revival of the Irish language.

The rebellion was planned by the Citizen Army, and the left wings of the Volunteers and Sinn Fein. But the German aid which had been arranged for did not arrive; the German vessel "Aud" containing the arms for the rebels was captured off the coast of Kerry; and Sir Roger Casement, who came from Germany in a submarine, was taken and later executed. The Volunteers tried to call the rebellion off, but the Citizen Army forced it on and it broke out on Easter Sunday of 1916. The actual fighting, which was chiefly street fighting in Dublin, lasted a week; there were only 2,000 rebels in all engaged. The British troops lost 377, including 106 killed; the rebel losses were trifling. Fifteen rebels, including James Connolly, were executed. The executions that followed the rebellion made its leaders heroes and won considerable sympathy for the Sinn Fein cause.

The Government at once set on foot negotiations for an Irish settlement, but these broke down, as also did a convention of Irishmen called under Government sanction which sat in deliberation for nearly a year. Ulster wanted its six counties intact; the Nationalists would not budge an inch on that question. It is probable, however, that the rebel movement would have died down, temporarily at least, had it not been for the introduction in 1918 of the Military Service bill of that year. The measure raised the age for compulsory service to 55 and it applied to Ireland. The country rose against the measure; funds were collected at every Catholic church in the country and a total of £200,000 was gathered. The act was never enforced, but Ireland swung definitely to the left. At the general election of 1918, at which the Sinn Fein party raised the Republican standard, the old Irish party was routed, and 73 Sinn Feiners were elected out of a total Irish representation of 106.

The "Anglo-Irish War."—The 73 met in Dublin, calling themselves the Dáil (national assembly), passed a declaration of independence and appointed ministers. But apparently it was no part of the original policy of the Dáil to resort to violence. A new departure was made in Irish politics by Daniel Breen who thought that the best method to clear the British out of the country was to kill off the Irish Constabulary, who were the eyes and ears of Dublin Castle, the seat of Irish Government. The "Anglo-Irish War," which began in Jan. 1919 and ended in May 1921 and which brought about a dominion status for 26 counties of Ireland, is surely one of the strangest episodes in history. Daniel Breen, who occupied the position of track walker on one of the Irish railways, began it, and in his book he tells the story with great frankness. Breen and seven comrades waylaid two Irish policemen in Tipperary and shot them dead (Jan. 1920). The same procedure or procedure somewhat similar was followed in other places. The idea caught on and Michael Collins, who was at one time a postal clerk in London, had crossed to Ireland in 1916, and was engaged in the rebellion of that year, took it up. Soon a process which its supporters call war and its opponents assassination became general.

The various stages of the "Anglo-Irish War" were: (1) the shooting, at rare intervals, of policemen as they moved about a city, town, village or countryside; (2) the like, at more frequent intervals; (3) attacks upon remote and outlying police barracks; abandonment of such barracks; alarm amongst the police and some defections; (4) the advent, in June 1920, of armed men from England to take the place of the police—some called Auxiliaries, to the number of 1,500, and others, from the colour of their clothing, Black-and-Tans, numbering 5,800; (5) a "war" as before, consisting of the shooting of policemen as before; the shooting of civilians engaged in the British service who were suspected of activity in putting down the revolutionary movement; ambushing with bomb or rifle or revolver fire of Auxiliaries, Black-and-Tans, police and sometimes of regular troops; the shooting of persons suspected of giving information to the British forces; the destruction, by arson or other means, of public or private property; the destruction or obstruction of roads and bridges; a general espionage among the lower classes of the community; a collection of moneys by those engaged in the "war" by threats of murder or destruction of property, and the general terrorism of the country.

It has been stated on very good authority that the actual number of gunmen engaged was only 2,000. At first, the great bulk of Irish public opinion was opposed to the guerrilla warfare. But soon its daring, its success and the ingenuity and resource shown in many of its episodes captured the support of the lower orders of the people. A ruthless system of terrorism intimidated responsible people, for no man could safely venture upon a public expression of a hostile opinion. The premises of the *Daily Independent*, which termed an attempt on the Viceroy's life "murder," were burned to the ground, and every newspaper in Ireland knew right well that a like measure would be dealt out to it in similar circumstances. The counter-terrorism and activities of the Black-and-Tans greatly helped the revolutionaries, for they created a hatred of British rule where it did not exist before and strengthened it where it did. But it was not till the "war" was coming to an end that the Dáil (March 1921) purported to ratify it.

The Irish Catholic bishops in secret sessions were of opinion that the "war" was not morally justified and some of them openly said so, but there was no public expression of opinion from the episcopal bench as a whole. The morality of the "war," however, was upheld by many if not most of the other Catholic clergy.

As the result of the activities of the Black-and-Tans and Auxiliaries the houses of those suspected of being revolutionaries were destroyed, as were many creameries. A great portion of the city of Cork was burned down by the regular military by way of revenge for some outrages committed upon them. Many murders of real or supposed revolutionaries were committed. There was a competition in crime.

The British Government winked at these performances. It even encouraged them. The Weekly *Summary*, an organ printed and published by the authorities in Dublin Castle, was a direct incitement to murder. "British rule became a byword and a scoff

in every country in Europe and across the Atlantic" (letter of Rev. D. C. MacGregor, Moderator of the Presbyterian Church of England to the *Times*, March 5, 1921). Public opinion in England was deeply stirred, and formed its expression in vehement denunciations of Black-and-Tan terrorism by many public men, foremost of whom was the archbishop of Canterbury. The events in the south of Ireland had their repercussion in the violent religious disturbances in the north. From July 1920 to June 1922 the city of Belfast was the scene of many shocking murders.

Soon after the beginning of the "war," the cabinet introduced and passed the Home Rule Act, 1920, which divided Ireland, for political purposes, into two areas, namely (1) six counties carved out of Ulster and (2) the other the remaining 26 counties. The statute, while transferring the administration of Ireland, north and south to Irish hands, left the great bulk of the taxing powers in the control of the British parliament. The passing of the measure rather aggravated the situation than otherwise, so far as the south was concerned. The six-counties parliament, however, was' duly established.

The growing pressure of English public opinion was the principal factor that induced Lloyd George and his cabinet to enter into negotiations with E. De Valera, then the president of the Dáil. A time was arranged (July 1921) and the Anglo-Irish treaty, which was confirmed by the British parliament and by the Dáil, was entered into in Dec. 1921.

The treaty gave Ireland the political status of the dominion of Canada, with liberty, however, to the Ulster parliament to opt out of the measure. The new dominion was to be called the Irish Free State. Certain harbour and other facilities were reserved to Great Britain, and provision for other facilities in time of war or of strained relations with a foreign power. If Ulster opted out, a commission, consisting of one representative of the Irish Free State, one representative of Ulster, and a chairman to be appointed by Great Britain, was to be set up to readjust the boundaries between the six county area and the 26 county area. The treaty provided for the ascertainment by arbitration of the Irish Free State's liability for the national debt.

Ulster did opt out, but objected to the appointment of the boundary-fixing commission, upon the ground, which was wholly untenable, that Ulster was not a party to the treaty. The Free State Government strenuously pressed for the commission, and ultimately a supplementary statute was passed, under which a commission was set up consisting of a representative of Ulster, John MacNeill representing the Irish Free State and a South African judge as chairman. The commission arrived at a finding that was unanimous, and which was not favourable to the Free State. A premature publication of the finding led to a storm in Ireland. For the sake of peace it was agreed that the commission and its findings should be scrapped, and that Great Britain should abandon any claim to an Irish contribution to the national debt.

The Irish Free State, accordingly, started on its way under favourable auspices. It was a rich agricultural community, yielding a national income, as the events proved, of £25,000,000 per year, on the same taxation basis as Great Britain. It had made enormous profits by the war. In 1921 there were nearly £200,000,000 on deposit in Irish banks, nearly £100,000,000 invested in Government securities and over £200,000,000 invested in England or abroad. A proportion of about two-thirds of this may safely be attributed to the Free State. It was an admirably equipped going concern, with excellent railway, telegraph and telephone systems, roads at least up to the European average, a full equipment of buildings, of schools and educational appliances, numerous public buildings, many of which were of great beauty. It was under no obligation to provide its own defence, or to have a single soldier or a single ship of war, or to pay Great Britain, which must always, in the nature of things, provide for its defence, a sixpence for doing so. It had not a farthing of national debt. (For the subsequent history of Ireland *see* IRISH FREE STATE and IRELAND, NORTHERN.)

ARCHAEOLOGY

Human Inhabitants. — The human occupation of Ireland does not begin until a late date in the history of Europe. The island seems to have been uninhabited by man throughout the whole of the ice age: at least, no trace even of an interglacial colonization has as yet been found anywhere within its borders.

The raised beach at Larne, Islandmagee, and other sites in Co. Antrim, have yielded the oldest relics of man as yet found in Ireland. These have affinities in two directions; they indicate that even at the beginning of human occupation in the country there was a racial admixture. On the one hand, there is a clear association suggested with northern Spain; on the other, there is evidence of influences from north-eastern Europe. The first association is indicated by certain roughly pointed choppers or picks, cognate with the tools of the Asturian type, first brought to notice by Obermaier. The other is suggested by the so-called "Lame celt," a hand-pick which has all the appearance of being a degenerate form of the Campignian pick.

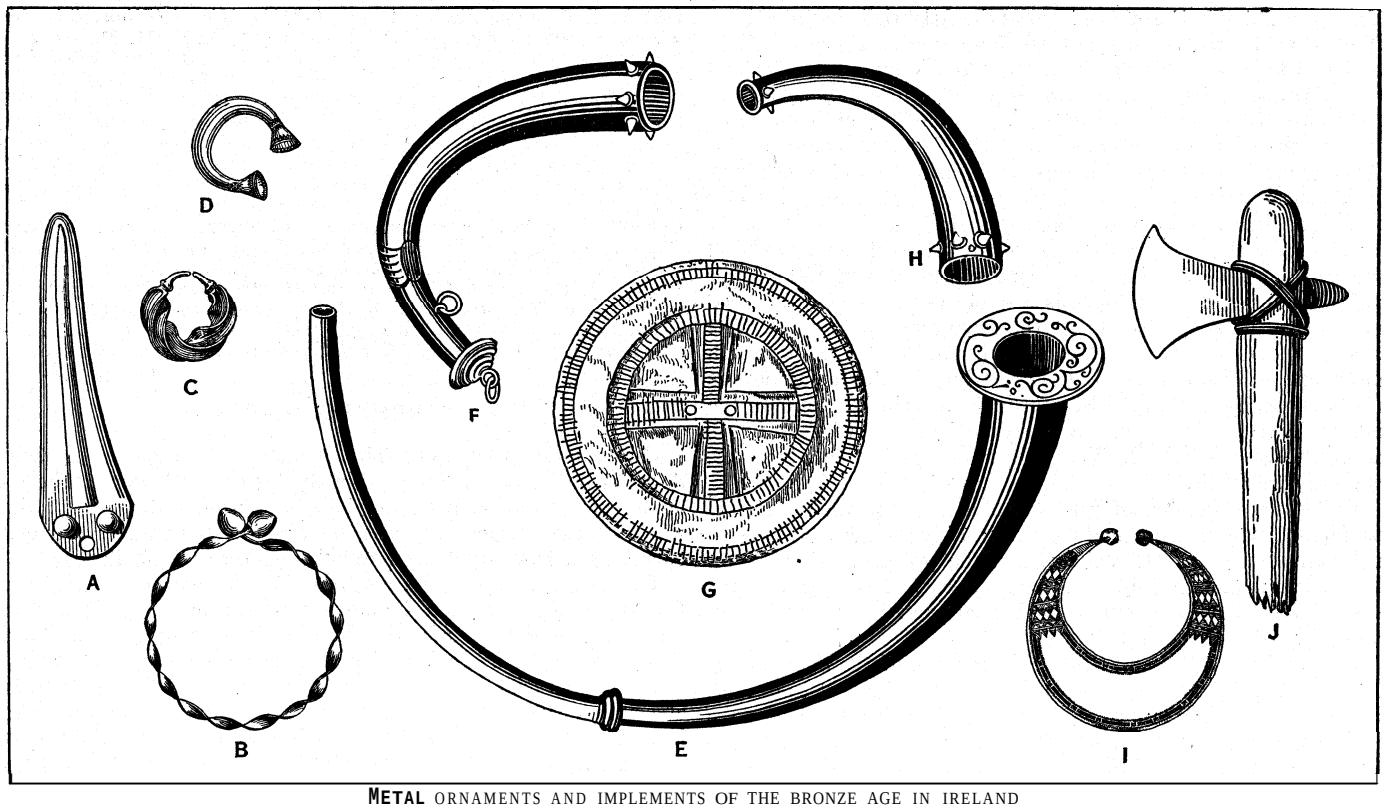
These two civilizations, the Asturian and the Campignian, were contemporary, each in its own region. The Asturian is a very primitive north Spanish and Pyrenean culture, the remains of which, in stratified deposits, overlie the Palaeolithic beds and underlie the Neolithic, and therefore belong to a time intermediate between the two main stone age cultures. The Campignian culture, which is distinguished by the presence of pottery (for the first time in Europe), of picks consisting of bars of flint so chipped as to have a blunt point at each end, and the *tranchet* or kitchen-midden axe (an implement with a bevelled edge, resembling the point of a gigantic turnscrew), extends over the greater part of northern Europe from Denmark (Maglemose and the shore-dwellers' shell-heaps) to France: in the latter country is the typical station of Le Campigny, which has given its name to this phase of civilization. The Campignian is intermediate between the Palaeolithic and the Neolithic cultures.

Thus there was a double immigration into Ireland at the beginning of its time of human occupation: an immigration from Spain, which must have crossed the Bay of Biscay — for the Asturian culture is not found in France — and one from some nearer place in northern Europe — but not from Great Britain, in which country the Campignian is all but completely absent.

As yet nothing but the implements have been found. No human remains have come to light associated with them. Nor are there any known inland sites yielding relics of these two occupations. They must, however, have endured for a considerable time, as the gravels where they are found are stratified to a considerable height, and artifacts are found practically through the entire deposit.

It is improbable that any human bones will ever come to light to tell us about the physical characters of these earliest immigrants. In the damp climate of Ireland the human bones that are found are so decomposed as to be almost useless for scientific purposes. No inland sites existed, because the interior of the country at the time was thickly covered with virgin forests, infested by dangerous wild beasts: and the shore offered a safe and comparatively easy source of sufficient food.

The ultimate fate of these first immigrants is unknown. They



METAL ORNAMENTS AND IMPLEMENTS OF THE BRONZE AGE IN IRELAND

(A) Copper halberd blade, the characteristic weapon of the early bronze age; (B) Gold torque, evidently a neck ring; (C) One of a pair of gold ear rings formed of four flat narrow fillets joined at their inner edges in torque pattern; (D) Gold open ring of the type probably used as currency; (E) Bugle-horn shaped trumpet made in two portions soldered together; (F) Cast trumpet, 34½ inches on concave side, probably used as a speaking trumpet; (G) Circular gold plate or "sun-disc," probably worn on breast; (H) Trumpet, 24 inches along curved edge; (I) Gold lunar or "moon disc" worn around the neck; (J) Copper hatchet, secured to a wooden handle by strings of hide or gut

may have endured to form the bulk, or at least the basis, of the later occupation of the Neolithic period, having learnt the Neolithic arts by way of trade: or else they may have been extinguished by a new immigration, introducing the Neolithic culture. Practically nothing is known but the bare fact of the existence of the Asturian-Campignian settlement.

THE STONE AGE

It becomes increasingly difficult to separate distinctly the Neolithic culture from the culture of the bronze age which followed it. Over the whole continent of Europe objects once classified as Neolithic persisted into the bronze age, if they were not actually introduced in this later period. For two reasons this difficulty is especially acute in Ireland. In the first place, the population was continuous throughout the two stages of culture. There is no racial break at the introduction of bronze, as there is in Great Britain. The latter country was invaded, at the beginning of the bronze age, by the (round-headed) folk commonly known as "The Beaker People": a body of invaders coming from the Rhineland. But beakers are all but unknown and brachycephalic skulls are rare in bronze age Ireland, where there was no change of population; and the bronze culture was introduced gradually, by way of trade.

Again, the stone age in Ireland was seemingly of very short duration. The metal culture must have reached that country considerably earlier than it reached Great Britain. All the archaeological evidence points to the conclusion that Ireland is an island of the Atlantic, Great Britain is an island of the North sea; and that though so close together, they do not therefore form one archipelago. Culture came into Ireland from the south-west, from Spain across the Bay of Biscay. The old connection between Ireland and Spain was maintained for many centuries. One of the most remarkable monuments of this connection is the inscribed slab at Clonfinloch, in the county of Offaly. This is a great flat stone, upon which is a sculpture indistinguishable in style from the Neolithic devices painted on the walls of certain Spanish caverns. This monument is undoubtedly the record of some sort of connection between the two countries; and we may call it the oldest historical record in northern Europe.

The remains naturally associated with the stone age in Ireland are implements of flint and of other stones, and certain classes of rude stone monuments. Such objects were certainly produced in the stone age: but they continued in use into the bronze age—indeed, flint tools continued in use in the country to an even later date, for in Ireland there is practically no native source of supply of tin, and no reason to believe that such a source ever existed. Tin was a necessary ingredient of bronze, and all the tin used in the country had to be imported from abroad. In consequence it must have been expensive, even if we accept the theory of the late Dr. Bremer, that the tin mines of Cornwall were at first an Irish possession, and were worked by Irish artificers down to the middle of the bronze age. This would account for the early pre-eminence of Ireland in the bronze age civilization, and for Ireland's precedence over Britain in the matter of the introduction of bronze (even although the want of tin in Ireland handicapped that country in the race); it also accounts for the frequent discovery of objects of Irish provenance in Cornwall, and, on the other hand, for the absence thence of definite traces of the Beaker people. On the other hand, the loss of the control of the Cornish mines is the most obvious explanation that can be made of a decline in the prestige of Ireland which we can trace, from the archaeological evidence afforded by the remains of about the middle of the bronze age.

Particulars of the various types of stone implements found in Ireland will be found in the works enumerated in the bibliography (*q.v.*). They correspond with the stone objects of the rest of northern Europe in general, though with certain local differences of detail. Their standard of excellence of workmanship is high on the whole; the knives and arrowheads, formed by chipping over the entire surface of the object, are often real works of art, showing great delicacy of touch on the part of their makers, and appreciation of beauty and symmetry of form. A peculiar type

of lance-head, of a lozenge shape with flat sides and chipped along the edges, is especially characteristic of Ireland, and affords one more link between this country and Spain, where similar weapons are also found.

Rude Stone Monuments. — Ireland is pre-eminently a country of rude stone monuments. some of them of great size. There is a considerable number of stone circles in the country, but on the whole the stones of which they are composed are comparatively small and few in number, though there are some notable examples here and there. On the other hand she possesses some of the most notable dolmens (table-stone monuments) in Europe. There are about 900 dolmens in the country — a large number for so small a region, especially since many must have been destroyed from time to time — but until a satisfactory archaeological survey has been carried out it will be impossible to say how nearly this number approximates to reality. Among the dolmens of Ireland is the great monument at Mt. Browne, near Carlow, whose immense cover-stone, weighing about 100 tons, is surpassed in size only by the cover-stone of one monument in Spain. In the matter of rude stone monuments, also, the affinities of Ireland with Spain are very close.

Gold.--One of the chief determining influences which gave to Ireland its important position during the bronze age was the gold in which at the time the alluvial gravels of certain parts of the present Co. Wicklow must have been very rich. There is no evidence that the parent vein of these deposits was ever discovered: there is no trace of early mining in the region; and indeed the parent vein has never been found, even in modern times. It is probably by now exhausted; gold in commercially remunerative quantities is no longer to be found in the district. But the large number of early gold ornaments found in Ireland prove that in the first stages of the bronze age there was a considerable store of the metal at the disposal of its inhabitants; and the wide dispersal of gold ornaments of Irish provenance over the continent of Europe shows that this metal formed an important material of trade.

The chief gold ornaments that have come down from the early stages of the bronze age are discs of thin gold plate, with a slight geometrical ornament engraved or embossed upon them. These are of Irish origin, wherever found. At a later stage in the bronze age, when Ireland had become a receiver rather than a giver in the matter of culture, the twisted *torque* was introduced — a collar consisting of a bar or ribbon of metal, twisted into a screw and curved into a loop; the ends being drawn out and bent abruptly, so as to hook into one another. Later still, as the bronze age was drawing to its close, a peculiar form of ornament of a problematical kind came into use. This is in the shape of an open ring with the ends terminating in discs, or in expanding solid or hollow conical knobs. Various conjectures have been made as to the use of these objects; one of the most probable is that they were media of currency.

THE BRONZE AGE

Of the bronze implements many types are similar to those found elsewhere in northern Europe, but some have distinctive character. The flat copper hatchet is probably indigenous to the country, from which it spread over the continent. The copper halberds are especially remarkable. They are a kind of dagger-axe, being in essence triangular dagger-blades mounted at right angles at the end of a long handle. Here again there is evident connection with Spain, where this form of weapon reappears. About the middle of the bronze age Ireland seems to have lost her initiative in civilization; the later types of hatchet-heads, etc., are imported into the country, rather than exported abroad. To the last, however, the Irish metallurgists of the bronze age retained their skill and their appreciation of beauty and symmetry; some of the late spear-heads, for example, are of admirable workmanship. For one class of objects Ireland was the source of supply for Europe till the end of the bronze age — the horn-shaped trumpets, made by the *cire perdue* process. which are found in many places on the Continent; there is one represented as lying by the side of the well known statue of the Dying Gaul.

The rude stone monuments show a power of manipulating enormously heavy masses of stone; and as this required the collaboration of a very large number of men, it presupposes no small degree of social organization. The great monuments that appear to have been erected in honour of deceased lords are impressive evidence of the respect in which they were held; such are the Giant's Ring near Belfast and, especially, the tumuli in the ancient royal cemetery on the river Boyne, about gm. above the town of Drogheda. Of these tumuli, the most noteworthy is the famous mound of New Grange, which covers an acre of ground. It is about 40ft. in height, and encloses a large chamber the walls of which are lined with huge slabs of stone. A passage between 50 and 60ft. in length gives admission to this chamber. Many of the stones used in the construction of the passage and chamber, as well as certain stones of a surrounding kerb outside the mound, are covered with symbolic devices — spirals, lozenges, zigzags, etc., the meaning of which must be a matter of conjecture, as we possess no direct clue to their interpretation. A circle of pillar-stones, the tallest of which is about 8ft. in height, surrounds the mound. The neighbouring mound (called **Dowth**) possesses two independent chambers, the stones of which bear similar ornamentation. To the north of the same county of Meath, near the town of Oldcastle, the Lochcrew hills bear a series of carns containing similar but smaller chambers, likewise enriched with sculptured symbols; and there are others at Knockmany and Sess Kilgreen in Co. Tyrone, and in the Deerpark of Castle Archdall, Co. Fermanagh.

The few human bones found in Irish bronze age sites indicate that the population of the country during this period belonged to the Mediterranean race (*see* RACES OF MAN) — a relatively short, dolichocephalic (long-headed) and dark-complexioned people, to be seen to-day in their fullest purity in Spain. This population was apparently dominant all through the stone and bronze ages, for the few skulls of round-headed individuals that have been found are to be taken as those of casual wayfarers. Of the language of this people we are absolutely ignorant. Some of the river names, which cannot be explained with the aid of Celtic, may belong thereto: and a few inscriptions in the Ogham character, found in the Pictish regions of Scotland, may possibly preserve some words of this tongue, or of a cognate dialect. These inscriptions have defied all attempts to decipher them.

Scandinavian and other foreign objects of the late bronze age found in Ireland speak of an oversea trade with eastern and southern Europe; the centre of activity shifted eastward in the course of the bronze age. We may assume that the technical skill displayed by the bronze objects which have survived was likewise shown by the objects in wood and in textiles, which no longer exist. Here, as elsewhere, owing to the decay of organic materials, only a very incomplete picture of ancient civilization can be reconstructed. The bronze age was illiterate, so that no literary documents have survived, even indirectly; though there very likely is a considerable body of bronze age material embedded in the vast body of Irish literary and oral tradition.

THE IRON AGE

The Celtic (Iron Age) Immigration. — This ancient people remained in undisturbed possession of the country down to about 400–350 B.C. It is possible that there were occasional immigrations such as a gold-producing country would naturally attract; but if so these became absorbed in the aboriginal population, and cannot now be isolated. But at the date indicated a much more formidable immigration took place, doubtless only one phase of the movements of peoples in central Europe, of which the Gaulish sack of Rome in 390 B.C. and the attack on Delphi about 100 years later were outstanding incidents. The Celtic people seems to have had its origin in the regions between the head-waters of the Rhine and the Danube. There they developed their peculiar linguistic characteristics, which is the chief if not the only common mark of "Celticity" in the modern world. They seem early to have become acquainted with the iron-smith's craft, and with the aid of their iron weapons they subdued one by one the petty peoples of the area of Europe north of the Alps. Over these peoples they

spread a veneer of Celticity; they Celticized them in speech, in religion, and in organization: but could not make any very great modification in their racial affinities. This explains the racial diversity which underlies the superficial unity of the Celtic peoples, and which makes it difficult to determine to what people the term "Celtic" most fittingly belongs.

A community — or more probably, several communities — of this people effected an entrance into Ireland in or about the middle of the 4th century B.C. They were probably few in numbers; but they had the advantage of a superior military organization, and, especially, of iron weapons. In time they effected a complete revolution in the life of the country. Their Celtic speech completely ousted the aboriginal Pictish. Their Indo-European patriarchal organization took the place of the aboriginal matriarchate. New gods and new methods of government, new arts and new crafts, were introduced. The aborigines were reduced to vassalage, which, though mitigated with the establishment of Christianity, was never completely terminated until conqueror and conquered alike were subdued by the Norman. The newcomers were a tall fair people, of Nordic extraction, and contrasted physically with the aborigines. The contrast was maintained, as we cannot doubt, by restrictions on intermarriage. In the literature which a little later began to come into being, an aristocratic product, the distinction between fair and dark people is of paramount importance. Every person who is spoken of with respect, save for a number of individuals of exceptional character who "prove the rule" much more clearly than in most cases of the kind, is described as being tall and fair, with long flowing locks. Every person who for any reason is spoken of with disdain is described as being short, dark, and with close-cropped hair.

The culture which the newcomers brought into the country belongs to the later stage of the iron culture of Europe, which goes by the name of La Tène. The earlier phase of the iron culture, called by the name of Hallstatt, is not represented in Ireland save by a few stray objects which came in by way of trade or by mere accident, and do not indicate a permanent settlement. This enables us to assign a date to the Celtic invasion with tolerable exactness. The legends of the landing of the invaders, attracted by the country's store of gold, may at least be historical in that they represent the landing as taking place in the south-east corner of the island: the place where the gold-bearing gravels are to be found.

Iron Age Remains. — The actual remains of the pagan iron age in the country are, comparatively speaking, scanty. They include a number of types of bronze objects, some peculiar to Ireland, and several of very problematical use: some spearheads and other objects of iron: and, most remarkable of all, a few large stones, probably sepulchral gravemarks, bearing sculptured ornament of the geometric-floral type associated with the art of the La Tène period. In other respects the pagan iron age was of very great importance in the history of Ireland. At this time the literature began to come into being, though the documents which transmit it to our time are of much later date, and show clear evidence of editorial manipulation. The oldest written relics are the Ogham inscriptions, which preserve early forms of the Irish language not otherwise illustrated. Such of the inscriptions as have been deciphered contain nothing but names, with words denoting relationship linking them together. The Ogham alphabet is a cipher, based upon an abbreviated form of the Roman alphabet, and doubtless originally intended, not for writing at all, but for secret communication by means of the fingers. The letters are combinations of strokes, in number from one to five (representing the fingers) disposed in various positions around a central line. *(See OGHAM.)*

Probably the majority of the numerous ancient fortifications are also to be reckoned to this period. These are as a rule circular enclosures, surrounded by one, two or three ramparts of earth or of stone. Others, however, are much more complex in their plan. Very little is known of these enclosures, which are common everywhere. Probably some of them are as early as the bronze age; others, certainly, are quite late in date (say A.D. 700–1000) for inscribed stones are used as building material in their construction. Some are burial-enclosures; some, perhaps, sanctuaries; others cattle-pens; the majority, fortified steadings. Most likely many were erected as defences against wolves. They are often in positions strategically worthless, and show a singular carelessness with regard to facility of water-supply if they were expected to stand a siege.

CHRISTIAN REMAINS

We may safely date the beginning of Christianity as a power in Ireland to somewhere about A.D. 350–400. There probably were individual Christians even before this date, but they cannot have made much impression on the life of the community. But after about three centuries we begin to find definite traces of a specific Christian art. The earliest church buildings, and for a long time the most important ones, were built of wood, not of stone; and these have all disappeared through fire and decay. Stone building was in a rudimentary stage of development throughout the country; the extensive forests supplied the most obvious and the most easily worked building material. Probably also carved wooden plates did duty for sepulchral memorials: wooden tomb "stones" are still to be seen in some of the country graveyards. Early remains very likely lie hidden in some of the monastic sites; but these are effectually sealed from the excavator by modern interments. The Viking raids of the 9th and 10th centuries must be responsible for the disappearance of many of the earliest works of art.

The only remains of wooden constructions that we possess are the fragments of framed houses found in some of the lake-dwellings (commonly called in the country *crannogs*)—artificial islands made by piling earth and stones on the bottoms of the shallower lakes, and after securing them with a revetment of stones or wattlework, erecting a dwelling-house in the middle. These structures began in the La Tène period, were much in use (to judge by the remains found within them) about the 7th century, and were not wholly abandoned until about the end of the 16th century. The fragmentary structures which they bear are insufficient for us to gauge fairly the skill of the ancient builders in wood. Certain features of the earliest stone churches are evidently translations, so to speak, of constructional details proper to wood into stone, where they are merely otiose. The arch is not used for the larger openings in the earliest structures, though its use for small windows shows that its principle was understood from the first. The stones are set without mortar, or at most in mud. There is much variety in the character of the masonry, but this depends on the skill of the local masons and on the materials at their disposal, and is of no chronological significance. After the Irish missions to the Continent began, the stone building in the country began to improve notably. The Romanesque style was introduced and successfully practised: some very remarkable buildings were produced especially in the 12th century, such as King Cormac's chapel at Cashel, the Nunnery church at Clonmacnois, and the cathedral of Clonfert.

The round towers possess neither the historical nor the architectural importance which controversialists once attributed to them. They are simply the detached campaniles of the churches with which they are invariably associated: they were erected during the time of the Scandinavian raids, when watchtowers and keeps were as necessary as belfries to the churches which had treasures to guard.

The *scriptorium* was one of the busiest centres of industry in an ancient monastery. A sufficient number of manuscripts survive to prove the nature of the work there carried on. The oldest manuscript completely in the Irish language, the Book of *the* Dun *Cow* (so called from the animal from whose hide its vellum was said to have been manufactured) was written at Clonmacnois some time before A.D. 1106, but is founded on much earlier exemplars, now lost. These literary manuscripts however concern us less than the illuminated books, of which a considerable number was produced: those that survive date from the 8th century to the 11th. The documents thus enriched are psalters, service-books, and, especially, gospels; the enrichments consist not so much in miniatures as in an artistic treatment of the letters of the text itself; these are worked with great ingenuity into fantastic knots

and monograms, and decorated with applied ornament of great beauty. In the Gospels of Kells (probably of the middle of the 9th century) the art attains its high-water mark; some pages of this manuscript, especially the monogram of the name of Christ at the beginning of the Gospel of St. Matthew, rank among the finest illuminations in existence.

The art of these illuminations is one with the art of the metal-worker and the sculptor, differing only in the medium employed. It is a provincial phase of the great decorative art practised by Celtic and Teutonic peoples alike, though with differences of idiom, in the 6th to the 12th centuries. It consists of devices founded on such geometrical devices as spirals and interlacements, and on figures of animals or parts thereof, often conventionalized almost out of recognition. Patterns derived from the vegetable world are found in certain of the Teutonic regions, but are almost completely absent from the Celtic works of art.

Like the art of illumination, that of the metal-worker was almost wholly devoted to the service of the Church—save for ornamental pins and brooches, ,of which a number of very fine specimens have survived. Of these the best-known is the (falsely so called) *Tara* brooch, a work probably of about A.D. 800. It was found on the sea-shore at Bettystown, south of Drogheda, and is now preserved in the collection of the Royal Irish academy. On the reverse side is elaborate chasing, founded mainly on animal forms; on the face are sunk panels filled with ornament in extremely delicate filigree.

The more specifically ecclesiastical works in metal may be classed under the headings of bells, shrines, chalices and processional crosses. The bells used by the early Irish ecclesiastics were adaptations of cattle-bells, like those in Switzerland and elsewhere. They are rectangular, not round, in horizontal section. The earlier specimens, including the famous bell of St. Patrick, are of iron (sometimes brazed on the surface); the later are cast bronze. Bells are usually without ornament, save occasional decorative treatment of the handle; a few specimens are engraved with simple decoration. One is inscribed, and can be dated A.D. 908.

The shrines are of several different varieties, depending upon the nature of the object to be enshrined. Caskets for bones were made in the form of the ordinary church building of the time (understood to be the form in which the Temple of Solomon had been designed); or else in the shape of the part of the body from which the bone came. The best-known example of the latter type is the shrine of St. Laichtin's forearm, in the Royal Irish academy's collection, a work of the 12th century. Those meant for books were flat square boxes, of the size and shape of the volume which they were intended to contain. The books were not preserved in these shrines for perusal; they were holy relics, and were not meant to be taken out of their receptacle. Had they not been thus preserved, they would have perished: for the book which had belonged to a notable saint was accredited with miraculous powers; strips were cut from it to make amulets, water was poured over it to acquire healing virtues, and, according to Bede, books from Ireland were in especial request in England, for scrapings from their pages were a remedy against snake venom. Shrines for bells and crosiers, again, took the form of the object enclosed within them.

The solitary chalice which has survived from the days of Celtic Christianity far surpasses the best of these objects in artistry. It was found near Ardagh, Co. Limerick, and is now in the Royal Irish academy's collection. It is richly decorated with bands of chased and filigree panels, and its beauty is enhanced by the use of enamel, crystal, mica, glass and amber. It is a worthy companion to the Gospels of Kells, with which it is probably contemporary.

The one processional cross that has survived is the so-called Cross of Cong, made at Roscommon in or about 1125 to enshrine a fragment of the true cross. Its late date is reflected in the character of its ornament; the pure interlacements and other geometrical decoration of the Ardagh chalice give place to patterns founded on contorted animal figures. The cross-head, which alone remains, is about 2ft. high. It rises from the jaws of a monstrous animal head. The surface is covered with bronze plates, enriched with silver and enamel, and with applied panels of open work or what we may call false filigree representing animal figures in fantastic knots. In the centre of the face is a large crystal, behind which we may presume that the relic, or what is left of it, is still lying. On the sides are inscriptions in Latin and in Irish, explaining the purpose of the cross, and asking for prayers for all those concerned in its manufacture. The back had an inlaid saltire, presumably of gold, which some sacrilegious thief has picked out.

Numerous remains of sculptured art in stone exist in Ireland, beginning about the middle of the 8th century. They take the form of sepulchral slabs, carved crosses, or the sculptured decoration of church buildings. At Clonmacnois there is a valuable series of slabs, commemorating inmates of the monastery. These sometimes bear the names of persons known from other sources, and are therefore datable: it has been found possible to determine a sequence of styles from these, extending over four centuries. Of much greater importance are the standing crosses, erected in various important ecclesiastical centres. These are in some cases memorials of individuals, such as the fine cross erected at Clonmacnois by Abbot Colman in memory of his friend and patron, Flann, king of Ireland, who died in A.D. 914. Others seem to mark the limits of the monastic enclosure. Others are dedicatory, erected, perhaps, in fulfilment of a vow; such is the "Cross of Patrick and Columba" at Kells, Co. Meath. The earliest standing crosses are perfectly simple, being merely stones carved into a cross form. But about the beginning of the 10th century a much greater elaboration began. The so-called Celtic cross had by now been evolved—a Latin cross with a circular wheel surrounding the centre, probably an attempt to suggest a halo of glory. The surface of the shaft and head of the cross is usually divided into panels, each containing either ornamental devices or else figure subjects. The great majority of the latter which have been identified represent biblical scenes, chosen for their homiletic value—the Fall of Man, the Sacrifice of Isaac, and so forth. **A** few scenes which cannot be identified may possibly represent local events familiar at the time of the erection of the monument, but now forgotten.

The Scandinavians. — Two important foreign influences have profoundly affected the life of Ireland. The first was that of the Scandinavians, who began their piratical raids in the latter part of the 8th century. For over 200 years they continued their depredations, and did incalculable damage to the material welfare and to the morale of the country. But on the other hand they imported their own peculiar variety of the north European art, and from this and the native style there sprang a hybrid which produced works of great beauty: the cross of Cong is one of these. Nevertheless, despite the hold which the Scandinavians had upon the country, comparatively few objects of definitely Scandinavian type have been found there. Only one Scandinavian cemetery has been discovered, and the number of Runic inscriptions is far less than analogy with other Scandinavianized countries would lead us to expect.

The Anglo-Normans. — In 1172 came the Anglo-Norman invasion, which completely overturned the traditional life of the country. From that date onwards foreign methods and ideas impressed themselves with increasing intensity. The immediate result of the invasion was the total extinction of the traditional arts. Typical of the resultant chaos is that strange product, Irish Gothic architecture. There is nothing like it anywhere else. It is a curious jumble of styles and periods; and the mouldings which in English Gothic afford an infallible guide to chronology in ambiguous cases, are either totally absent, or else share in the general eccentricity. The Romanesque style had been voluntarily adopted, and had a healthy natural growth in the country: the Gothic style was violently forced on the country from without, and was never assimilated.

More prominent and characteristic remains of mediaeval Ireland are the numberless castles. At first wooden towers (bretesche) erected on earth mounds (motte), these developed along lines parallel to those followed by castles in England. They are thus

hardly monuments of Irish archaeology pure and simple, but of the archaeology of an extension of England. Naturally none of the temporary wooden towers survive, though the place-name *Brittas*, which is not infrequent, preserves a reminiscence of them, "Brittas" being a corruption of *bretesche;* and there are numerous *mottes* still in existence, such as the splendid example at Castletown Geoghegan, Co. Westmeath. The castles of Ireland are of all sizes and dates, from the great structure at Trim, founded in 1173, down to the humble "peel-towers"—small square structures of two or three storeys—some not earlier than the 17th century. The history of Ireland after the Norman invasion is a history of decay and degeneration, and it is vividly reflected in all the remains of antiquity that have come down out of those troubled centuries.

IRELAND, CHURCH OF. The beginnings of Christianity in Ireland are difficult to trace, but there is no doubt that the first Christian missionary whose labours were crowned with any considerable success was Patrick (*fl.* c. 450), who has always been reckoned the patron saint of the country. For six centuries the Church of which he was the founder occupied a remarkable position in Western Christendom. Ireland, in virtue at once of its geographical situation and of the spirit of its people, was less affected than other countries by the movements of European thought; and thus its development, social and religious, was largely independent of foreign influences, whether Roman or English. In full communion with the Latin Church, the Irish long preserved many peculiarities, such as their monastic system and the date at which Easter was kept, which distinguished them in discipline, though not conspicuously in doctrine, from the Christians of countries more immediately under papal control *(see* IRELAND: *Early History).* The incessant incursions of the Danes, who were the scourge of the land for a period of nearly three hundred years, prevented the Church from redeeming the promise of her infancy; and at the date of the English conquest of Ireland (1172) she had lost much of her ancient zeal and of her independence. By this time she had come more into line with the rest of Europe, and the Synod of Cashel put the seal to a new policy by its acknowledgment of the papal jurisdiction and by its decrees assimilating the Church, in ritual and usages, to that of England. There was no thought of a breach of continuity, but the distinctive features of Celtic Christianity gradually disappeared from this time onwards.

The Church of Ireland, as at present constituted, is the outcome of the extension to Ireland of the principles of the English Reformation. English influence was strong only in the region round Dublin (known as the Pale); and beyond this district the Irish were not disposed to view with favour any ecclesiastical reforms which had their origin in England. Thus from the days of Henry VIII. the Reformation movement in Ireland was hindered by national prejudice, and it never succeeded in gaining the allegiance of the Irish people as a whole. The policy which directed its progress was blundering and stupid, and reflects little credit on the English statesmen who were responsible for it. No attempt was made to commend the principles of the Reformation to the native Irish by conciliating national sentiment; and the policy which forbade the translation of the Prayer Book into the Irish language, and suggested that where English was not understood Latin might be used as an alternative, was doomed to failure from the beginning. And, in fact, the reformed church of Ireland is to this day the church of a small section only of the population.

REFORMATION AND AFTER

The Reformation period begins with the passing of the Irish Supremacy Act 1537. In Ireland the mass of the people were less deeply affected by the religious controversies of the times than in Great Britain. At Mary's accession five bishops either abandoned, or were deprived of, their sees; but the Anglo-Irish who remained faithful to the Reformation were not subjected to persecution such as would have been their fate on the other side of the Channel. Again, under Elizabeth, while two bishops were deprived for open resistance to the new order of things, and while stern measures were taken to suppress treasonable plotting against the constitution, the uniform policy of the government in ecclesiastical matters was one of toleration. James I. caused the Supremacy Act to be rigorously enforced, but on political rather than on religious grounds. The episcopal succession, then, was unbroken at the Reformation. The question of the continuity of the pre-Reformation Church with the Church of the Celtic period before the Anglo-Norman conquest of Ireland is more difficult. The present Church of Ireland claims to be the direct and legitimate successor of the Church of the 14th and 15th centuries, but it cannot be demonstrated that any existing organization is continuous with the Church of St. Patrick.

On the accession of Charles II. the Church was strengthened by the translation of John Bramhall (the most learned and zealous of the prelates) from Derry to the primatial see of Armagh, and the consecration of twelve other bishops, among whom was Jeremy Taylor. But though the Church had now been reformed for more than 100 years, she had made little progress; and the tyrannical provisions of the Penal Code introduced by the English government made her more unpopular than ever. The clergy, finding their ministrations unacceptable to the great mass of the population, were tempted to indolence and non-residence; and although bright exceptions could be named, there was much that called for reform. To William King (1650–1729) bishop of Derry, and subsequently archbishop of Dublin, it was mainly due that the work of the Church was reorganized, and the impulse which he gave it was felt all through the 18th century. In 1800 the Act of Union was passed by the Legislature; and thenceforward, until Disestablishment, there was but one "United Church of England and Ireland."

The dissatisfaction felt by the majority of Irishmen, because of

the continued existence of the Established Church in her privileged position, became increasingly plain as the years passed. Her position had been pledged to her by the Act of Union, and she was undoubtedly the historical representative of the ancient Church of the land; but such arguments proved unavailing in view of the visible fact that she had not gained the affections of the people. The census of 1861 showed that out of a total population of 5,798,967 only 693,357 belonged to the Established Church, 4,505,265 being Roman Catholics; and once this had been made clear, the passing of the Act of Disestablishment was only a question of time. Introduced by W. E. Gladstone, and passed in 1869, it became law on the 1st of January, 1871.

The Church was thus suddenly thrown on her own resources, and called on to reorganize her ecclesiastical system, as well as to make provision for the maintenance of her future clergy. A convention of the bishops, clergy and laity was summoned in 1870, and its first act was to declare the adherence of the Church of Ireland to the ancient standards, and her determination to uphold the doctrine and discipline of the Catholic and Apostolic Church, while reaffirming her witness, as Protestant and Reformed, against the traditions of Rome. Under the constitution then agreed on, the supreme governing body of the Church is the General Synod, consisting of the bishops and of 208 clerical and 416 lay representatives of the several dioceses, whose local affairs are managed by subordinate Diocesan Synods. The bishops are ejected as vacancies arise, and, with certain restrictions, by the Diocesan Synods. There are two sees, Armagh and Dublin, the archbishops being chosen by the bishops out of their own number. The patronage of benefices is vested in boards of nomination.

The finances are controlled by the Representative Church Body, to which a sum sufficient to provide life annuities for the existing clergy (2,043 in number) was handed over by the Church Temporalities commissioners in 1870, together with £500,000 in compensation for private endowments. The annuities provided were subsequently commuted for a capital sum. So skilfully was this fund administered, and so generous were the contributions of clergy and laity, at and since Disestablishment, that the total assets of the Representative Church Body amounted in 1941 to £11,593,647. This sum comprised private endowments, £341,130; parochial sustentation, £7,626,034; episcopal sustentation, £572,087; general synod funds, £804,657; and miscellaneous purposes, £2,249,739. Church of Ireland membership in 1941 was 428,516.

IRELAND, NATIONAL UNIVERSITY OF. The National University of Ireland had its beginning in the Queen's university—incorporated in 1850. In 1880 the Queen's university was superseded by the Royal University of Ireland. It in turn was dissolved on Oct. 31, 1907, giving place to the National university. Of the three Queen's colleges, founded in 1845 at Belfast, Cork and Galway, which had formed the constituent colleges of its two predecessors, Belfast became a separate university, Cork and Galway were taken over as constituent colleges, while a new college was projected in Dublin and Maynooth added as a recognized college. The headquarters of the university are in Dublin.

The senate consists of 35 members, one of whom, it is laid down in the charter, must be a woman. Certain of the members are elected by Convocation, others are nominated and four are co-opted.

University representation in Dail Eireann was discontinued on June 14, 1937, and under the Seanad Electoral (University Members) act, 1937, the university is entitled to three representatives in Seanad Eireann. There were, on the register of 1941–42, 4,040 students and 316 professors, lecturers and assistants. The president of each university college becomes in rotation a vice-president of the National university. There are ten faculties, in arts, philosophy and sociology, Celtic studies, science, medicine (including dentistry), engineering and architecture, law, commerce, general agriculture (University college, Dublin, only) and dairy science (University college. Cork. only). Music is included in arts and Celtic studies. (See also UNIVERSITIES.)

See *Yearbook of the Universities of the Empire* (1940 and *Supplement*, 1941); *Calendar of the National University of Ireland* (annual).

IRELAND, NORTHERN, a part of the United Kingdom of Great Britain and Northern Ireland, with a certain measure of local self-government. The article on IRELAND (*q.v.*) describes the geology, physical geography and archaeology of Northern Ireland. The capital city (a county borough with a population of 438,086 in 1937) is Belfast, situated on the river Lagan, which is an important centre of the shipbuilding, linen, tobacco, rope-making and distilling industries. A considerable trade in live-stock and agricultural produce is also carried on from this port. The following table shows the populations (census 1937) and areas of the counties and county boroughs composing Northern Ireland:—

County or County Borough	Area in sq. mi. (exclusive of water)	Persons	Males	Females
Antrim	1,098	197,266	96,003	101,263
Armagh	489	108,815	54,271	54,544
Belfast Co. Borough	24	438,086	205,538	232,548
Down	952	210,687	102,535	108,152
Fermanagh	653	54,569	28,856	25,713
Londonderry (excluding Co. Borough)	801	94,923	47,929	46,994
Londonderry Co. Borough	3	47,813	22,344	25,469
Tyrone	1,218	127,586	65,678	61,908
Total	5,238	1,279,745	623,154	656,591

See also the articles on the separate counties and boroughs.

Belfast is by far the largest city, and other cities and towns with a population of 10,000 or more at the 1937 census were Londonderry (47,813), Bangor (15,768), Lurgan (13,764), Lisburn (13,051), Ballymena (12,928), Nemry (12,738), Portadown (12,440), Larne (11,090) and Newtownards (10,149).

EDUCATION

The administration of public education in Northern Ireland, other than university education, is under the general control of the ministry of education, local educational authorities being committees of county councils and county borough councils. Attendance in elementary school is free and compulsory bet een the ages of 6 and (after 1939) 15. The average attendance at public elementary schools in 1937 was 149,570. Secondary and junior technical and commercial schools are financed in the main through grants from the ministry of education and by pupils' fees. On Dec. 1, 1937, 13,683 pupils were enrolled in grant-earning secondary schools. Teachers are trained at Stranmillis and St. Mary's colleges, in Belfast, and at St. Nary's college, Strawberry Hill, Middlesex, England.

Evening technical schools provide a wide variety of courses for pupils who have ceased full-time attendance at school, and for adults. In addition, facilities are provided at the Municipal College of Technology in Belfast for both day and evening students; certain university courses may be followed in conjunction with the Queen's university.

The Queen's university of Belfast grew out of the Queen's college, Belfast, founded in 1845, and a constituent college of the Queen's university of Ireland until the latter was disestablished in 1882; the college continued as a teaching institution until 1909, when it was reconstituted as a self-governing university. The university receives annual parliamentary grants, and aid from the rates of Belfast and the councils of various counties. Instruction is given in eight faculties: arts (including music), medicine (including dentistry), science (including civil engineer-

ing), applied science and technology, law, commerce, agriculture and theology. The total number of students enrolled during 1941–42 was 1,844.

RELIGION

The census of 1937 recorded the religious professions as follows: Roman Catholics 428,290, Presbyterians 390,931, Church of Ireland (including all other Protestant Episcopalians) 345,474, Methodists 55,135, others 59,915.

CENTRAL GOVERNMENT

Northern Ireland as a separate area of government was created by the Government of Ireland act, 1920. This act provided for the setting up of a separate parliament for Northern Ireland within the United Kingdom, the lord lieutenant having the authority to summon, prorogue and dissolve it, and to give or withhold the royal assent to bills passed by both houses. In 1922 the office of lord lieutenant was abolished and the powers invested in a governor of Northern Ireland.

Executive Government. — All executive and administrative powers are vested in the crown, and exercised through the governor. The first governor was the Duke of Abercorn, appointed for a term of six years from Dec. 8, 1922; he was reappointed in 1928, 1934 and 1940. The governor's executive committee, or cabinet, comprises a prime minister and seven ministers administering departments. The departments are those of finance, home affairs, labour, education, agriculture, commerce and public security; a minister of public security was first appointed on Oct. 23, 1941. The prime minister receives an annual salary of £2,850, and ministers administering departments £1,800 each. Only members of the privy council of Northern Ireland are eligible for appointment as ministers, and they must be (or become within six months after appointment) members of the Northern Ireland parliament. A minister may sit and speak in both houses of parliament, but may vote only in that house of which he is a member.

Parliamentary Representation. — Since certain legislative and fiscal powers are reserved to the parliament of the United Kingdom, Northern Ireland is represented in the parliament at Westminster by 13 members. For the purposes of local self-government the country has a parliament consisting of two houses (1) the senate, composed of the lord mayor of Belfast, the mayor of Londonderry and 24 senators elected by the members of the house of commons, and (2) the house of commons, composed of 52 members who are elected by the same electors and in the same manner as the members returned by constituencies in Northern Ireland to the parliament of the United Kingdom. The term of-office of every elected senator is eight years, and continues independently of the life of parliament, one-half of the elected members retiring at the end of each fourth year. The house of commons, unless sooner dissolved, continues in existence for a term of five years. While no salary attaches to the office of senator, an allowance of £2 5*s.* per diem may be made (with a maximum of £90 in any one year), and travelling expenses are also paid; a member of the house of commons draws no salary, but receives £210 per annum for expenses (unless in receipt of an official salary), together with travelling expenses.

Legislative Procedure. — Money bills can originate only in the house of commons and may not be amended by the senate. If the senate rejects, or fails to pass, or passes with amendments to which the house of commons will not agree, a public bill which is sent up to the senate at least one month before the end of the session, and if the house of commons in the next session again passes the bill, with or without any amendments which have been made or agreed to by the senate, and the senate rejects or fails to pass it, or passes it with amendments to which the house of commons will not agree, provision is made for the holding of a joint session.

Limitation on Legislative Powers. — The parliament has power generally to make laws for the peace, order and good government of Northern Ireland for matters exclusively relating to the province. The Northern Ireland (Miscellaneous Provisions) acts of 1928 and 1932, passed by the parliament of the United Kingdom, included provisions to overcome some minor difficulties in respect of transferred services under the 1920 act. The crown, armed forces, defense of the realm, relations with foreign states, and certain other matters are excepted services, power to legislate upon them being withheld from the parliament of Northern Ireland. Reserved services, which remain within the sphere of the imperial parliament, include the postal service, post office savings banks, registration of deeds and the supreme court of judicature; there are also reserved taxes, such as customs and excise duties, and income tax. Although the supreme court of judicature and the registry of deeds are reserved services under the control of the United Kingdom authorities, they are local to Northern Ireland.

LOCAL GOVERNMENT

Local administration in Northern Ireland is based mainly on the Local Government (Ireland) act, 1898. There are seven types of authority engaged in local government administration. The six county councils are responsible for the welfare of the blind, the treatment of tuberculosis, education, medical inspection of school children, supervision of the sale of food and drugs, the treatment of venereal diseases, and administration of roads, mental hospitals and county infirmaries. The two county boroughs (Belfast and Londonderry) exercise the same powers and perform the same duties as county councils, and also those of urban district councils. Three borough councils (Bangor, Coleraine and Newtownards) have the powers of urban district councils and also certain powers and privileges under the Municipal Corporations act, 1840. The 30 urban district councils are responsible for matters pertaining to public health and public roads, and the housing of workers; they also have duties in relation to town planning and allotments, and are authorized to provide water, gas and electricity supplies. The 32 rural district councils, while primarily public health authorities, control unclassified roads and provide houses for agricultural labourers. Three towns (Antrim, Gilford and Aughnacloy) have town commissioners, responsible for street maintenance, regulation of traffic and markets, and formulation of housing schemes. Poor relief and dispensary medical relief are administered by 27 boards of guardians, and these bodies also administer the vaccination acts and register births, deaths and marriages.

JUSTICE AND POLICE

Judicature. — The superior courts in Northern Ireland comprise the supreme court of judicature, the court of criminal appeal and the railway and canal commission, all under the jurisdiction of the imperial parliament. The supreme court of judicature consists of the high court of justice (having jurisdiction over the king's bench, chancery, assize courts and matters of lunacy and minors) and the court of appeal (from which appeals lie to the house of lords in certain conditions). The court of criminal appeal was established in 1930. The jurisdiction of the railway and canal commission relating to the work of railway and canal companies was terminated by virtue of the Road and Railway Transport act (Northern Ireland), 1935, and no matters of any kind within its jurisdiction in Northern Ireland were heard by its court after 1921.

The inferior courts, dealing with minor criminal and civil matters, comprise the courts of quarter sessions, the county courts, and the courts of summary jurisdiction (petty sessions). By the Summary Jurisdiction act (Northern Ireland), 1935, justices of the peace were relieved of their judicial functions, petty sessions courts thereafter being conducted exclusively by resident magistrates, permanent judicial officers remunerated from public moneys. Justices of the peace retained administrative functions and, when sitting out of petty sessions, could hear and determine cases of drunkenness and vagrancy.

Police. — The Constabulary act (Northern Ireland), 1922, authorized constitution of the Royal Ulster constabulary, the members of which were recruited from the disbanded Royal Irish constabulary. The Belfast corporation contributes £25,000 annually towards the expenses of the constabulary. In 1936 the police took over the duty of the customs patrols on the boundary with

Eire. At the end of that year the strength of the force was 2,867 officers and men.

The special constabulary comprises a small number of full-time personnel (Class A) and a reserve organization (Class B) directed and administered on a county basis by full-time staffs. Members of Section A of Class B must attend annually a specified number of drills and musketry practice, and Section B may perform voluntary drills. Class B of the special constabulary numbered 11,514 on Dec. 31, 1936, of whom 52 comprised the full-time establishment and 383 were part-time officers.

SOCIAL SERVICES

Poor Relief.—The Unemployment Assistance act (Northern Ireland), 1934, transferred administration of relief to able-bodied unemployed to the Unemployment Assistance board for Northern Ireland. Other forms of poor relief are administered by the boards of guardians. Indoor relief in workhouses and outdoor relief at home are afforded to the destitute; while medical relief in union infirmaries and fever hospitals, in district hospitals, and under the dispensary system, is available for poor as well as destitute persons.

Health Services.—The ministry of home affairs is the central authority for public health matters, local administration being carried out by urban and rural district councils and, in regard to certain special matters, by county councils. The councils are responsible for control of infectious diseases, supervision of the sale of food, the registration of medical and dental practitioners, nurses and midwives, and sanitary measures and vaccination. The ministry of labour supervises the general administration of the National Health Insurance acts (Northern Ireland), 1936–38, which resemble the corresponding acts in force in Great Britain. Medical benefits are administered directly by the ministry, and others by approved societies.

Unemployment Insurance and Unemployment Assistance.—In all essentials, provision for the assistance of unemployed persons in Northern Ireland is identical with that made in Great Britain, the scheme of insurance being administered by the ministry of labour. The Unemployment Assistance board, constituted in 1934, disburses the allowances as prescribed by the ministry of labour. Those not coming within the scope of the unemployment legislation may receive poor relief from boards of guardians. The Unemployment Insurance act (Northern Ireland), 1938, enabled educational authorities to provide meals and medical treatment for unemployed juveniles between school-leaving age and 18 who were attending courses of instruction, as was already being done in the case of needy school children. The act also brought into the scheme of unemployment insurance outdoor private domestic employees. On Sept. 14, 1942, there were 18,019 unemployed persons.

Contributory Pensions.—The Widows', Orphans' and Old Age Contributory Pensions act (Northern Ireland), 1936, corresponded in every substantial particular with the scheme in Great Britain. Further legislation in 1937 extended the benefits on a voluntary basis to certain classes which were previously outside the scope of the scheme. The 1936 act was also amended by the Blind Persons act, 1938, which lowered from 50 to 40 the age which blind people must have attained in order to be entitled to old-age pensions; it also transferred from poor law authorities to local authorities the responsibility for assisting blind persons other than by way of institutional and medical relief. A person over the age of 70, not qualified to receive an "insurance" (contributory) old-age pension, may be entitled to a "means" pension (payable from the exchequer) provided that statutory conditions are complied with.

Housing.—The Housing (Northern Ireland) act, 1923, empowered the government to make grants to urban authorities and rural district councils for the erection of houses by those authorities or by private persons, and loans also could be advanced to finance schemes for housing. Grants in respect of houses erected by private persons terminated in 1936, and in respect of those by local authorities the next year. Government housing subsidies to private builders amounted to £2,232,260 and to local authorities to £152,845 by March 31, 1937. By that date, private builders had erected 32,383 houses and local authorities 2,668, and rural authorities had built 2,049 cottages.

LAND TENURE AND DRAINAGE

Land Tenure.—Under the terms of the Government of Ireland act, 1920, the completion of the purchase of iand, and repayment of advances and payment and redemption of purchase annuities under the Land Purchase (Ireland) acts (1870–96, 1903 and 1909) became reserved services. A further Land Purchase act passed in 1925 enabled remaining land tenants in Northern Ireland to buy out their holdings and provided for the compulsory sale of all tenanted land through a newly constituted tribunal, the Land Purchase commission. Sale under the act of 1925 was automatic, terms of purchase being fixed by the commission. On an "appointed day" each tenant was deemed to have agreed to purchase his holding at the price fixed, and the holding. charged with the repayment of that sum, was vested in him Proceedings having approached completion, the powers of the commission to make advances for the purchase of land were terminated by the Northern Ireland Land Purchase (Winding Up) act, 1935, of the imperial parliament, and on April 1, 1937, the "appointed day" under the act, the Land Purchase commission ceased to exist. The functions of the court of the commission and of the judicial commissioner were transferred to the chancery court. The ministry of finance continued to collect land purchase annuities. The following table shows the extent of the land purchase sales effected in Northern Ireland under the several acts.

Acts	Number of purchasers	Area in acres	Purchase price	Amount of advances
1870–96	20,800	550,800	£5,817,200	£5,621,000
1903	57,400	1,219,800	14,448,800	14,306,800
1909	5,500	139,600	1,091,900	1,064,400
1925	38,500	805,500	5,894,700	5,885,900
Totals . .	122,200	2,715,700	27,252,600*	26,878,100*

*Approximate figures based on gross rent.

Arterial Drainage.—The Drainage acts (Northern Ireland), 1925–35, empowered county councils to borrow funds, to make contributions and to draft by-laws for the carrying out of drainage schemes. The drainage districts of Lough Neagh and Lough Erne were not included in this legislation. The Drainage act, 1929, constituted the ministry of finance the drainage authority for the Lough Neagh district. Widening and deepening of the Lower Bann river over a distance of 32 mi. were undertaken, and new weirs and other special works were constructed, at a total cost of £850,000; £200,000 of this sum was paid by the county councils of Antrim, Armagh, Down, Londonderry and Tyrone, and the remainder by the government. The problems of the Lough Erne drainage district affected both Northern Ireland and Eire; joint official studies were completed in 1934, but because of the high cost remedial measures were not initiated prior to World War II. The Drainage act of 1933 authorized execution of a drainage scheme on the River Quoile; a small share of the £24,000 expended was borne by the Down county council and the urban district council of Downpatrick.

INDUSTRIES

Agriculture and Livestock.—Nearly three-quarters of Northern Ireland is normally under crops and pasture, a system of mixed farming predominating. While much is ordinarily exported, the greater part of the potato and wheat crops is retained for home consumption. The country also grows about one-fifth of the flax used in the Belfast linen industry. In 1938 there were 306,200 ac. under corn crops, and 2,483,600 ac. under other crops and grass. The principal corn crop is oats, 296,500 ac. in 1938 yielding 289,700 tons of produce. In that year there were 123,500 ac. under potatoes, the yield totalling 711,400 tons.

The mild climate enables cattle to be reared in the open during the greater part of the year. Alongside the livestock industry, the most developed branch of agriculture, has gone the produc-

tion of butter, bacon and hams, eggs and poultry, the principal export market for which is Great Britain. The numbers of livestock on Jan. 1, 1939, were as follows: cattle, 700,564; sheep, 551,262; pigs, 565,726; and poultry, 6,038,001.

Fisheries.—Herring fishing is the most important of the sea fisheries, the industry being centred at Portavogie, Ardglass and Kilkeel. More than half of the catch is pickled for export to the Baltic countries and to America. In 1938, 35,383 cwts, of herring valued at £11,596 were landed. The total quantity of wet fish of all kinds landed that year amounted to 65,505 cwts., having a value of £39,280. Plaice is caught in trawling off the north coast, Danish seine netting for whiting is carried on off the County Down coast, and line fishing along the entire coast. Shell fish were landed in 1938 to the value of £4,957. The important oyster beds on the Northern Ireland shore of Carlingford Lough were intensively stocked, and escallop fishing was revived on the coast of County Down.

The fine river system of Northern Ireland affords ideal feeding grounds apd spawning beds for salmon, trout, eels and pollan. The salmon and eel fisheries are operated commercially—the former by means of fixed nets along the coast and, principally, in the tidal waters of the rivers Foyle, Bann and Bush; the latter in the River Bann and, by means of long lines, in Lough Neagh and Lough Erne Netting for trout is permissible only in Lough Neagh.

Manufactures.— Next to agriculture, the most important industry in Northern Ireland is the manufacture of linen, which was established by Huguenot weavers who fled from France as a result of the revocation of the Edict of Nantes at the end of the 17th century. Some 80% of the flax employed is ordinarily imported. The greater part of the total output is produced within a radius of 30 mi. from Belfast. The census of production in 1935 (the last such quinquennial report prior to World War II) showed that Northern Ireland manufactured 146,042,000 sq.yd. of linen piece goods, valued at £6,074,000.

Belfast is also a centre of great shipbuilding and engineering industries, and it carries on the manufacture of aircraft and tobacco. The city also possesses one of the largest rope factories in the world. Shirts, collars and underwear are manufactured in Londonderry and the surrounding district. Factory and non-factory trades combined had a gross output in 1935 valued at £58,300,000 (£59,300,000 in 1930) and employed on the average 139,000 persons (146,000 in 1930).

Legislation was enacted in 1937 and 1938 to encourage establishment of new industries in Northern Ireland. Free sites were authorized or five-year grants were made for rented premises, and exemption from local rates was given for 20 years to any person or company establishing an undertaking for the manufacture or production of goods not being manufactured or produced in the country.

Mining.— The principal mineral industry of Northern Ireland is the working of basalt and igneous rocks other than granite. The output in 1937 amounted to 461,813 tons, valued at £76.246. Clay is worked in Antrim and Londonderry; sandstone and grit in Armagh, Down, Fermanagh and Tyrone; bauxite in Antrim; limestone in Armagh, Fermanagh and Tyrone; gravel and sand in Tyrone; and granite in Armagh and Down. In 1937, 1,349,737 tons of all minerals were produced, the value being £234,575.

TRANSPORTATION

With certain exceptions, all existing road transport undertakings (both passenger and goods) were taken over by a Road Transport board, established by the Road and Railway Transport act (Northern Ireland), 1935.

A joint committee representing both the board and the railway companies co-ordinated road services with those of the railways, fixed fares, rates and charges, and drafted a scheme for pooling traffic receipts.

Railways.— The three major railway systems operating in Northern Ireland are those of the London, Midland and Scottish Railway company (Northern Counties committee), the Great Northern Railway company (Ireland) and the Belfast and County Down Railway company. Five out of six minor systems operate mainly in Eire. At the end of 1936, the route mileage of standard gauge (5 ft.) within the country amounted to 622 mi., and there were also 124 mi. of narrow gauge (3 ft.) line.

Roads.—A Road fund derived from motor vehicle duties and drivers' fees and administered by the ministry of home affairs assists local highway authorities in the maintenance and improvement of roads.

The Roads Improvement act, 1937, empowered the ministry to construct necessary new roads at state expense, the roads becoming the property of local authorities on completion. In 1937 there were 13,043 mi of roads, and grants paid from the Road fund amounted to £420,706.

FINANCE

Approximately 90% of the taxes are imposed and collected by the imperial parliament. From this "reserved revenue" is deducted the cost of the reserved services (see *Limitation on Legislative Powers,* above) and the country's contribution toward imperial services, and the balance, termed the "residuary share of reserved taxes," is paid into the exchequer of Northern Ireland. Transferred revenue, within the direct control of the parliament of Northern Ireland, is derived from death, stamp and motor vehicle duties, excise licence duties other than those for manufactures where the duty varies with the production of goods, and mineral rights duty.

Financial relations between Northern Ireland and Great Britain were modified in 1938. It was agreed that if there were a deficit in the country's budget which was not the result of a standard of social expenditure higher than that of Great Britain, nor the result of a standard of taxation lower than that of Great Britain, it would be equitable that means should be found to make good this deficit in such a way as to ensure that Northern Ireland should be in a financial position to continue to enjoy the same social services as Great Britain.

HISTORY

King George V formally opened on June 22, 1921, the first parliament of Northern Ireland created under the Government of Ireland act, 1920. The first prime minister was Sir James Craig (later Lord Craigavon), who held office continuously until his death on Nov. 24. 1940; his successor as head of the government was John Miller Andrews, hitherto minister of finance, who served until April 30, 1943 and was succeeded by Sir Basil Brooke. From the outset it was the government's policy to preserve the existence of Northern Ireland as an integral part of the United Kingdom, rejecting any form of union with the rest of Ireland which would involve separation from Great Britain and abandonment of the representation of Northern Ireland in the imperial parliament.

Within the month prescribed, Northern Ireland voted not to accept the dominion status for Ireland as a whole envisaged in the Irish Free State (Agreement) act, 1922, and declined to appoint a member of the commission to be created in that event to determine the common boundary with the rest of Ireland. The power of appointment residing in the Northern Ireland government was transferred to the British government by the Irish Free State (Confirmation of Agreement) act, 1924, but the work of the boundary commission then set up proved fruitless when the Free State commissioner withdrew.

Settlement was achieved with passage of the Ireland (Confirmation of Agreement) act, 1925, the extent of Northern Ireland being such as was fixed by the Government of Ireland act, 1920; the 1925 act also provided for the transfer from April 1, 1926, of the Council of Ireland powers in relation to Northern Ireland to the government of Northern Ireland.

The establishment of a separate legislature did not lead to a differentiation of the law in Northern Ireland from that in other parts of the United Kingdom. Social legislation kept pace with that at U7estminster. Northern Ireland adopting its various measures for unemployment insurance and pensions for widows, orphans and the aged The franchise mas conferred upon

women in 1928 on the same terms that it had hitherto been enjoyed by men, and the abandonment of proportional representation in 1929 and a reversion to single-member constituencies brought electoral practice into line with that of Great Britain. At the general election on Feb. g, 1938, there were returned 39 Unionists, eight Nationalists, two Independent Unionists, one Labour, one Independent and one Independent Labour.

IRENAEUS (b. *c.* 130), bishop of Lyons at the end of the 2nd century, was one of the most distinguished theologians of the ante-Nicene Church. Very little is known of his early history. His childhood was spent in Asia Minor, probably at or near Smyrna; for he says (Adv. haer. iii. 3, 4, and Euseb. *Hist.* Eccl. v. 20) that as a child he heard the preaching of Polycarp, the aged bishop uf Smyrna (d. 156). He can hardly have been born very long after 130, for later on he frequently mentions having met certain Christian presbyters who had actually seen John, the disciple of our Lord. At the time of the persecution of the Gallic Church under Marcus Aurelius (177) he was a presbyter of the church at Lyons. In 177 or 178 he went to Rome on a mission from this church, to make representations to Bishop Eleutherius in favour of a more lenient treatment of the Montanists. (See MONTANISM; EUS. v. 4. 2.)

On his return to Lyons Irenaeus was called **upon** to replace Bishop Pothinus, who had perished in the persecution (Eus. v. 5. 8). As bishop he carried on a great and fruitful work. Though the statement of Gregory of Tours (*Hist.* Franc. 1. 29), that within a short time he succeeded in converting all Lyons to Christianity, is probably exaggerated, from him at any rate dates the wide spread of Christianity in Lyons and its neighbourhood. He sought to reconcile the numerous sects which menaced the existence of the church. In the dispute on the question of Easter, he endeavoured to effect a compromise, and in particular to exercise a moderating influence on Victor, the bishop of Rome, and his unyielding attitude towards the dissentient churches of Africa, thus justifying his name of "peace-maker" (Eirenaios) (Eus. H.E. v. 24. 28). The date of his death is unknown. His martyrdom under Septimius Severus is related by Gregory of Tours, but by no earlier writer.

The chief work of Irenaeus, written about 180, is his "Refutation and Overthrow of Gnosis, falsely so called" (usually indicated by the name *Against* the Heresies). Of the Greek original of this work only fragments survive; it only exists in full in an old Latin translation. The treatise is divided into five books: of these the first two contain a description and criticism of the tenets of various heretical sects, especially the Valentinians; the other three set forth the true doctrines of Christianity. His work is the first systematic exposition of Catholic belief. The foundation upon which Irenaeus bases his system consists in the episcopate, the canon of the Old and New Testaments, and the rule of faith. With their assistance he sets forth and upholds, in opposition to the gnostic dualism, *i.e.*, the severing of the natural and the supernatural, the Catholic monism, *i.e.*, the unity of the life of faith as willed by God. The "grace of truth" (the *charisma*), which the apostles had called down upon their first disciples by prayer and laying-on of hands, and which was to be imparted anew by way of succession (διαδοχή, *successio*) to the bishops from generation to generation without a break, makes those who receive it living witnesses of the salvation offered to the faithful by written and spoken tradition. The Scriptures of the Old and New Testaments, rightly expounded by the church alone, give us an insight into God's plan of salvation for mankind, and explain to us the covenant which He made on various occasions (Moses and Christ; or Noah, Abraham, Moses and Christ). Finally, the "rule of faith" (*regula fidei*), received at baptism, contains in itself all the riches of Christian truth.

This exposition by Irenaeus of the divine economy and the incarnation was taken as a criterion by later theologians, especially in the Greek Church. (Cf. Athanasius, Gregory of Nyssa, Cyril of Alexandria, John of Damascus.) He himself was especially influenced by St. John and St. Paul. Before him the Fourth Gospel did not seem to exist for the Church; Irenaeus made it a living force. His conception of the Logos is not that of the philosophers and apologists; he looks upon the Logos not as the "reason" of God, but as the "voice" with which the Father speaks in the revelation to mankind, as did the writer of the Fourth Gospel. And the Pauline epistles are adopted almost bodily by Irenaeus, according to the ideas contained in them; his expositions often present the appearance of a patchwork of St. Pad's ideas. Certainly, it is only one side of Paul's thought that he displays to us. The great conceptions of justification and atonement are hardly ever touched by Irenaeus.

Till recent times whatever other writings and letters of Irenaeus are mentioned by Eusebius appeared to be lost, with the exception of a fragment here or there. Two Armenian scholars, Karapet Ter-Měkĕrttschian and Erwand Ter-Minassianz, published from an Armenian translation a German edition (Leipzig, 1907; minor edition 1908) of the work "in proof of the apostolic teaching" mentioned by Eusebius (H.E. v. 26). This work, which is in the form of a dialogue with one Marcianus, otherwise unknown to us, contains a statement of the fundamental truths of Christianity. It is the oldest catechism extant, and an excellent example of how Bishop Irenaeus was able not only to defend Christianity as a theologian and expound it theoretically, but also to preach it to laymen.

BIBLIOGRAPHY.—The edition of the Benedictine R. Massuet (Paris, 1710 and 1734, reprinted in Migne, *Cursus patrologiae,* Series Graeca, vol. v., Paris, 1857) long continued to be the standard one, till it was superseded by the editions of Adolph Stieren (2 vols., Leipzig, 1848–53) and of W. Wigan Harvey (2 vols., Cambridge, 1857), the latter being the only edition which contains the Syriac fragments. For an English translation *see* the ***Ante-Nicene Library.*** Of modern monographs consult H. Ziegler, ***Irenaeus, der Bischof von Lyon*** (1871); Friedrich Loofs, ***Irenaeus-Handschriften*** (Leipzig, 1888); Johannes Werner, ***Dsv Paulinismus des Irenaeus*** (Leipzig, 1889); Johannes Kunze, ***Die Gotteslehre des Irenaeus*** (Leipzig, 1891); Ernst Klebba, ***Die Anthropologie des heiligen Irenaeus*** (Miinster, 1894); Albert Dufourcq, ***Saint Irénée*** (Paris, 1904); Franz Stoll, ***Die Lehre des heil. IRENE, the name of several Byzantine empresses.

1. IRENE (752–803), the wife of Leo IV., East Roman emperor. Originally a poor but beautiful Athenian orphan, she speedily gained the love and confidence of her feeble husband, and at his death in 780 was left by him sole guardian of the empire and of their ten-year-old son Constantine VI. Seizing the supreme power in the name of the latter, Irene ruled the empire at her own discretion for ten years, displaying great firmness and sagacity in her government. Her most notable act was the restoration of the orthodox image-worship, a policy which she always had secretly favoured, though compelled to abjure it in her husband's lifetime. Having elected Tarasius, one of her partisans, to the patriarchate (784), she summoned two church councils. The first, held in 786 at Constantinople, was frustrated by the opposition of the soldiers. The second, convened at Nicaea in 787, revived the adoration of images and reunited the Eastern church with that of Rome.

As Constantine approached maturity he began to grow restive under her autocratic sway. An attempt to free himself by force was met and crushed by the empress, who demanded that the oath of fidelity should thenceforward be taken in her name alone. The discontent which this occasioned swelled in 790 into open resistance, and the soldiers, headed by the Armenian guard, formally proclaimed Constantine VI. as the sole ruler. A hollow semblance of friendship was maintained between Constantine and Irene, whose title of empress was confirmed in 792; but the rival factions remained, and Irene, by skilful intrigues with the bishops and courtiers, organized a powerful conspiracy on her own behalf. Constantine could only flee for aid to the provinces, but even there he was surrounded by participants in the plot. Seized by his

attendants on the Asiatic shore of the Bosporus, the emperor was carried back to the palace at Constantinople; and there, by the orders of his mother, his eyes were stabbed out.

Irene reigned in prosperity and splendour for five years. She is said to have endeavoured to negotiate a marriage between herself and Charlemagne; but according to Theophanes, who alone mentions it, the scheme was frustrated by Aetius, one of her favourites. A projected alliance between Constantine and Charlemagne's daughter, Rothrude, was in turn broken off by Irene. In 802 the patricians, upon whom she had lavished every honour and favour, conspired against her, and placed on the throne Nicephorus, the minister of finance. The haughty and unscrupulous princess, "who never lost sight of political power in the height of her religious zeal," was exiled to Lesbos and forced to support herself by spinning. She died the following year. Her zeal in restoring images and monasteries has given her a place among the saints of the Greek church.

See E. Gibbon, *The Decline and Fall of the Roman Empire* (ed. J. Bury, London, 1896), vol. v.; G. Finlay, *History of Greece* (ed. 1877, Oxford), vol. ii.; F. C. Schlosser, *Geschichte der bilderstürmenden Kaiser des oströmischen Reiches* (Frankfort, 1812); J. D. Phoropoulos, **Εἰρήνη ἡ αὐτοκράτειρα Ῥωμαίων** (Leipzig, 1887); J. B. Bury, *The Later Roman Empire* (London, 1889), ii. 480–498; C. Diehl, *Figures byzantines* (Paris, 1906), pp. 77–109, and in *Cambridge Mediaeval History*, vol. iv., pp. 19–25. (M. C.)

2. IRENE [DUCAS] (*c.* 1066–*c.* 1120), the wife of Alexius I. The best-known fact of her life is the unsuccessful intrigue by which she endeavoured to divert the succession from her son John to Nicephorus Bryennius, the husband of her daughter Anna. Having failed to persuade Alexius, or, upon his death, to carry out a *coup d'état* with the help of the palace guards, she retired to a nunnery and ended her life in obscurity.

3. IRENE (d. 1161), the first wife of Manuel Comnenus. She was the daughter of the count of Sulzbach, and sister-in-law of the Roman emperor Conrad III., who arranged her betrothal. The marriage was celebrated at Constantinople in 1146. The new empress, who had exchanged her earlier name of Bertha for one more familiar to the Greeks, became a devoted wife, and by the simplicity of her manner contrasted favourably with most Byzantine queens of the age.

H. v. Kap-Herr, *Die abendländische Politik des Kaisers Manuel* (Strasbourg, 1881).

IRETON, HENRY (1611–1651), English parliamentary general, eldest son of German Ireton of Attenborough, Nottinghamshire, was baptized on Nov. 3, 1611, became a gentleman commoner of Trinity College, Oxford, in 1626, graduated and entered the Middle Temple in 1629. On the outbreak of the Civil War he joined the parliamentary army, fought at Edgehill (1642) and at Gainsborough (1643), was made by Cromwell deputy-governor of the Isle of Ely, and next year served under Manchester, afterwards supporting Cromwell in his accusations of incompetency against the general. On the night before the battle of Naseby, in June 1645, he surprised the Royalist army and captured many prisoners, and next day was made commissary-general and appointed to the command of the left wing, Cromwell himself commanding the right. The wing under Ireton was broken by the charge of Rupert, and Ireton was wounded and taken prisoner, but after Cromwell's rout of the enemy he escaped. He took an active part in the campaign which resulted in the overthrow of the royal cause. On Oct. 30, 1645 Ireton entered parliament as member for Appleby, and while occupied with the siege of Oxford he was, on June 15, 1646, married to Bridget, Cromwell's daughter. He was opposed to the destructive schemes of the extreme party, disliked especially the abstract and unpractical theories of the Republicans and the Levellers, and desired, while modifying their mutual powers, to retain the constitution of King, Lords and Commons. He urged these views in the negotiations of the army with the parliament, and in the conferences with the king, being chiefly entrusted with the drawing up of the army proposals. He endeavoured to prevent the breach between the army and the parliament, but when the division became inevitable took the army side. He aroused great suspicion by supporting the negotiations with the king, But becoming at length convinced of the hopelessness of dealing with Charles, after the king's flight to the Isle of Wight he urged the parliament to establish an administration without him. Ireton served under Fairfax in the second civil war in the campaigns in Kent and Essex. and was responsible for the executions of Lucas and Lisle at Colchester. After the rejection by the king of the last offers of the army, he showed special zeal in bringing about his trial, was one of the chief promoters of "Pride's Purge," attended the court regularly, and signed the death-warrant. Ireton accompanied Cromwell in his Irish campaign, and was appointed major-general: on the recall of his chief to take the command in Scotland, he remained as lord-deputy to complete Cromwell's work of reduction and replantation. He was rapidly bringing his task to a close, when he died on Nov. 26, 1651 of fever after the capture of Limerick. His loss "struck a great sadness into Cromwell," for while he possessed high abilities as a soldier, and great political insight, he resembled in stern unflinchingness of purpose the protector himself. Ireton left one son and three daughters.

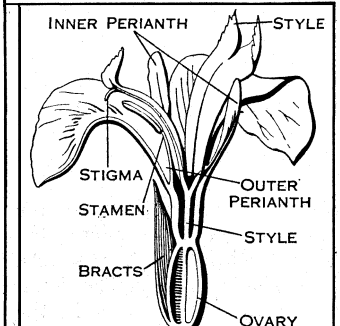
IRIARTE (or YRIARTE), **TOMÁS** DE- (1750–1791), Spanish poet, was born in the island of Teneriffe. His *Fdbulas literarias* (1781), composed in a great variety of metres, show considerable ingenuity in their humorous attacks on literary men and methods; but their merits have been greatly exaggerated. During his later years, partly in consequence of the *Fdbulas*, Iriarte was absorbed in personal controversies with Forner and others.

See E. Cotarelo *y* Mori, *Iriarte* y *su época* (1897).

IRIDACEAE (the iris family), a family of flowering plants belonging to the order Liliiflorae of the class Monocotyledons, containing about 600 species in 60 genera, and widely distributed in temperate and tropical regions. The members of this family are generally perennial herbs growing from a corm as *Crocus* and *Gladiolus*, or a rhizome as *Iris;* more rarely, as the Spanish iris, from a bulb. A few South African representatives have a shrub-by habit. The flowers are hermaphrodite and regular as in *Iris* and *Crocus*, or with a symmetry in the median plane as in *Gladiolus*. The arrangement of the flower parts resembles that in the nearly allied order Amaryllidaceae *(Narcissus, Snowdrop)*, but differs in the absence of the inner whorl of stamens.



FROM GROOM, "ELEMENTARY BOTANY" (G. BELL)

IRIS (IRIS PSEUDACORUS), LONGITUDINAL SECTION THROUGH FLOWER

The most important genera are *Crocus* (*q.v.*), with about 75 species, *Iris* (*q.v.*), with about 200 and *Gladiolus* (*q.v.*), with 200. *Ixia, Freesia* (*q.v.*) and *Tritonia* (including *Montbretia*), all natives of South Africa, are well known in cultivation. *Sisyrinchium*, blue-eyed grass, is a new-world genus of 75 species, extending from arctic America to Patagonia and the Falkland Isles. One species, S. *angustifolium*, an arctic and temperate North American species, is also native in Galway and Kerry in Ireland. Other British representatives of the family are: *Iris pseudacorus* (yellow iris), common by river-banks and ditches, *I. foetidissima* (stinking iris), *Gladiolus illyricus*, a rare plant found in the New Forest and the Isle of Wight, and *Romulea columnae*, a small plant with narrow recurved leaves a few inches long and a short scape bearing one or more small regular funnel-shaped flowers, which occurs at Dawlish in Devonshire. In the eastern United States there are 10 species of *Iris* and 13 species of *Sisyrinchium*, but in the Rocky Mountain region these genera are represented by only 2 or 3 species. Many new species of *Iris* have been described from the southern United States.

For a treatment of the genera see L. Diels, "Iridaceae," in Engler and Prantl, Die *Natürlichen Pflanzenfamilien,* ed. z, 15a.463–505, fig. 207–223 (1930).

IRIDIUM, a metal found in small amounts in ordinary platinum ore, but generally obtained from the native alloy osmiridium. (Symbol Ir, atomic number 77, atomic weight 193.1) The best method of obtaining it is that of Deville and Debray (*see* RUTHENIUM and OSMIUM), the process having been further simplified by G. Matthey (Proc. Roy. *Soc.,* 1879). The metal was first definitely identified by Smithson Tennant in 1804 (although other chemists, such as Descotels, Faucroy and Vauquelin, had previously indicated its separate existence) and was by him named iridium in consequence of the varying colour of its compounds. The metal is usually separated in the form of sparingly soluble ammonium iridium chloride, $(NH_4)_2IrCl_6$; this salt on ignition gives a residue of pure spongy iridium from which the massive form of the metal may be obtained by fusion. Iridium is a white metal possessing a lustre similar to that of steel; it is very hard and somewhat brittle when pure, but loses the latter property when alloyed with small quantities of other metals. Next to osmium, it has rhe greatest density of any substance (sp. gr. —22.42), and melts at about 2,260° C., volatilizing at a little higher temperature. In the massive state the metal is practically insoluble in all acids, but in the spongy or finely divided condition it is attacked by aqua regia producing the higher chloride $IrCl_4$.

Iridium is known to form two oxides, Ir_2O_3 and IrO_2, which both act as bases forming salts with acids. The former is produced by igniting the finely divided metal in oxygen at a temperature below 800° C.; at a higher temperature decomposition into its elements results. The higher oxide is formed by gentle ignition of the corresponding hydroxide, $Ir(OH)_4$. The salts of iridium are not of great importance. Two chlorides, $IrCl_3$ and $IrCl_4$, are known, and with chlorides of the alkali metals these readily form double salts of the types M_3IrCl_6 and M_2IrCl_6, most of which are easily soluble in water. Corresponding bromine compounds of iridium are also known, and at least three sulphides have been identified. Iridium forms many compounds with ammonia (see AMINES) which in their properties are generally similar to those of the corresponding rhodium and platinum derivatives. The metal iridium is of considerable importance in industry, the chief use being in the form of platinum alloys. Platinum itself is a soft metal and as such is not suitable for general use. If, however, a small percentage of iridium is alloyed with it, the metal becomes very much harder, and hence ordinary platinum dishes, crucibles and weights always consist of a platinum iridium alloy, unless for special reasons pure platinum is necessary. The standard metre (étalon) is made of an alloy containing 90 parts of platinum and 10 parts of iridium (see PLATINUM). Iridium is also used to a small extent for producing a splendid black colour on china or porcelain. In magnetos, iridio-platinum is a necessity for contacts, screws, etc., as it resists the temperature of the electric spark much better than pure platinum. As a material for anodes in electrolytic reduction, platinum is the most suitable metal, but when the electrolyte contains chlorides pure platinum undergoes corrosion and iridio-platinum alone is satisfactory. Iridium is always determined quantitatively by ignition of any of its salts and conversion into the metal. (F. E. M)

IRIGA, a municipality (with administrative centre and 10 barrios or districts) of the province of Camarines Sur, Philippine Islands, on the Bikol river, about 20 mi. S.E. of Naga, the provincial capital, and near the southwest base of Mt. Iriga, a volcanic peak reaching a height of about 4,000 ft. above sea level. It is on the railway running south from Manila through Naga. Pop. (1939) 31,005, of whom 15,339 were males, and 8 were whites. The soil of the surrounding country is fertile and produces a great variety of crops, palay (rice), maize (corn), sugar, pepper, cacao, cotton, abaci (Manila hemp), tobacco and copra. The near-by forests also contain valuable hardwood. Bikol is the vernacular. (C. S. L.)

IRIS, in Greek mythology, daughter of Thaumas and the ocean nymph Electra (according to Hesiod), the personification of *the rainbow and* messenger *of the* gods; as *a* messenger of the gods, she is mentioned frequently in the Iliad, but never in the Odyssey, where Hermes takes her place. She is in Homer the messenger of both Zeus and Hera, but later the servant of Hera. By command of Zeus she carries in a ewer water from the Styx. with which she puts to sleep all gods who perjure themselves. Her attributes are the caduceus (herald's staff) and a vase.

IRIS, a large genus of popular herbs of the family Iridaceae much grown for ornament. They have a petaloid six-parted perianth, an inferior ovary and only three stamens (the outer series). being thus distinguished from the Amaryllidaceae family, which has six stamens. They are handsome showy-flowered plants, the Greek name having been applied on account of the hues of the flowers. The genus contains about 200 species widely distributed throughout the north temperate zone. The Eurasian I. *pseudacorus,* the yellow flag or iris, is common in Britain on river-banks and in marshes and ditches. It is called the "water-flag" or "bastard floure de-luce" by Gerard; its flowers appear in June and July, and are of a bright golden-yellow colour. **I.** *foetidissima,* the fetid iris, gladdon or roast-beef plant, the Xyris or stinking gladdon of Gerard, is a native of England south of Durham and also of Ireland, southern Europe and North Africa. Its bruised foliage is fetid.

IRIS

In North America there are about 20 native species, found chiefly in the eastern United States; among the best known are the blue flag (I. *versicolor*) which grows in wet places from Newfoundland to Manitoba and southward to Florida and Arkansas, and the western blue flag (I. *missouriensis*), native to wet soils from North Dakota and New Mexico westward to California and British Columbia.

Iris florentina, with white or pale-blue flowers, is a native of the south of Europe, and is the chief source of the violet-scented orris root used in perfumery. Iris pallida and its relatives appear to be the origin of "the most common purple Fleur de Luce" of Ray, the large common blue iris of gardens, the bearded iris or fleur de luce and probably the Illyrian iris of the ancients. **I.** pallida and **I.** *variegata* are also the parents of the so-called German iris, better known as tall bearded iris. The garden plants known as the Spanish iris and the English iris are both of Spanish origin and have very showy flowers. Along with some other species, as *I. reticulata* and **I.** persica, both of which are fragrant, they are great favourites with florists. All these just mentioned differ from those formerly named in the nature of the underground stem, which forms a bulb and not a strict creeping rhizome as in I. *pseudacorus, pallida,* florentina, etc.

For many centuries, probably long antedating the culture of any of the above species, Japanese horticulturists were hybridizing what are today known as Japanese iris. Hundreds of named forms in a variety of colours are perhaps the showiest of all garden irises. They appear to be derived from **I.** *kaempferi* or its allies, a plant with a creeping rootstock, long leaves, and, in the cultivated forms, very large flowers (6 in. across in some varieties). The original species, which is wild in eastern Asia, was in ancient times developed by Japanese families or guilds, some of whom produced identical varieties, but applied their own names to them. Today the hundreds of named forms are hence in much confusion, but the following appear to be reasonably accurate: Gold Bound and Morning Mists (white); Blue Danube and Blue Jay (blue); Pink Progress (pink) and Mahogany and Orion (reddish purple). Most Japanese vernacular names are hopelessly confused. The iris flower is of interest as an example of the relation between its shape and its insect visitors, *which* appear to pre-

vent self-pollination and ensure cross-pollination. The flower parts are so ingeniously arranged that an insect bearing pollen from one flower will in entering a second deposit the pollen on the stigma, while in backing out of a flower the pollen which it bears will not be rubbed off on the stigma of the same flower.

There are large collections of iris at Washington, D.C., and the American Iris society has published a catalogue comprising thousands of varietal names. (N. TR.)

IRISH, the Celtic language of Ireland (*q.v.*), also called Erse. Old Irish (700–1100) contains a wealth of inflectional forms in declension and conjugation. Many of the forms, however, disappeared early. An interesting rule of vocalic harmony (slender to slender and broad to broad) is recorded. In Irish final syllables in general disappear except long vowels followed by *s* or *r* and *u/o* preceded by i. There were difficulties due to the insufficiency of symbols, and it is possible that popular speech moved rapidly ahead of the written language in phonetic developments. In Middle Irish the declensions and conjugations were much simplified. The neuter gender disappeared. In several respects the verbal system is developed as compared with the old Irish forms, details of which are given in standard grammars. Dialectical variations must have existed from early times, and while Leinster Irish has disappeared, there are still peculiarities distinguishing the Irish of Munster, Connaught and Ulster, the south being more conservative than the north. In the early period a number of loan words appear from Latin connected with the church or with articles of civilization. There are some of Norse origin. In the Middle Irish periods many French words were accepted. English provided a large number of words.

IRISH FREE STATE (SAORSTAT EIREANN). The Irish Free State, with the status of a British dominion, came officially into being on Jan, 15, 1922, when the Irish Peace Agreement, signed in London on Dec. 6, 1921, by the British and Irish delegations, already ratified by the British Parliament on Dec. 16, was adopted by a meeting of elected members of the parliament of Southern Ireland convened by Arthur Griffith. In 1923 the State was admitted a member of the League of Nations. It was composed of 26 of the counties and four of the county boroughs of Ireland. According to the census (1936) its area was 26,601 sq.mi. and its population was 2,968,420. The Irish Free State became Eire or Ireland according to the constitution which went into effect on Dec. 29. 1937. The constitution declares Eire to be a sovereign, independent and democratic state. The British crown is no longer recognized except for specifically authorized external affairs. Eire claims to be associated with the British empire but not a member of it.

The treaty which led to the creation of the Irish Free State was concluded by the British government with representalives of an Irish government, previously not recognized by Great Britain. From Jan. 1919, onwards, a large majority of the members of parliament elected for Irish constituencies had styled themselves DBil Eireann — the Assembly of Ireland — had declared the Irish republic in existence and had chosen a president and ministers. In May 1921, when elections were held under the Government of Ireland Act, 1920, Republican candidates were returned unopposed for all constituencies outside of Northern Ireland (except that of Dublin university) and for several constituencies in Northern Ireland. This, the second Dáil, met for the first time after the truce at the Dublin Mansion House on Aug. 16, 1921. All its members took the oath to the republic. Negotiations with Great Britain, at first conducted by E. de Valera, were resumed by a delegation headed by Arthur Griffith and Michael Collins. When the terms of the treaty were published on Dec. 6, 1921, de Valera announced his opposition. In the Dáil's debate, prolonged until Jan. 8, 1922, it was generally admitted that the country at large was for acceptance, but the treaty was accepted by the Dáil with a majority of only 64 to 57; and when de Valera resigned the presidency, Griffith was elected by only two votes.

The Provisional Government. — Under Article 17 of the treaty a provisional government was appointed at a meeting in which all members elected for constituencies in Southern Ireland were summoned Opponents of the treaty absented themselves. Eight men were named members of the Provisional government, Collins being chairman. Griffith remained outside it. So did General Mulcahy, who became minister for defense. In theory the army was still the army of the republic, and the Provisional government had no force at its dispcsal. The old constabulary was at once disbanded. Collins and his colleagues decided at once to form a new "Civic Guard," but it necessarily took time to organize, and its creators had decided in principle that it should be unarmed. British troops were rapidly evacuating the country. There was the Irish army, now largely in uniform; but it soon became clear that the army was a source of danger.

With the exception of Collins, only one man in the Provisional government, Prof. Eóin MacNeill, was widely known in Ireland. Of the others, William Cosgrave, minister for local government, had been a prominent member of the Dublin corporation from 1913 on, and in 1917 was returned as a Sinn Féin member of parliament. Duggan had been one of the signatories to the treaty. The others, K. O'Higgins, J. Magrath, F. Lynch and P. J. Hogan, were still young men with their careers yet to come.

Collins, a man of immense resource and energy, sought to strengthen his position by the reunion of Ireland. Under the treaty, if Northern Ireland consented, all powers retained in that province by the parliament at Westminster would pass to the parliament of the Free State. Interviews with Sir James Craig (Lord Craigavon), the Ulster prime minister, were arranged. Settlement was desirable for North as well as South, since in Belfast there raged a murderous strife between Catholic and Protestant; but no accommodation proved possible. Both Griffith and Collins desired a general declaration from the country by an election. But the Republicans, knowing as well as they what the result would be, resisted this, and de Valera called instead, on Feb. 21, a convention of delegates of the whole Sinn Féin organization. At this meeting, Collins consented to delay the election.

Meanwhile, various acts of open disorder were committed in the name of the republic, which Collins, in hope of avoiding conflict, declined to punish. De Valera proclaimed at meetings that there was only one legitimate government in Ireland — that of the republic. The Republican party desired renewal of war with England, and their armed bands still moved uncontrolled.

It appeared from his public utterances that President Griffith desired drastic action; but Michael Collins, the head of the Provisional government, whose personal hold was stronger still, compromised, and on May 20 announced that he had reached agreement with de Valera. An election was to be held, but Free Staters and Republicans were to put forward a joint panel of candidates, so arranged as to reproduce the distribution of views in the existing Dáil. After the election a coalition ministry was to be formed, giving de Valera four seats in nine. The result of the election was not to be considered as a vote on the treaty. Appeal was made jointly that no other candidates be selected. But organized labour insisted on putting forward candidates, and other interests took courage to follow their example. Michael Collins, at Cork, publicly advised the people to vote as they chose. There resulted some appearance of a free election in some constituencies, where the polling took place on June 16. Thirty-four candidates not on the agreed panel were elected — all supporting the treaty. The Republican defeat was evident.

The doctrinaire Republicans refused to accept the authority of the third Dáil. They recognized only the republic they had fought to defend. As the new government had disavowed the republic, the Republicans claimed that the only legal authority in Ireland was the Republican remnant of the second Dáil, which also soon ceased to have any influence over the Irish Republican army.

Several aggressive actions by the mutinous section of the army then followed, and on June 22 Sir Henry Wilson was murdered in London by two Irishmen who had served in the British army. The British government made it clear that the Free State must act. A definite cause of action was afforded when the mutineers captured, in Dublin, the assistant chief of staff of the Free State army and held him as a hostage. On June 28 the Four Courts headquarters were summoned to surrender, and on refusal

PAINTED FOR THE ENCYCLOPÆDIA BRITANNICA BY ISABEL COOPER

TWELVE CULTIVATED VARIETIES OF IRIS'

The iris family (*Iridaceae*) comprises about *1,000* species and has representatives throughout the temperate and tropical regions. Besides the familiar irises the family includes many other plants cultivated for ornaments, as gladioli, freesias and crocuses

TALL BEARDED IRISES: **1.** Iris (*Plicata* type). 2. Iris (*Kochi*). **3.** Hybrid **Trojan** iris (*I. trojana* x). 4. Iris (Flavescens). 6. Iris (*Neglecta* type). **8.** Trojan iris (*I. trojana*). 9. Celeste iris. **11.** Yemen iris (I. *albicans*)

BULBOUS IRISES: 5. Purple Spanish iris (I. Xiphium). 7. Dutch iris (I. *Xiphium hybridum*). *10.* White Spanish iris (I. *Xiphium* var.). 12. Dutch iris (*Xiphium hybridum*)

siege was laid. After eight days' of localized fighting the struggle in Dublin was over. Rory O'Connor, who led the section in the army that demanded the right to be consulted on the terms of any settlement, was captured after he had blown up the Four Courts with all their records. De Valera, who had joined the insurgents, escaped.

Some districts of the country south and west were held by Republicans. The Government's army had neither a trained staff nor a system of supply. Five members of the Government took rank as generals, and Collins himself, flinging his whole energy into the struggle which he had so long sought to avoid, became commander-in-chief. But on Aug. 12 Arthur Griffith died suddenly. Ten days later, on the 22nd, Collins was killed in an ambush in the Co. Cork. Thus the task of establishing the Free State fell not to any man but to a group, the right wing of Sinn Féin.

Framing the Constitution.— It was necessary under the treaty that the third Dáil should as a provisional parliament frame a constitution which should also be adopted by the British Parliament before Dec. 6, 1922. On Sept. g it was possible to summon this body to meet in Leinster House, the premises of the Royal Dublin Society. In the adjacent College of Science the Government had established their offices. The block of buildings was placed under guard. None but carefully scrutinized representatives of the Press assisted at the nominally public debates. Under these conditions the Irish parliament and Irish government operated for nearly a year. Ministers lived as in a fortress.

At the Dáil's first meeting Cosgrave was elected president of the Irish Free State and he assumed the ministry of finance. Eleven ministers, proposed by him, were elected by the Dáil. The Dáil sat persistently to fulfil its task. The clauses of the constitution, which defined the relations between the Irish Free State and the British Crown and imperial defence, had been settled in discussion between Arthur Griffith and the British Government. Ministers had the task of persuading the Dáil to accept this limitation; they had also to put forward their own proposals for all that was left free.

The Restoration of **Public** Order.—By the end of Sept. 1923 at latest, there were no formed forces of the irregulars in the field, and all towns were held for the Government. Demand began to be heard for courts to which men could bring their cases. But the essential was to restore order. Property of all kinds was assailed. Whole bands of men in the name of the Republic were commandeering what they required. Much private robbery followed. More serious than all, the permanent land-hunger awoke.

Courts were long in being framed. The Civic Guard was being organized; but gunmen flouted, beat and in certain cases killed, members of this unarmed force. O'Higgins, minister for justice, however, stood resolutely to his principle: Ireland must be taught to regard the police, not as the agents of an outside power, but as its own servants, needing and deserving public assistance. The issue has justified his view; but for immediate purposes this body was useless. The Government on its side was driven, like the British, to enrol a large force of soldiers, which finally exceeded 50,000. This force, hastily levied, with officers as untrained as the men, did not always give satisfaction by its conduct.

Neither was Ireland, at the close of a movement extending over more than 40 years, easily able to support government in the face of terrorism; and terror was applied. The ministry was slow to counter this menace. Trial by jury was futile in such a state of things. The gaols were crammed with prisoners, untried and unpunished. Power to try and to punish most drastically by court-martial was given by an act of the Diil; yet till November fear of the irregulars was stronger than fear of the Government throughout the country. At last a proclamation was posted announcing that four men had been tried, convicted and executed—in each case for having a revolver without licence. In the following week seven men were sentenced, on the same charge, to long terms of penal servitude. Thus the right of Government to deal at its will with persons in arms against the State had been asserted. But the irregular campaign of wreckage went on. More executions followed, among them that of Erskine Childers, who had been the most powerful influence over de Valera. There was no improvement perceptible by Dec. 6, when the Irish Constitution was formally ratified by both parliaments.

FORMAL INAUGURATION

Ratification completed, Northern Ireland notified the British Government by address of both houses of Parliament, that exercising its right under Article 12 of the treaty, it refused to come under the Free State, and desired to retain its position created by the act. The Free State being now formally constituted as a "Dominion," sensation was created by the appointment (Dec. 1922) of T. M. Healy, K.C. as its first governor general. On Dec. 8, when the Dáil assembled to choose a senate, as provided by the Constitution, President Cosgrave announced that one member of the Diil had been shot dead and another wounded on the way to the meeting. Next morning four of the leading irregulars who were in prison were shot without trial by way of reprisal. Among them was Rory O'Connor. All these had been arrested long before the proclamation of martial law. General Mulcahy's justification was not given till some months later. when he pointed out that no other member of the Dail had been attacked. In fact, the counter-terror succeeded. The country might now be terrorized into silence by the irregulars, but it gave them no such willing support as it had given to the Irish Republican army. Information came, surreptitiously but steadily, to the Free State troops. Further, in Dublin, where courts were now in session, juries did their duty fearlessly.

In nominating one half of the members of the Senate, President Cosgrave made good the promise given by President Griffith to leading Irish Unionists that they should be generously treated; his nominations comprised several leading landlords and other prominent Protestants. The Senate when constituted chose as its chairman Lord Glenavy, who as Sir James Campbell had been Sir Edward Carson's chief lieutenant.

The gravest danger was that foreseen by Michael Collins when he pointed out that criminal folly might destroy "our belief in ourselves as a nation." There was an orgy of destruction, which almost paralysed communication by road and rail; houses were burnt or bombed by dozens, and the Government, once started on their path of severities, pursued it ruthlessly. By the end of January executions had risen to 50, and the prisoners to 10,000. No government could be popular under such conditions. Yet signs of weakening began to show. By May 1923, de Valera called upon his followers to abandon hostilities and dump their arms in concealment. The sound of firing was no longer heard in the streets, and public meetings were once more held. When August brought the annual horse show, ministers were seen moving freely in the crowd. The resumption of normal civic life may be dated from this time.

In April the Free State, still maintaining and collecting the British system of taxes, found it necessary to set up a customs system at the ports and along the Ulster border. The first object was merely ascertainment of revenue, but the machinery for a protective tariff existed. In June the minister for agriculture introduced a measure for the completion of land purchase, and this was carried through hastily. The third Dáil, which had passed the constitution, still existed, but a general election on the new register with adult suffrage was fixed for the last days of August, The Government's action had exposed it to much odium. Some 10,000 prisoners were detained in gaol, mostly untried, and over 70 men had been executed. Yet President Cosgrave, Mr. O'Higgins and General Mulcahy were returned by huge majorities at the head of the group in which they stood. But de Valera also headed the poll in County Clare and the Republicans returned no less than 44 members out of 128. Government had in its own following less than half the Dáil. But the various groups of Independents were notably increased. All these supported the treaty and the constitution.

The New Government. — Ireland's accession to her new status was practically signified on Sept. 10, 1923, when her representatives took their place with acclamation in the Council of the

League of Nations. A month later Cosgrave attended the Dominion Conference in London, where he was warmly welcomed. At home the executive council was for the first time constituted, consisting of seven. Four other ministers were chosen as "extern," having individual, not collective, responsibility. Ernest Blythe, who now became minister for finance, had at once to face a serious situation. It had become clear that the State would not be destroyed by violence—there was fear lest it should be bankrupt. Civil war had produced damages, then reckoned at £50,000,000, though, when compensation came to be paid, the bill reduced itself to about ten. But the army was costing over £14,000,000 a year, and taxation stood at the peak point to which Great Britain had raised it. In December the Government came to the country for a loan of £10,000,000 at 5%—the issue figure being 95, repayable at par in 20 years. It was oversubscribed in ten days, the subscribers numbering over 22,000. This demonstration of confidence greatly cheered the country, and rounded off the satisfaction felt in comparing the settled order of Christmas 1923, with the ruinous anarchy in which the year opened.

Yet the year 1924 was a very unhappy period. Organized resistance to the State was withdrawn, but de Valera's followers refused to surrender or hand in their arms. There was much crime, especially robbery with violence. The army, so rapidly raised, was reduced, for motives of economy, with equal rapidity, and men were suddenly thrown out of employment. A bad harvest in 1923 had left acute financial depression, and work was scarce.

Legislation.—Added to this was the unpopularity of the Government's measures. Blythe reduced old age pensions from ten shillings to nine shillings. Taxation was severely levied; tenants in default with their land purchase annuities were forced to pay up; citizens who had withheld their income tax during the last years of the British administration, with Sinn Fein's approval, were now called upon for their arrears. More widely felt was the innovation of a customs barrier, causing delay in the delivery of goods; and, in addition, Blythe decided to embark experimentally on a measure of protection, its main feature being a duty of 15% on imported boots.

In framing the new judicial system, the number of judges and their salaries were reduced, the office of lord chancellor disappeared; a supreme court was constituted, and a high court, both sitting in Dublin. High court judges no longer went on circuit; a new order of circuit judges was instituted. As regards the magistracy, unpaid justices of the peace were abolished, and stipendiary district justices were appointed to cover the whole country.

Judges of the previous régime were free to retire on rather more than four-fifths of their salary, and most of them did so. In making the new appointments the Government showed a fine disregard of political record, and totally ignored religious differences. By 1925, five out of the nine high court judges were Protestants, and several had been strong Unionists. The effect of this was to confirm the allegiance already promised by the minority in the Free State; and leading members of it, notably divines of the Church of Ireland and of the Presbyterian Church, offered testimony to the impartiality of the Government.

People were forced to see that no alternative to it existed, and ministers showed little disposition to win support by conciliating public feeling. O'Higgins forced on a drastic bill to restrict the facilities for buying and selling drink; Burke, the new minister for local government, by simple administrative act suppressed the corporations of Dublin and Cork and put civic affairs into the hands of commissioners; and presently, when the commissioners produced improved administration and reduced the inordinate rates, this experiment was approved. Outside the towns, the ministry abolished district councils, thus throwing more work on the county councils. A tendency to centralization and even to bureaucratic administration showed itself in all directions.

Such a policy made enemies everywhere, and the weather was no friend to Cosgrave. A second bad season in 1924 hit the farmers hard, and Blythe was still levying taxes that were now actually higher than the British scale; for the reduction of income tax from 5s. to 4s.6d. in 1924 was not followed in the Free State. The new postmaster greatly cut down the public facilities, and kept the stamp at twopence. If there had been any alternative ministry the Government would have fallen, but there was none: and the bellicose protestations of Republicans kept them in power. Another thing assisted them: when a turn in English politics replaced a Labour Ministry by a strong Tory Government, English ministers kept faith absolutely with Ireland.

BOUNDARY TROUBLES

The Boundary Commission.—No step had been taken until 1924 to give effect to the provision in Article 12 of the treaty under which, if Northern Ireland decided to remain outside the Free State a commission of three was to be appointed to "determine in accordance with the wishes of the inhabitants, so far as may be compatible with economic and geographical considerations, the boundaries between Northern Ireland and the rest of Ireland." But with the cessation of civil war Cosgrave's Government was pressed to demand its application. Immediately threats came from Ulster of resistance by force to the cession of a single inch of territory. Ramsay MacDonald attempted to settle the matter by private negotiations, but this failed. The Free State named Prof. MacNeill as their representative on the commission, but Northern Ireland refused to recognize the commission in any way. MacDonald appointed Justice Feetham, a South African judge, as chairman, but Northern Ireland contended that its own refusal to appoint a representative would make the constitution of the commission void. The difficulty was referred by the Labour Government to the judicial committee of the Privy Council, which found that without a new act of Parliament enabling the Imperial Government to appoint a commissioner to represent Northern Ireland nothing could be done.

Parliament was summoned on Sept. 30 instead of on Oct. 28, as had been originally intended, in order to pass through its stages the Irish Free State (Confirmation of Agreement) bill, which had been introduced by the Government at the end of the session. The defeat of the Labour Government on another issue was not allowed to prejudice the Irish settlement, and just before the dissolution the bill received the royal assent. A well known publicist, from Ulster, was appointed; and the commissioners, after long preliminaries in London, proceeded to investigate opinion on the border itself during several months in 1925 without the least disturbance. In the meanwhile, from many quarters, but notably from Cosgrave and his ministers, came utterances to the effect that there was no intention of coercing Ulster. She must choose her own time for uniting, if she chose, with the rest of Ireland. This indicated a departure from the expectations held out by Michael Collins after the treaty was signed, for he had led Ireland to hope that the commission's award would transfer so much territory to the Free State that Northern Ireland would not be able to maintain its separate status.

At the opening of 1925 Blythe's budget of April marked the beginning of normal finance. It soon became apparent that the ministry was not proposing a mere negative policy of economy, and early in 1925 they committed themselves to a project for utilizing the Shannon (see SHANNON) for a considerable electric power scheme. Nor did this stand alone. By promise of a subsidy amounting to a total of over £1,000,000 a Belgian firm was induced to start the sugar beet industry on a large scale, Carlow being chosen as the site for the central factory. Simultaneously came a whole group of proposals for the development of Irish industry and Irish agriculture, which had been interminably discussed in and out of Parliament during the British régime. They stood committed to a policy of industrial development, having as the pivot of the whole an enterprise so colossal that its possibility had never even been seriously considered under the old order. In the meantime tranquillity returned to the country so completely that it seemed dull. Tourists refilled their old haunts in summer; the Dublin Horse Show enlarged its scope.

The Ulster Boundary Crisis.—In the late autumn a new crisis threatened the Government's prestige and even existence. The report of the boundary commission was awaited without emotion, though a London newspaper published a forecast of its decision differing widely from any anticipations that had been formed

in the Free State. There was a fierce outcry, and President Cosgrave reiterated the Free State's contention that the commission was only entitled to transfer to their natural destination those parts of the six counties whose inhabitants desired to be in the general body of Ireland. These declarations were followed by the announcement that the Free State iepresentative had withdrawn from the commission. Prof. MacNeill followed this up by resigning his post on the executive council.

Both the Government and Prof. MacNeill were attacked with great violence in the DBil and outside it. The Republican leader came into new prominence. Cosgrave refused to commit himself publicly to any line of action, and went to London, where negotiations proceeded. Sir James Craig was summoned from Ulster; and on Dec. 3, a new agreement was concluded, to which not only Great Britain and the Free State were parties, but Northern Ireland also. It was agreed that the award of the commission should not be published and that the existing boundary should stand. This gave to Ulster all that Ulster claimed, but it gave to Ireland the repose of finality. Further, the treaty was aitered by the cancellation of Article 5, under which Ireland assumed liability for rhe public debt of the United Kingdom as existing in 1921 "in such proportion as may be fair and equitable, having regard to any just claims on the part of Ireland by way of set off on counter claims." This at once liberated the Irish exchequer from an undefined, hanging liability injurious to its borrowing power. Ireland, however, undertook to repay to Great Britain compensation already paid for war damages in the period 1919–21, and to add 10% to the compensation awarded to claimants for damages suffered in the civil war from 1922 on. The total cost to Ireland was estimated at under £5,000,000.

Legislation embodying the terms of this agreement was carried without difficulty in Great Britain, and the Northern Parliament expressed its satisfaction. But in the Dáil President Cosgrave was angrily opposed by the Labour Party and by some of his own followers, and after much talk the bill was carried by 71 to 20. Business men as a whole regarded the issue as fortunate for Ireland, which now definitely became a country with a total national debt of under £20,000,000 and less than a year's gross revenue. Other sections found their chief satisfaction, as did President Cosgrave, in the changed relation of the governments concerned. An immediate consequence was the disbandment of the Ulster special police in two of its three branches.

The Imperial Conference.— Freed from these long-standing anxieties, the fourth DBil made steady progress with the work of reorganization, and extended the foundations of further economic development. In the spring of 1926 questions of external affairs and imperial relations occupied considerable attention. The Free State's membership of the League of Nations had brought definite responsibilities for the prevention of future wars; and the approach of the Imperial Conference turned the attention of the Government towards a fuller insistence upon the international rights of the Free State. A conflict over appeals from the Irish courts to the Privy Council, the position of the governor general, the question of passports for Irish citizens in foreign countries, and other questions affecting the international status of the Free State, were vigorously canvassed before the Imperial Conference met in the autumn. When the conference assembled, Kevin O'Higgins, who had already assumed a more prominent part in the representation of the Free State at the League of Nations, quickly became one of its most important figures. His insistence upon a fuller definition of the rights inherent in dominion status found strong support among some of the other dominions, and had a profound influence upon the decisions which the conference reached.

GOVERNMENTAL PROGRESS

Reconstruction.— By the spring of 1927 the Dáil could look back upon four years of solidly constructive work as the general elections approached. McGilligan, in introducing the Electricity Supply bill, reported very satisfactory progress with the Shannon scheme. Hogan was able to report an immense improvement in the prospects of Irish trade owing to the Government's enforcement of an official grading of exported butter and eggs; and he introduced a bold measure for giving long term credits to farmers to supplement the facilities offered by the banks. Blythe's budget for 1927 announced that the Government now felt it safe to reduce the estimate of normal army expenditure by £500,000; and with the assistance of certain economies he was thus able to lower the income tax to below the English level, at 3s. in the pound.

Within four years nearly 200 acts had been passed by the fourth Dáil, and the foundations of the new State had been laid, while all the compensation claims arising before the Anglo-Irish truce had been dealt with, and only 400 out of some 20,000 subsequent claims still remained. Members of all parties gave expression to their sense of a new comradeship acquired during the work of the Dáil and congratulated each other on the rapid growth of a parliamentary tradition which had produced new feelings of mutual respect and confidence.

At the elections held in June the strong desire for a change of government after the first trying years of the new State was clearly manifest. The smaller parties which criticized the Government on various grounds gained in strength, and Cosgrave came back at the head of a party of 45 instead of 57, unable to command a majority in the Dáil. No other party, however, found itself able to form a government, and Cosgrave consented to resume office on the clear understanding that he would pursue his own programme until the other parties agreed to defeat his ministry.

Murder of Kevin **O'Higgins.**—Then, to the consternation of the whole country, on July 10, Kevin O'Higgins, the vice-president of the executive council, was assassinated outside his house near Dublin. The Republicans immediately disclaimed responsibility for, or sympathy with, his murder, but Cosgrave expressed the popular indignation and horror by denouncing it as a deliberate attack upon the State. The Government, unable to trace the authorship of the crime, sought drastic powers by the new Public Safety Act, which proclaimed all revolutionary societies as being treasonable and gave powers to arrest or deport suspected persons, in addition to introducing the death penalty for any treasonable offence.

Holding the Republicans responsible for having encouraged acts of murder, the Government also introduced a bill designed to force the Republican deputies to enter the Dáil, by prescribing an oath of willingness to enter the Dáil and also the oath of allegiance to the Constitution, for every candidate at future parliamentary elections. De Valera exhausted every effort to defeat the passage of the bill, and finally, in despair, consented to lead his party into the DBil at once. They agreed at last to take the oath of allegiance, while proclaiming in advance that they all regarded it as an "empty formula" which would not bind their actions in any way. An agreement was quickly reached with the Labour Party and with Capt. Redmond's National League to outvote the Government on a motion of no confidence, on the understanding that Johnson was to assume office with the support of the Republicans. When the motion was debated on Aug. 16, it was anticipated that Cosgrave would be in a minority of one, but the disappearance of Alderman Jinks at the last moment enabled the Speaker to save the Ministry by his casting vote.

In such circumstances a second general election was obviously inevitable. Cosgrave awaited the results of two by-elections in Dublin, which both gave him large majorities, and then suddenly announced a dissolution before any party could prepare for an election or replenish its funds. The election resulted in a drastic reduction of the smaller parties, Cosgrave winning many seats from the Farmers' Party and the National League, and de Valera many more from the Labour Party. The sixth DBil assembled on Oct, 11, with Cosgrave's party of 61 still in a minority of the Dáil, and with the Republicans' strength increased to 57.

The Sixth **Dáil.**—But with the support of the Farmers' Party and the Independents, against a combination of Republicans, Labour Party and National League, Cosgrave could count on a safe majority of six votes, and he did not hesitate to accept office. On the first division in the Dáil the Labour Party voted with the Government, and a little later de Valera's effort to repeal the Public Safety Act was defeated by a majority of six. The first

serious business of the government was to float a new loan of £7,000,000 at the same price of issue as before. The general belief that de Valera's accession to office would shake public credit had been the chief deterrent to a change of government; which in spite of all that Cosgrave's ministry had accomplished, had long been desired, in view of the widespread unpopularity that the government had inevitably incurred by its vigorous enforcement of the law and its policy of drastic retrenchment. For the first time the Dáil now included all its elected deputies, and contained an alternative government in the Republicans, now at last ready to participate directly in the development of the Free State, and pledged to do so on constitutional lines. (S. G.; D. G.)

The Depression. — The Cosgrave government followed a policy of accepting the Free State's position within the British commonwealth. At home its policy favoured the middle-class and the farmer. Its tariff policy was extremely moderate and it made serious attempts to effect economies in government. Cosgrave's party, however, was not well organized. Because of de Valera's earlier abstention from the Dáil, Cosgrave's government had been able to carry out necessary policies without much concern about their political effect.

Fianna Fail's entrance into the Dáil gave the country the opportunity of picking an alternative government.

The depression's effects were not especially noticeable in Ireland until 1930. Then Ireland began to be affected, especially because of its close economic ties with Great Britain. Unemployment and lower farm and cattle prices created considerable discontent. The Irish Republican army began to be active again. A series of terroristic outrages and cowardly shootings, though generally deplored, were not punished. In Oct. 1931 the Cosgrave government put through an amendment to the constitution, article 2(a). This article established a tribunal of five military men to deal with political crime. The certification of an executive minister would bring a case before the tribunal which could perform all the functions of justice. The article also gave the police extensive powers of arrest and made an order of the executive council that an association was unlawful, conclusive evidence of its illegality. It was enforced by the Cosgrave government but allowed to lapse by de Valera who had criticized it when it was proposed.

Elections to the seventh Dáil were held in Feb. 1932. Cumann na nGaedheal (Cosgrave's party) and its supporters lost several seats so that de Valera with the support of the Labour party assumed control of the government. Among the reasons for the defeat of Cosgrave were: the accumulated unpopularity of ten years' power; the depression; de Valera's promises of extensive social services; and a number of political blunders made just before the election, such as the reduction of the salaries of some civil servants and legal action against a correspondent of de Valera's *Irish* Press.

In June 1932 the 31st Eucharistic congress took place at Dublin. A million people, many of them Irish from other lands, attended this demonstration of faith.

Meanwhile de Valera's program of abolishing the oath of allegiance to the king and of withholding the land annuities strained Anglo-Irish relations. The dominion status of the Irish Free State certainly permitted abolition of the oath, but it was difficult to see how it could do so and remain in the British empire. More serious consequences derived from the withholding of the land annuities which were due to English investors through the British government for money advanced to Irish farmers for the purchase of lands. De Valera claimed that the annuities, £5,000,000 a year, had been cancelled by the Government of Ireland Act of 1920. This act had been resisted at the time and another agreement about the annuities was made by Britain and the Cosgrave government in 1926. De Valera refused to recognize it since it had not been submitted to the Dáil.

The British government with James H. Thomas, dominions secretary, as spokesman, imposed tariffs on Irish cattle and farm produce. These duties aimed to collect the equivalent of the annuities. De Valera took advantage of these duties to retaliate and to embark upon a program of economic self-sufficiency. He had no illusions about making Ireland wealthy but hoped to encourage agriculture and especially small farms while abetting many diversified and decentralized industries. These would relieve the Irish of their dependence on imports, create a market for the Irish farmer, and provide opportunities for those who normally would have emigrated from the Free State. British tariffs hurt the important Irish cattle trade, the Danes and the dominions began to take over the Irish market in Britain, the Free State's revenue declined, the Irish farmer's prices declined, and yet the government continued to collect the annuities it was withholding from Britain. The Free State government attempted to help the Irish farmer by grants of subsidies. Although represented at the Ottawa conference in 1932, its economic war with Britain prevented it from obtaining any benefits. Early efforts at settling the dispute came to nothing since the British government refused to accept an arbitration tribunal whose personnel would be drawn outside of the empire and since de Valera, instead of narrowing the dispute, continued to bring up more difficulties.

In Sept. 1932 de Valera made an impressively honest and critical speech as president of the council of the League of Nations.

The Dáil was dissolved Jan. 1933 and elections to the eighth Dáil were held before the government's opponents had been able to consolidate. De Valera continued to receive the support of ardent nationalists, of the small farmers and the lower classes generally. He made special appeals to them in the offer of social services. The elections gave Fianna Fail 77 seats as compared with 70 in the previous Dáil. But since its majority was only one, it was still dependent on the Labour party.

In 1933 there was a railway strike which lasted ten weeks. Meanwhile the I.R.A. carried on its campaign of violence. De Valera had vainly hoped that the removal of the oath of allegiance would bring the Republicans to accept the government and to take a part in politics. Another disturbing factor was the appearance and spread of communism, especially in the I.R.A. This provoked a reaction, for the Army Comrades association, which became the national guard, adopted an anti-communist program. The national guard chose as its leader Gen. Eoin O'Duffy, who had been removed by de Valera from the command of the civic guard after the I.R.A. had demanded his dismissal. The general subsequently headed a union of opposition forces, the United Ireland party. Under the influence of the papal encyclicals there was a good deal of talk about a corporative state. Gen. O'Duffy also headed a section of the United Ireland party, the Blue Shirts, who later became the Young Ireland association, and finally a fascist organization. The government was so disturbed by the national guard that it revived the military tribunal under article 2 (a), and declared the national guard an illegal organization. But as it was a part of the constitutional opposition —the United Ireland party—this was difficult to maintain. Some court proceedings were begun against Gen. O'Duffy. Although the government suppressed the paper of the Republican movement it did not declare the I.R.A. an illegal organization until 1936.

O'Duffy was not a successful politician. The opposition failed to prosper. Indeed, much of its program was remarkably similar to de Valera's. The general's indiscretions led to a breakup of the United Ireland party. O'Duffy became openly fascist and led a group of Irish volunteers to fight for Francisco Franco.

Irish and English trade suffered as the economic war continued. About one-half of Ireland's imports came from Britain, and it sold more than 90% of its exports to Britain. Self-sufficiency and the trade war did not alter the percentages. But the government continued to urge and protect new industries, preferably controlled by Irish capital. It undertook an ambitious housing scheme and because of its reliance on the Labour party continued to extend its social services.

Appeals to the British privy council were forbidden. The governor-general's office was first restricted and then abolished. Finally the senate was also done away with. De Valera had resented its opposition to many of his anti-British policies. But there had been much criticism of the senate as a purely political

body. It was hoped that the senate would be replaced by some vocational representative body.

The abdication of Edward VIII occurred at the very time when de Valera was proposing the new constitution. He expressed his aim: "We propose to bring in a constitution as if there were no relationship with the states of the British commonwealth." The Irish Free State therefore did not request the imperial parliament under the terms of the Statute of Westminster to enact a statute of abdication. Later the Dáil passed a bill which accepted the abdication. It further authorized George VI to act as symbol of co-operation in the empire for the Free State as and when the Free State executive council advised him.

The new constitution (see ***The*** Constitution of Eire) sought to make more systematic the changes just previously effected. It did not declare a republic but changed the name of the government to Eire (Ireland), placing reliance upon the national appeal of the name. The constitution was ratified in a plebiscite held concurrently with the elections of 1937. It went into effect Dec. 29,1937.

EIRE

The new constitution called for a Dáil eiecred by proportional representation, and a vocational senate also elected by proportional representation. The leader of the majority party was to become the prime minister and the governor-general's position was to be occupied by the president, who wculd be the nominal head of the state. De Valera became prime minister and the Gaelic scholar Dr. Douglas Hyde, a Protestant, became president. His selection was uncontested and was regarded as a most happy one.

In the Italo-Ethiopian war de Valera supported sanctions, and in other public utterances criticized the weaknesses of the league. During the Spanish Civil War he ardently supported the nonintervention fiasco. In Feb. 1937 the Dáil passed a bill forbidding Irish volunteers to go to Spain. Later the government showed great concern about a future war. De Valera himself said that Eire would have trouble in remaining neutral because of its economic dependence on Britain. His plea for peace was based on the familiar argument that war would achieve nothing permanent and that it would be well to have a peace conference before the war rather than after it. This attitude coincided with the appeasement policy of Neville Chamberlain.

The Agreements of 1938.—Eire's own economic needs and Britain's realization of the importance of Irish friendship and food in a war prepared the way for an end of the economic war and other questions. In Dec. 1937 the British foreign office defined the attitude of the British and dominion governments to the new constitution: "They are prepared to treat the new constitution as not affecting a fundamental alteration in the position of the Irish Free State." Conversations between the two governments were held from Jan. to April 1938. The questions were settled in three agreements on April 25, 1938. Their scope was far greater than had been anticipated. The preamble to them explained that the two governments had entered into agreements for promoting friendly relations, for a final settlement of all financial claims and to facilitate trade between the two countries.

I. *The Naval* Bases.—Article 6 of the treaty of 1921 provided that until arrangements were made between the two governments whereby the Free State would undertake its own coastal defense, "the defence by sea of Great Britain and Ireland should be undertaken by the imperial forces." As the Free State (Eire) could not provide a navy, this was common sense. But Eire now promised to attempt its own defense. This was criticized by both the Cosgrave party and the Republicans as assuming an unnecessary burden.

Article 7 of the treaty of 1921 afforded certain harbours and other facilities to the imperial forces. In time of war or strained relations with a foreign power the Free State government undertook to grant other facilities which the imperial forces might require. These concessions meant that even aside from partition, Eire did not enjoy territorial integrity for British garrisons occupied the naval bases of Cobh, Bere Haven and Lough Swilly. In time of war they would pass under British military rule, along with the surrounding country. If Eire remained neutral in the war, this created tremendous problems. At best the relations of British and Irish would have been strained. The Chamberlain government determined to depend on Eire's friendship.

The agreement provided that before Dec. 31, 1938, the United Kingdom would transfer to Eire the admiralty property and rights at Bere Haven and the harbour defenses there and at Cobh and Lough Swilly. This treaty was carried out despite the serious opposition of Winston Churchill, who argued then and later as prime minister, that the relinquishing of the naval bases placed a grievous burden on the British navy.

II. The Annuities.—A second agreement provided that Eire should pay £10,000,000 to the British government before the end of Nov. 1938. This was to be a final settlement of all financial claims of either of the governments up to the time of the agreement. A payment for damages to British property agreed upon in 1925 was excepted from the agreement. It also provided for the abolition of the speciai duties imposed by the United Kingdom in 1932 to collect the equivalent of the withheld annuities.

III. The Trade War.—In 1932 the United Kingdom levied special duties of 20% ad valorem (later raised as high as 40%) on all the chief British imports from Ireland, except beer. Cattle, horses, butter, eggs, bacon, pork, poultry and game fell under these duties. No imperial preference was given to Ireland. Serious quota restrictions were imposed on Irish farm produce from Jan. I, 1934. At first the duties were meant to raise the annuities money. But they were extended as part of England's new protective policy and as retaliation for Irish duties.

The Irish Free State retaliated and pursued de Valera's self-sufficiency policy by high tariffs on British coal, iron, steel goods, sugar and cement. In 1931 the Irish tariff had only 68 items. In Oct. 1936 it had 288 items, many as high as 40% ad valorem and some reaching 100%. The withheld annuities payments were used to pay export subsidies. Sugar factories were set up. Wheat acreage increased so that while in 1933–34 Irish wheat production furnished but 10% of home needs, in 1935–36 it furnished 33⅓%.

The trade war was modified by coal-cattle pacts in Jan. 1935, Feb. 1936 and Feb. 1937. These provided that the Free State reduce duties on British coal and some other duties and controls over imports from Britain which in return relaxed duties and restrictive quotas on Irish cattle.

The agreement of April 1938 was to go into effect as soon as the necessary legislation could be passed, and to remain in force for three years, subject thereafter to termination on six months' notice [it has not yet (1943) been terminated]. It provided for the admission into the United Kingdom of goods from Eire free of other than revenue duties. Some provisions were made about regulation of the quantities of agricultural imports. In return Eire was to continue free entry for such British goods as then enjoyed that privilege, to continue tariff preferences to British goods, to review existing protective tariffs, and to reduce the duties on certain British products.

World War II.—Eire proclaimed its neutrality quickly after the outbreak of World War II. In Sept. 1939 the government was given emergency powers, and carried out its policy of neutrality into an extensive news censorship (added to a repressive literary censorship) to avoid giving offense to the nazis. No newsreel pictures of the war were shown in Eire. But the neutrality policy had the support of most of the nation. Only one member of the Dáil called for Irish participation in the war. The Catholic hierarchy often called for a negotiated peace and pointed to the danger of a communist victory.

Co-operation in volunteer home defense forces brought forth a greater unity in Eire. Its sympathy for the U.S. did not affect its stand in the war. The entrance of the U.S. probably reinforced its neutrality. De Valera more than once declared the firm intention of Eire to defend itself against any attempt whatsoever to occupy the country.

Eire twice successfully protested against the extension of conscription to Northern Ireland. Nonetheless a considerable number of Irish were serving with the British. The closing down of Eire's

factories due to supply difficulties forced many Irish labourers, more than 50,000, to seek employment in England. Eire protested in Nov. 1939 against the extension of U.S. neutrality legislation to cover its waters. Supply difficulties were generally smoothed out between the English and Irish. But drastic rationing of gas, kerosene, tea, coal and even clothing was established. The Irish railways were reduced to the use of wood and were operating under great difficulties. This experience might have some effect on de Valera's desire for self-sufficiency.

In Jan. 1939 the I.R.A. began a terrorist campaign featured by placing bombs in public buildings in England. The following December its forces raided a Dublin arsenal and stole vast quantities of ammunition, most of which was later recovered. From Aug. 1940 on, Eire was bombed many times by German planes. The night bombings of Dublin in Jan. 1941 could hardly have been accidental, as Dublin was not blacked out. Eire protested the German bombings and attacks on Irish ships. The nazi government accepted some of the claims.

CONSTITUTION AND AMENDMENTS

The political status of the Irish Free State was that of a co-equal member of the community of nations forming the British commonwealth. It had a written constitution which rested on the provisions of an act passed by Dáil Eireann sitting as a constituent assembly in the autumn of 1922.

It was provided in this act that the constitution was to be construed with reference to the treaty between Great Britain and Ireland, and that if any provision of the constitution or of any amendment thereof or of any law made thereunder was in any respect repugnant to any of the provisions of the treaty, it would, to the extent of such repugnancy, be void and inoperative. It was also provided that to the extent to which they were not inconsistent with the constitution all laws in force in the Free State at the time of passing of the constitution were to continue to have full force and effect until repealed or amended by the Oireachtas.

In conformity with practice in the British Commonwealth the executive authority was vested in the king. The governor, general represented and fulfilled the functions of the crown. He was appointed "in like manner as the governor general of Canada and in accordance with the practice observed in the making of such appointments." His powers were strictly limited as in the case of the sovereign in Great Britain, all executive acts being done on the advice of the executive council. The latter consisted of not more than 12 nor less than five ministers, and was directly responsible to Dáil Eireann, retiring from office when it had lost the support of a majority of deputies.

The Dáil was to be dissolved only on the advice of the executive council. The maximum life of a parliament was six years. The president of the executive council, who was appointed on the nomination of Dáil Eireann, nominated the executive council. These had to be members of the Dáil.

The legislature (Oireachtas) consisted of the king and two houses, Dáil Eireann (the chamber of deputies) and Seanad Eireann (the Senate).

In the Oireachtas was vested "the sole and executive power of making laws for the peace, order and good government of the Irish Free State."

Seanad Eireann was composed of 60 members, the term of office of each member being 12 years. One-fourth of the members were elected every three years by proportional representation, the whole of the Free State forming one electoral area. Candidates had to be 35 years old but this was later amended to 30. They were nominated by the Dáil and the Seanad. A number of changes were made in the manner of electing the Seanad and in its powers. The senate opposed several of de Valera's policies. He moved for its abolition, which was accomplished in 1936, and called for the creation of a vocational second chamber.

Dáil Eireann was composed of 153 members directly elected by proportional representation. The two universities each elected three members. Until 1933 each member had to take the oath of allegiance to George V. The Dáil was elected by all citizens of both sexes who were over 21 and had complied with the electoral laws.

Seanad Eireann had no authority to amend a money bill. It could make recommendations regarding such a bill within 21 days after a bill certified to be a money bill had been passed by Dáil Eireann. The Seannd was able to reject or amend all other bills, and to initiate legislation. The Seanad's rejection delayed legislation for nine months (later changed to 18 months). There were

various provisions making possible a referendum on bills passed by the Dáil.

The Oireachtas had the exclusive right of raising and maintaining armed forces in the Free State. The treaty of 1921 regulated its size. The constitution guaranteed freedom of conscience and the free practice of religion, subject to public order and morality. Nor was there to be any endowment of religion. No discrimination could be made as respects state aid between schools under the management of different religious denominations.

The supreme court of the Free State was a court of final appeal. This was made more definite with the abolition of appeals to the privy council.

Amendment of the constitution was possible by ordinary legislation for eight years. In 1928 the time was extended. Various amendments were passed about the automatic return of the speaker, the increase of the Dáil's term, the increase of the membership of the executive council, and several amendments about the Senate. In 1927 the oath of allegiance and a declaration of willingness to sit in the Diil were prescribed for Dáil candidates. Various police and military trial amendments were made in reference to the I.R.A.

BIBLIOGRAPHY.—J. G. Swift McNeill, *Studies in the Constitution of the Irish Free State* (1925); L. Kohn, *The Constitution of the Irish Free State* (1932); N. Mansergh, *The Irish Free State* (1934).

The Constitution of Eire.—De Valera had opposed Ireland's Free State status. He had espoused Erskine Childers' proposal that Ireland as an independent nation should accept a form of external association with Britain. In pursuit of his goal. the Free State constitution which had been drafted in the difficult times of civil war was amended so that all references to the king and the governor-general were removed. To systematize the changes which had been made and to prepare a basis on which a republic could be proclaimed. a constitution was drawn up and approved in July 1937. Provision was made for the eventual extension of the constitution to all of Ireland.

The constitution shows three main influences: Irish nationalism (especially in the use of Gaelic names for the officers of government, in the name of the state Eire, Ireland, and in the naming of Irish as the first official language); English and Free State parliamentary traditions; and Catholic philosophy.

The preamble of the constitution invokes the Holy Trinity and acknowledging the dependence of the people of Eire, declares that the purpose of the constitution is the promotion of "the common good, with due observance of prudence, justice and charity, so that the dignity and freedom of the individual may be assured, true social order attained, the unity of our country restored, and concord established with other nations."

The constitution declares Eire to be a democratic state, sovereign and independent.

The head of the state is the president (Uachtaran na hEireann) who is elected for seven years by the direct vote of all citizens. Nominations are made by members of the Oireachtas or of the county councils. The president appoints the prime minister on the nomination of the Dáil, and on the nomination of the prime minister and with the previous approval of the DBil he appoints the other members of the government. He signs and promulgates laws. He can refer certain bills to the supreme court to test their constitutionality. He also has power to refer certain bills to a popular referendum upon petition of a prescribed percentage of the Dáil membership. He is supreme commander of the armed forces. The president is advised by a council of state consisting of former presidents, former and incumbent prime ministers and chief justices, as well as of others, some of whom he may name.

The parliament (Oireachtas) consists of the president and two houses. The house of representatives (Dáil Eireann) consists of 138 members elected by adult suffrage under a system of proportional representation. The government which consists of from 7 to 15 members is responsible to the DBil. The maximum term of the Dáil is seven years. The Dáil alone can initiate money bills, and the Seanad may only make recommendations on them. Seanad Eireann, an unsuccessful attempt to create a vocational chamber, is composed of 11 members nominated by the prime minister and 49 members who are elected by the Dáil and the county councils from panels representative of the universities, culture and education, agriculture, labour, industry and public administration and social services. The system of proportional representation is used in the election of a Seanad which has to take place within go days after a dissolution of the Dáil The Seanad cannot veto legislative proposals and has but 90 days for the consideration or amendment of bills passed by the Dáil.

The constitution recognizes the family as the unit of society with rights superior to all positive law. Divorce is practically forbidden. Private property is recognized as a natural right of man. But this and other personal rights may be limited by law out of consideration for the common good. No religious endowment is permitted.

An interesting feature of the constitution is the enumeration of directive principles of social policy. The courts may not take cognizance of them in determining the application of laws. The principles, intended for the guidance of the Oireachtas, include the right of every citizen to a decent livelihood, the establishment of families in economic security on the land, the regulation of credit and of the distribution of property in the interests of the common good.

For the first three years after its establishment the constitution was amendable by ordinary legislation. Thereafter a popular referendum was necessary to amend the constitution.

ECONOMIC AND FINANCIAL HISTORY

The area of Eire is 26,601 sq.mi. or 17,024,485 ac. In 1939 the distribution of this surface was as follows: crops and pasture, 11,606,235 ac.; woods and plantations, 257,944 ac.; other land, including grazed mountain land, 5,160,306 ac.

Population.— The last census of Ireland was taken in 1936. The population of Eire was 2,968,420. This was slightly less than the figure for 1926 and over 5% less than that for 1911.

In 1939 the number of marriages registered mas 15,192, being about 5.1 per 1,000 of the population; the number of births was 56,097, being about 18.9 per 1,000; and the number of deaths was 41,730, being about 13.8 per 1,000. While the death rate from tuberculosis decreased, the death rate from cancer and other causes increased. The relatively high death rate and continued emigration to the British empire resulted in the slight decline of Eire's population. The marriage rate of Eire is extremely low. Eire's population is overwhelmingly rural. The largest towns are Dublin, Kingstown, Cork, Waterford and Limerick. Waterford's population is only 27,000.

The vast majority of the people are English-speaking. The government has attempted to promote the Gaelic language. The enthusiasm for Gaelic was considerable during the struggle with Great Britain but slackened with the attainment of independence.

Agriculture to 1928.—The total acreage under crops on June 1, 1927, was 3,694,285.

There were 442,606 agricultural holdings, of which 86,033 were less than one acre, 223.991 above one and not exceeding 30 ac., 130,807 above 30 and not exceeding 500 ac. and 1,775 above 500 acres. Official figures show that the percentage of land plowed varied inversely with the size of the holding; that for equal areas of crops and pastures, the number of livestock (especially milch cows, pigs and poultry, and excepting sheep) rapidly increased as the size of the holding diminished; and that the larger the percentage of land tilled, the larger the number of animals supported.

The cultivation of cereal crops played a comparatively unimportant part in the agricultural economy of the Free State, and the bulk of the attention of the farmer was devoted to the raising of stock. As between the production of beef and of dairy produce, conditions vary in different parts of the country. In certain areas dairy breeds, in others beef breeds, are predominant. The type of cultivation favoured by the soil, climate and prevailing holding is extensive. In 1927 the percentage of the total area plowed was 12.7% as compared with 56.7 in Denmark, and the net value of agricultural exports per 1,000 ac. was £1,227 as compared with £4,939 in Denmark.

In accordance with detailed recommendations made by the commission which reported in 1924, an act was passed (No. 3j of 1924) providing for the testing, grading and packing of exported eggs, for the prohibition of the export of dirty or bad eggs, and for the registration of all premises where grading, packing or preserving is carried on. Another act (No 58 of 1924) made elaborate provision for the regulation of the butter trade. Butter can be exported only by registered creameries, factories or exporters, and must be packed and marked in a specified manner The most minute regulation of creameries and factories is insisted on, and provision is made for the establishment at a later date of a national mark or brand for creamery butter. A federation of co-operative creameries has been established with the aim of introducing a system of "orderly marketing" of butter, and the majority of the privately owned creameries have been purchased by the state and transferred to co-operative societies. The dairy industry has thus been rationalized The licensing of bulls was made compulsory by another statute (No. 3 of 1925) This measure, together with the government's scheme for providing premium bulls and boars and for subsidizing the purchase of pedigree rams, has resulted in levelling up the standard of the livestock in the country.

The government has set up an agricultural credit corporation designed to provide long-term loans for farmers and to co-ordinate the activities of the local co-operative credit societies. Other measures taken to develop agriculture are the increase of the grant in aid of agricultural rates, the provision of higher agricultural education in the National university and the undertaking of extensive arterial drainage.

Land Purchase. — The total amount of the purchase money for which advances have been made under the land purchase acts of 1870–1909 in respect of lands in the Free State is £99,800,000, the total area comprised in the sales being 11,290,000 acres. The land commission also advanced £3,796,000 to rural district councils for the erection of labourers' cottages under the labourers' acts.

The land act of 1923 aimed at attaining the dual object of completing land purchase and relieving congestion. This act provided for the creation of land bonds, bearing interest at the rate of 4½%, in which all payments to landlords and encumbrancers were to be made. These bonds were later guaranteed, as to principal and interest, by the British government. Advances made to purchasers were to be repaid by an annuity at the rate of 4¾% of the amount advanced, and the price to be paid was roughly equal to about 15 years' purchase of the value of the holding, of which the government contributed 10% in relief of the tenant. Very wide powers were given to the land commission to acquire untenanted land for the creation of holdings in relief of congestion, and to consolidate and exchange holdings with the same object.

The area of untenanted land already acquired by the land commission and the late congested districts board and utilized for the relief of congestion amounted to 860,000 acres. Advances were authorized to be made to tenants of uneconomic holdings, tenants exchanging their holdings, persons who had been evicted and labourers who had lost their employment through the progress of land purchase. The money required by the land commission for making roads, fences, drains, etc., and for the erection of buildings on newly created holdings was provided out of public funds, and so much as the land commission decided could be repaid by the purchasers was made repayable by them along with their purchase annuities.

All arrears of rent due before the first gale day of 1920 were remitted; but rent due after that date (subject to 25% reduction) was made recoverable.

It was estimated that advances amounting to £30,000,000 would be required to complete land purchase under the 1923 act. As regards tenanted land, holdings situated on 6,000 estates had to be dealt with, while as regards untenanted land, the land commission had inspected or was making inquiries in respect of 1,000,000 ac., with a view to their acquisition for the purpose of distribution; and of this area the land commission had acquired or entered into agreements for the acquisition of over 250,000 acres. Of the untenanted land acquired 130,000 ac. were already divided among allottees

Fisheries. — The work formerly done by the department of agriculture and the congested districts board in connection with fisheries and with rural industries has been transferred to a separate ministry, whose policy is to develop the deep-sea fisheries and to organize the home demand for fish, which is very small. The government is helping the fisheries by making loans for boats and gear, erecting and maintaining curing stations, and subsidizing fishery schools A brand for mackerel has been instituted. One urgent requirement, namely, a second patrol boat to keep the coast free from the numerous foreign trespassers who infested it, was being delayed for financial reasons. In 1927 the land commission was transferred to the ministry of fisheries.

Agriculture After 1928. — The self-sufficiency policy of de Valera's government and the trade war with England led to a greater diversity in Irish agriculture and to a slight lessening of Eire's dependence on exports of livestock. Notable changes have taken place in the growing of sugar beets and of wheat The blockade effects of World War II intensified the movement toward self-sufficiency. The government continued the policy of land purchases and division, and sponsored rural as well as urban housing.

A comparison of acreage under crops and numbers of livestock in 1926 and 1939 will illustrate some of these changes:

	1926	1939
Crops		
Wheat	29,386	255,280
Oats	647,407	536,749
Barley	141,009	73,784
Rye	6,645	1,728
Flax	6,802	4,123
Potatoes	374,771	317,169
Turnips	194,600	141,384
Mangolds	80,839	85,502
Sugarbeet	9,483	41,661
Cabbage	34,428	14,295
Hay	2,287,849	2,061,881
Livestock		
Cattle	3,947,249	4,057,338
Sheep	3,003,080	3,047,813
Pigs	884,216	930,907
Horses	424,304	445,148
Poultry	21,366,801	19,551,211

INDUSTRY AND TRADE TO 1928

Manufactures. — Ireland was, even before partition, an overwhelmingly agricultural country, but the predominance of agriculture became greater than ever after the exclusion of the six counties. The agricultural commission reckoned that three-quarters of the real wealth produced in the Free State was farm produce Too great dependence upon any one industry is always undesirable. and the government took steps to redress the unequal balance between the agricultural and manufacturing industries.

The treaty left the Free State at liberty to frame its tariff policy as it chose. There was a widespread popular belief that Irish industry could best be revived by the adoption of a high protective tariff, and the government appointed a small committee of economists to inquire into the probable effects of protective duties. The report of this committee was strongly free trade in tone. It pointed out the numerous factors, besides external competition, that operated to retard the growth of industry in Ireland. The necessity for a dominantly agricultural country of the lowest possible prices of raw material and consumable commodities was pointed out. Nevertheless the government proceeded to institute a number of experiments in protection.

On the setting up of the customs barrier in April 1923 the manufacture of tobacco automatically secured protection. The finance act of 1924 imposed a duty of 3⅝*d*. per lb. on sugar

confectionery, of 6d. per lb. on cocoa preparations, of 10% *ad valorem* on candles, 15% *ad valorem* on boots and shoes, 333% on glass bottles (not white glass) and 10% *ad valorem* on soap. The McKenna duties were altered so as to provide encouragement for the building of commercial motor bodies, and the imperial preference on manufactured tobacco was abolished, The finance act of 1925 went a good deal farther in the same direction, but the minister for finance declared that the new duties were purely experimental in nature. This act imposed a duty of 15% *ad valorem* on clothing, wearing apparel, blankets and blanketing, and 33⅓% on bedsteads and wooden furniture; the duty on bottles was extended, and an additional duty of 10% was put on toilet soaps.

In 1926 a duty of *2s.* 6d. per cwt. was imposed on imported oatmeal, and in 1927 duties of 333% on rosary beads and of *3d.* per lb. on margarine. All applications for protection were heard by a tariff commission composed of three civil servants representing respectively the ministries of finance, agriculture and industry and commerce.

This commission rejected the application for a duty on imported flour.

At the same time some important revenue duties were abolished or reduced. It would appear, however, from the cost of living index numbers that the result of the new tariff (in conjunction with other causes, such as a bad system of retail distribution) was to prevent the cost of living in the Free State from being reduced at the same rate as in Great Britain.

In addition to giving the protective assistance outlined above, the government endeavoured to encourage industry by means of subsidies, the development of cheap sources of power, and the provision of credit facilities.

The growth of sugar beet and the manufacture of beet sugar were encouraged by the grant of a subsidy payable for ten years to persons manufacturing in the Free State sugar from home-grown sugar beet. A large Belgian-Czechoslovakian group, encouraged by the subsidy, opened a sugar beet factory in Carlow. The result of the first year's working was successful beyond all expectations.

An important attempt is also being made to provide the Irish manufacturer with cheap power. The government sought the advice of Messrs. Siemens-Schuckert, who drew up a scheme for utilizing the great water power of the Shannon. Another method by which the government attempted to encourage industry was by helping enterprises to obtain capital on easy terms under the trade loans guarantee act (No. 41 of 1924). The maximum amount that might be advanced under government guarantee under the act was fixed at £750,000. The minister was further authorized to grant or to guarantee loans proposed to be raised by any public authority or any association of producers or consumers "calculated to promote a reduction in the retail prices in Saorstat Eireann of essential commodities." The maximum grant under this action was limited to £50,000, and the maximum grant and guarantee together to £250,000. By an amending act (No. 19 of 1925) the period in which this assistance might be rendered was extended; and the finance act of 1925 provided for the advance of £300,000 to the National Land bank for the purpose of trade loan guarantees.

An Industrial Trust company designed to provide long-term credits for manufacturers has been established, part of the capital being subscribed by the state.

Banking. — All the banks having their head offices in the Free State have numerous branches in Northern Ireland, and two of the Belfast banks have numerous southern branches. Shortly after the treaty, the Belfast bank, which is affiliated with the Midland bank, sold its branches situated in the Free State to the Royal Bank of Ireland. Later the Bank of Ireland absorbed the National Land bank. The government's banking business is transacted by the Bank of Ireland. The deposits of the six Free State banks amounted in 1927 to £127,798,000 as against £133,035,000 in 1926, and the amount of the Dublin clearings in 1927 was £253,817,000, an increase of £3,798,000 on 1926.

Communications.--In 1914 there were in Ireland 28 railway companies operating 3.454 mi. of line. The Irish railways were placed under the control of the British government in 1917 and were released in Aug. 1921, a few months before the treaty. During the control period, the net receipts for 1913 were guaranteed, and on the cessation of control the government paid the railways £3,000,000 in full settlement of all claims. Meanwhile, wages had been raised by about 200%, while freight and passenger rates had been raised only by 120% and 100% respectively. The resulting difficulties led to the railways act of 1924, modelled on the British act of 1921, for amalgamating all the lines situated wholly in the Free State. On Jan. 1, 1925, came into being the new Great Southern railway, comprising all the companies in the Free State, but excluding the Great Northern railway (Ireland), which is partially situated in Northern Ireland. The traffic receipts of the Great Southern railway in 1927 were £4,247,244, an increase of £61,210 on 1926.

The conditions which prevail in Eire render the competition of the road vehicle very formidable; the average journey is short, and many places in the country are several miles from a railway station. The number of motor vehicles licensed in 1926 was 44,962 and in 1927, 45,774.

Irish Industry After 1928.—Under the Cosgrave government a number of industrial projects were begun. notably the Ford tractor works at Cork. De Valera's self-sufficiency policy and the financial and tariff inducements he offered were responsible for a considerable development of industrial life in Ireland. The sugar industry increased, the boot industry, milling, tobacco, building materials, among many others, greatly increased. World War II, however, slowed up and in some cases stopped this progress, for Eire was unable to obtain raw materials which the belligerents needed for war materials.

Banking After **1928.**—*The Currency.* Eire has its own paper and metallic currency. The unit of Irish currency is the Irish pound which has the same value as the pound sterling. Other circulating media are legal tender notes and consolidated bank notes. The consolidated bank notes are issued by the currency commission which consists of three representatives of the banks, three members nominated by the minister for finance, and a chairman elected by the other members of the commission.

These notes are secured by a reserve held by the currency commission, and are a first charge on all the banks. Legal tender notes are convertible into British legal tender at the Bank of England.

Total notes in circulation in 1938, 1939 and 1940 respectively were £15,906,673; £16,058,921; and £18,980,262.

Trade.—The table shows the imports and exports of Eire, the figures indicating thousand £s.:

Imports and Exports of Eire
(in thousands of £)

Year / Year	1935	1936	1937 / 1937	1938 / 1938	1939	1940
Imports	37,347	39,912	44,108	41,414	43,415	46,790
Exports	19,920	22,405	22,848	24,239	26,892	32,066

Before World War II Eire received a number of invisible export credits from the Irish sweepstakes, investments throughout the world, remittances from the U.S. and British pension payments.

Transportation. — The shortage of coal and oil drastically curtailed Irish railway service and motor transportation. In 1937, 44,491 private cars were licensed. By 1941 this number was reduced to 31,780, and during 1942 private motor cars had practically ceased to operate.

Finance. — The Free State's favourable arrangements with the British government permitted it to begin with a very small debt. Early deficits were due to military expenditures and to money advanced for such schemes as the Shannon electrical project. The economic policy of the Cosgrave government kept the public debt around £20,000,000. The depression, de Valera's policies and the trade war increased the deficits rather more. The payment of £10,000,000 to Great Britain in connection with the financial agreement of 1938 raised the government debt to £44,000,000. Defense expenditures during World War II necessi-

tated considerable borrowing. As opportunities for the investment of Irish capital were curtailed by the war, the government had little trouble in floating its loans.

Taxation.—The system of taxation in operation at the time of the treaty was taken over, and, owing to the difficult financial situation created by the civil war, no reductions were attempted for a couple of years. In the years 1923–24 and 1924–25 the income tax was maintained at the rate of 5*s.*, and the corporation profits tax was retained. In both these respects the Free State taxes were higher than the British. The budget of 1924 reduced the super tax on very high incomes, and reduced the tea duty from 8*d.* to jd. per pound. In 1925 the income tax was reduced to the British rate of 4*s.*, and the exemption limit to corporation profits tax was raised.

The duty on sugar was considerably reduced and imperial preference in that commodity discontinued, and the duties on tea, coffee, cocoa and chicory were abolished. In 1927 the income tax was reduced to 3*s.*

The relief which the taxpayer might have derived from these concessions was to some extent counterbalanced by the burden of the new protective duties.

In addition to the sums raised by national taxes, the following sums were raised by local taxation: year ending March 1922, £6,762,672; March 1923, £4,153,060; March 1924, £5,327,341; March 1925, £5,310,550; March 1926, £5,296,977. The total (national and local) taxation amounted (1928) to about £10 per head of the population.

The depression, the trade war, social services and defense expenditures increased Eire's taxes. The country had few people to pay surtaxes. Excise taxes mere steeply raised. The tax on motor cars and gas was raised. The budget for 1942 called for an income tax of 7*s.*6*d.* in the £ and for a high corporations' profits tax. Oil, tobacco and cider, among other commodities, were heavily taxed.

DEFENSE

Historical.—Immediately after the ratification of the Anglo-Irish treaty in Jan. 1922, British troops began to withdraw from Free State territory, and soon afterwards the Irish regiments included in that territory, with a magnificent fighting record, were withdrawn from the British army In the terms of the treaty it was agreed that responsibility for defense by sea both of Great Britain and of Ireland should be undertaken by imperial forces. and that the Irish defense forces should not exceed, in their military establishments, the proportion to the British army which the population of Ireland bears to the population of Great Britain.

The question of Irish participation in coastal defense was postponed for five years.

The civil war and the mutiny of March 1924 led to several changes in the organization of the Irish army.

Recruitment and Service.—Recruitment is based upon voluntary enlistment, from the age of 18 onwards, for periods up to 12 years' service, of which periods of 1 month up to 3 years in the infantry, and up to 5 years in other arms, are spent with the colours.

The minister of Defense has the power to vary the terms of service; and re-engagements up to 21 years, with the right to discharge on three months' notice, are permitted. All soldiers, on completion of their term of service with the colours, if shorter than the term for which they originally enlisted, are transferred to the reserve. Reservists can be called up for training for 30 days in any one year. They can be called up for permanent service in the event of imminent national danger, but not for more than 12 months over the unexpired portion of their time in the reserve.

Strength, Organization and Higher Command.—The strength of the Field Army in 1937 was 21,765, including 928 officers up to the rank of major-general. The (1928) organization included 27 battalions of infantry, grouped in 9 brigade areas; 4 armoured car companies; 2 battalions of artillery; various engineer units (5 companies. 1 of them a training company, and a depot); army medical services; military police (5 companies and 4 detention barracks); a signal corps of 5 companies; and army transport companies.

After September, 1939, the civil and military defense of Eire was coordinated by the minister for coordination of defensive measures. Under him are his parliamentary secretary, responsible for civilian defense, and the minister for defense. The armed forces are administered and controlled by the Department of Defense, which consists of the minister, the secretariat and the Army Headquarters staff. The last is composed of the chief of staff, the adjutant general and the quartermaster general. Under the Department for Defense Eire is divided into four military districts, each forming a separate command. These are No. 1, Western command; No. 2, Southern command; No. 3, Eastern command; No. 4, Curragh training camp.

Each military district contains a certain number of brigade areas.

The Curragh training camp contains schools of instruction for officers and for noncommissioned officers, and a reception and training depot, as well as training companies for engineers, medical services and army transport.

By terms of the Anglo-Irish treaty signed April 25, 1938, Great Britain relinquished its last defense posts in the Irish Free State —the admiralty property and rights at the ports of Cobh, Berehaven and Lough Swilly.

The Garda Siochana, or unarmed civic guard, was in 1925 amalgamated with the Dublin metropolitan police. The combined force so formed has a maximum establishment strength of 6,454, including 192 officers.

Under the new constitution the president of Eire is the commander in chief of the defense force. In 1940 the air' corps included a headquarters, a depot, a training school and three squadrons. The permanent force was expanded with the war and also undertook the job of training the large volunteer force which was enrolled. It was estimated in 1941 that about 200,000 men were in the army and the volunteers. Perhaps 50,000 were armed and trained. The government attempted the creation of a small navy. But Eire had trouble in securing arms and munitions. Pres. Roosevelt refused to send arms to noncombatants such as Eire.

(G G A.)

IRISH LITERATURE. The English occupation of Ireland raised its first literary monument in the *Kildare Poems* of the early 14th century whose interest is now mainly philological. Up to the middle years of the 16th century the use of English was limited to a few towns and to the confines of the Pale. It was not until the close of the next century that the conflicting policies of the two countries produced a special colonial spirit, whose spokesman was Molyneux, and a literature of corresponding character, Irish to the English, English to the Irish. This Janus-faced attitude of Anglo-Irish literature lasted almost into the 20th century, injuring its artistic integrity by its partisan spirit. In the 17th century the author of the *Hiber-*

niad proudly counts Swift, Denham, Parnell, Farquhar, Steele, Southerne, Roscommon, Boyle, Ussher and Berkeley amongst the Irish authors of his day. Only of the two greatest of these, Swift and Berkeley, may it be fairly said that their life in Ireland left a deep impress on their work. Ireland taught Swift his fierce hatred of injustice and that deep compassion for material suffering which Lecky observes. The same spectacle of Irish conditions added to Goldsmith's incomparable charm a sense of social values which lifts him above the urbane and artificial poets, and it gave to Burke the passion for justice which glows in his political philosophy. A strong Irish accent marked the thought as it marked the speech of both men. These men were born into the violent contrasts of the Irish 18th century where the most artificial inequalities of status and political control maintained a brilliant and corrupt society in the capital, firing the eloquence of Grattan and Curran and pointing Sheridan's wit.

Thomas Moore.—Into this strife, too, was born Thomas Moore (1779–1852) whose Irish Melodies had in their day a European vogue and were acclaimed by the greatest of his contemporaries. His practice of writing to music necessarily betrayed him into a diffuse and cloying sweetness, and writing before the Wordsworthian reaction his language and imagery are often out-moded. But he remains a master of swift, light and musical verse as well as of witty political satire. His control of varied metres restored to the English lyric the freedom of 17th century verse. In this he was an innovator as well as in his introduction of certain Irish modes to English metre. With him for the first time there entered into Anglo-Irish poetry some faint breath of the Gaelic spirit which is the vital force of its later development. The cadences and imagery of Gaelic poetry give whatever is of value to the folk-verse of Callanan (1795–1829) and Walsh (1805–50), and the scholarly George Darley (1795–1846) dipped his pen in the same glittering honeydew. Its influence is supreme in the visionary James Clarence Mangan (1805–49), whose genius let and hampered, as has been said, by inborn physical and spiritual sensitiveness, reached in his best work the highest lyrical levels. Lionel Johnson, a kindred soul, ranks Mangan's "Dark Rosaleen" with the great lyrics of the world where the chivalry of a nation's faith is struck of a sudden into the immortality of music. His "Nameless One" has the troubled and vehement sincerity of Villon and Byron. At this time O'Curry, O'Donovan and Petric were laying the foundations of Gaelic scholarship but with slight influence, Mangan excepted, upon the poets of their day.

The writers of The Nation newspaper, Duffy, D'Arcy McGee and the rest who followed the fruitful plough-share of Thomas Davis (1814–45) were pre-occupied with the Repeal and '48 movements and the work of politics. Literature was to them a tool and not an end in itself. Similarly, the new scholarship touched but did not greatly affect the impersonal and meditative Aubrey de Vere (1814–1902), Denis Florence M'Carthy, the translator of Calderon, or John Auster the translator of Faust. But as the fruits of their studies ripened, Sir Samuel Ferguson (1810–86) found Irish themes to fit "the epic largeness of his conception" and he revealed to the younger poets the harvest about their feet.

Gaelic Influence.—The modern school traces its ancestry back in this way through Ferguson and Mangan to the Gaelic poets. The way to their ancient founts was pointed by the scholars already mentioned and by their successors, Whitley Stokes, Standish Hayes O'Grady, Kuno Meyer, Dr. Sigerson, Dr. Douglas Hyde and the editors of the Gaelic poets of the 17th and 18th centuries. Particular importance attaches to the publication of Hyde's Love Songs of Connacht and his edition of Raftery which notably influenced the new school in the direction of folk-simplicity, and to the works of Standish O'Grady, second of that name, who influenced it in the contrary direction by the glamour with which he invested the older heroic literature. The emergence of this group about 1900 was the literary evidence of a resurgent national spirit as race-conscious in literature as the Gaelic League in education, or Sinn Fein in politics. It had its origin in this race-consciousness stimulated by the study of the old heroic literature and of the folk poetry which still existed in Irish. It might have been a phenomenon of merely political or antiquarian interest if its chiefs were not primarily artists.

W. B. Yeats worked to a standard of well-nigh perfect artistry and the writings of George Russell (A.E.) were deepened and generalized with a profound consciousness of the divine origin and destiny of man. Yeats's interest in magic and A. E.'s pantheism remove their work still further from the kingdoms of this world. Yeats was always a very highly self-conscious artist. His early work broods in sorrowful ecstasy over visionary beauty; his later work is more austere in form, deliberately fashioned into abstract simplicity, very personal and often petulant. About these two writers and the Abbey theatre, the Gaelic League and Sinn Fein, were grouped in diverse relations the poets, novelists and dramatists of the so-called Irish literary revival. Ethna Carbery impersonated its spring-tide, Alice Milligan its clean-cut masculine purpose; there were nature poets like Katharine Tynan and Francis Ledwidge; poets of the people like Padraic Colum, Joseph Campbell, Moira O'Neill; town poets like Seumas O'Sullivan who introduced a new and mordant note into his fastidious art; the newcomers, Austin Clarke, whose imagination is fitly exercised in epic subjects, F. R. Higgins, who seeks to develop the subtle Gaelic mode in clarity, and Oliver Gogarty, a writer of witty and lapidary verse. Reaction from cloudy abstraction and a transition to prose marked the passing of youth and the coming of age of the movement. The appearance of James Stephens may be taken as the turning point, who passes indifferently from verse to prose, from slum idylls to the riotous invention of the Crock of Gold and The Demigods, and exhibits at each turn the same leaping fancy and the same wise and witty humanity.

Fiction.—The politics which became prose literature under Swift's pen remained literature in the hands of Wolfe Tone (Autobiography), Mitchel (Jail *Journal*) and Padraic Pearse, but the novel had a later start. Maria Edgeworth (1767–1849), the earliest of Anglo-Irish novelists, still remains a central figure amongst them. Equalling any of her successors in the vivacity of her dialogue and in the fidelity of her character studies she brought to bear on Irish life a criticism more serious and candid than any of the group after her. Samuel Lover (1797–1868) redeems with a touch of poetry his inclination to buffoonery. Charles Lever (1806–72) excels in the rollicking novel of adventure. He rarely touches serious issues but fills his pages with the "half-sirs" and "squireens" who swarmed in Ireland up to the date of the Incumbered Estates Act. He fashioned out of this class a pseudo-national figure of the hard-drinking, devil-may-care Irishman, and succeeded in impressing it on his foreign readers as the national type. The once popular Lady Morgan enjoyed a social and political vogue, and the singular figure of Maturin, whose influence Balzac admitted, will always hold the attention of literary historians. Of more importance is the group which includes the Banim brothers (John, 1798–1842; Michael, 1796–1824), and the charming idyllist of peasant life, Charles Kickham (1826–82). With their knowledge of the people, but not without a sentimental and idealizing tendency, they penetrated the surface upon which Lever's school was content to play. With better models and technical equipment this period might have produced an Irish Turgeniev. Between the frivolous and the idealists stands the considerable figure of Carleton (1794–1869), a twisted genius of unusual intensity, the opposite of Maria Edgeworth in all points, his blind power, grotesque humours and native, uncertain art contrasting with the security of her judgment and technique. Emily Lawless and Jane Barlow continue the study of the Irish peasant with the seriousness of their age, and contemporary with them the two writers who, under the names of Somerville and Ross, reproduce the laughing surface of Irish life in the true rhythm of Anglo-Irish speech—all three with a poet's sensitiveness to the changing beauty of the Irish landscape. The modern novelists, George Moore at their head, range themselves less consciously along the lines drawn by the religious and agrarian struggle of the 19th century. They are more pre-occupied with their art than with politics. The realism of the early Moore and of The Real *Char*lotte fortifies but does not displace the creative imagination of

which James Stephens is the exemplar. Daniel Corkery's short stories and his single novel, *The Threshold of Quiet*, are studies of intense though quiet reality with which may be mentioned Colum's *Castle Conquer*. The premature death of Seumas O'Kelly was a great loss to Irish literature. His *Weaver's Grave* is the best modern Irish short story. Post-war conditions explain the brutal and immature talent of O'Flaherty whose short stories deserve recognition. There remains the unique personality of James Joyce, who passes the bounds of Anglo-Irish, if not indeed of English, literature.

The Literary Theatre. — The history of the Irish theatre begins in the mid-17th century and the stage was firmly established in the 18th when Garrick and Mrs. Siddons were welcomed in the rivalry of genius with the native Spranger Barry and Peg Woffington. Congreve was contemporary in Dublin with Farquhar who made his first appearance as an actor in the famous Crow street theatre, and on them followed Goldsmith and Sheridan — the twin glories of the 18th century stage. Macklin, O'Keeffe, Gerald Griffin and Dion Boucicault carry on the succession into the 19th century when the supremacy of Dublin, and Ireland, in this field is resumed first with the brilliant and unhappy Oscar Wilde and in our day with Bernard Shaw and the Abbey dramatists. The movement which resulted in the foundation in 1904 of the Abbey theatre began in the meeting of the writers Russell and Yeats with the actors W. G. and Frank Fay. It was a fortunate junction of poets with actors who sought in simplicity for truth. The first plays were heroic and poetical. With the accession of Synge (1871–1909) the movement received its most powerful impulse. He founded no school; his tragic imagination was not hereditable and his gift of richly imaged speech could not safely be imitated. Lady Gregory contributed comic verse, inexhaustible invention and an instinct for cumulatively absurd dramatic situation. These, with Padraic Colum, were the foundation dramatists. Colum, with his social sense and grave beauty of speech, was the first begetter of the peasant drama; his best play *Thomas Muskerry* was produced in the year of Synge's death and it is to his idiom rather than to Synge's that later dramatists returned. The new writers include T. C. Murray, Lennox Robinson, St. John Ervine and Lord Dunsany. Murray uniformly shows a strong sense of dramatic situation, the technique of an accomplished artist and a faculty for significant and beautiful speech. Lennox Robinson is master of easy, graceful dramatic conversation while the highly personal talent of Lord Dunsany exhibits itself in unusual invention and verbal felicities. Sean O'Casey's first play was staged in 1923. His advent is significant of the vitality of the movement and its change. The heroic play in verse or prose has given place to the drama of realism, and the townsman is challenging the peasant's monopoly of the stage. O'Casey has a consummate power of creating and energizing character, a speech that holds rich local savour without losing its natural rhythm, pity and humour that transcend the squalor of the slums. In these gifts and in his passion for truth, the fruit of enthusiasm and disillusion, lies his promise. (C. P. Cu.)

GAELIC

In the absence of a native coinage it is extremely difficult to say when the use of letters was introduced into Ireland. It is probable that the Latin alphabet first came in with Christianity. With the exception of the one bilingual Ogam inscription as yet discovered in Ireland (that at Killeen Cormac) all the inscriptions in Roman letters are certainly later than 500. With regard to the Ogam inscriptions we cannot make any confident assertions. Owing to the lack of criteria for dating certain Irish sound-changes accurately it is impossible to assign chronological limits for the earlier stones, which cannot be later than the 5th century, but there is nothing to show whether they are Christian or not. The Ogam system is certainly based on the Latin and not the Greek alphabet, and was probably invented by some person from the south of Ireland who received his knowledge of the Roman letters from traders from the mouth. of the Loire.

Early Irish Mss.—The great bulk of Irish literature is contained in mss. belonging to the Middle Irish period (1100–1550), but it will be convenient for us to deal first with those documents which are termed Old Irish. Most of the Old Irish documents have been printed by Stokes and Strachan in the *Thesaurus Palaeohibernicus*, and where no reference is given the reader is referred to that monumental work. The extraordinary outburst of intellectual activity in Ireland from the 6th to the 9th centuries and the compositions of Irishmen in the Latin language, belong to the history of mediaeval European literature and fall outside the scope of this article. For the *Confessions of St. Patrick* and his "Letter to the Subjects of Coroticus" *see* PATRICK. The only Irish document ascribed to the saint is the strange so-called "Hymn," the *fáeth fiada*, more properly *fdid fiada*, "the cry of the deer." This hymn, which contains a number of strange grammatical forms, is undoubtedly referred to in the Book of Armagh, and may very well go back to the 5th century. The date of the Irish hymns in the *Liber Hymnorum* ranges, according to Stokes and Strachan, from the 7th to the 11th centuries. Ultán's hymn on St. Brigit beginning *"Brigit be' bithmaith,"* which is by far the most artistic of the collection, was perhaps composed in the 7th century. Definite metrical laws had evidently been elaborated when this poem was written. The beat is iambic, but the natural accent of the words is rigidly observed. The long line consists of two units of five syllables each, The rhymes are dissyllabic and perfect. Alliteration is always observed in the latter half of each line and assonances are found knitting up the half-lines. The well-known hymn on St. Patrick traditionally ascribed to Fiacc, bishop of Sletty, and the piece beginning *Sén Dé,* traditionally ascribed to Colmán, are assigned on linguistic grounds to the beginning of the 9th century. The Patrician documents by Muirchu Maccu Machthéni, who professed to write at the command of Bishop Aed of Sletty (d. 698), and by Tirechán, who is said to have received his information from Bishop Ultán (d. 656), are contained in the Book of Armagh, a ms. compiled by Ferdomnach in 807.

The earliest pieces of connected prose in Irish are three: — (1) the Cambray Homily, contained in an 8th-century codex at Cambray: the language dates from the second half of the 7th or the beginning of the 8th century; (2) the additions to the notes of Tirechan on the life of St. Patrick in the Book of Armagh; these seem to go back to the early 8th century; (3) the tract on the Mass in the Stowe Missal, which is in all probability nearly as old as the Cambray Homily. Of especial interest are the spells and poems found in the Stowe Missal and two Continental mss. A St. Gall codex has preserved four Irish incantations of the 8th and 9th centuries. The 9th-century codex preserved at the monastery of St. Paul in Carinthia contains several interesting short poems in Irish.

For our knowledge of the older language, however, we have to rely mainly on the numerous glosses scattered about in a large number of mss., which it is impossible to enumerate here. It will be sufficient to mention the three most important codices containing Old Irish glosses. These are as follows: — (I) The Codex Paulinus at Würzburg. The date of this highly important ms. is much disputed; part of the Irish glosses seem to date from about 700, whilst the rest may be placed a little before 800. (2) The Codex Ambrosianus, formerly at Bobbio, now at Milan; these glosses were copied in the first half of the 9th century. (3) Glosses on Priscian contained in four mss. The other chief texts or authors provided with Irish glosses are Augustine, Bede, the Canons, the Computus, Eutychius, Juvencus, Philargyrius, Prudentius and Servius. The Milan and the St. Gall codices just mentioned both contain several short poems in Irish.

Two ponderous religious poems have now to be noticed. To Oengus the Culdee is attributed the lengthy *Félire* or Calendar of Church Festivals, consisting of 365 quatrains in *rinnard* metre, one for each day in the year. The language of this dry compilation, which is heavily glossed and annotated, points to 800 as the date of composition, and Oengus, who is stated to have lived about that time, may well have been the author.

It may perhaps be as well to enumerate here the later Irish martyrologies. (1) The *Martyrology of Tallaght*, founded on an 8th-century calendar, but containing additions down to goo (ed.

D. H. Kelly, 1857). (2) The metrical *Martyrology of O'Gorman, c.* 1166–74, edited by Stokes for the Bradshaw Society (1895). (3) The *Martyrology of Donegal,* an important compilation in prose made by Michael O'Clery in 1630, edited by J. H. Todd (1864). A composition which is wrongly assigned to Oengus the Culdee is the *Saltair na Rann* or Psalter in Quatrains, published without a translation by Stokes (1883). The work proper consists of 150 poems, but 12 poems have been added, and in all it contains 2,098 quatrains. This psalter received additions as late as 998. We should perhaps also mention here the famous *Amra* or Eulogy of St. Columba, commonly attributed to Dallán Forgaill, a contemporary of the saint, but Stokes takes t h view that it was written in the 9th century, and is intentionally obscure.

During the 9th and 10th centuries Ireland was harassed by the Vikings, and a host of scholars seem to have fled to the Continent, carrying with them their precious books, many of which are preserved in Italy, Switzerland, Germany and elsewhere. Hence very few early Irish mss. are preserved in Ireland itself. When the fury of the storm was past, Irish scholars showed increased interest in the old literary documents, and copied all that they could lay hands on into miscellaneous codices. The earliest of these collections, such as the *Cin of Druim Snechta,* the *Yellow Book of Slane,* the *Book of Dubdaleithe,* the *Psalter of Cashel,* exist no longer, though their names have come down and certain of them were known in the 17th century. However, copies of a goodly portion of the contents of these old books are preserved to us in one form or another, but mainly in a series of huge miscellaneous codices ranging in date from the 12th to the 16th century. The oldest is *Lebor na h-uidre,* which we shall abbreviate as LU., preserved in the Royal Irish Academy and published in facsimile (1870) by the Academy, which is also publishing the entire text of this codex in Roman letters marking the different handwritings. This ms. was compiled in part in the monastery of Clonmacnoise by Moelmuire MacCelechair, who was slain in 1106. LU. is almost entirely devoted to romance, the stories which it contains belonging mainly to the Ulster cycle. The next ms. in point of age is the Book of Leinster (abbreviated LL.) now in Trinity college, Dublin, which was transcribed by Finn, son of Gorman, bishop of Kildare (d. 1160), and also contains a large number of romances in addition to other important matter bearing more particularly on the affairs of Leinster. The Yellow Book of Lecan (YBL.), also in Trinity college, Dublin, was written at different times by the MacFirbis family, and it also contains a vast amount of romance. The most extensive collection of all is the Book of Ballyrnote (BB.), now belonging to the Royal Irish Academy, which was compiled about the beginning of the 15th century by various scribes. In 1522 it was purchased by the O'Donnells for 140 milch cows. The contents of the *Leabhar Breac* (LB.), or Speckled Book, now in the Royal Irish Academy, are chiefly ecclesiastical and religious. All these five codices have been published in facsimile by the Royal Irish Academy with a description of their contents. Two important Mid. Ir. mss. in the Bodleian (Rawlinson B 512 and Laud 610) are also published in facsimile by Henry Frowde.

Other mss. which require special mention are (1) The Great Book of Lecan, compiled in the year 1417 by Gilla Isa Mór MacFirbis, in the Royal Irish Academy, for whose checquered history *see* the Marquis MacSweeny's article R.I.A. (1928). (2) The Book of Lismore, the property of the duke of Devonshire at Lismore castle, whose contents are described in the introduction to Stokes's *Lives of Saints from the Book of Lismore* (1890). (3) The Book of Fermoy in the Royal Irish Academy. The contents are described in the introduction to O'Beirne Crowe's edition of the *Táin Bó Fraich* (1870). *(4)* The Book of Hy Maine now in the Royal Irish Academy. The scribe who wrote it died in 1372. O'Curry, O'Longan and O'Beirne Crowe drew up a ms. catalogue of the Irish mss. in the Royal Irish Academy, completed by Purton in over 30 ms. volumes. The Academy has since published in 1927–28 three fascisculi of a new catalogue by O'Rahilly, Miss Mulchrone and Miss Byrne. O'Donovan performed the same service for the Trinity college, Dublin, collection. A briefer account of the Irish mss. in TCD. will be found in Abbott's and Gwynn's Catalogue of the mss. in that library. O'Curry also drew up a list of the Irish mss. in the British Museum, and S. H. O'Grady printed part i. of a descriptive catalogue of this collection (1901). Robin Flower completed this catalogue in 1926. The mss. in the Franciscan monastery in Dublin are described by J. T. Gilbert in the *Fourth Report of the Royal Commission on Historical MSS.* W. F. Skene catalogued the collection of mss. in the Advocates' Library, Edinburgh, a printed catalogue of which has been issued by D. Mackinnon (1909; *see* also *Trans. Gaelic Soc. of Inverness,* xvi. 285–309).

O'Curry states that if the five oldest vellum mss. were printed the result would be 9,400 quarto pages. Other mss. ranging in date from 1300 to 1600 would fill 9,000 pages of the same size. D'Arbois de Jubainville, published in 1883 a tentative catalogue of Irish epic literature. He mentions 953 Irish mss. containing epic matter preserved in Irish and English libraries. To these have to be added another 56 in Continental libraries.

The language in which the huge miscellaneous codices enumerated above are written is called by the general name of Middle Irish, which is a very wide term. Irish scribes often copied their original somewhat mechanically, without being tempted to change the language to that of their own time. Thus in many parts of LU. we find a thin Middle Irish veneer on what is largely Old Irish of the 8th or 9th century, and it may even happen that a 14th or 15th century ms. such as YBL. contains much older forms than a corresponding passage in LL.

The "Filí."—It remains for us to say a few words about the *filí,* the professional literary man in Ireland. The *filí* (from the stem *vel-,* "to see," Welsh, Breton, *gwelet,* "to see") appears to have been originally a diviner and magician, and corresponds to the *vates, οὐάτεις,* of the ancient Gauls mentioned by classical writers. Part of the tremendous influence exercised by the *filí* was due to the belief in his powers of satire. The *filid* were held in such esteem that the annalists give the obituaries of the head-ollams as if they were so many princes. With the introduction of Christianity they seem to have gradually superseded the druid. We are here only concerned with the *filí* in his capacity of story-teller and poet. (1) The highest degree of *filí* is the *ollam* (ollave), who knows 350 stories; (2) the *ánruth,* 175 stories; (3) the *clíi,* 80 stories; *(4)* the *cana,* 60 stories; (5) the *doss,* 50 stories; (6) the *macfuirmid,* 40 stories; (7) the *fochlocon,* 30 stories; (8) the *drisac,* 20 stories; (9) the *taman,* 10 stories; (10) the *oblaire,* 7 stories. In LL. we are told that the stories (*scél*) are divided into primary and secondary, and that the latter are only obligatory on the first four of the grades enumerated. The higher grades were allowed a number of attendants, whom the kings had to support along with the poet himself. The 6th century monarch, Aed MacAinmirech, weary of the pretensions of the poets, attempted to banish them, which led to the famous assembly of Druim Ceta, where Columba intervened and reduced their number.

We have already stated that the stories which formed the stock-in-trade of the poets were divided into primary and secondary stories. Of the latter there were roo, but little is known of them. The oldest catalogue (contained in LL.) gives the titles of 187 of the primary tales arranged under the following heads—destructions, cow-spoils, courtships, battles, caves, navigations, violent deaths, expeditions, elopements and conflagrations; together with the following, which also reckon as prime-stories—irruptions, visions, loves, hostings and migrations. Of these stories 68 have been preserved in a more or less complete form. The tales enumerated in these catalogues in their substance doubtless go back to the 8th or even to the 7th century. It ought to be observed that the church never showed itself hostile to the *filid,* as it did to the druids. Dubthach, chief *filí* of Ireland in the time of St. Patrick, is represented as the saint's constant companion.

Like the official *filid,* the bards, an inferior class of poets, were divided into grades. There were both patrician and plebeian bards, each subdivided into eight degrees, having their own peculiar metres. In course of time the office of *filí* became extinct,

owing to a variety of causes, and from the 13th to the 16th century we find the hitherto despised family bard stepping into the place of the most influential literary man in Ireland. His importance was fully realized by the English Government, which did its best to suppress the order.

Mediaeval Romances.—The mediaeval romances form by far the most attractive part of Irish literature. Two main groups of stories have to be distinguished. The one is the Ulster cycle, with Conchobar and Chchulinn as central figures. The other is the Southern or Leinster-Munster cycle, revolving round Finn and Ossian.

The Ulster cycle may be regarded as Ireland's most important contribution to the world's literature. The chief and at the same time the lengthiest romance in which the heroes of this group figure is the great epic, the *Tdin Bó Cualnge* or the Cattle-raid of Cooley (Co. Louth). Here we find ourselves in a world of barbaric splendour, and we are constantly reminded of the *Iliad*, though the Irish epic from a purely literary point of view cannot bear comparison with the work of Homer. The main actors in the drama are Conchobar, king of Ulster, the great warrior Chchulinn (*q.v.*), Ailill and Medb, king and queen of Connaught, and Fergus, Conchobar's predecessor as king of Ulster, now in exile in Connaught. These persons may or may not have actually lived, but the Irish annalists and synchronists agree in placing them about the beginning of the Christian era. And there cannot be any doubt as to the antiquity of the state of civilization disclosed in this great saga. It has been repeatedly pointed out that the Irish heroes are equipped and conduct themselves in the same manner as the Gauls described by the Greek traveller Posidonius, and Prof. W. Ridgeway has shown that several articles of dress and armour correspond exactly to the La Tène types of the Continent. To mention a few primitive traits among many—the Irish champions of the *Tdin* still fight in chariots, war-dogs are employed, whilst the heads of the slain are carried off in triumph and slung round the necks of the horses. It may also be mentioned that Emain Macha, Conchobar's residence, is reported by the annalists to have been destroyed in A.D. 323, and that portions of Meath, which is stated to have been made into a separate province in the 2nd century A.D., are in the *Tdin* regarded as forming part of Ulster. Noteworthy is the exalted position occupied by the druid in the Ulster sagas, showing how little the romances were influenced by Christianity. No Roman soldier ever set foot in Ireland, and this early epic literature is of supreme value as a monument of primitive Celtic civilization. The YBL. version of this epic preserves a number of forms as old as the O.Ir. glosses (*i.e.*, 8th century or earlier), and a curious story contained in LL. seems to point to the fact that the *Tdin* was first committed to writing in the 7th century.

At this point it will be well to say a few words about the form of the *Tdin*. The old Irish epic is invariably in prose with poems of varying length interspersed. The narrative and descriptive portions are in prose and are frequently followed by a brief epitome in verse. Dialogues, eulogies and laments also appear in metrical form. The oldest poems, termed rhetoric, which are best represented in LU., seem to be declamatory passages in rhythmical prose, not unlike the poetical passages in the Old Testament, and the original *Tdin* may have consisted of such rhetorics bound together with short connecting pieces of prose. At a later date poems were inserted in the metres of the *jilid*. The genesis of the *Tdin* may thus be briefly summarized as follows. The story was first committed to writing in the 7th or 8th century, after which it was worked up by the *jilid*. Extended versions existing in the 10th or 11th century form the basis of the copies we now possess.

Though the sagas of the Ulster cycle are eminently Irish and pagan in character and origin, it cannot be denied that traces of foreign influence are to be observed. A number of Latin and Norse loan-words occur in them, and there can be little doubt that the monkish scribes consciously thrust the supernatural element into the background.

From what we have already said it will be plain that the Irish epic is in a fluid state. The *Táin* is of interest in the history of literature as representing the preliminary stage through which the great verse epics of other nations have had to pass, but its value as a work of art is limited by its form. As already stated, the atmosphere is frankly pagan and barbaric, with none of that courtly element which we find in the Arthurian epics. The two features which strike one most forcibly in the mediaeval Irish romances are dramatic force and humour. The unexpected and weird is always happening, the effect of which is considerably heightened by the grim nature of the actors. In particular the dialogues are remarkably brilliant and clever, and it is a matter for surprise that this gifted race never developed a drama of its own. This is doubtless partly due to the political conditions of the island. And, moreover, we are constantly struck by the lack of sustained effort which prevented the *filid* from producing great epics in verse. Dramatic material is abundantly present in the old epics, but it has never been utilized. Perhaps the most serious defect of most Irish literary products is the lack of any sense of proportion, which naturally goes hand in hand with the love of the grotesque.

The Ulster Cycle.—The *Tdin* Bd *Cualnge* formed a kind of nucleus round which a number of other tales clustered. A number of these are called *remscéla* or introductory stories to the *Tdin*. Such are the "Revealing of the Táin," the "Debility of the Ultonians," "The Cattle-Driving of Regamon, Dartaid and Flidais," *Tdin* bd *Regamna*, "The Cattle-Driving of Fraech," "The Dispute of the Swine-herds," telling the previous history of the Bulls, "The Capture of the Fairy Mound," "The Dream of Oengus," the "Adventures of Nera," the "Wooing of Ferb." Other stories form a kind of continuation of the *Tdin*. Such are the "Battle of Rosnaree," the "Great Rout of the Plain of Murthemne" and "Chchulinn's Death." We are also told of the vengeance taken on the slayers by Conall Cernach. Other stories deal with the "Conception of Conchobar," the "Conception of Chchulinn," "The Glories of Conchobar's Reign," with an account of how he acquired the Throne from Fergus, "The Wooing of Emer and the Hero's Education in Scotland under Scathach," "The Siege of Howth," "Bricriu's Feast and the Exile of the Sons of Doel Dermait," "The Battle of the Boyne" (*Eriu*, vol. ii.), "The Deaths of Ailill, Medb and Conall Cernach," "Destruction of Bruden Dá Choca," "The Tragical Death of Conlaech at the hands of Chchulinn his father," "The Deaths of Goll and Garbh," "The Sickbed of Chchulinn," "The Intoxication of the Ultonians," "The Death of Conchobar," "The Phantom Chariot of Cúchulinn," in which the hero is brought up from the grave.

Four other stories in connection with the Ulster cycle remain to be mentioned. The first is *Scél mucci Maic Datho* ("The Story of MacDatho's Pig"). In this savage but picturesque Irish story we find the Ulstermen vaunting their achievements against the Connaughtmen. Nowhere, perhaps, is the dramatic element better brought out. Apart from the *Tdin* the greatest and at the same time the longest saga in which Chchulinn figures is *Fled Bricrend* (Bricriu's Feast). Bricriu is the mischief-maker among the Ulstermen, and he in turn incites the three chief heroes, Chchulinn, Conall Cernach and Loigaire Buadach, to claim the champion's portion in a feast which he prepared. In order to decide the dispute, visits are paid to Medb at Rath Cruachan and to Curói in Kerry, and the story ends with the "beheading incident," which occurs in the romance of "Sir Gawayne and the Green Knight."

But the story of the Ulster cycle which is better known than any other, is the story of the "Tragical Death of the Sons of Usnech. or the Life and Death of Deirdre," one of the "Three Sorrows of Story-telling." This is almost the only tale of the group which has survived in the minds of the common people down to the present day. It is foretold of Deirdre, a girl-child of great beauty, that she will be the cause of great misfortunes, but Conchobar, having lost his wife, determines to have her brought up in solitude and marry her himself. The oldest version of the story is found in LL., and the characters are as rugged and unsophisticated as those of the *Tdin*. But in the later versions the savage features are toned down.

Few of the old romances deal directly with what we may call Irish mythology. The "Battle of Moytura" tells of the tre-

mendous struggle between the Tuatha DC Danann and their enemies, the Fomorian pirates. Connected with the events of this saga is the story of the "Tragic Deaths of the Sons of Tuirenn," which, though mentioned in Cormac's glossary, is not found in any ms. older than the 18th century. This is the second of the "Three Sorrows of Story-Telling." An old story dealing with Tuatha Dé Danann personages, but having a certain bearing on the Chchulinn cycle, is the "Courtship of Etáin," who, though of supernatural *(sid)* birth, is wedded to a mortal king. Her former husband wins back Etáin from her mortal husband in a game of chess and carries her off to his fairy mound. For sake of completeness we may add the titles of two other well-known stories here. The one is the "Story of Baile the Sweet-Spoken." The other is the "Fate of the Children of Lir," the third of the "Three Sorrows of Story-telling," which is only known in a modern dress.

A large number of sagas, which claim to be founded on historical events, present a great similarity to the tales of the Ulster cycle. The "Destruction of Dind-Rig and Exile of Labraid Loingsech" 'relates how the kingdom of Leinster was snatched by one brother from another in the 6th century B.C. The story of the visit of the pigmies to the court of Fergus MacLeite, king of Ulster in the 2nd century *B.C.,* contained in a 15th-century ms., is commonly stated to have given Swift the idea of his *Gulliver's Travels to Lilliput. Caithréim Chonglzail Claringnigh,* which only occurs in a modernized 17th-century version, deals with a revolution in the province of Ulster, supposed to have taken place before the Christian era. The most important Old Irish saga after the *Táin* is beyond doubt the *Destruction of Dd Derga's Hostel,* contained in LU. It deals with events in the reign of the High-King Conaire Mór, who is said by the annalists to have been slain in 43 B.C. after a reign of 70 years.

We can do no more than enumerate the titles of other historical tales: The "Destruction of the Hostel of MacDareo," describing the insurrection of the Aithech-Tuatha (1st century A.D.), "The Expulsion of the Déisi" and the "Battle of Mag Lemna" (2nd century A.D.), "Battle of Mag Mucrime" (A.D. 195 or A.D. 218), "Siege of Drom Damgaire" (3rd century), "Adventures of the Sons of Eochaid Muigmedóin, father of Niall Nóigiallach" (4th century), "Death of Crimthann" (reigned 366–378), "Death of Dathi" (d. 428), "Death of Murchertach, son of Erc," and "Death of Diarmait, son of Cerball" (6th century) "Wooing of Becfola, who became the wife of Diarmait, son of Aed Slane" (reigned 657–664), "Battle of Mag Rath" (637), "Battle of Carn Conaill" *(c.* 648), "Death of Maelfothartaig MacRonain" (7th century), who was a kind of Irish Hippolytus, "Battle of Allen" (722).

The visits of mortals to the Irish Elysium form the subject of three romances, and the whole question has been exhaustively dealt with by Kuno Meyer and Alfred Nutt in the *Voyage of Bran* (1895–97). Condla Caem, son of Conn Cétchathach, was one day seated by his father on the hill of Usnech, when he saw a lady in strange attire approaching invisible to all but himself. She describes herself as coming from the "land of the living," a place of eternal delight, and invites the prince to return with her. This is the *Imram* or Adventure of Condla Caem, the oldest text of which is found in LU. A similar story is entitled *Imram Brain maic Febail,* contained in YBL. and Rawlinson B 512 (the end also occurs in LU.). A later story preserved in BB., YBL. and the Book of Fermoy, tells of the visit of Cormac, grandson of Conn Cétchathach, to Tir Tairngiri. The romances we have just mentioned are almost entirely pagan in character, but a kindred class of story shows us how the old ideas were transformed under the influence of Christianity. A typical instance is *Imram curaig Maelduin,* contained in YBL. and in part in LU. *Imram ua Corra* (Book of Fermoy) and *Imram Snedgusa ocus Mac Riagla* (YBL.) resemble this, but in these cases, the voyage is undertaken as an expiation for crime. In the 11th century an unknown monkish writer compiled the *Navigatio S. Brendani,* drawing the material for his episodes from *Imram curaig Maelduin.*

Fenian or Ossianic Cycle.—Unfortunately the origin of the stories and poems connected with Finn and his warriors is obscure, and scholars are by no means agreed over the question *(see* FINN MAC CUMHAIL). In the earlier, the Ultonian, cycle the figures and the age in which they live are sharply drawn, and we can have no hesitation in assuming that the *Táin* represents in the main the state of Ireland at the beginning of the Christian era. Finn and his companions are more nebulous personages, and, although it is difficult to discover the actual starting-point of the legend, yet from the 12th century onwards we are able to trace the development of the saga with some degree of certainty. Of the 134 pages contained in LU. only half-a-dozen deal with Finn as against 58 with Chchulinn. Again in Urard MacCoisi's list of tales, which seems to go back to the 10th century, only two appear to deal with subjects taken from the Ossianic cycle. The vehicle of the older epic is prose, but this later cycle is clothed in ballad form. Of these ballads about a dozen, apart from poems in the *Dindsenchus* are preserved in LU., LL. and YBL., and none of these poems is probably much older than the 11th century. At the same time we do find a few prose tales, *e.g., "Fotha catha Cnucha"* in LU., describing the death of Cumall, Finn's father, and in LL. and Rawlinson B 502, part of which Zimmer assigns to the 7th century, we have the first story in which Finn actually occurs. But it is remarkable that in no case do tales belonging to the Finn cycle contain any of the old "rhetorics" which occur in the oldest of the Ulster romances. By the 12th century the stories of the Fiann and their destruction at the battle of Gabra must have been fully developed, and from this time onward they appear gradually to have supplanted the Chchulinn cycle in popular favour.

We have already stated that the form assumed by the stories connected with Finn in the earliest mss. is that of the ballad, and this continued down to the 18th century. But here again the Irish poets showed themselves incapable of rising from the ballad to the true epic in verse. The oldest composition of any length which deals with the Ossianic legends is the *Acallam na Sendrach* or Colloquy of the Old Men, which is mainly preserved in three 15th-century mss., the Book of Lismore, Laud 610 and Rawlinson 487. In this text we have the framework common to so much of the later Ossianic literature. Ossian and Cailte are represented as surviving the battle of Gabra and as living on until the time of Patrick. The inflated style to which the Irishman is so prone is seen at its worst in the 16th century *Battle of Ventry,* and we are treated to a nauseous heaping up of epithet upon epithet, *e.g.,* we sometimes find as many as 27 adjectives accompanying a substantive running in alliterating sets of three.

Of greater literary interest are the later ballads connected with Finn and Ossian. Nutt has pointed out that there is a striking difference in spirit between the *Acallam na Sendrach* and the 15th–16th century poems. In the latter Ossian is represented as a "pagan, defiant and reckless, full of contempt and scorn for the howling clerics and their churlish low-bred deity," whilst Patrick is a sour and stupid fanatic, harping with wearisome monotony on the damnation of Finn and all his comrades. The earliest collection of these later Ossianic poems is that made in Scotland by James Macgregor, dean of Lismore, early in the 16th century. Two other published collections are the first half of *Duanaire Finn* and the *Transactions of the Ossianic Society* (1854–61). We further possess a number of prose romances, which in their present form date from the 16th to the 18th century; *e* g., *The Pursuit of Diarmaid and Griiinne, Finn and Grdinne, Death of Finn, The Clown in the Drab Coat, Pursuit of the Gilla Decair, The Enchanted Fort of the Quicken-tree, The Enchanted Cave of Ceis Corann, Tlze Feast in the House of Conan.*

At the present moment it is impossible to give a complete survey of the other branches of mediaeval Irish literature. The attention of scholars has been largely devoted to the publication of the sagas to the neglect of other portions of the wide field. An excellent survey of the subject is given by K. Meyer, *Die Kultur der Gegenwart,* i. xi. *1,* pp. 78–95 (Berlin-Leipzig, 1909).

As early as the Old Irish period nameless Irish poets were singing the praises of nature in a strain which sounds to our ears peculiarly modern, but it is, generally speaking, quite an accident

if any of the delightful little lyrics entered in the margins or on blank spaces in the mss. have remained. There are exquisite nature poems ascribed to Finn, which have been collected into a pamphlet with English renderings by Kuno Meyer (under the title of "Four Old Irish Songs of Summer and Winter," 1903), and he has edited a native poem referred to the 10th century in the form of a colloquy between Guaire of Aidne and his brother Marban. Another text full of passionate emotion and tender regret ascribed to the 9th century tells of the parting of a young poet and poetess, who after plighting their troth are separated for ever (Liadain and *Curithir,* ed. with trans. by K. Meyer, 1902). In the *Old* Woman of *Beare* (publ. K. Meyer, in *Otia Merseiana*) an old courtesan laments her departed youth, comparing her life to the ebbing of the tide (10th century).

Professional Literature. — We must now step aside from pure literature and turn our attention to the various productions of the professional learned classes of Ireland during the middle ages. The range of subjects coming under this heading is a very wide one, comprising history, genealogies, hagiology, topography, grammar, lexicography and metre, law and medicine. Irish tradition preserves the names of a number of antiquarian poets of prehistoric or early mediaeval times, such as Amergin, one of the Milesian band of invaders; Moran Roigne, Adna and his successor Ferceirtne, Torna (c. 400), Dallán Forgaill, Senchán Torpéist, and Cennfaelad (d. 678), but the poems attributed to these writers are of much later date. To Maelmura (d. 887) is attributed a poem on the Milesian migrations. Flanagan, son of Cellach, wrote a long composition on the deaths of the kings of Ireland, and Flann MacLonáin (d. 918), called by the Four Masters the Virgil of Ireland, wrote poems, of which about 1,000 lines survive. Cormacan, son of Maelbridge (d. 946), composed a vigorous poem on the circuit of Ireland. A poet whose poems are most valuable from an antiquarian point of view is Cinaed Ua h-Artacáin (d. 975). Contemporary with him is Eochaid O'Flainn (d. c. 1003). A little later comes MacLiac (d. 1016), who celebrated in verse the glories of the reign of Brian Boroime. Contemporary with MacLiac is Urard MacCoisi (d. 1023). To Cúán ua Lothcháin (d. 1024), chief poet in the reign of Maelsheachlainn II., are ascribed poems on the antiquities of Tara. A writer who enjoyed a tremendous reputation in mediaeval Ireland was Flann Mainstrech (d. 1056), who in spite of his being a layman was head of the monastery school at Monasterboice. Flann's successor, Gilla Coemgin (d. 1072), gives us a chronological poem dealing with the annals of the world down to A.D. 1014. He also is the author of the Irish version of Nennius which contains substantial additions dealing with early Ireland. Minor writers of the same nature, some of whose works have come down to us, are Colmán O'Sesnáin (d. 1050), Néide ua Maelchonaire (d. 1136), Gilla na noem ua Duinn (d. 1160), Gilla Moduda O'Cassidy (1143). In the 13th century these historical poems become very rare. In the next century we again find antiquarian poets of whom the best-known is John O'Dugan (d. 1372), whose work was completed by his younger contemporary Gilla na naem O'Huidhrin. From the beginning of the 13th century the official poets began to give way to the hereditary bards and families of scribes. Among the chief bardic families we may mention the O'Dalys, the MacWards, the O'Higinns, the MacBrodys and the MacDaires, and in Scotland the MacVarrichs descendants of O'Daly (c. 1214–40). Gilla Brigde MacConmidhe was a contemporary of the last-mentioned bard. Donnchad Mór O'Dálaig is said to be the greatest religious poet that Ireland has produced. Angus O'Daly, who lived in the second half of the 16th century, was believed to have been employed by the English to satirize the chief Gaelic families in Ireland. Two members of the O'Higinn family deserve mention, Tadg mór O'Higinn (d. 1315) and Tadg Óg O'Higinn (d. 1448). A *duanaire* was inserted into YBL, which contains a large number of poems by him.

Closely connected with the compositions of the official poets are the works of native topography. The Dindsenchus is a compilation of etymologies of place names. But its chief value consists in the amount of legendary matter it contains, adduced in support of the etymologies given. A kindred compilation is the *Cóir Anmann* (Fitness of Names), which does for personal names what the Dindsenchus does for geographical names.

History. — No people on the face of the globe have ever been more keenly interested in the past of their native country than the Irish. We may now describe briefly the historical works in prose which have come down to us. They may be divided into two classes, (1) works containing a connected narrative, (2) annals. Closely allied to these are the sagas dealing with the high-kings. The earliest of these histories is the wars of the Gael and Gall (*Cogad* Gaedel re Gallaib), which gives an account of the Viking invasions of Ireland, the career of Brian Boroime and the overthrow of the Norsemen at the battle of Clontarf, obviously written by an eye-witness of the battle, or from materials supplied by a person actually present. *Caithreim Cellacháin Caisil* treats of the conflicts between the Vikings and the Irish, and the Leabhar *Oiris* gives an account of Irish history from 979 to 1027. Another ancient work also partly preserved in LL. is the Book of Invasions (Leabhar Gabhdla). This deals with the five prehistoric invasions of Ireland (see IRELAND: Early History) and the legendary history of the Milesians. Part 1 of O'Clery's recension was edited by Macalister and MacNeill (Dublin, n.d.). The Boroma or History of the Leinster Tribute contained in LL. belongs rather to romance. Another history is the Triumphs of Turlough *O'Brian,* written about the year 1459 by John MacCraith, a Munster historian. This inflated composition is an important source of information on Munster history from the landing of the Normans to the middle of the 14th century. A life of Hugh Roe O'Donnell, by Lughaidh O'Clery, and also a contemporary history of the *Flight* of the Earls, by Tadhg O'Cianan, have been published. See also Leabhar *chlainne Suibhne* (Walsh, 1920) and *mcGuidir Fhearmanach* (Dinneen, 1917). But the most celebrated Irish historian is certainly Geoffrey Keating (c. 1570–1646), who is at the same time the greatest master of Irish prose. He travelled up and down Ireland examining all the ancient records, and compiled a history of Ireland down to the Norman Conquest. Its value for the scholar lies in the fact that the author had access to many important sources of information now lost, and has preserved accounts of events independent of and differing from those contained in the Four Masters. In addition to the history and a number of poems, Keating is also the author of two theological works in Irish which are models of Irish prose.

From the writers of historical narrative we turn to the annalists, the most important sources of information with regard to Irish history. We may here mention the Synchronisms of Flann Mainistrech. Apart from this work the earliest collection of annals which has come down to us is the compilation by Tigernach O'Braein (d. 1088), abbot of Clonmacnoise. Tigernach, whose work is partly in Latin, partly in Irish, states that all Irish history previous to 305 B.C. is uncertain. The Annals of *Innisfallen* were perhaps compiled about 1215. The invaluable Annals of Ulster were compiled on Belle Isle on Upper Lough Erne by Cathal Maguire (d. 1498), and afterwards continued by two different writers down to 1604. The Annals of Loch *Cé* (near Boyle in Roscommon) were copied in 1588 and deal with Irish events from 1014 to 1636. The Annals of *Connaught* run from 1224 to 1562. The Chronicon *Scotorum* deals with Irish affairs down to 1135. The Annals of Boyle extend down to 1253. The Annals of Clonmacnoise, which come down to 1408, only exist in an English translation made by Connell MacGeoghegan in 1627. The most important of all these collections is the Annals of the Four Masters (so christened by Colgan), compiled in the Franciscan monastery of Donegal by Michael, Conary and Cucogry O'Clery and Ferfesa O'Mulconry. Michael O'Clery (1575–1643), the greatest of the four, was a lay brother in the order of St. Francis, and devoted his whole life to the history of Ireland. He collected all the historical mss. he could find, and was encouraged in his undertaking by Fergal O'Gara, prince of Coolavin, who paid all expenses. The great work, which was begun in 1632 and finished in 1636, comes down to 1616. Nearly all the materials from which O'Clery drew his statements are now lost. Very important, are the lists of genealogies which occupy a great deal of

space in the older mss, But by far the most important collection of all is that made by the last great shanachie Duald MacFirbis, compiled between 1650 and 1666 in the college of St. Nicholas at Galway.

Religious Literature.—When we turn from secular to religious themes we find that Ireland is also possessed of a very extensive Christian literature, which is extremely valuable for the comparative study of mediaeval literature. One of the most important documents is the Tripartite Life of St. Patrick. The *Leabhar Breac* contains a quantity of religious tracts, most of which have been published. R. Atkinson issued a number of them under the title of *Passions and Homilies from Leabhar Breac* (1887). They do not however deal with the lives of any Irish saints. Stokes has published nine lives of Irish saints from the Book of Lismore. These lives also occur in the *Leabhar Breac.* Other lives of saints have been published by O'Grady in *Silva Gadelica.* Plummer published 17 lives in Irish and a volume of Latin lives. The longest life of St. Columba was compiled in 1536 at the command and with the heip of Manus O'Donnell (O. Kelleher and Schopperle, Chicago, 1918).

But the most interesting Irish religious text is the *Vision of Adamnan* (preserved in LU.), which Stokes assigns to the 11th century. The soul of Adamnan is represented as leaving his body for a space to visit heaven and hell under the conduct of an angel. The whole treatment of the theme challenges comparison with Dante's great poem, but the Irish composition contains many ideas peculiar to the land of its origin. Later specimens of this kind of literature tend to develop into grotesque buffoonery. We may mention the *Vision of Fursae,* the *Vision of Tundale* (Tnugdal), published by V. Friedel and K. Meyer (Paris, 1907), Laisrén's *Vision of Hell* and the *Vision of Merlino.* Kuno Meyer edited a tract on the Psalter in his *Hibernica Minora* from a 15th century Oxford ms., but he holds that the text goes back to 750. For the religious literature in general the reader may refer to O'Curry, *Lectures on the MS. Materials of Ancient Irish History* (pp. 339–434), and G. Dottin, "Notes bibiiographiques sur l'ancienne littérature chrétienne de l'Irlande," in *Revue d'histoire et littérature religieuses,* v. 162–167. *See* also *Revue celtique,* xi. 391–404; *ib.* xv. 79–91.

An extraordinary production is *Aisling Meic Conglinne,* the Vision of Mac Conglinne, found in LB. and ascribed to the 12th century (ed. K. Meyer, 1892). The composition seems to be intended as a satire on the monks, and in particular as a travesty of mediaeval hagiology. Another famous satire, entitled "The Proceedings of the Great Bardic Institution," holds up the professional bards and their extortionate methods to ridicule (see *Transactions of the Ossianic Society,* vol. v.).

Collections of pithy sayings in the form of proverbs and maxims must have been made at a very early period. Not the least remarkable are the so-called Triads, 9th century (publ. K. Meyer, 1906), which illustrate every statement with three examples. There are also two documents attributed to 1st-century personages, "The Testament of Morann MacMóin to his son Feradach," which is quoted as early as the 8th century, and "The Instructions of Cúchulinn to his foster-son Lugaid." K. Meyer has published *Tecosca Cormaic* or the Precepts of Cormac MacAirt to his son Cairpre (1909), and R. M. Smith the *Senbriathra Zithaic* (1928).

Classical Stories.—With that enthusiasm for the classics which is characteristic of the Irish, it is not strange that we should find mediaeval versions of some of the better-known authors of antiquity. It is interesting to note that only those works are translated that could be utilized by the professional story-teller. So much so, that in the 10th century catalogue of sagas enumerated by Urard MacCoisi we find mention of *Togail Troi* and *Scéla Alexandir maic Pilip.* An Irish abstract of the *Odyssey,* following an unknown source, and part of the story of Theseus have been published by K. Meyer. *Zmthechta Aeniusa,* taken from the *Aeneid,* is contained in BB. and published by Calder (1903). A number of mss. contain the *Cath Catharda,* a version of books vi. and vii. (?) of Lucan's *Pharsalia,* which has been published by W. Stokes. There is further at least one ms. containing a version of Statius's *Thebaid* and of Heliodorus's *Aethiopica.* Somewhat later we have Irish versions, amongst others of the *Gesta Romanorum,* the *Historia Brittonum,* the Wars of Charlemagne (Hyde, 1917), the History of the Lombards, Sir John Maundeville's Travels (trans. by Fingin O'Mahony in 1475), the Book of Ser Marco Polo (abridged), Guy Earl of Warwick, Bevis of Southampton, the Quest of the Holy Grail, Octavian, the chronicle of Turpin, Balaam and Josaphat, and the story of Fierabras. For translation literature *see* M. Nettlau, *Revue celtique,* x. pp. 184, 460–461.

By the beginning of the Middle Irish period a good part of the cumbrous Old Irish verb-system had become obsolete, and texts which were at all faithfully copied had to be plentifully supplied with glosses. But even before this Cormac mac Cuillenáin, the bishop-king of Cashel (d. 903), had compiled a glossary of archaic words containing much invaluable information. Later collections of archaic words are O'Mulconry's Glossary (13th century), the Lecan Glossary (15th century), which draws principally from the glosses in the *Liber Hymnorum,* O'Davoren's Glossary (16th century), drawn principally from the Brehon Laws, a 16th century list of Latin and Irish names of plants employed in medicine, and O'Clery's Glossary (published at Louvain, 1643). BB. contains a curious tract on Ogamic writing. An Irish treatise on grammar, called *Uraicept na n-éces,* the Poet's Primer, traditionally ascribed to Cennfaelad and others, is contained in BB. and YBL. (Calder, 1917). The St. Gall glosses on Priscian contain Irish terms for all the nomenclature of the Latin grammarians, and show how extensive was the use made of Irish even in this department of learning.

Thurneysen has edited from BB., Laud 610 and TCD. ms. three treatises on metric which give an account of the countless metres practised by the *filid.* We have seen that there is some reason for believing that the primitive form of Irish verse was a kind of rhythmical alliterative prose as contained in the oldest versions of the sagas. The *filid* early became acquainted with the metres of the Latin church hymns, whence rhyme was introduced into Ireland. (This is the view of Thurneysen and Windisch. Others like Zeuss have maintained that rhyme was an invention of the Irish.) In any case the *filid* evolved an intricate system of rhymes for which it is difficult to find a parallel. The result of the complicated technique evolved in Ireland was an inclination to sacrifice sense to musical harmony. *See* K. Meyer, *A Primer of Irish Metrics* (1909).

Law and Medicine.—We can conclude this survey of mediaeval Irish literature by mentioning briefly two departments of learning to which much attention was paid in Ireland. These are law and medicine. The so-called Brehon Laws (*q.v.*) are represented as having been codified and committed to writing in the time of St. Patrick. The Brehon Laws were no doubt originally transmitted from teacher to pupil in the form of verse, and traces of this are to be found in the texts which have been preserved. But the Laws as we have them do not go back to the 5th century. Kuno Meyer has pointed out that in the commentary to one text, *Crith Gablach,* there are linguistic forms which must go back to the 8th century, and Arbois de Jubainville, who apart from Sir Henry Maine is the only scholar who has dealt with the subject, has attempted to prove from internal evidence that part of the oldest tract, the one on *Athgabdil* or Seizure, cannot, in its present form, be later than the close of the 6th century. Kuno Meyer has published the *Cdin Adamnáin* or Adamnan's Law from an Oxford ms. Adamnan succeeded in getting a law passed which forbade women to go into battle. An interesting text in prose and verse called *Leabhar na gCeart* or Book of Rights was edited with an English translation by O'Donovan (1847).

The medical profession in Ireland was hereditary in a number of families, such as the O'Lees (from Irish *liaig,* "a leech"), the O'Hickeys (Irish *icide,* "the healer"), the O'Shiels, the O'Cassidys, and many others. These families each had their own special leech-books, some of which are still preserved. The medical literature which has come down to us is contained in mss. ranging from the 13th to the 18th centuries. The Irish mss. are translations from the Latin with the invariable commentary, and they further contain additions derived from experience. YBL. contains

four of these tracts, and amongst others we may mention the Book of the O'Hickeys, a translation of the *Lilium Medicinae* of Bernard Gordon (written 1303), the Book of the O'Lees (written in 1443), the Book of the O'Shiels, transcribed in 1657, and the Book of MacAnlega, transcribed in 1512. Of these texts two have been published from mss. in Edinburgh and one from a ms. in R.I.A. Some few mss. deal with the subject of astronomy, one of which was published by Miss Power (1916).

LATER IRISH LITERATURE

With the steady advance of English culture on the heels of the English power after 1600 it was only natural that the school of bardic poets should decline. Amongst the prominent poets of this later period may be mentioned Tadhg Dall O'Higinn (d. shortly before 1617), published by Miss Knott (1922 and 1926), and Eochaidh O'Hussey, who between them have left behind nearly 7,000 lines in the classical metres, Bonaventura O'Hussey and Ferfesa O'Cainti. The intricate classical measures gradually broke down. Dr. Douglas Hyde gives it as his opinion that the exceedingly numerous metres known in Middle Irish had become restricted to a couple of dozen, and these nearly all heptasyllabic. However, during the 17th century we find a new school arising with new principles and new methods. These consisted in (1) the adoption of vowel rhyme in ,place of consonantal rhyme, (2) the adoption of a certain number of accents in each line in place of a certain number of syllables. (For English imitations *see* Hyde, *A Literary History of Ireland,* pp. 548 ff.)

The consequences of the changed political conditions were of the greatest importance. The bards, having lost their patrons in the general upheaval, threw behind them the old classical metres and turned to the general public. It is only during the last 25 years that the works of any of the poets of the 17th and 18th centuries have been published. Pierce Ferriter was the last chieftain who held out against Cromwell's army, and he was hanged in 1653. His poems have been edited by P. S. Dinneen (1903). The bard of the Williamite wars was David O'Bruadar (d. 1697–98), published by MacErlean (3 vols., 1910–17). From this period date three powerful satires on the state of affairs in Munster, and in particular on the Cromwellian settlers. Their titles are the Parliament of Clan Thomas, the Adventures of Clan Thomas, and the Adventures of Tadhg Dubh (by Egan O'Rahilly). A description of the parliament of Clan Thomas is given by Stern in the *Zeitschr. f. celt. Phil.* v. pp. 541 ff.

A little later we come across a band of Jacobite poets, whose pet theme was the *Aisling* or Vision, and we find several noteworthy war-songs. We can do no more than mention the names of John O'Neaghtan (d. *c.* 1720; edition of his poems by A. O'Farrelly, 1908), Egan O'Rahilly, who flourished between 1700 and 1726 (published by Irish Texts Society), Tadhg O'Naghten, Hugh MacCurtin, author of a grammar and part editor of O'Begley's *Dictionary,* John Clárach MacDonnell (1691–1754), John O'Tuomy (d. 1775), Andrew Magrath, Tadhg Gaolach O'Sullivan (d. *c.* 1795), author of a well-known and often published volume of religious poems, and Owen Roe O'Sullivan (d. 1784), the cleverest of the Jacobite poets (his verses and *bons mots* are still well known in Munster). These poets hailed mostly from the south, and it is chiefly the works of the Munster poets that have been preserved. Ulster and Connaught also produced a number of writers. The best known are *Seumas Mac Cuarta* (O'Muireadhaigh, Dundalk, 1925), *Art MacCooey* (O'Muirgheasa, Dundalk, 1913) and the Connaught poet Raftery (1784–1835), whose compositions have been rescued by Hyde *(Abhrdin an Reachtúire,* 1903). Turlogh O'Carolan (1670–1738), "the last of the bards," was really a musician. Having become blind he was educated as a harper and won great fame. Michael Comyn (b. *c.* 1688) is well known as the author of a version based upon older matter of "Ossian in the Land of Youth." This appears to be the only bit of deliberate creation in the later Ossianic literature. Brian MacGiolla Meidhre or Merriman (d. 1808) is the author of perhaps the cleverest sustained poem in the Irish language. His work, which is entitled the *Midnight Court,* was written in 1781 and contains about 1,000 lines with four rhymes in each line. Donough MacConmara (Macnamara) (d. *c.* 1814) is best known as the author of a famous lyric "The Fair Hills of Holy Ireland," but he also wrote a mock epic describing his voyage to America and how the ship was chased by a French cruiser.

The translation of the New Testament made by William O'Donnell and published in 1603 was first undertaken in the reign of Queen Elizabeth, who sent over to Dublin the first fount of Irish type. It is perhaps of interest to note that the earliest specimen of printing in Irish is a poem on Doomsday (1571).

The scholars of the various Irish colleges on the Continent were particularly active in the production of books of devotion, many of them translated from Latin. We can mention only a few of the more important. *Sgathdn an chrdbhaidh (The Mirror of the Pious),* published in 1626 by Florence Conry; *Sgatháin sacramente na h-Aithrighe* (Mirror of the Sacrament of Penance), by Hugh MacCathmhaoil, published at Louvain, 1618; *The Book of Christian Doctrine,* by Theobald Stapleton (Brussels, 1639); *Pdrrthas an Anma, or The Paradise of the Soul,* by Anthony Gernon (Louvain, 1645); a book on *Miracles,* by Richard MacGilla Cody (1667); *Lochrdn na gcreidmheach, or Lucerna Fidelium,* by Francis O'Mulloy (Louvain, 1676); O'Donlevy's *Catechism* (Paris, 1742). O'Gallagher, bishop of Raphoe, published a collection of sermons which went through 20 editions and are still known at the present day. It is only within recent years that attention has been paid to the collection of folk-songs and tales in Irish. The first collection of the sort was Hyde's *Leabhar Sgeuluigheacta* (1889). We may mention among others Patrick O'Leary's *Sgeuluidheacht Chuige Mumhan* (1895); Hyde's *Beside the Fire* (1890) and *An Sgeuluidhe Gaedhealach,* 35 tales in Irish and French, reprinted from the *Annales de Bretagne* (1901); Daniel O'Fogharta's *Siamsa an Gheimhridk* (1892); J. Lloyd's *Sgéalaidhe Oirghiall* (1905), his *Measgdn Mziscreahe,* his *Cruach Conaill* and *Tonn Tdime,* Michael Timony's *Sgealta Gearra* (1906), and Larminie's *West Irish Folk-Tales* (1893). The most important collections of folk-songs are *Love-Songs of Connaught* (1893) and *Religious Songs of Connaught* (2 vols., 1906), both published by Hyde. An extensive collection of proverbs is the one entitled *Seanflzocla Uladh* by Henry Morris (1907). *See* also a large collection by O. Siochfhradha (1927), Hydes' *An Scathrunn,* O'Rahilly's *Miscellany of Irish Proverbs* (1922) and O'Donoghue's *Munster Proverbs* (1902). It should be mentioned that the Saor-Stát is encouraging and paying for new contributions to Irish literature. About a score of books, chiefly stories and novels have been published in 1927 and 1928. Plays are being produced in Irish.

BIBLIOGRAPHY.—In the absence of a comprehensive history, the best manual is Eleanor Hull, *Text Book of Irish Literature* (2 parts, 1904–08; vol. 2 contains a bibliographical appendix). D. Hyde's larger *History of Irish Literature* (1899) is valuable for the more modern period. A full bibliography of all published material is contained in G. Dottin's article "La littérature gaklique de l'Irlande" *(Revue de synthèse historique,* vol. iii., p. 1 ff.). Dottin's article has been translated into English and supplemented by Joseph Dunn under the title of *The Gaelic Literature of Ireland* (Washington, 1906, privately printed). The following are important works:—W. Stokes and J. Strachan, *Thesaurus Palaeohibernicus* (2 vols., 1901–03); J. H. Bernard and R. Atkinson, *Liber Hymnorum* (1895); E. O'Curry, *Lectures on the ms. Materials of Ancient Irish History* (1873) and *Lectures on the Manners and Customs of the Ancient Irish* (3 vols., 1873); P. W. Joyce, *A Social History of Ancient Ireland* (2 vols., 1903); E. O'Reilly, *Irish writers* (1820); S. H. O'Grady, *Catalogue of Irish mss. in the British Museum* (1901; Robin Flower completed this catalogue in 1926); H. d'Arbois de Jubainville, *Introduction à l'étude de la littérature celtique* (1883), *Essai d'un catalogue de la littérature épique de l'Irlande* (1883), *L'Epopée celtique en Irlande* (1892), *La Civilisation des Celtes et celle de l'tpope'e homtrique* (1899); E. Windisch, *Thin Bó Cualnge,* ed. with an introd. and German trans. (Leipzig, 1905); L. Winifred Faraday, *The Cattle-Raid of Cualnge* (1904); the Irish text according to LU. and YBL. has been published as a supplement to *Eriu;* Eleanor Hull, *The Cuchulinn-saga* (1899); W. Ridgeway, "The Date of the First Shaping of the Cuchulinn Cycle," *Proceedings of the British Academy,* vol. ii. (1907); A. Nutt, *Cuchulin, the Irish Achilles* (1899); H. Zimmer, "Keltische Beitrage" in *Zeitschrift f. deutsches Altertum,* vols. 32, 33 and 35, and "Uber den compilatorischen Charakter der irischen Sagentexte im sogenannten Lebor na hUidre," Kuhn's *Zeitschr.* xxviii. pp. 417–689. We cannot here enumerate the numerous heroic texts which have been edited. For texts published before 1883 *see* d'Arbois's

Catalogue, and the same writer gives a complete list in *Revue Celtique,* vol. xxiv. pp. 237 ff. The series of *Irische Texte,* vols. i.–iv. (Leipzig, 1880–1901), by E. Windisch (vols. ii.–iv. in conjunction with W. Stokes), contains a number of important texts. The Irish Texts Society has published 24 volumes of texts with translations. Others, more particularly these belonging to the Ossianic cycle, are to be found in S. H. O'Grady's *Silva Gadelica* (2 vols., 1902). *See* also R. Thurneysen, *Sagen aus dem alten Irland* (1901); P. W. Joyce, *Old Celtic Romances* (1901).

For the Ossianic cycle *see* H. Zimmer, "Keltische Beiträge III." in vol. 35 of the *Zeitschr. f. deutsches Altertum,* also *Gottinger Gelehrte Anzeigen,* 1887, pp. 153–199; A. Nutt, *Ossian and the Ossianic Literature* (1899); L. C. Stern, "Die ossianischen Heldenlieder," in *Zeitschr. f. vergleichende Litteraturgeschichte* for 1895, trans. by J. L. Robertson in *Transactions of the Inverness Gaelic Society,* vol. xxii.; J. MacNeill, *Duanaire Finn* (1908); *Book of the Dean of Lismore,* ed. by T. Maclauchlan (1862), and in vol. i. of A. Cameron's *Reliquiae Celticae* (1892); *Transactions of the Ossianic Society* (6 vols., 1854–61); Miss Brooke, *Reliques of Ancient Irish Poetry* (1789).

Keating's *History* was translated by John O'Mahony (1866). The first part was edited with Eng. trans. by W. Halliday (1811) and the whole work in 3 vols. for the Irish Texts Society by D. Comyn and P. Dinneen (1901–08). For the work of the older bards *see* O'Rahilly's *Dauta grndha* (Dublin 1916 and Cork 1926) and his *Measgra Dnuta* (1927); Father McKenna's *Dán Dé* (Dublin, n.d.); Bergin's contributions to *Studies;* McKenna's *Poems of Aongus O'Dálaigh.* Editions of the poems of Ferriter, Geoffrey O'Donoghue, O'Rahilly, John O'Tuomy, Andrew Magrath, John Claragh MacDonnell, Tadhg Gaolach and Owen Roe O'Sullivan by Dinneen, Gaelic League, Dublin, and Irish Texts Society, London, 1900–03; Loyd's *Duanaine na Midhe* (Dublin, 1914); O. Muirgheasa's *Cead de Cheoltaibh Vladh* (Dublin, 1915), *etc.* (E. C. Q.; D. Hy.)

IRISH MOSS or **CARRAGEEN** (Irish *carraigeen,* "moss of the rock"), a seaweed *(Chondrus crispus)* which grows abundantly along the rocky parts of the Atlantic coast of Europe and North America.

In its fresh condition the plant is soft and cartilaginous, varying in colour from a greenish-yellow to a dark purple or purplish-brown; but when sun-dried and bleached it has a yellowish translucent horn-like aspect and consistency.

The principal constituent of Irish moss is a mucilaginous body, of which it contains about 55%; and with that it has nearly 10% of nitrogenous material and about 15% of mineral matter rich in iodine and sulphur. When softened in water it will form a jelly on boiling with from 20 to 30 times its weight of water. The jelly thus formed of Irish moss is used as food. It is used as a thickener in calico-printing, for clarifying beer and as a suspension medium in pharmaceutical preparations.

IRKUTSK, a town in the Siberian Area of the R.S.F.S.R. in lat. 52° 36' N., long. 104° 10' E., altitude 1,490 ft. It is situated on the right bank of the Angara river, a tributary of the Yenisei river, 45 m. below its outflow from Lake Baikal; its suburb Glazkovskoe lies on the left bank, and a pontoon bridge spans the river, which is 630 yd. wide. The railway and station are on the left bank. The Irkut river, from which the town of Irkutsk takes its name, enters the Angara river on its left bank, but is not navigable and the small Ushakovka river flows through the town and enters the Angara on the right bank. The town grew out of the winter quarters established by Ivan Pokhabov in 1652 for the collection of the fur tax from the Buriats. Its advantageous position for trade with China, the Amur region, the Lena goldfields and the fur regions of Siberia have made it an important city; its population in 1933 was 158,500. A post road runs north to the Lena and Yakutsk and south-east to Listvenichnoe on Lake Baikal, and other roads link it with the east. The Angara is navigable for steamers to Lake Baikal, though the current is against them. The river is frozen from January to April. The average January temperature is −5·4° F, July 65·1° F; the average rainfall per annum is 14·5 in. The town is well built with wide streets and has a drainage system and an electric power station. In 1879 fire destroyed many of the public buildings, including the library and museum of the Russian Geographical Society which has here the headquarters of its Siberian section, with valuable books, maps and exhibits. The town has long been a cultural centre for the district. It contains schools, a training college for teachers and a recently established Workers' Scientific Institute. St. Innocent's monastery, five miles outside the town influenced much of Eastern Siberia. Its industries include brewing, timber-milling, flour-milling, leather works, the making of fur and sheepskin coats and various small articles especially for the posting routes. It was a storm centre from 1918 to 1921 and much damage was then done to the town and railway. The State gold treasure, which had been removed from Leningrad under the charge of employees of the tsarist régime, was handed over by them to the Bolshevists in Irkutsk in 1920; and here Admiral Kolchak was executed in the same year. The town was in tsarist times the centre of the Irkutsk government, an area occupying 287,061 sq.m., but is now only the centre of one of the twenty counties of the Siberian Area (*q.v.*).

IRMIN or **IRMINUS,** in Teutonic mythology, a deified eponymic hero of the Herminones. The chief seat of his worship was Irminsal, or Ermensul, in Westphalia. Wooden pillars raised to his honour were regarded as sacred by the Saxons.

IRNERIUS, Italian jurist, sometimes referred to as "lucerna iuris." He taught the "free arts" at Bologna, his native city, during the earlier decades of the 12th century. Of his personal history little is known, except that he died, perhaps during the reign of the emperor Lothair II., but certainly before 1140. He was the first of the Glossators (see GLOSS), and according to ancient opinion (which, however, has been much controverted) was the author of the epitome of the *Novellae* of Justinian, called the *Authentica,* arranged according to the titles of the *Code.* (*See* ROMAN LAW.)

IRON, a metallic chemical element. Although iron (symbol Fe, atomic number 26, atomic weight 55.84, isotopes 56 and 54) occurs only sparingly in the free state, the abundance of ores from which it may be readily obtained led to its application in the arts at a very remote period. It is generally agreed, however, that the iron age, the period of civilization during which this metal played an all-important part, succeeded the ages of copper and bronze, notwithstanding the fact that the extraction of these metals required greater metallurgical skill. The Assyrians and Egyptians made considerable use of the metal; and in Gen. iv. 22 mention is made of Tubal-cain as the instructor of workers in iron and copper. The earlier sources of the ores appear to have been in India; but it was also obtained by the Greeks from the south coast of the Black sea, and by the Romans from Spain and Elba.

The chief occurrences of metallic iron are as minute spiculae disseminated through basaltic rocks, as at Giant's Causeway and in the Auvergne, and, more particularly, in meteorites (*q.v.*). In combination it occurs, usually in small quantity, in most naturai waters, in plants and as a necessary constituent of blood. The economic sources are treated under IRON AXD STEEL below; in the same place will be found accounts of the manufacture, properties and uses of the metal, the present article being confined to its chemistry. The principal iron ores are the oxides and carbonates, and these readily yield the metal by smelting with carbon. The metal so obtained invariably contains a certain amount of carbon, free or combined, and the proportion and condition regulate the properties of the metal, giving origin to the three important varieties: cast iron, steel, wrought iron. The perfectly pure metal may be prepared by heating the oxide or oxalate in a current of hydrogen; when obtained at a low temperature it is a black powder which oxidizes in air with incandescence; *i.e.,* it is "pyrophoric." It may be obtained electrolytically from solutions of ferrous salts.

Properties.— Iron has a silvery lustre and takes a high polish. Its specific gravity is 7·84; and the average specific heat over the range 15°–100° C is 0·10983; this value increases with temperature to 850°, and then begins to diminish. It is the most tenacious of all the ductile metals at ordinary temperatures with the exception of cobalt and nickel; it becomes brittle, however, at the temperature of liquid air. It softens at a red heat, and may be readily welded at a white heat; above this point it becomes brittle. Pure iron melts at *c.* 1525° C and may be distilled in the electric furnace. It is attracted by a magnet and may be magnetized, but the magnetization is quickly lost. The variation of physical properties which attends iron on heating has led to the view that the metal exists in allotropic forms. This has been proved

recently by X-ray analysis. (See IRON AND STEEL.)

When pure iron is cooled from its melting point, its temperature falls evenly to 1400° and then remains almost stationary for a time; the cooling again becomes regular when 890° is reached, where a similar lag occurs or even a rise of temperature (which may be so pronounced as to cause a flow or recalescence); with still further cooling, yet a third lag is found at 760°. Similar irregularities occur at nearly the same (but slightly higher) temperatures when iron is slowly heated. Moreover, at these temperatures other physical properties of the metal (such as the coefficient of expansion, electrical resistance, and especially the characteristic magnetic property) undergo sudden changes, which lead to the assumption that there are four allotropic modifications of iron with transition points thus:

$$\alpha \overset{760^\circ}{\rightleftharpoons} \beta \overset{906^\circ}{\rightleftharpoons} \gamma \overset{1404^\circ}{\rightleftharpoons} \delta$$

The crystal structure of a, β and 6 is the same, viz., body-centred cubic (see CRYSTALLOGRAPHY), but that of γ-iron is a face-centre cube, and this difference is held by some metallurgists to show that /?-iron is not a distinct modification, but only a solid solution of a and y-iron.

It should be pointed out that "pure" iron is almost a curiosity, for the metal, as commonly used, nearly always contains a certain small proportion of carbon which much modifies its properties.

Iron is very reactive chemically. Exposed to atmospheric influences it is more or less rapidly corroded, giving the familiar rust (*q.v.*). For the production of rust, the presence of water and oxygen does not seem to be sufficient, and an "impurity" seems to be essential; this is provided usually in the iron itself or by the presence of carbon dioxide. The decomposition of steam by passing it through a red-hot gun-barrel, resulting in the liberation of hydrogen and the production of magnetic iron oxide, Fe_3O_4, is a familiar laboratory method for preparing hydrogen (*q.v.*). When strongly heated, iron inflames in oxygen and in sulphur vapour; it also combines directly with the halogens. It dissolves in most dilute acids with liberation of hydrogen, the reaction between sulphuric acid and iron-turnings being used for the commercial manufacture of this gas. It dissolves in dilute cold nitric acid with the formation of ferrous and ammonium nitrates, no gases being liberated; when heated, or with stronger acid, ferric nitrate is formed with evolution of nitrogen oxides.

After having been immersed in strong nitric acid, iron neither dissolves in acids nor precipitates metals from solutions. This "passivity" may be brought about by immersion in other solutions, especially by those containing such oxidizing anions as NO'_3, ClO'_3, less strongly by the anions SO''_4, CN', CNS', $C_2H_3O'_2$, OH', while Cl', Br' practically inhibit passivity; H. is the only cation which has any effect, and this tends to exclude passivity. It is also occasioned by anodic polarization of iron in sulphuric acid. Several hypotheses have been promoted to explain this behaviour, and, although the question is not definitely settled, the more probable view is that it is caused by the formation of a film of an oxide (see U. R. Evans, *Journ.* Chem. *Soc.*, 1927, p. 1020). Other metals also exhibit the phenomenon of passivity under similar conditions.

COMPOUNDS OF IRON

Oxides and Hydroxides. — Iron forms three oxides: ferrous oxide, FeO; ferric oxide, Fe_2O_3; and ferroso-ferric oxide, Fe_3O_4. The first two give rise to well-defined series of salts, the ferrous salts, wherein the metal is bivalent, and the ferric salts wherein the metal is trivalent; the former readily pass into the latter on oxidation, and the latter into the former on reduction.

Ferrous oxide is obtained as a black pyrophoric powder when ferric oxide is reduced in hydrogen at 300°. Sabatier and Senderens obtained it by acting with nitrous oxide on metallic iron at zoo°, and Tissandier by heating the metal to 900° in carbon dioxide; Donau, on the other hand, obtained a magnetic and crystalline ferroso-ferric oxide at 1200°. It may also be prepared as a black velvety powder which readily takes up oxygen from the air by adding ferrous oxalate to boiling caustic potash. Ferrous hydrate, $Fe(OH)_2$, when prepared from a pure ferrous salt and caustic soda or potash free from air, is a white powder which may be preserved in an atmosphere of hydrogen. Usually, however, it forms a greenish mass, owing to partial oxidation. It oxidizes on exposure with considerable evolution of heat; it rapidly absorbs carbon dioxide, and readily dissolves in acids to form ferrous salts, which are usually white when anhydrous, but greenish when hydrated.

Ferric *oxide* or iron sesquioxide, Fe_2O_3, constitutes the valuable ores red haematite and specular iron; the minerals brown haematite or limonite, and gothite and also iron rust are hydrated forms. It is obtained as a steel-grey crystalline powder by igniting any ferric salt containing a volatile acid or by passing ferric chloride vapour over heated lime. When finely ground it forms a brownish red powder which dissolves slowly in acids, the most effective solvent being a boiling mixture of eight parts of sulphuric acid and three of water. Ferric oxide is employed as a pigment, as jeweller's rouge and for polishing metals. Several ill-defined hydrates are known, corresponding to various minerals in composition, and "colloidal" solutions have also been prepared. (See COLLOIDS.) Thomas Graham obtained a soluble hydrate by dissolving the freshly prepared hydrate in ferric chloride and dialysing the solution, the soluble hydrate being left in the dialyser. All the chlorine, however, does not appear to be removed by this process, the residue having the composition $8Fe(OH)_3{\cdot}FeCl_3$; but it may be by electrolysing in a porous cell. On standing, the solution usually gelatinizes, a process accelerated by the addition of an electrolyte. It is employed in medicine under the name Liquor *ferri dialysati*, or "dialysed iron."

Red ferric hydroxide dissolves in acids to form a well-defined series of salts, the ferric salts, also obtained by oxidizing ferrous salts; they are usually colourless when anhydrous, but yellow or brown when hydrated. It has also feebly acidic properties, forming ferrites with strong bases.

Magnetite, Fe_3O_4, is regarded as ferrous ferrite, $FeO{\cdot}Fe_2O_3$. Most "mill scale," *i.e.*, the oxidized surface formed on red hot iron and steel, is Fe_3O_4. This important ore of iron is most celebrated for its magnetic properties, but the mineral is not always magnetic, although invariably attracted by a magnet. It may be obtained artificially by passing steam over red-hot iron. It dissolves in acids to form a mixture of a ferrous and ferric salt, and if an alkali is added to the solution a black precipitate is obtained which dries to a dark brown mass of the composition $Fe(OH)_2{\cdot}Fe_2O_3$; this substance is attracted by a magnet, and thus may be separated from the admixed ferric oxide. Calcium, magnesium and zinc ferrites, $RO{\cdot}Fe_2O_3$(R=Ca, Mg, Zn), are obtained by intensely heating mixtures of the oxides; magnesium ferrite occurs in nature as the mineral magnoferrite, and zinc ferrite as franklinite, both forming black octahedra.

Ferric Acid, H_2FeO_4.—By fusing iron with saltpetre and extracting the melt with water, or by adding a solution of ferric nitrate in nitric acid to strong potash, an amethyst or purple-red solution is obtained which contains potassium ferrate. The same solution results when chlorine is passed into strong potash solution containing ferric hydrate in suspension. Haber and Pick prepared potassium ferrate by electrolysing concentrated potash solution at 70 degrees Centigrade, between two cast iron electrodes, the current being reversed every few minutes. When concentrated, the solution is nearly black, and on heating it yields a yellow solution of potassium ferrite, oxygen being evolved. Barium ferrate, $BaFeO_4{\cdot}H_2O$, obtained as a dark red powder by adding barium chloride to a solution of potassium ferrate, is fairly stable It dissolves in acetic acid to form a red solution, is not decomposed by cold sulphuric acid, but with hydrochloric or nitric acid it yields barium and ferric salts, with evolution of chlorine or oxygen.

Halogen Compounds. — Ferrous fluoride, FeF_2, is obtained as colourless prisms (with $8H_2O$) by dissolving iron in hydrofluoric acid, or as anhydrous colourless rhombic prisms by heating iron or ferric chloride in dry hydrofluoric acid gas. Ferric fluoride, FeF_3, is obtained as colourless crystals (with $4\frac{1}{2}H_2O$) by evaporating a solution of the hydroxide in hydrofluoric acid. When heated in air it yields ferric oxide. Ferrous chloride, $FeCl_2$, is obtained as shining scales by passing hydrochloric acid gas over red-hot iron, or by reducing ferric chloride in a current of hy-

drogen. It is very deliquescent, and freely dissolves in water and alcohol. Heated in air it yields a mixture of ferric oxide and chloride, and in steam magnetic oxide, hydrochloric acid, and hydrogen. It absorbs ammonia gas, forming the compound $FeCl_2 \cdot 6NH_3$, which on heating loses ammonia, and, finally, yields ammonium chloride, nitrogen and iron nitride. It fuses at a red-heat, and volatilizes at a yellow-heat; its vapour density at 1300°–1400° corresponds to the formula $FeCl_2$. By evaporating in vacuo the solution obtained by dissolving iron in hydrochloric acid, there result bluish monoclinic crystals of $FeCl_2 \cdot 4H_2O$, which deliquesce, turn greenish on exposure to air, and effloresce in a desiccator. By adding ammonium chloride to the solution, evaporating in vacuo and then volatilizing the ammonium chloride, anhydrous ferrous chloride is obtained. The solution, in common with those of most ferrous salts, absorbs nitric oxide with the formation of a brownish solution.

Ferric chloride, $FeCl_3$, may be obtained anhydrous by the action of dry chlorine on the metal at a moderate red-heat, or by passing hydrochloric acid gas over heated ferric oxide. It forms iron-black plates or tablets which appear red by transmitted and a metallic green by reflected light. It is very deliquescent, and readily dissolves in water, forming a brown or yellow solution, from which several hydrates may be separated. The solution is best prepared by dissolving the hydroxide in hydrochloric acid and removing the excess of acid by evaporation, or by passing chlorine into the solution obtained by dissolving the metal in hydrochloric acid and removing the excess of chlorine by a current of carbon dioxide. It also dissolves in alcohol and ether; boiling-point determinations of the molecular weight in these solutions point to the formula $FeCl_3$. Vapour density determinations at 448° indicate a partial dissociation of the double molecule Fe_2Cl_6; on stronger heating it splits into ferrous chloride and chlorine. It forms red crystalline double salts with the chlorides of the metals of the alkalis and of the magnesium group. An aqueous solution of ferric chloride is used in pharmacy under the name *Liquor ferri perchloridi.*

Ferrous bromide, $FeBr_2$, is obtained as yellowish crystals by the union of bromine and iron at a dull red-heat, or as bluish-green rhombic tables of the composition $FeBr_2 \cdot 6H_2O$ by crystallizing a solution of iron in hydrobromic acid. Ferric bromide, $FeBr_3$, is obtained as dark red crystals by heating iron in an excess of bromine vapour. It closely resembles the chloride in being deliquescent, dissolving ferric hydrate and in yielding basic salts. Ferrous iodide, FeI_2, is obtained as a grey crystalline mass by the direct union of its components. Ferric iodide does not appear to exist.

Sulphur Compounds. — Ferrous sulphide, FeS, results from the direct union of its elements, best by stirring molten sulphur with a white-hot iron rod, when the sulphide drops to the bottom of the crucible. It then forms a yellowish crystalline mass, which readily dissolves in acids with the liberation of sulphuretted hydrogen. Heated in air it at first partially oxidizes to ferrous sulphate, and at higher temperatures it yields sulphur dioxide and ferric oxide. It is unaltered by ignition in hydrogen. A black amorphous form results when ferrous salts are precipitated by ammonium sulphide.

Ferric-sulphide, Fe_2S_3, is obtained by gently heating a mixture of its constituent elements, or by the action of sulphuretted hydrogen on ferric oxide at temperatures below 100°. It is also prepared by precipitating a ferric salt with ammonium sulphide; unless the alkali be in excess a mixture of ferrous sulphide and sulphur is obtained. Magnetic pyrites or pyrrhotite has a composition varying between $5FeS \cdot Fe_2S_3$ and $6FeS \cdot Fe_2S_3$. It has a somewhat brassy colour, and occurs massive or as hexagonal plates; it is attracted by a magnet and is sometimes itself magnetic. The mineral is abundant in Canada, where the presence of about 5% of nickel makes it a valuable ore of this metal. Iron disulphide, FeS_2, constitutes the minerals pyrite, which is important as a source of sulphuric acid, and marcasite (*q.v.*); copper pyrites is (Cu, Fe)S_2 Pyrite may be prepared artificially by gently heating ferrous sulphide with sulphur, or as brassy octahedra and cubes by slowly heating an intimate mixture of ferric oxide, sulphur and sal-ammoniac. It is insoluble in dilute acids, but dissolves in nitric acid with separation of sulphur.

Ferrous sulphate, green vitriol or copperas, $FeSO_4 \cdot 7H_2O$, was known to, and used by, the alchemists; it is mentioned in the writings of Agricola, and its preparation from iron and sulphuric acid occurs in the Tractatus *chymico-philosophicus* ascribed to Basil Valentine. It occurs in nature as the mineral melanterite, either crystalline or fibrous, but usually massive; it appears to have been formed by the oxidation of pyrite or marcasite. It is manufactured by piling pyrites in heaps and exposing to atmospheric oxidation, the ferrous sulphate thus formed being dissolved in water, and the solution run into tanks, where any sulphuric acid which may be formed is decomposed by adding scrap iron. By evaporation the green vitriol is obtained as large crystals. Ferrous sulphate forms large green crystals belonging to the monoclinic system; rhombic crystals, isoinorphous with zinc sulphate, are obtained by inoculating a solution with a crystal of zinc sulphate, and triclinic crystals of the formula $FeSO_4 \cdot 5H_2O$ by inoculating with copper sulphate. By evaporating a solution containing free sulphuric acid in a vacuum, the hepta-hydrated salt first separates, then the penta-, and then a tetra-hydrate, $FeSO_4 \cdot 4H_2O$, isomorphous with manganese sulphate. By gently heating in a vacuum to 140°, the hepta-hydrate loses 6 molecules of water, and yields a white powder, which on heating in the absence of air gives the anhydrous salt. The monohydrate also results as a white precipitate when concentrated sulphuric acid is added to a saturated solution of ferrous sulphate. Alcohol also throws down the salt from aqueous solution, the composition of the precipitate varying with the amount of salt and precipitant employed. The solution absorbs nitric oxide to form a dark brown solution, which loses the gas on heating or by placing in a vacuum. Ferrous sulphate forms double salts with the alkaline sulphates. The most important is ferrous ammonium sulphate. $FeSO_4 \cdot (NH_4)_2SO_4 \cdot 6H_2O$, obtained by dissolving equivalent amounts of the two salts in water and crystallizing It is very stable and is much used in volumetric analysis. It is often called Mohr's salt.

Ferric sulphate, $Fe_2(SO_4)_3$, is obtained by adding nitric acid to a hot solution of ferrous sulphate containing sulphuric acid, colourless crystals being deposited on evaporating the solution. The anhydrous salt is obtained by heating these, or by adding strong sulphuric acid to a solution. It is sparingly soluble in water, and on heating it yields ferric oxide and sulphur dioxide. Many basic ferric sulphates are known, some of which occur as minerals. The iron alums are obtained by crystallizing solutions of equivalent quantities of ferric and an alkaline sulphate. Ferric potassium sulphate, common iron alum, $K_2SO_4 \cdot Fe_2(SO_4)_3 \cdot 24H_2O$, forms bright violet octahedra.

Nitrides, Nitrates, **etc.**—Several nitrides are known. Guntz obtained ferrous nitride, Fe_3N_2, and ferric nitride FeN, as black powders by heating lithium nitride with ferrous potassium chloride and ferric potassium chloride respectively. Fowler obtained a nitride Fe_2N by acting upon anhydrous ferrous chloride or bromide, finely divided reduced iron, or iron amalgam with ammonia at 420°; and also, in a compact form, by the action of ammonia on red-hot iron wire. It oxidizes on heating in air, and ignites in chlorine; on solution in mineral acids it yields ferrous and ammonium salts, hydrogen being liberated. A nitride appears to be formed when nitrogen is passed over heated iron, since the metal is rendered brittle. Ferrous nitrate, $Fe(NO_3)_2 \cdot 6H_2O$, is a very unstable salt, and is obtained by mixing solutions of ferrous sulphate and barium nitrate, filtering and crystallizing in a vacuum over sulphuric acid. Ferric nitrate, $Fe(NO_3)_3$, is obtained by dissolving iron in nitric acid (the cold dilute acid leads to the formation of ferrous and ammonium nitrates) and crystallizing, when cubes of $Fe(NO_3)_3 \cdot 6H_2O$ or monoclinic crystals of $Fe(NO_3)_3 \cdot 9H_2O$ are obtained. It is used as a mordant.

Ferrous solutions absorb nitric oxide, forming dark green to black solutions. The coloration is due to the production of unstable compounds of the ferrous salt and nitric oxide, probably of the type $2FeSO_4 \cdot NO$; the reaction, however, is reversible, the composition varying with temperature, concentration and nature of the salt. The reaction is utilized in the "brown ring" test for

nitrates. Reddish brown amorphous powders of the formulae $2FeCl_3{\cdot}NO$ and $4FeCl_3{\cdot}NO$ are obtained by passing the gas over anhydrous ferric chloride. By passing the gas into an ethereal solution of the salt, nitrosyl chloride is produced, and on evaporating over sulphuric acid, black needles of $FeCl_2{\cdot}NO{\cdot}2H_2O$ are obtained, which at 60° form the yellow $FeCl_2{\cdot}NO$. Complicated compounds discovered by Roussin (Ann. *Chim. Phys.*, 1858, 52, p. 285) are obtained by the interaction of ferrous sulphate and alkaline nitrates and sulphides. Two classes may be distinguished: — (I) the ferrodinitroso salts; *e.g.*, $K[Fe(NO)_2S]$, potassium ferrodinitrososulphide, and (2) the ferroheptanitroso salts; *e.g.*, $K[Fe_4(NO)_7S_3]$, potassium ferroheptanitrososulphide. These salts yield the corresponding acids with sulphuric acid. For further information the above paper by Roussin, and also one by Pavel (Ber., 1882, 15, p. 2600), should be consulted.

Phosphides, **Phosphates.**—H. Le Chatelier and S. Wologdine obtained Fe_3P, Fe_2P, FeP, Fe_2P_3, but failed to prepare five other phosphides previously described. Fe_3P occurs as crystals in the product of fusing iron with phosphorus; it dissolves in strong hydrochloric acid. Fe_2P forms crystalline needles insoluble in acids except aqua regia; it is obtained by fusing copper phosphide with iron. FeP is obtained by passing phosphorus vapour over Fe_2P at a red-heat. Fe_2P_3 is prepared by the action of phosphorus iodide vapour on reduced iron. Ferrous phosphate occurs in nature as the mineral vivianite $Fe_3(PO_4)_2{\cdot}8H_2O$. It may be obtained artificially as a white precipitate, which rapidly turns blue or green on exposure, by mixing solutions of ferrous sulphate and sodium phosphate. It is employed in medicine. Normal ferric phosphate, $FePO_4{\cdot}2H_2O$, occurs as the mineral strengite, and is obtained as a yellowish-white precipitate by mixing solutions of ferric chloride and sodium phosphate. It is insoluble in dilute acetic acid, but dissolves in mineral acids. The acid salts $Fe(H_2PO_4)_3$ and $2FeH_3(PO_4)_2{\cdot}5H_2O$ have been described. Basic salts have been prepared, and several occur in the mineral kingdom; dufrenite is $Fe_2(OH)_3PO_4$.

Arsenides, Arsenites, **etc.**—Several iron arsenides occur as minerals; mispickel or arsenical pyrites, Fe_2AsS_2, is an important commercial source of arsenic. A basic ferric arsenite, $4Fe_2O_3{\cdot}As_2O_3{\cdot}5H_2O$, is obtained as a flocculent brown precipitate by adding an arsenite to ferric acetate, or by shaking freshly prepared ferric hydrate with a solution of arsenious oxide. The last reaction is the basis of the application of ferric hydrate as an antidote in arsenical poisoning. Normal ferric arsenate, $FeAsO_4{\cdot}2H_2O$, constitutes the mineral scorodite. On the constitution of pharmacosiderite and acid arsenates, see N. H. Hartshorne, Journ. Chem. *Soc.*, 1927, p. 1759.

Carbides, Carbonates. — The carbide of iron Fe_3C plays an important part in determining the properties of the different modifications of the commercial metal, which are discussed under IRON AND STEEL.

Ferrous carbonate, $FeCO_3$, or spathic iron ore, may be obtained as microscopic rhombohedra by adding sodium bicarbonate to ferrous sulphate and heating to 150° for 36 hours. Ferrous sulphate and sodium carbonate in the cold give a flocculent precipitate, at first white but rapidly turning green owing to oxidation. A soluble carbonate and a ferric salt give a precipitate which loses carbon dioxide on drying. Of great interest are the carbonyl compounds. Ferropentacarbonyl, $Fe(CO)_5$, obtained by L. Mond, Quincke and Langer, by treating iron from ferrous oxalate with carbon monoxide, and heating at 150°, is a pale yellow liquid which freezes at about —20°, and boils at 102·5°. Air and moisture decompose it. The halogens give ferrous and ferric halides and carbon monoxide; hydrochloric and hydrobromic acids have no action, but hydriodic decomposes it. On exposure to sunlight, either alone or dissolved in ether or ligroin, it gives lustrous orange plates of diferrononacarbonyl, $Fe_2(CO)_9$. If this substance be heated in ethereal solution to 50°, it deposits lustrous dark green tablets of ferrotetracarbonyl, $Fe(CO)_4$, very stable at ordinary temperatures, but decomposing at 140°–150° into iron and carbon monoxide. For the cyanides see PRUSSIC ACID.

Ferrous salts give a greenish precipitate with an alkali, whilst ferric give a characteristic red one. Ferrous salts also give a bluish white precipitate with ferrocyanide, which on exposure turns to a dark blue; ferric salts are characterized by the intense blood-red coloration with a thiocyanate. Iron is estimated either by reduction to the ferrous condition and titration by potassium permanganate or dichromate, or by titration in the ferric condition by means of titanous chloride. (See also CHEMISTRY: Analytical.)

A. Werner prepared salts of ferrous tri-dipyridyl, $[Fe(C_{10}H_8N_2)_3]X_2$, which were resolved into dextro- and laevo-rotatory forms (see STEREOCHEMISTRY), and W. Thomas similarly resolved potassium ferrioxalate, $K_3[Fe(C_2O_4)_3]$.

MEDICAL USES

All the official salts and preparations of iron are made directly or indirectly from the metal. The pharmacopoeia1 forms of iron are as follow:—

Ferri *sulphas exsiccatus,* which has two subpreparations: (a) Pilula ferri, "Blaud's pill," (b) Pilula aloes et ferri.

Ferri *phosphas,* a slate-blue powder of ferrous and ferric phosphates with some oxide. Its preparations are: (a) *Syrupus* ferri *phosphatis;* (b) *Syrupus* ferri phosphatis *cum quinina* et *strychnina,* "Easton's syrup," in which each fluid drachm represents 1gr. of ferrous phosphate, $\frac{4}{5}$gr. of quinine sulphate, and $\frac{1}{32}$gr. of strychnine.

Syrupus ferri iodidi (strength 5·5gr. of ferrous iodide in one fl.dr.).

Liquor ferri perchloridi fortis, strong solution of ferric chloride (strength, 22·5% of iron); its preparations only are prescribed, viz.: Liquor *ferri* perclzloridi and Tinctura ferri *perchloridi.*

The scale preparations of iron, so called because they are dried to form scales, are three in number, the base of all being ferric hydrate:

(a) Ferrum tartaratum, dark red scales, soluble in water.

(b) Ferri et quininae citratis, greenish yellow scales soluble in water.

(c) Ferri *et* ammonii citratis, red scales soluble in water, from which is prepared *Vinum* ferri citratis (ferri et ammonii citratis 1gr., orange wine 1 fl.dr.).

Substances containing tannic or gallic acid turn black when compounded with a ferric salt, so it cannot be used in combination with vegetable astringents except with the infusion of quassia or calumba. Iron may, however, be prescribed in combination with digitalis by the addition of dilute phosphoric acid. Alkalis and their carbonates, lime water, carbonate of calcium, magnesia and its carbonate give green precipitates with ferrous and brown with ferric salts.

There are numerous organic preparations of iron. Ferratin is a reddish brown substance which claims to be identical with the iron substance found in pig's liver. Carniferrin is a tasteless powder containing iron in combination with the phosphocarnic acid of muscle preparations, and contains 35% of iron. Ferratogen is prepared from ferric nuclein. Triferrin is a paranucleinate of iron, and contains 22% of iron and 2½% of organically combined phosphorus, prepared from the casein of cow's milk. Haemoglobin is extracted from the blood of an ox and may be administered in bolus form. Dieterich's solution of peptonated iron contains about 2gr. of iron per oz. Vachetta used the albuminate of iron with striking success in grave cases of anaemia. Succinate of iron has been prepared by Hausmann. Haematogen, introduced by Hommel, claims to contain the albuminous constituents of the blood serum and all the blood salts as well as pure haemoglobin. Sicco, the name given to dry haematogen, is a tasteless powder. Haemalbumen, introduced by Dahmen, is soluble in warm water.

Therapeutics. — Iron is a food and a medicine. Externally its salts are not absorbed by the unbroken skin, but when applied to the broken skin, sores, ulcers and mucous surfaces, the ferric salts are powerful astringents, because they coagulate the albuminous fluids in the tissues themselves. The salts of iron quickly cause coagulation of the blood, and the clot plugs the bleeding vessels. They thus act locally as haemostatics.

Internally, a large proportion of ordinary diet contains iron.

When given medicinally preparations of iron have an astringent taste, and the teeth and tongue are blackened owing to the formation of sulphide of iron. It is therefore advisable to take liquid iron preparations through a glass tube or a quill.

In the stomach all salts of iron are converted into ferric chloride. If given in excess, or if the hydrochloric acid in the gastric juice be deficient, iron acts directly as an astringent upon the mucous membrane of the stomach wall. Acid preparations are more likely to do this, and the acid set free after the formation of the chloride may act as an irritant. Iron, therefore, must not be given to subjects in whom the gastric functions are disturbed, and it should always be given after meals. Preparations which are not acid, or are only slightly acid, such as reduced iron, dialysed iron, the carbonate and scale preparations, do not disturb the digestion. In the intestine the ferric chloride becomes changed into an oxide of iron; the sub-chloride is converted into a ferrous carbonate, which is soluble. Lower in the bowel these are converted into ferrous sulphide and tannate, and are eliminated with the faeces, turning them black. Iron in the intestine is astringent or constipating and is therefore useful occasionally to check diarrhoea and dysentery. Salts of iron being constipating; they are best used in combination with a purgative. The pill of iron and aloes (B.P.) is designed for this purpose. Iron is certainly absorbed from the intestinal canal. As the iron in the food supplies all the iron in the body of a healthy person, there is no doubt that it is absorbed in the organic form. Whether inorganic salts are directly absorbed has been a matter of much discussion; it has, however, been directly proved by the experiments of Kunkel *(Archiv fur die gesamte Physiologie des Menschen und der Tiere,* lxi.) and Gaule. The amount of iron in the human blood is only 38gr.; therefore, when an excess of iron is absorbed, part is excreted immediately by the bowel and kidneys, and part is stored in the liver and spleen.

Iron is prescribed when the amount of haemoglobin in the blood is lowered or the red corpuscles are diminished. In certain forms of anaemia its administration rapidly improves the blood in both respects, though the exact method in which it acts is a matter of dispute. In cases with toxaemia from absorption of intestinal products, not only laxatives in combination with iron but intestinal antiseptics are necessary. That form of neuralgia which is associated with anaemia usually yields to iron.

IRON AGE: *see* ARCHAEOLOGY.

IRON AND STEEL. Iron is the most useful metal of material civilization; it means plant, tools, machinery. It is principally used when alloyed with other elements, notably carbon; a moderate amount produces steel, an excess produces cast iron. Many special steels for particular uses have been devised in recent years; these steels contain a proportion of other metals, such as manganese or chromium (resulting in manganese steel, or chromium steel in these two cases, for instance). About 100 million gross tons of pig iron and 13½ million gross tons of steel were made in 1937—a fairly active year.

Outline of Manufacturing Process.—The source of commercial iron and steel is the oxide ores of iron, occurring in great abundance in all continents. This is charged into the top of a shaft-like blast furnace together with coke and some limestone. Hot air is blown into this furnace near the bottom, burning the coke and furnishing the gases and heat necessary to reduce the iron oxide to molten iron metal; trickling down over the white hot coke it absorbs an excess of carbon; drsined from the bottom is the impure high-carbon alloy pig iron, which is merely remelted and cast into moulds to form the familiar iron castings of commerce. Limestone is charged into the furnace to convert earthy minerals mixed with the iron ore (gangue) and the coke ash into a fusible slag; this is also drained periodically from the furnace hearth. The blast furnace therefore operates continuously; solids are charged at the top, liquid iron and slag are drawn from the bottom.

To change pig iron into steel two methods are used extensively, the Bessemer converter and the Siemens-Martin open-hearth furnace. The converter is a brick-lined vessel, with perforations in the bottom through which air is blown. Into this vessel some molten pig iron is charged, and the air blowing through the metal burns out the carbon and some of the other impurities; at these high temperatures there is a pronounced selective action so that relatively little of the iron is burned. Combustion of these impurities furnishes the necessary heat to maintain operations. At the end of the blow, a matter of ten to 15 min., the purified metal is dumped into a ladle, and an alloy of manganese and iron known as spiegel is added to degasify the melt, whereupon the finished steel is poured into ingot moulds. Refining pig iron in an open-hearth furnace is a much more deliberate process, requiring about 13 hours. The furnace is a flat shallow basin with a low roof. At either end are ports through which fuel and hot air enter; the flame sweeps through, out the ports at the other end, and thence into chambers filled with checker brick to absorb some of the waste heat. At intervals the flow of gases is reversed by suitable valves thus returning the recovered heat to the furnace hearth. Scrap and pig iron are placed in the furnace through side doors, and melted down. Iron ore and limestone are also added, and a series of chemical reactions take place between the iron oxide and the impurities in the metal; the latter either vanish as gases or accumulate in a scum of thin slag. When the reactions are complete the bath is tapped into a ladle from which the slag overflows, and the finished steel is then cast into ingots. Ingots are squat prisms of steel and are given marketable shape in the rolling mills. By successively passing between rolls with steadily diminishing apertures, bulky ingots are converted into long rods, bars, plates, rails or various structural shapes. Rather thicker bars are known as billets and are used in forge shops for hammering out more intricate pieces of non-uniform cross section. Specially shaped rolls and auxiliary machinery also convert bars into sheet-steel, plate into pipe, and rods into wire products.

EARLY HISTORY

Antiquity of Iron.—Few implements of iron or steel survive for many years before they rust away, consequently there is little direct evidence to prove the point; nevertheless the antiquity of iron smelting is great. It doubtless has been discovered and rediscovered many times; explorers reaching primitive peoples in many parts of the world find the native blacksmith using methods very similar to those known to other tribes at far distant times and places. An iron blade, probably 5,000 years old, has been found in one of the Egyptian pyramids. Even without this discovery one could plausibly maintain that the ancient Egyptians *must* have had skilled steel workers in order to have built the great pyramids and other monumental architecture, to say nothing of the statuary and hieroglyphics cut into the hardest rocks. Steel working and hardening, an advanced stage in the art which doubtless required centuries to reach, was common 3,000 years ago in Greece, and is mentioned in Homer. It is more probable that iron was first found in the ashes of a big fire built near some red paint-rock than that the first tools were made from meteorites. When paint-rock and fire came to be associated with iron as cause and effect, the next step was to produce it intentionally in fires built against a bank exposed to prevailing winds, or in pits or rude rock furnaces where the fires were fanned by bellows, one of the earliest mechanical devices.

These are the primitive methods which survive to-day in the Catalan forge (*q.v.*): a mixture of charcoal and iron ore, selected for its purity, is heated intensely for several hours, with fuel additions made from time to time, and a vigorous blast of air fanning the fire. The iron ore becomes an incandescent sponge of metal; the clay or other minerals mixed with the iron oxide together with the charcoal ash sinter into a slag, permeating the sponge and protecting the freshly reduced iron from further chemical action. After a given time, the furnace is broken into, the glowing ball of iron pulled out, and immediately, while still white hot, hammered vigorously to expel as much of the slag as possible, and to weld the hot particles of metal into a coherent mass.

Steel from Indirect Processes.—With various changes in the furnace details, and in methods of producing the air blast, these methods produced all the iron available from the beginning up to the 14th century. It was truly a *wrought* iron, the best product containing no more than 0·1% of total impurities alloyed with the

metal, but shot through with microscopic slag particles, aggregating 3% or more of the total weight. Steel was made sometimes as an accidental product in the old forges; by design the wrought iron bars would be packed with charcoal in clay boxes or jars, and heated for days, whereupon the iron absorbed enough carbon to become steel and thus acquired the superior hardness and strength necessary for keener tools.

As the demand for iron grew, the furnaces became bigger and a stronger blast of air was required to drive the products of combustion from the bottom up through the mixed charge. It resulted that the iron ore was reduced to spongy metal in the upper part of the furnace, and it then proceeded to absorb more carbon as the charge settled down, thereby converting itself to pig iron, a much more readily fusible alloy. The bigger, taller furnaces introduced in the early 14th century therefore produced liquid pig iron, a complex alloy of iron, carbon and other elements. Subsequent developments have been along three main lines; (a) increasing the size of the furnace and developing mechanical auxiliaries to produce pig iron more economically and in greater amounts, (*b*) invention of various processes for changing this impure pig iron into the more useful wrought iron, (*c*) production of steel either by way of wrought iron, or from pig iron direct. Sir Henry Bessemer's process, announced in 1856, for making steel from pig iron in a pneumatic converter, began the steel epoch. Cheap and ample supplies of steels in a wealth of sizes, shapes and surface finishes, grades of hardness, or types of alloy, are now available to meet the special demands of metal workers, machinery builders, or tool users.

Modern metallurgical developments have consequently been away from the simple and direct production of wrought iron to the complex indirect manufacture of steel. The change from the small, intermittent operations controlled by a highly skilled artisan to the large continuous furnaces, machine driven, has been associated with enormous expansion in total output and as great a saving in labour, and a notable conservation of raw materials.

Steel from Direct Processes.—Some metallurgists, however, believe that the excessively high temperatures attained in the modern blast furnace cause the pig iron to alloy with undesirable compounds, notably of nitrogen, which cannot be eliminated later, and which, they say, cause the present day metal to be inferior to that produced by the old direct processes operating at a low temperature. Hence many methods of making iron and steel direct from the ore have been proposed since 1910, and extended experimentation on a semi-commercial scale has produced some marketable metal by these processes. Most of them rely upon the fact that iron ore is reduced by gas in the upper cooler part of the blast furnace. That is, the reaction

$$Fe_2O_3 + 3CO \rightarrow 2\,Fe + 3CO_2$$

is substantially completed at 800° C, low red heat, too low to break up other minerals in the ore. Consequently hot iron ore is passed through a revolving kiln containing producer gas, and the iron sponge formed therein is either passed direct to an electric melting furnace, or quenched rapidly to prevent re-oxidation, separated from unreduced ore and gangue, and the metallic portion briquetted or melted. That these so-called direct steel-making processes are destined to supplant the present indirect system of smelting ore to an impure product, and refining the latter, is very unlikely. In view of the great investment in the present plants for making steel which is reasonably satisfactory to the user, any innovation would have to show a considerable saving in costs, or have material collateral advantages or improved quality, before it could be widely adopted. Such savings and advantages have not yet been demonstrated.

IRON ORE

Iron is smelted from several oxidized minerals occurring in abundance in the earth's crust. In order of commercial importance these minerals are hematite (Fe_2O_3), magnetite (Fe_3O_4), limonite (hydrated iron oxide) and the carbonate siderite ($FeCO_3$). Great deposits of these minerals in relatively pure state, close enough to the surface to be mined easily, are in many regions. They are so common that an iron and steel industry will be developed whenever and wherever a population of machinery-using humanity accumulates. Iron deposits located in sparsely settled countries are potential ores of the future; for present uses an ore must be so situated and of such a nature that it can be mined, smelted by methods now known, and transported to market at a profit. Proximity to cheap fuel will enhance the value of ore—in Great Britain inland furnaces smelt local ores containing as low as 23% iron. The enormous ore deposits near Lake Superior in North America are a thousand miles from coking coal and an iron-consuming population, but intensive production and cheap water transport on the Great Lakes enables them to dominate the American market. On the other hand Brazil has huge untouched reserves of iron too far inland to export and with no home demand. The Continent depends upon the minette ores of Lorraine—ores which until the beginning of this century were valueless for steel making because no way was known to eliminate a high percentage of harmful phosphorus.

American Deposits.—The most productive iron ore region in the world is in very old (pre-Cambrian) strata surrounding Lake Superior, on the border between United States and Canada. Several long narrow areas called ranges contain the workable ores, which are hematites. Data on these ranges follow (shipments in long tons of 2,240 lb.):

"Old Ranges"					
Name	Location	Opened	Shipments in 1937	Total shipments including 1937	Greatest yearly shipments
				Million	
Marquette	Michigan	1854	5,747,812	194	6,747,812
Menominee	Michigan	1872	2,649,062	103	6,349,000
Gogebic	Michigan & Wisconsin	1884	5,661,270	207	8,763,000
Vermillion	Minnesota	1884	1,453,080	65	2,084,000
"New Ranges"					
Mesabi	Minnesota	1892	45,823,571	1,031	45,823,571
Cuyuna	Minnesota	1911	1,775,445	38	2,479,000

The deposits in the Mesabi range are flat, thick and close to the surface, and are therefore mined in open cuts by steam shovels. Underground mining is the rule in the others, the veins being fairly steep and worked to 3,000 ft. depth. The wealth of these ranges is such that ores of various analyses and textures are available. One-fourth the output is Bessemer ore, suitable for acid steel, containing on the average 55% iron and 0·04 phosphorus. The Cuyuna ore contains notable amounts of manganese. Basic or non-Bessemer ores from the ranges are higher in phosphorus and averaged 51·5% iron in 1937, with silica forming the principal impurity.

In view of the tremendous annual production of the Mesabi range, it may be questioned how long it will be before the region is worked out. The average iron content of all lake ores dropped from 553% in 1902 to 51¾% in 1910, and has been maintained since then only by mining increasing amounts of high grade ore, and washing, screening, or drying one-third of the remainder. Minnesota is estimated by the State geologist to have demonstrated reserves of 1,250 million tons of recoverable ore. Unless these reserves are increased by new discoveries the Mesabi range will be worked out by 1975 or 2000, depending on whether the pre-depression or the post-depression rate is figured. But any prediction about the age of a mining district must prophesy also the state of the future art of ore concentration—lean rock today may be workable ore tomorrow. In fact, this region contains an unlimited tonnage of magnetite-bearing strata just outside the classification of ore, as defined by conditions in 1937.

While seven-eighths of American ore comes from the Lake ranges, the balance of about eight million tons is taken from many ore occurrences in the Clinton formation in the Appalachian mountains, an uplift which parallels the Atlantic coast from north

to south. In the northern region the ores are predominantly magnetites; at the southern end in the State of Alabama, deposits of a low-grade red hematite with an easily fusible gangue are found near extensive coal measures. All these deposits are mined by underground methods; among them are mines which have produced continuously since the earliest iron smelting in America.

Lorraine Deposits.—Ore beds second in importance only to those in the Lake Superior region occur in strata of Mesozoic age near the Franco-German border, extending northward into Luxembourg and Belgium. They are of recent commercial development. While only 830,000 tons were produced in 1897, they are now the chief ores for the French, Belgian, German and Luxembourg blast furnaces which together in 1937 produced 30% of the world's pig iron. Mining is done in three principal basins, Longwy near the Belgian border, Briey, and Nancy at the south. Previous to the World War much of this area was German territory, and practically all of the rest was promptly overrun and occupied by the invading army. Possession of this all but essential region was thereafter one of the aims of the contending Powers. Great damage was done during the occupation and the retreat, and not until 1926 did the area approach the productivity of 1913. While the output of the region exclusive of Belgium and Luxembourg was about 40 million tons in 1913, equally divided between France and Germany, the French department of Meurthe-et-Moselle was able to hoist only 5 million tons in 1920. Recovery of the reunited provinces has been so rapid, however, that the output of ore reached 37 million tons in 1926. The ore beds occur in flat strata 60 to 120 ft. thick, from 300 to 750 ft. below the surface. The iron is contained in tiny nodules of hematite, cemented with a calcareous or a siliceous gangue. It is only necessary to combine these two to procure a self-fluxing, easy smelting mixture, very desirable commercially even though its iron content is quite low Representative analyses, after driving off 8 to 12% moisture, are as follows:

	Siliceous ore	Calcareous ore
	%	%
Iron	35 to 37	38 to 42
Silica	12 to 18	4 to 8
Alumina	3 to 7	3 to 7
Lime	3 to 7	9 to 13

Phosphorus is strikingly uniform, being 1.7 to 1·9% of the iron contained, and the Lorraine pig iron must therefore be used in basic steel making, as later to be explained.

Ores in Great Britain.—Since the rich blackband, clay iron stone and brown hematites of the Carboniferous strata have been almost exhausted, 80% of the iron ore mined in Great Britain is now taken from leaner strata, averaging only 27½%, which are a continuation of the Lorraine beds. Workable deposits extend in a broad strip from the coast of Yorkshire south-west to that of Dorset and are estimated to contain 3,400 million tons of workable ores. The beds are nearly horizontal, and consequently have broad outcrops in gently rolling ground, thus permitting them to be mined by quarrying operations. As a rule the individual deposits are small, and do not warrant the powerful excavating machinery installed in the great Mesabi pits. A maximum working face is 30 ft. Such "marlstones" (or simply "stone") contain the iron in tiny ooliths like the Lorraine ore, but near the surface the iron has been oxidized and hydrated to limonite, and at depth is a carbonate. Gangue materials are either calcareous or siliceous. These deposits have been longest mined at Cleveland, and here a limited area has produced 5½ million tons a year since 1875. All mining is underground in carbonate ores sometimes as deep as 600 ft.; g to 12 ft. beds are reckoned excellent. A governmental survey made in 1918 found only 200 million tons of recoverable ore here in reserve. An average analysis follows:

Oxide (FeO)	28%*
Silica (SiO_2)	12%
Alumina (Al_2O_3)	10%
Lime (CaO)	5%
Sulphur	0·26%
Phosphorus	0·47%
Water	6·8%

*(24·6 to 33·3%)

Cleveland ores therefore are suitable for basic steel making, wrought iron manufacture or general iron foundry work. Except for the several post-war years of acute industrial depression, Great Britain's ore demands have been about stationary since the turn of the century. Each year Cleveland hoists 5½ million tons, other regions dig g million tons and 6 million tons are imported, principally low-phosphorus ore from Spain and Sweden.

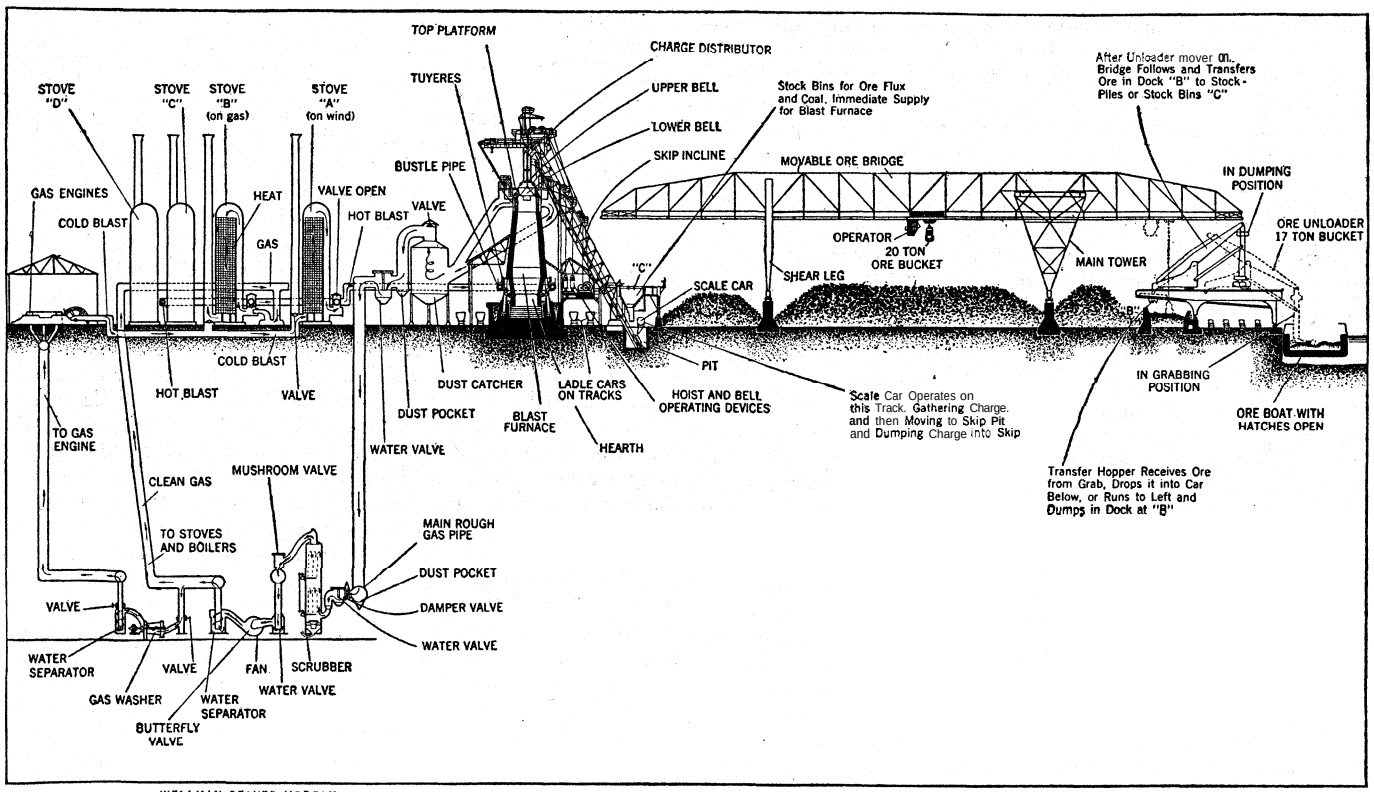
Future Stores of Iron.—Whether there is any likelihood of exhausting the available iron ore is a question which has occupied some minds. From the above remarks, it may appear that certain regions, such as the Mesabi range and the Cleveland beds, may be exhausted in the near future. However there is little to fear but that other deposits, only slightly less favoured, will supply the gap. Conservative estimates by economic geologists indicate that there are now about 30 billion tons of ore in reserve. which at the present annual consumption of 100 to 125 million tons, should last 200 years. Of this huge tonnage, two-thirds is located in the Western hemisphere; Brazil and United States possess most of this, but Newfoundland and Cuba both have notable deposits; France has half the balance, and the rest is scattered about in readily accessible locations. All such computations assume a certain state of metallurgical art in order to define ore. But metallurgical art is constantly advancing. Since so large a proportion of the earth is iron, it is safe to say that in the future, as in the past since before history began, the mind of man will always find means to win from mother earth this most useful metal, in supply ample for his current needs.

PREPARATION OF ORE FOR SMELTING

Transport.—In England and on the Continent much of the iron ore is smelted in furnaces erected nearby—even at the mine mouth. Freight is a minor matter. That which is transported from overseas is handled for the most part in ordinary cargo vessels. In America, however, the long haul down the Lakes from the ranges to the furnaces has caused the development of very specialized handling equipment. At the mines, hopper-bottom railroad cars of 50 to 60 tons capacity are loaded by steam shovels in the pit, or from storage bins at the mine, and hauled to the nearest port. Here long lines of ore bins are built out into the water; whole trainloads of ore are dumped in a few minutes by pneumatic devices. When these bins are full an ore boat docks alongside, opens her hatches, and a load of 10,000 tons of ore is spouted into her in less than a half hour. Ore boats that are used for service on the relatively calm Great Lakes are of special construction and are essentially long, self-propelling barges with a movable deck. Arrived at its destination, the hatches are again opened, and enormous grab-buckets reach through into the hold, scooping out the ore and dropping it inshore, either in railroad cars, or on a stock pile. If the furnace plant is inland, trainloads of ore are hauled to the site, and dumped in bins or placed in stock piles. Hopper-bottomed cars are used almost exclusively for this purpose, although for stockpiling it is generally found better to install a car-dumper, which turns the car upside down, and then to move the ore to the pile by a grab-bucket and overhead bridge. One cannot comprehend the magnitude and power of this unloading machinery, unless it has been seen in operation. Large stock piles, which are almost unknown elsewhere, are the general rule in America, where water transportation is entirely suspended by ice during the winter months. Limestone and coke are also stocked in sufficient quantity to provide against irregular deliveries from a distance.

Dressing.—Up to the beginning of the 20th century iron ore was seldom treated in any way prior to its utilization. High grade materials, however, are becoming increasingly scarce, and the future will see a rapid extension of ore dressing methods.

Screening is the simplest method. Some 17 million tons of Lake ore were improved by this method in 1927. In England, as well the miner frequently digs marlstone without removing the



BY COURTESY OF THE WELLMAN-SEAVER-MORGAN COMPANY, CLEVELAND, OHIO

FIG. 1.— DIAGRAMMATIC ELEVATION OF BLAST FURNACE WITH AUXILIARIES AND STOCK PILES

loamy overburden; the quarried material is then crushed, and the fine particles screened out and discarded. In this way the average iron content of the ore is increased, and the suitability for smelting improved, for too many fines in the charge slow down blast furnace operations.

Washing is also common in America. This is an application of the water concentration methods so highly developed in ore dressing (*q.v.*) used at copper, lead and zinc mines. Some five million tons of Mesabi ore were treated in log washers in 1927. The washer is an inclined trough; from end to end is a stout shaft or log, with plow blades so set on its circumference that when the shaft revolves the plows clear the trough bottom and move any solid material gradually along. The fine screenings enter at one end, and travel against a copious current of water, which washes out the finer, clay bearing particles, lean in iron.

Calcining is common in England, particularly on the Cleveland carbonate ores. A Gjers kiln is ordinarily used, a short cylindrical steel shell set vertically, and lined with fire brick. A mixture of ore, with about 5% slack coal, is charged through the top as the burned ore is withdrawn at the base. Such a kiln will drive moisture and carbon dioxide from about 1,000 tons of ore in a week; Cleveland ores lose 27 to 30% in weight, but the resulting ore has had its iron percentage increased thereby to about 31%; still a very lean ore, viewed by American standards. Lorraine ores contain much moisture, but cannot be calcined, because this preliminary heating causes them to fall to powder.

Sintering is a method of converting fine ores or flue dusts into a porous clinker which can easily be smelted. American and Swedish magnetite ores, low in grade, are frequently concentrated by fine grinding, and drawing the iron bearing minerals out of waste rock with strong magnets. This fine magnetite is then moistened and mixed with fine coal and a little flux or with blast furnace flue dust, and spread over a travelling grate, the coal ignited and burned in a strong down-draft. The resulting clinker smelts so much more easily than the dense magnetic ores that the latter, even of high grade, are frequently sintered at the American plants.

BLAST FURNACES

Having followed thus far the mining, transport and preparation of ore, attention should next be given to the process of smelting it into metal. In the present state of the art, this is done in a blast furnace, and the metallic product is a high carbon alloy of iron called pig iron and containing more or less silicon and manganese. Since an article is devoted to the construction and operation of the blast furnace (*q.v.*) these matters will be summarized only briefly here; more attention however will be given to that entire assemblage of auxiliary equipment (*see* fig. 1) which together goes to form the blast furnace department of a modern steel making plant. A blast furnace and its top works often rise 200 ft. above the ground level. It is round in cross section, bound with steel plates, and lined with a thick wall of special fire brick. Piercing the very top of the shell are two side openings leading into brick lined pipes—downcomers—for venting the furnace gases. The top is closed by a double bell, which in effect is an air-lock for introducing charges of ore, coke and limestone, while permitting no gas to escape. Charging is continued at such a rate that the furnace shaft is always full. About 8 ft. above the furnace base is a series of 10 or 12 water-cooled nozzles called tuyères, equally spaced around the circumference, through which hot air is blown into the interior. The coke in the mixed charge burns in this air, producing a region of intense heat sufficient to melt the metallic iron descending to that level from above, and superheat it so much that when it trickles to the hearth it collects at the bottom of the shaft in a pool which remains molten for hours. Five or six times a day this iron is drawn off or cast by opening a tap-hole at the very bottom.

Reduction of Iron Ore.—Much study has been given to the chemical reactions which reduce the ore to iron. They can only be presented here in highly simplified form. At the tuyères the heat is so intense that coke burns to carbon monoxide, thus:

$$2C + O_2 = 2CO$$

It is this gas which reduces the ore, and at a fairly low temperature, *i.e.*, near the top, by a series of reactions which may be simplified as

$$Fe_2O_3 + 3CO = 2Fe + 3CO_2$$

The secret of rapid furnace driving to produce big tonnages is to use such ore, or prepared sinter, that the gases may permeate it readily and completely. Pure iron is relatively infusible—melting point 1,530° C; when alloyed with 4.3% carbon its melting point

is about 1,130° C. The freshly reduced iron in the blast furnace picks up this necessary carbon to convert it into the more fusible pig iron, either by physical contact with the hot carbon, or by the gas reaction

$$3Fe + 2CO = Fe_3C + CO_2,$$

a reaction which is the basis of the case-hardening phenomena. By no means all the CO is oxidized to CO_2 by the furnace reactions. A typical analysis of the gases from the furnace top is

Carbon monoxide (CO)	24·5% by volume
Carbon dioxide (CO_2)	12·0
Hydrogen (H_2)	1·25 (from moisture in the air blast)
Methane (CH_4)	0·25
Nitrogen (N_2)	62·0

rich enough in the combustible gases CO, H_2 and CH_4 to be valuable as a fuel. Leakage must be carefully avoided, for the monoxide content makes it highly lethal.

Slag Formation.— Impurities in the ore and the coke ash must also be disposed of. They consist of earthy substances like clay. If they contain a preponderance of a single oxide like silica (SiO_2) they cannot even be melted unless sufficient limestone is present to flux them—that is to say, convert them into an easily fusible glass or lava-like substance called slag (*q.v.*) or cinder. The formation temperature of slag depends upon the relative proportion of basic oxides (lime CaO, or magnesia MgO) and acid oxides (silica SiO_2, or alumina Al_2O_3) which are present in the furnace charge. The operator therefore chooses his ores and fluxes with the aim of producing a slag which works well at some temperature, which he does not measure, but which he knows will produce the kind of pig iron which is demanded by his customers. Like the iron, slag melts in the hot region above the tuyères and trickles down, forming a pool floating on the iron. It is tapped or flushed through a cinder notch located between the tuyère line and the furnace bottom; usually just before the iron is tapped.

Ore Handling.— A medium-size furnace making 600 tons of pig iron a day will consume 1,160 tons of ore, 580 tons of coke, 290 tons of limestone, and 2,370 tons of air blast. It produces in addition to the iron, 330 tons of slag, 70 tons of dust and 3,400 tons of gas. It requires 17,000 tons of water to keep the furnace parts cool and to wash the dust from the gas. Therefore equipment must be provided to handle expeditiously no less than 26,000 tons of material each 24 hours. Such auxiliaries are so large and so numerous that the furnace itself is frequently inconspicuous, despite its huge bulk (fig. 1). In America, much space is ordinarily given to stock piles. Ore that comes from such storage, or direct from the mine, is dumped into bins alongside the furnace. Other compartments hold coke and flux. On a track underneath operates a scale car, which stops under appropriate gates and the attendant draws off a specified amount. When the proper quantities have been assembled, the car proceeds to the skip pit, and drops its load into a car which in turn is hoisted up the inclined bridge and dumped into a hopper at the very top of the furnace.

Furnaces a century ago were usually built on sloping ground, and the ore and charcoal wheeled off the hill top and dumped into the furnace. Later, when the value of the gases was discovered, a single bell was used to close the furnace top, and as the tonnage requirements increased, ore, coke and flux were shovelled from stock piles into carts, which were then pushed to the furnace, hoisted on platform elevators, and dumped by hand. Material handling by machinery is essential for furnaces making more than a hundred tons of iron a day.

Disposal of Iron and Slag.—In view of the congested surroundings, the pig iron and slag tapped from a big furnace are led by clay-lined troughs or runners to the edge of the foundation where they flow into ladle-cars standing below, and are hauled away while still liquid. If the furnace is serving a steel-making plant, the iron may be taken direct to a steel-making furnace, More usually it is poured into a mixer that is in effect a storage reservoir, sometimes of 1,500 tons' capacity. A mixer is usually shaped like a huge barrel, made of strong steel plate and lined with fire brick; it may be rolled on its foundation by suitable trunnions so the opening may at one time receive metal from a ladle-car above, or later discharge it into another for transfer to the steel furnace. The bad effect on steel-making processes of sudden variations in composition of the pig iron, so-called off casts, is minimized by dilution in a pool of reserve metal. Furthermore, some of the harmful sulphur may be eliminated from high manganese pig iron in the mixer. if the temperature is properly controlled. Iron which cannot be converted promptly must be cast into pigs. Much of this work is done by machinery. A pig casting machine is an endless chain to which is attached a series of moulds. A ladle-car of iron pours slowly as this conveyor moves underneath. After the iron is chilled, the conveyor passes through a long water tank for more rapid cooling. When the chain moves over the tail pulley the moulds turn upside down and the now solid pig iron drops into a railroad car. Some furnaces specializing on foundry iron, and of rather limited tonnages, run their iron direct from the tap hole into pig moulds formed in the sandy floor of the furnace house (see PIG IRON). Slag may be hauled to a nearby bank, dumped and wasted. In some localities, the slag may be marketed for railway ballast, filling material, or concrete aggregate. It would then be run molten into a water sump, the stream being broken up by a strong jet of water. Granulated in this manner, it can be reclaimed by grab-bucket and crane and shipped. Since the slag is essentially a calcium aluminium silicate, large tonnages are utilized as raw material in the manufacture of Portland cement.

Utility of Blast Furnace Gas.—As noted above, gases from the furnace top are good fuels, but they bear too much dust to be used without cleaning. Even when burned under boilers it is found that dust will fuse to the water tubes, reducing the efficiency of heat transfer and increasing the cost of maintenance to a prohibitive figure. For use in internal combustion engines, the cleaning must be even more complete. Much of the coarser ore and coke particles swept out of the furnace with the gas remains in the dust catchers, one or two cylindrical tanks placed in series just alongside the furnace proper. Essentially they are enlargements of the downcomer pipes; the velocity of the gas and its carrying power are reduced in passing through them. A change in direction of travel also aids in catching solids, which as they accumulate are drawn off from the hopper-like bottom. Usually the reclaimed dust is mixed with fine ore, sintered, and resmelted. Mixed blast furnace and coke oven gas is a good fuel for heating cold steel. Formerly it was usual to send hot gas from the dust catchers direct to the stoves, but lately furnace managers have been convinced that this rough gas contains entirely too much dust for this purpose, and the efficiency of the heat transfer suffers therefrom. Consequently further cleaning, either by scrubbing towers, by electrostatic precipitation, or by filtering through bags is now commonly undertaken. Electrostatic precipitation has the advantage that it handles gas without cooling it and may recover valuable amounts of potash for fertilizer. In this process the slightly humidified gas is passed through vertical pipes; in the centre of each is a wire charged at high voltage. In the electrical field so formed solid particles drift toward the grounded pipe walls, adhering there until dislodged by hammering.

Fig. 1 shows a scrubber, of which two would be required, each about 80 ft. high by 12 ft. diameter. By means of spray nozzles and screens the ascending gas is intimately mixed in these towers with fine particles of water. The dust content, which on entering is about 3.5 grains per cu. ft. is washed out except for about 0·2 grain. A powerful fan is necessary to draw the gas through the scrubber and to give it the necessary delivery pressure; water jets are introduced through the shell at several places so the fan acts as a further cleaner, delivering gas to stoves or boilers with about 0·05 grain of dust per cu. ft. Frequently all the gas is burned in this way, utilizing the steam so generated to drive blowing engines or electric generators. When it is desired to use the heat more efficiently, internal combustion prime movers may be installed (see GAS ENGINES) whereupon an even cleaner gas is required. Dust may be reduced to less than 0·01 grain per cu. ft. by a rotary washer. which is a combination turbo-blower and cleaner. The water used for these cleaning purposes may be again used after passing it through a cooling tower and settling basin.

BLAST FURNACE PLANT

Blowing **Engines.**—Fig. 1 indicates the essential steps whereby the energy contained in the furnace gases is utilized to generate hot blast and auxiliary power for pumping, hoisting and lighting. Cleaned gas is used to drive gas engines direct connected with compressor cylinders. Compressed air goes to the furnace by way of a stove, therein acquiring a temperature of some 550° C, and on through a brick lined hot blast main to a bustle pipe circling the furnace. From the bustle pipe gooseneck connections deliver blast to the furnace through the tuyère openings. The required amount of air is fixed by the size of the furnace and the pressure, which varies from 12 to 20 lb. per sq. in. with operating conditions, and must be delivered without fail. About 50,000 cu. ft. of air per min. is necessary for a furnace making 600 tons of pig iron per day (see BLOWING ENGINES).

Dry Blast.—One auxiliary (not shown in fig. 1) more commonly installed in Great Britain, although proposed by the American James Gayley, reduces the humidity of the blast. Gayley showed that water vapour entering the tuyères, amounting in summer to about 250 gals. per hour, is dissociated into its elements by the white hot coke, this action absorbing heat not usefully regained within the furnace. Variations in moisture content are especially undesirable, for these produce variations in the temperature at the focus, and consequently change the chemical composition of the pig iron. To produce a low and uniform humidity in the air blast, the compressors may suck air through an adequate refrigeration system. (See AIR CONDITIONING.) Silica gel has been proposed as a more proper medium to dry the air blast.

Stoves.—Four stoves are usually installed to heat the blast. These are steel cylinders up to 100 ft. high and 22 ft. diameter. Each has a vertical combustion chamber, either at side or centre; the burned gases then return to the bottom through a multitude of narrow flues made of fire brick (see COWPER STOVE). In the passage they give much of their heat to the brick work, and flow off through a chimney. In operation (fig. 1), stoves B, C, and D may at any hour be filled with burning gas, thus acquiring heat; the cold blast passes through one of them, stove A; when this one cools off, valves are changed in a certain order, to prevent accumulation of explosive gas-air mixtures; stove A will then be on gas, *i.e.*, heating; stove B will be on wind, *i.e.*, giving up its heat to the air passing through it enroute from engines to furnace. Usually valves are changed every hour. In a four-stove installation, therefore, each stove is heating for three hours, and cooling for one. Many designs have been proposed for the method of building the stove interior. A two-pass stove is simplest, and most favoured in America, where the trend is to use cleaner gas, injected with a regulated amount of air for combustion, through carefully designed burners. Cleaner gas permits much smaller chequer-work, higher heat capacity, longer life before the openings are plugged with fused dust, frequently enabling satisfactory furnace operation with only three stoves. A three-pass stove, where the gas is introduced at the bottom, goes up, down, up again and out a short stack built on top the stove, is favoured by some designers. (See HOT BLAST.)

Valves for handling these furnace gases are of special construction. On the cleaning system a water valve is favoured. As shown in the diagram of the blast furnace department, it is nothing much but a large pot with a diaphragm extending from top toward the bottom. To close this valve it is only necessary to fill the pot with water until the bottom of the diaphragm is submerged several inches; draining the pot opens the valve. Valves for handling hot blast are more difficult to construct and to maintain in good condition. Also, since the valve seat is exposed to the corrosive action of hot gases, it requires occasional replacement. This can be done by loosening all the turnbuckle clamps, wedging the flue sections apart, and sliding the old seat out sideways. The valve disc is also a hollow copper casting with spherical bottom; cooling water enters the hollow stem as shown. To open the valve it is only necessary to lift the disc up until it strikes the bricked dome. All blast furnace stoves have four valves. Two are shown on stove A (fig. 1); stove A is on wind, the chimney valve and the gas burner opening being closed. Stove B is on gas; the chimney valve is open, the gas burner in place, and the valves into the cold and hot blast mains are closed.

Blast Furnace **Operation.**—From the foregoing description it may be surmised that the blast furnace superintendent's task is primarily to harmonize operations of various large mechanical elements. But the furnace itself is his greatest care, even though the principal reactions within it are in mobile equilibrium. Slight variations from normal are self-adjusting—that is to say, if for some reason a surplus of heat is generated, the action within the furnace changes in the direction which will absorb that extra quantity of heat. Nevertheless the skilled operator is quick to observe clues which indicate deviations from the normal, and he immediately makes such adjustments in the operating conditions as experience tells him will avoid any serious irregularity. A hundred years ago his problem was simpler. His furnace plant consisted only of stack and blower; his ore was pure and rich, carefully selected by hand; his fuel was charcoal, ideal in character; the driving rate was slow; under such circumstances his pig iron was relatively free from impurities. Even to-day some of this charcoal pig iron is made in small furnaces with either cold blast or hot blast, and is favoured by foundrymen for castings which require a dense, tough and strong body, or by manufacturers of high grade tool steels. Rich ores and forests were very soon exhausted, however, and the progress of metallurgy has been associated with the ability to recognize the specific effects of each disturbing element and to devise ways and means to utilize the impure ores and coke fuel remaining, for many of the minerals entering the furnace top with the iron ore are broken up and the elements therefrom alloy with the pig iron, often to its detriment.

Control of Sulphur.—Sulphur, largely from iron pyrite contained in coke ash, is the worst offender; if left in the iron causes it to be very tender at red heat (red short), High sulphur castings often crack in the moulds after cooling, and high sulphur steels may break when being worked in rolls or forging. Since no sulphur is removed in the converter or open-hearth steel making processes, it is essential that this element be eliminated from the pig iron. This is done in the blast furnace by charging limestone so the slag shall be distinctly basic, and thus have a higher solubility for sulphur compounds. Such a slag requires more coke, and German works now smelt with minimum heat and desulphurize the pig iron with sodium carbonate. Once in the iron, its harmful effects may be mitigated in castings if two or three times as much manganese is present; an innocuous manganese sulphide results. In steel, zirconium has been found to have the same effect. Sulphur may be eliminated in electric furnace steel by refining at a high temperature under a "carbide" slag very high in lime on which floats some coke. Pig iron for grey iron castings must therefore have less than 0·10% sulphur; structural steel must contain less than 0·06%; many alloy steels are specified to contain less than 0·04% sulphur.

Effect of Silicon on Pig Iron.—A blast furnace working very hot tends to reduce silicon and manganese from any minerals containing them present in the charge. Manganese is now considered beneficial in all subsequent processes, but silicon must be sharply limited to pass some specifications. Silicon in pig iron causes much of the carbon present to separate and collect into tiny flakes of graphite, permeating the entire metallic structure; this graphite is responsible for the characteristic grey fracture of castings for machinery; its presence also makes for easy machineability. The carbon would otherwise exist in the alloy as a compound of iron, a carbide, Fe_3C, called cementite, and form a much harder, stronger alloy. Consequently in such things as car wheels or in white iron castings, which are later to be converted into malleable iron (*q.v.*) by annealing, the silicon must be strictly limited. Silicon in pig for steel making must also be under close control, as we shall presently see. Therefore for those irons where both sulphur and silicon are limited, the ore and fuel must be specially selected for a low content of sulphur.

Grey and *White* Iron.—Carbon is another element in pig iron which will vary somewhat. It may be from 3·0 to 4·25%, depending upon furnace conditions. Generally if either silicon or phosphorus runs unduly high, the carbon will be low. Manganiferous

STEPS IN STEEL MAKING

1. View of the upper part of a blast furnace, showing a skip car (lower left) on the inclined track carrying raw materials to the top for charging. These materials — iron ore, coke and limestone — are reduced to molten iron, the first step in the manufacture of steel. The iron is then tapped into waiting ladle cars which carry it to open-hearth furnaces, electric furnaces or Bessemer converters, where it is made into steel
2. A Bessemer converter in full blow. By forcing air through the molten Iron, the carbon, manganese, silicon, other elements and impurities are oxidized and eliminated to form steel in 15 minutes
3. The open-hearth process. The raw materials are charged into a large, shallow furnace hearth. About five hours are required for melting. For about six hours more the heat is allowed to "work" while the refining action takes place, forcing many of the impurities into the slag which forms on top of the molten metal. The picture shows the tapping of a finished heat of steel from the open hearth into a ladle (left). The slag floating on top runs off into the slag pot at the right
4. Pouring molten steel from a ladle into ingot moulds
5. The mouids are stripped from the formed ingots, which are then sent to the soaking pits pictured. These furnaces heat the ingots thoroughly and uniformly. The ingots are then ready for the first rolling in the blooming mill
6. First rolling operations of the steel in the blooming mill, where the ingotr are reduced and elongated as they pass back and forth through a set of rolls. UP to this point, the steps in making steel are similar, although hundreds of chemical formulae are used to vary its composition, and some variations in procedure are made during various steps according to the destined use of the steel

IRON AND STEEL

PROCESSES IN FINISHING STEEL

1. In the manufacture of welded pipe, blooms and billets are first rolled in the blooming mill, then rolled into skelp in the skelp mill. Buttweld pipe is made by drawing the heated skelp through a welding bell, as pictured
2. The Mannesmann process of making seamless pipe. The blooms are heated, then rolled into rounds at the round mill. The rounds are cut to desired length, centred for piercing and heated again to the proper temperature for piercing. Finally the pipe goes to the sizing mill, where it is brought to true diameter by a series of grooved rolls. In the picture, semifinished pipe is emerging from a seamless-tube mill
3. Ingots rolled in the blooming mill are cooled, conditioned and reheated to proper rolling temperature for operations known as descaling, roughing and finishing. In the picture the slab at the right has passed through the last roughing stand and is proceeding to the finishing train. The slab in the left foreground is entering the last roughing stand
4. Examining tin-plated steel. This type of steel is rolled from slabs on the continuous strip mill, wound into coils, placed in a continuous pickler, cold rolled and rewound before it is sent to the tin mill
5. Polishina machine which produces various degrees of brightness on sheets of stainless steel

irons, on the other hand, are usually high in carbon. The colour of a freshly broken piece of pig iron is due to the way the carbon is held, rather than its total quantity; in white iron, nearly all the carbon is combined with iron in the carbide cementite; in grey iron, seven-eighths of it is in the form of graphite; intermediate proportions are called mottled irons.

Phosphoric Ores and Iron.—Phosphorus, until about the turn of the rntury, was the most undesirable element entering the blast furnace. Whereas much sulphur can be slagged off, between 90 and 100% of the phosphorus entering with the ore and the fuel ash comes out with the iron, and an excess makes both iron castings and steel brittle. For some types of thin castings requiring fluid iron e.g, stove plates, from about 1·0 to 1·5% of phosphorus may be permitted, but in steel it is kept as low as sulphur, namely from 0·02 to 0·07%; in general, the lower the better the steel. Consequently the phosphoric iron ores of Lorraine were of small value—in fact of no value for steel-making until the Thomas-Gilchrist basic process was suggested (1878). Subsequent developments have converted the phosphorus in the ore to a pronounced economic asset. In view of all these facts, the furnace operator selects and mixes the ores and fuels which are available to him, and then adjusts his flux and controls his hearth temperature, by varying the amount of coke charged and the temperature of the blast, so the desired kind of iron will issue from the tap hole (see CAST IRON). Further notes on the varieties required for the various conversion processes will be given later.

WROUGHT IRON

Wrought iron, as compared to the total tonnage of steel, is an unimportant commodity. It amounts to less than 3% of the total production of steel. But it is important for its unique combination of physical properties, enabling it to survive since the time 75 years ago when it was the principal metal of engineering construction.

Puddling **Process.**—If about 600 lb. of pig iron and considerable iron ore are placed on the hearth of a small reverberatory furnace and melted, various reactions occur between the iron oxide from the ore and the impurities in the droplets of pig iron. The first reactions to occur may be simplified as follows:

$$2\,FeO + Si = SiO_2 + 2Fe$$
$$FeO + Mn = MnO + Fe$$

The iron thus reduced from the ore enters the pool of metal, and the silicon and manganese oxides join with the surplus ore to form a highly basic slag. This slag has the ability to absorb any phosphorus oxides which result from reactions between the phosphorus alloyed in the metal and the surplus iron oxide in the slag. The workmen stir the slag and iron together, an operation which is known as puddling; after the silicon and manganese have been substantially eliminated from the metal the carbon content begins to go down. The reaction may be written as follows:

$$Fe_3C + FeO = 4Fe + CO$$

Carbon monoxide gas bubbling upward causes the bath to boil. Removal of all these alloying elements leaves practically pure iron, of a much higher melting point. Toward the end of the process, therefore, the bath is converted into a metallic sponge of white hot, pasty iron, filled with liquid slag. This is cut into zoo lb. balls by the furnaceman, surplus slag squeezed from the dripping mass, and the resulting balls rolled into flat muck-bars. The metal is hot enough to weld together satisfactorily, and the process is accompanied by a great spray of slag sparks, squeezed out by the rolls. Muck-bars are cut to short lengths, arranged and wired together in piles, heated to a welding heat and re-rolled into marketable shapes.

Nature of Ferrite.—From a knowledge of the manufacturing process it may be understood that commercial wrought iron is essentially pure iron containing a greater or lesser number of slag particles.

The chemical changes which occur in the process of refining are thus indicated:

	Forge pig iron	Metallic portion of wrought iron
	%	%
Carbon	3·5 to 4·25	0·02
Manganese	0·25 to 1·0	0·005
Phosphorus	0·5 to 1·0	0·07
Sulphur	0·03 to 0·10	0·02
Silicon	1·0 to 2·0	0·03
Iron	95 to 92	99·855

About 3% of the best wrought iron by weight is slag.

A view of a polished section through a microscope shows the structure of wrought iron (Plate III., fig. 9). The mirror-like metal appears white in the photograph; the stony lustre of the slag particles appears grey. The slag itself is not a simple glass, it is a high iron silicate containing more or less manganese and phosphorus and frequently develops well crystallized minerals. Slight etching of the polished surface under examination develops characteristic markings; the metallic portion seems to consist of a number of closely fitted or interlocking grains. If one of these grains were picked out, it would have an irregular surface; nevertheless it is undoubtedly true that its inner structure is that of a true crystal—that is to say, the ultimate atoms are arranged in regular rows and ranks, in geometric order. Such tiny crystals of substantially pure iron are called ferrite.

Properties of Wrought Iron.—Wrought iron has superior properties for forge welding, because at high heats the slag particles melt and spread into a film protecting the metal from atmospheric oxygen. The purity of the iron is responsible for its toughness, resistance to shock and bending. It also resists atmospheric and aqueous corrosion, either by virtue of purity of the metal or by virtue of the slag inclusions, or for some other reason. These special properties cause it to be in demand for pipe, chain cable, boiler stays, sheet iron and blacksmith's bar iron. For some of these purposes a variety known as charcoal iron (*q.v.*) is preferred. Wrought iron is moderately strong in tension, developing from 45,000 to 55,000 lb. per sq.in. ultimate strength. Furthermore it is a soft metal—Brinell hardness measuring 75 to 80. Likewise the production of big masses of it is tedious, and puddling requires a large amount of exhausting labour from skilled workmen. These facts all combined to hamper competition with the harder and stronger steel—the Bessemer's process showing how to make the latter in great quantity, rapidly and almost automatically. In 1883 70% of all the pig iron made in England was made into puddled bar; in 1897 only 5%.

Aston's Process.—Mechanical puddling furnaces have been proposed and used to some extent, but the manufacture of metal in small batches is not in keeping with modern mass production. A more promising development consists of the process established in 1927 in America through James Aston. Knowing the essential characteristics of the ferrite and slag constituting wrought iron, he produced pure iron in a Bessemer converter, following the regular steel-making practice, and poured this iron into a pool of synthetic slag, which had been melted in a large cupola. Strong evolution of dissolved gas caused the metal to granulate into very fine particles; the resulting spongy mass of iron and slag was withdrawn, squeezed and rolled in the conventional manner.

BESSEMER STEEL

Early Steel-making Processes.—Prior to 1870 the principal metallic materials of construction were cast iron and wrought iron. The former could be made quite hard, but then was brittle; the latter resisted shock excellently, but was comparatively soft. There was a great and growing demand for metal which was both strong, wear resisting and tough, but there was no method of producing it cheaply enough to make, for example, railroad rails. Consequently, the discovery of the Bessemer process for making cheap steel was a godsend—an eager market was waiting; and in turn the satisfied market created other demands. Steel had been known for centuries. While accurate statistics are lacking one may reasonably guess that 250,000 tons a year of blister steel and crucible steel were being made in Europe in 1865. Blister steel

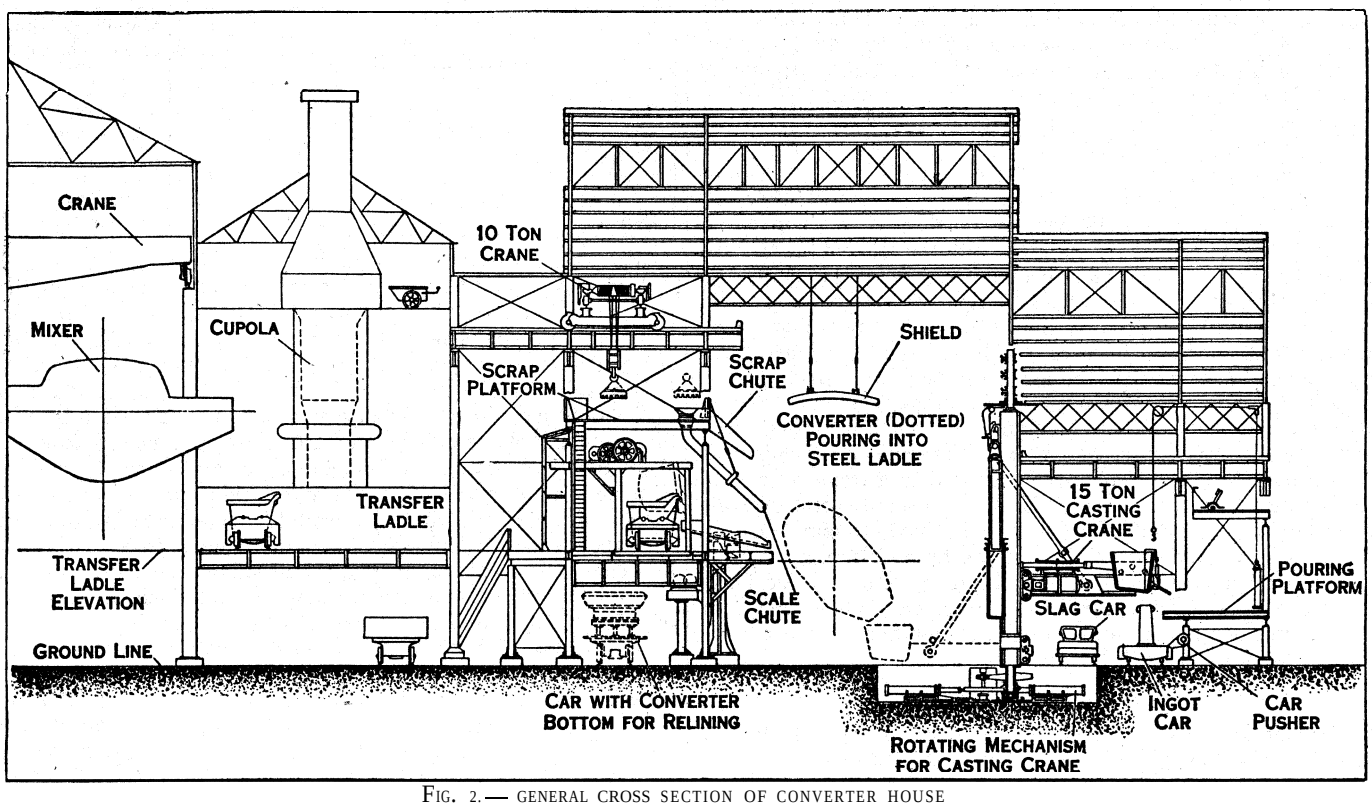

FIG. 2.— GENERAL CROSS SECTION OF CONVERTER HOUSE

was, and still is, made by packing wrought iron bars in a long stone box full of charcoal, and heating the container for several days at a full red (see BLISTER STEEL; CEMENTATION). Carbon gradually is absorbed by the iron under these conditions, and it becomes steel. In order to improve the quality by equalizing the carbon content in this steel, and also eliminating the slag contained in the original wrought iron, blister steel is cut in short lengths and melted in a clay crucible (see CRUCIBLE CAST STEEL). For the manufacture of fine tools and cutlery such processes survive even yet, principally in the Sheffield region where the industry formerly thrived. But obviously this very indirect method of getting steel, bit by bit, was totally incapable of supplying the needs of the coming mechanical age.

Bessemer's Invention.— As has been pointed out, the alloyed impurities in pig iron can be eliminated by oxidizing them. In all the old refining processes, iron oxide in the form of ore, mill scale, or iron silicate slag (basic cinder) is the means whereby the necessary oxygen is carried into the pig iron under purification. While experimenting on some methods for improving metal for cannon in 1856, it occurred to the English inventor Henry Bessemer that this oxygen for refining could be taken directly from the air if a blast were blown on or through the melted pig iron. On trial it not only purified the iron, but instead of blowing cold and freezing, the metal became hot enough to remain molten even when all the carbon was gone and hitherto infusible pure iron remained. The whole reaction required only a few minutes; at the end an ingot of mild steel could be cast, ready for the forge or rolling mill.

It took years of experimentation before the new process became a commercial success. The conservatism of engineers and constructors retarded the adoption of cheap steel and the useful mechanical auxiliaries, largely perfected by the American, Alexander L. Holley, which enables a modern plant with two converters to send forth a continuous procession of ingots, without halt, day and night (see BESSEMER, SIR HENRY; BESSEMER STEEL).

Converter House.—(See fig. 2.) Molten pig iron comes from the blast furnaces in ladle cars, and an overhead crane lifts the ladles and pours the contents into the mixer. By joining a reservoir of several hundred tons of metal wide variations in chemical composition in a single cast are lost by dilution. A reservoir of uniform and promptly available raw material is thus established. Uniformity and continuity are foundations of rapid production of Bessemer steel; neither of these results when converting metal direct from the blast furnace or remelted pig iron from the cupola —although the latter sources may be used in emergency. At the proper time a ladle of iron, 10 to 25 tons depending upon the size of the converter, is poured from the mixer; it tilts by rolling on a circular track under positive control of a screw mechanism or hydraulic ram. A small locomotive pushes this full ladle car to the converter house, and by means of a launder the contents are run into the hot converter, with mouth tilted over to receive the charge. The blast is turned on, the converter tilted up to vertical position, and the blow is on.

Conversion Process.—The converter itself is a cylindrical steel pot perhaps 10 ft. in diameter by 20 ft. high, mounted on elevated trunnions and geared into a rack and pinion so it can be turned completely over. It is lined a foot thick with a refractory mixture. The bottom bricks are perforated by many small openings, tuyères, through which air is sprayed into the metal at high enough pressure to keep it from trickling down into the wind box attached to the bottom of the converter shell, yet not so high as to throw too many splashings out the open mouth. Oxygen in the air blast burns the pig iron it first strikes. This product of reaction may be represented by FeO, and it is swiftly distributed throughout the churning mass. At the temperature of operation silicon and manganese atoms have a greater affinity for oxygen than iron has, so these two reactions occur:

$$Si + 2FeO = 2Fe + SiO_2$$
$$Mn + FeO = Fe + MnO$$

These oxides are insoluble in metal and accumulate into droplets of slag—a mixture of iron oxide, manganese oxide and silica. When the metals silicon, manganese and iron combine with oxygen, or burn, much heat is released-enough to heat the incoming air and escaping nitrogen, to provide for radiation losses, and to increase the temperature of the remaining metal and slag so it is always quite liquid. During this early stage of the blow the red hot nitrogen coming from the mouth glows faintly. Gradually the carbon begins to burn, thus:

$$FeO+Fe_3C=4Fe+CO.$$

A roaring boil then takes place in the vessel; the carbon monoxide burns in a big, yellow, luminous flame at the converter mouth, and countless flying sparks of metal and slag add to the spectacle.

In only a few minutes the carbon is gone; the flame flickers, and suddenly contracts. This is the signal for turning the vessel over on its side, and stopping the blast. Inside the hot converter is now a seething mass of fluid iron, practically free of silicon, manganese and carbon, covered with a thin layer of slag. The metal, however, contains much gas in solution and if cast immediately would solidify in a spongy mass. Consequently some cupola-melted spiegel—a pure pig iron containing 20% manganese—is run into the converter. A rapid reaction ensues, wherein the steel is freed of oxygen by combination with the excess of manganese and carbon in the spiegel. The converter then tilts further over, discharging its contents into a waiting ladle. The blow has taken perhaps 12 min.; no greater time is necessary to add the spiegel, pour out the steel, turn the converter upside down to discharge any loose slag chunks. and back up to receive another ladle of liquid pig iron. A second converter alongside will be blowing while the first is dumping. In fact the whole equipment of the converter department is co-ordinated for a complete cycle every 12 to 15 min., and is built of the most rugged proportions, so delays from breakdowns will seldom occur.

Converter Lining.—The violent reactions at high temperatures cause considerable scour on the lining of the vessel; especially the tuyère brick at the bottom must be replaced after 20 to 25 blows. Holley is responsible for the plan of sectionalizing the converter shell; when a new bottom is required a car carrying a stout jack is placed under the upright converter, a series of bolts unloosed, and the jack lowered away, carrying with it the entire bottom part of the shell. This car is immediately replaced by another carrying a newly made bottom, already warm, ready for lifting and bolting into place. It is therefore unnecessary to leave a shell in the stand while it cools and the lining is repaired, dried and reheated—a matter of several days—but these sectional lining operations are done in a separate department and replacement of bottom or mouth portion requires less than 30 min. In American practice the lining material is a highly siliceous rock, ground with a little fire clay, moistened and tamped in place with pneumatic rammers. Such a lining is known as an acid lining, and steel made therein is called acid Bessemer steel.

Pig Iron Used.—Since the reactions described above leave untouched any sulphur or phosphorus, it is necessary that the pig iron entering the converter be quite low in these two elements. Furthermore silicon is limited by the rate of driving. It is the chief heat-producing element; if silicon in the pig is high the converter shell and its contents get superheated during continuous blowings and must be cooled either by dropping a quantity of cold scrap into the shell, by blowing steam in with the blast (which dissociates and absorbs heat), or by delays for radiation. On the other hand if the converter with a new bottom is a little cold, it is tilted partly over so some blast does not penetrate the iron, but burns the CO to CO_2 thus liberating more heat within the vessel. Maximum production may be had by blowing a pig iron with higher silicon and lower carbon; reducing the blowing time by charging mill scale or ore at the beginning of the blow; and charging scrap to absorb the excess heat generated. But in general the pig iron used for acid Bessemer practice, and the product therefrom will be about as follows:

	Carbon	Silicon	Sulphur	Phos-phorus	Man-ganese
Pig iron	3½ to 4	1 to 1¼	0·05	0·09	½ to 1¾
Full blown	0·03	0·01	0·05	0·10	0·03
With spiegel	0·1 to 0·4	0·10	0·06	0·10	0·90

Growth of Uses.—Obviously such material as represented by the last analysis is immeasurably superior to wrought iron for railroad rails. The carbon content is responsible for hardness, wear resistance and strength which wrought iron could never acquire. Furthermore, the amount of carbon, and the corresponding degree of improvement in properties, is under control, for it is only necessary to place some charcoal in the steel ladle to make a higher carbon steel, or to use a spiegel or a ferro-manganese containing higher manganese and lower carbon when a milder or softer steel is desired. It is not surprising, then, that when the process was finally established on a producing basis in Bessemer's own plant in Sheffield, the product was rapidly absorbed for rails and tires. In 1868 there were 110,000 tons produced; in 1888 Bessemer steel reached its peak of production in Great Britain of 1,700,000 tons. Puddling had meanwhile declined; 70% of British pig iron went into wrought iron in 1883; only 5% in 1887. A similar story may be told of America. In 1867 460,000 tons of iron rails were made and sold for $83 per ton; that same year 2,550 tons of Bessemer steel rails were produced and some purchasers paid $170 a ton for them. By 1884, however, the last iron rails were made, steel had replaced them to an annual production of 1,500,000 tons a year, and the selling price was $32 per ton. In 1938 rails declined to a minor commodity in America and those were made of open-hearth steel, for reasons to be given later. Much Bessemer steel is still made into skelp for welded pipe, into wire and free machining steel (low in carbon, but high in sulphur and phosphorus).

THOMAS-GILCHRIST DISCOVERY

Control of Phosphorus.—This so-called acid process demands low-phosphorus ores and pig, and such material in Europe is relatively scarce and costly. Early efforts to remove phosphorus in the converter failed. Arguing from an analogy in the puddling furnace, where a slag rich in iron oxide will carry off phosphorus oxides, it was thought that if the converter blast was carried on after the carbon was gone, much iron oxide would go to the slag, and it would then be in a condition to absorb the phosphorus. When this was tried, however, the iron wasted away, ate into and ruined the lining, but unfortunately had no effect on the phosphorus. Not until 1876 did the Englishmen, Sidney G. Thomas and Percy C. Gilchrist discover that if the converter were lined with a basic material like burned limestone, dolomite or magnesite, and if burned lime were charged with the pig iron, then a basic slag would form and be maintained in such condition that it would absorb and hold phosphorous oxides produced during the blow. This is the basic Bessemer process now so widely used on the Continent for the production of so-called Thomas steel.

Basic Bessemer Process.—A modern basic plant is arranged much like its counterpart using the acid process. Converter shells are lined with different materials. Dolomite is freshly calcined in a cupola, ground with hot dehydrated tar, and the sticky mass tamped between the shell and a centre form. The perforated bottoms are lined two ft. thick, yet must be replaced daily.

In its modern development a heat of Thomas steel is made thus: Into a 10-ton converter 1½ tons of freshly burned lime are charged and then 10 tons of pig iron. The blast is turned on, the converter tipped up, and the blow proceeds exactly like an acid heat already described, but it continues after the carbon flame drops In this last stage the following reaction occurs:

$$5FeO+2P=5Fe+P_2O_5$$

and the phosphorus joins with excess lime in the slag to form a calcium phosphate. There is no flame to indicate occurrences in the converter during this period. The duration of the after blow is judged from a knowledge of the phosphorus contained in the original pig iron. When the process is thought to be complete, the converter is tipped to its side, the blast turned off, and a spoonful of metal cast into an iron mould. This test ingot is chilled, hammered into a bar, and nicked, bent and broken. If the metal is brittle and coarsely crystalline, the air blast is resumed for a few seconds, and another test taken, and repeated until the metal is tough and fine grained. This finishes the blow. Next the slag must be skimmed off as closely as possible, because phosphorus has a trick of returning to the metal on slight pretext; then the spiegel or other recarburizer and degasifier is added, and the steel poured into the ladle. About the only additional equipment in the converter house needed beyond that found in

an acid Bessemer plant is some handy means of caring for the large volume of slag produced. This slag, by the way, is ground and sold as fertilizer, it contains up to 20% of soluble phosphoric acid.

Thomas Steel.—In this Thomas-Gilchrist process, the pig iron must have relatively low silicon to limit the amount of slag formed. Phosphorus is the principal heat producing element, and it may be as high as 3%. It is doubly essential that a mixer be used to store pig iron, in order that phosphorus may never show wide fluctuations in analysis, heat to heat. Percentages in average analyses are as follows:

	Carbon	Silicon	Sulphur	Phosphorus	Manganese
Basic pig	3½ to 4	0·5 to 1	0·05	2 to 2½	1 to 1½
a stee	0 0 to 0·60	0	0 0	0·03 to 0·10	0·30 to 0·50

The process was introduced in Germany in 1879, and at the present time is used to refine the bulk of the pig iron produced from the Lorraine deposits in France, Germany, Luxembourg and Belgium.

Thomas steel provides satisfactory material for all classes of tonnage steels used on the Continent, such as bars, boiler plate, pipe, structural steel and rails. But despite the fact that the Thomas-Gilchrist process was proposed to solve the problem of high phosphorus British ores, Thomas steel is not popular among English engineers, and hardly any of it is now made in England. This is probably due to the fact that the home ores do not smelt into a low-silicon high-phosphorus pig iron necessary for the economical operation of a basic converter, and further that the basic open-hearth furnace has meanwhile been developed to refine such phosphoric pig irons as are made.

OPEN-HEARTH PROCESS

As soon as the Bessemer process attained a production stage it was found that the mild steels intermediate in carbon content, strength and ductility between carbon-free wrought iron on the one hand and high carbon crucible steel on the other, were most useful materials for machinery and engineering structures. These mild steels were really new materials, never before procurable in quantity, and inventors attempted to make them in ways which would not infringe the Bessemer patents. An insuperable difficulty was the inability of any furnace, even when burning high volatile coal under forced draft, to melt them. As in the puddling process, when the refining reached a certain stage, the metal became a pasty sponge. This obstacle was met by Sir William Siemens, who resurrected a forgotten proposal to regenerate some of the waste heat (see REGENERATIVE FURNACE). He passed the smoke through brick chequer-work; after the passages had thus been highly heated, air for combustion of the coal was drawn through the chamber. This pre-heated air had the effect of increasing the flame temperature materially. Using a furnace with such a device Emile and Pierre Martin made steel at Sireuil, France in 1864, by melting a good grade of pig iron, then adding some selected wrought iron scrap which alloyed with the pig iron, continuing these additions until the carbon content was reduced to the desired percentage mainly by dilution (the Martin pig and scrap process). William Siemens (*q.v.*) and his brother Friedrich found it necessary to erect an experimental furnace plant in Birmingham to develop the application of their ideas in the steel industry. By 1565 the principal features of the modern open-hearth process were there developed; namely, gaseous fuel, regenerative cheyuer-work for pre-heating both air and gas, a thin furnace roof of silica brick and the method of refining pig iron by ore or iron oxide (the Siemens pig and ore process). These entire furnaces, hearth, sidealls and roof were made of highly siliceous refractories; the only slags which would not corrode these contain an excess of silica—so-called acid slags. Not until Thomas had shown how to remove phosphorus by a basic, high lime slag in the basic lined converter did it occur to anyone to make an open-hearth furnace w with hearth and side walls of sintered dolomite—lime and magnesia oxide—and to refine the steel under a high lime slag. J. H. Darby built the first of these basic open-hearth furnaces at Brymbo, Wales in 1884. The most available ores in both England and America smelt into pig iron well suited for such basic open-hearth refining; furthermore the product is distinctly superior in quality to Bessemer steel. Consequently at the present time the latter is used in America for the production of low-carbon steels for non-engineering purposes. Basic open-hearth steel, however, makes boiler and ship plate, structural steel, rails and all the higher carbon machine steels (and even alloy steels), such as shafting and forging billets. Production by processes is shown in the following table—it will be observed that the basic open hearth is competing with the basic converter even on the Continent.

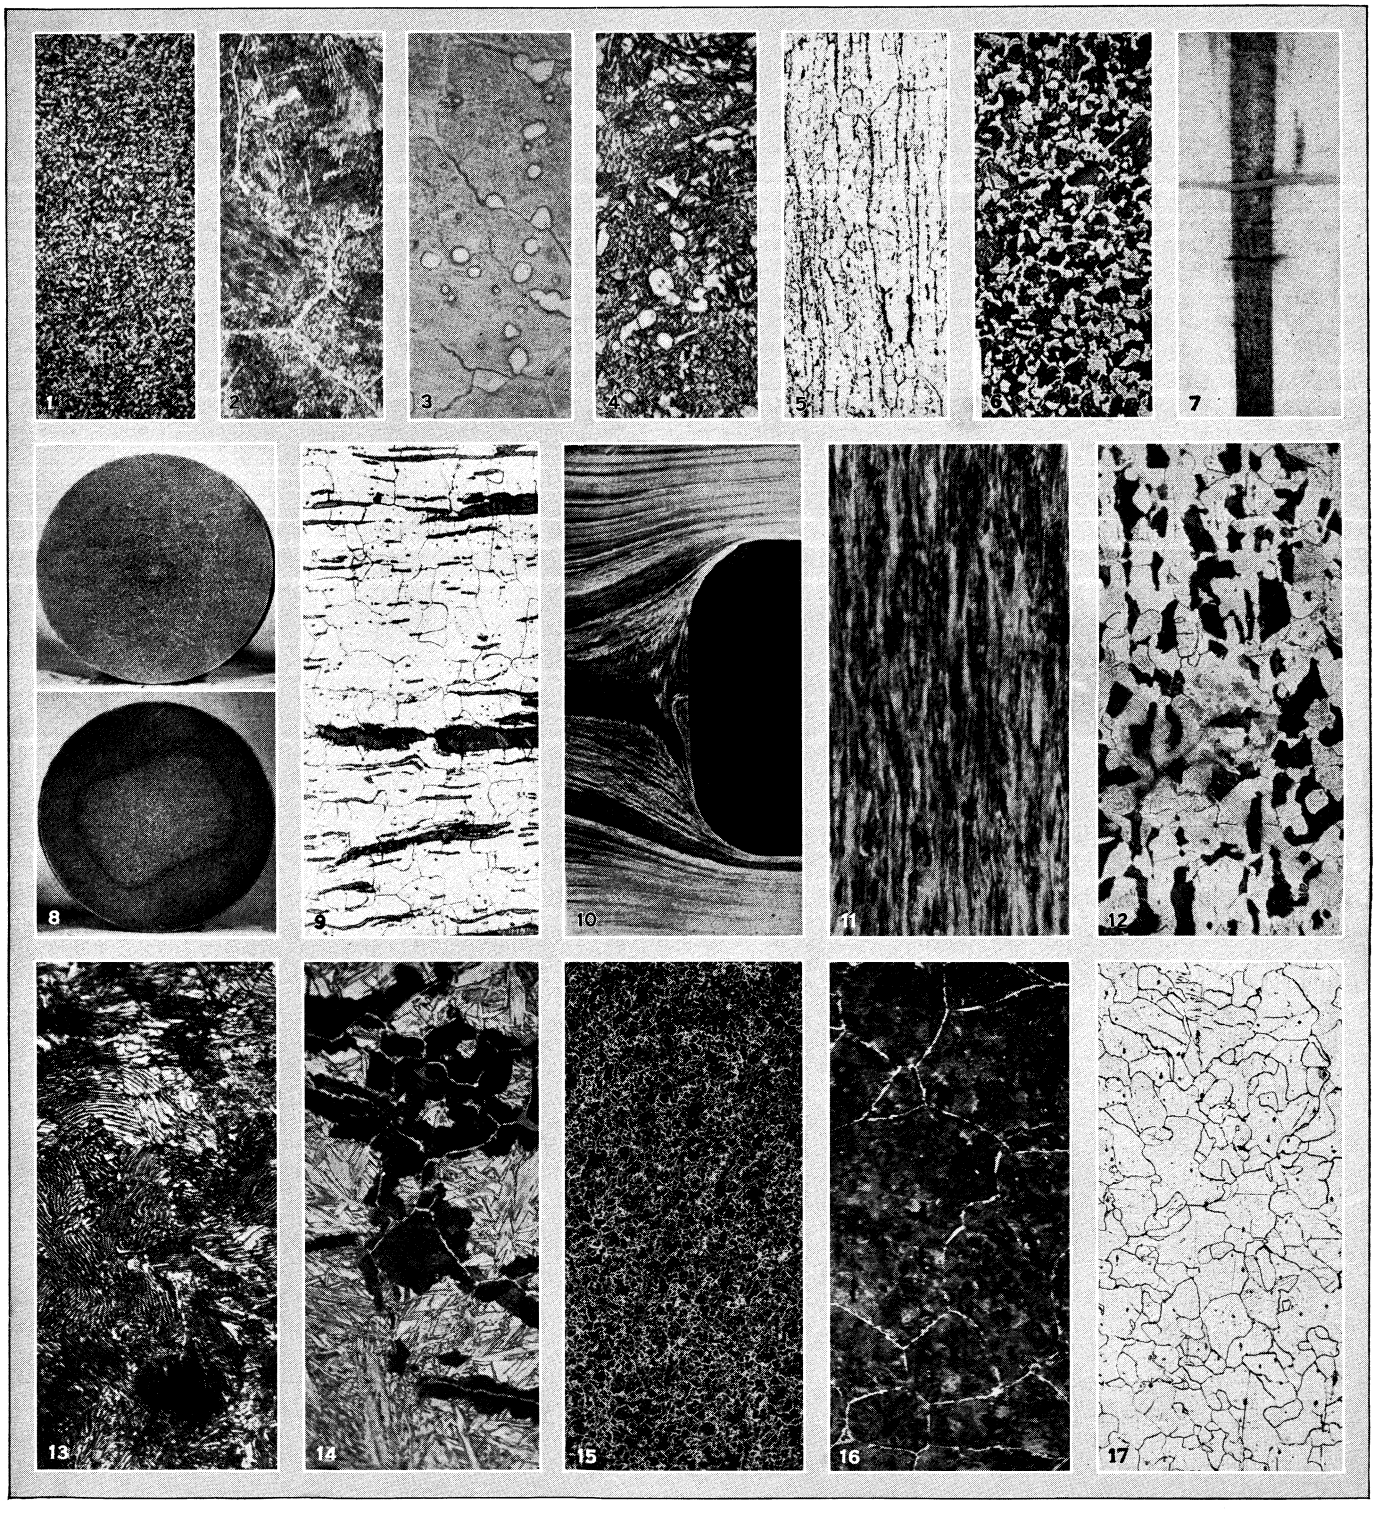
Steel Production in 1937

		Great Britain	France	Germany
Acid Bessemer	3,449,927	233,000	46,000	none
Basic Bessemer	none		5,258,000	7,958,000
Acid open hearth	499,793	2,260,000	2,279,000	164,000
Basic open hearth	45,772,510	9,677,000		10,494,000
Electric	845,537	452,000	308,000	535,000
Crucible	934	no estimate	12,000	

Furnace Auxiliaries.—The essential furnace is often dwarfed by the auxiliaries found necessary for rapid and economical production. (*See* fig. 3; also REGENERATIVE FURNACE.)

In the first place adequate fuel must be provided; consequently alongside is another building containing gas producers (*q.v.*) of the continuous type. A series of such producers in operation discharge gas into one main pipe from which it is drawn to the furnaces as needed. The producer house must have therefore adequate coal handling machinery; a plant with 10 60-ton furnaces would use 400 tons of coal a day, with means for hauling or sluicing the ashes away, and boilers for raising steam to blow into the producers. Gas producers are usually found as standby equipment, even where other fuels are used, such as mixtures of blast furnace gas, by-product coke oven gas, natural gas, tar, and oil. Next a stock of adequate raw material is necessary. If open-hearth and blast furnaces are within the same fence, melted pig iron (hot metal) will be used. That requires a mixer for intermediate storage. Otherwise an ample stock of iron in pigs is required. Furthermore a big tonnage of steel scrap of various kinds is used—the proportions of pig iron and scrap charged into steel making furnaces now depends solely upon the relative availability and cost of these two materials. Scrap must be segregated as to nature and approximate analysis; big shears and drop balls (skull crackers) are necessary for cutting and breaking unwieldy pieces; travelling cranes and lifting magnets are installed for economical handling of this material. Bins and stockpiles must be provided for the various special metals used for alloying or degasifying the hot steel, for the limestone, fluorspar and other fluxes, for the silica, chrome, magnesite and other fire brick to repair the furnace, for the dolomite or silica rock used for making the bottoms. In basic open-hearth plants an auxiliary building is necessary for grinding, calcining and storing the dolomite continually needed for repairing the furnace bottom and side walls (banks). Spiegeleisen, if used for a deoxidizer, must be melted in a cupola or electric furnace.

Means must be provided for introducing the fuel into the furnace, and reversing the flow of flame at frequent intervals. This requires proper valves in the flues, with an appropriate series of interlocking operating devices. Latter-day trends in furnace design call for much shorter and more direct flues than shown in the cross sectional view, and the use of water cooled gate valves offering no obstruction to gas flow when open. Waste heat boilers are also quite frequently placed between regenerators and chimney, together with fans to pull the hot gases through them. A most interesting device is installed to chdrge solid material through the doors into the furnace itself. By this means long delays between heats to refill the furnace are avoided, together



METALLOGRAPHY: ETCHING AND MICROSCOPIC EXAMINATION OF STEEL

1. Sorbite, showing structural fineness (50 diam.). Lightly etched
2. High carbon steel; carbon content 1.15% (500 diam.). Etched
3. Quenched high-speed steei; martensite, containing small grains of excess carbide (500 diam.). Etched
4. High-speed steel, properly drawn at 600" C to give best cutting properties; martensite changing to troostite; white grains are excess carbide. (500 diam.)
5. Steel sheet with grains flattened by moderate cold rolling (500 diam.). Etched
6. Annealed medium hard steel containing 0.40% carbon (100 diam.). Etched
7. Sulphur print from section along centre of steel bar, showing high sulphur core. Sulphur in bar reacts with silver compound on acidulated paper
8. Cross section of deeply etched steel bars showing uniform structure in bar above, segregated centre in bar below
9. Wrought iron, section parallel to rolling direction (500 diam.). Etched
10. Banding or flow lines due to high phosphorus regions in base of shrapnel shell forging (½ .size). Etched with ammonium persulphate
11. Section of high carbon steel wire, cold drawn to limit (350 diam.). Etched
12. Structural steei containing 0.25% carbon, showing banding of constituents (75 diam.). Etched
13. Annealed pearlite containing 0.80% of carbon (250 diam.). Etched
14. Dark areas are fine pearlite (primary troostite) in martensite (light crystals) (200 diarn.). Etched
15. Nickel steei forging (3%) before heat treatment (7 diam.). Etched
16. Nickel steel ingot (3%) showing coarse grain structure as compared with fig. 15 (7 diam.). Etched
17. Ingot iron, lightly etched. Pure ferrite with small non-metallic inclusions (100 diam.)

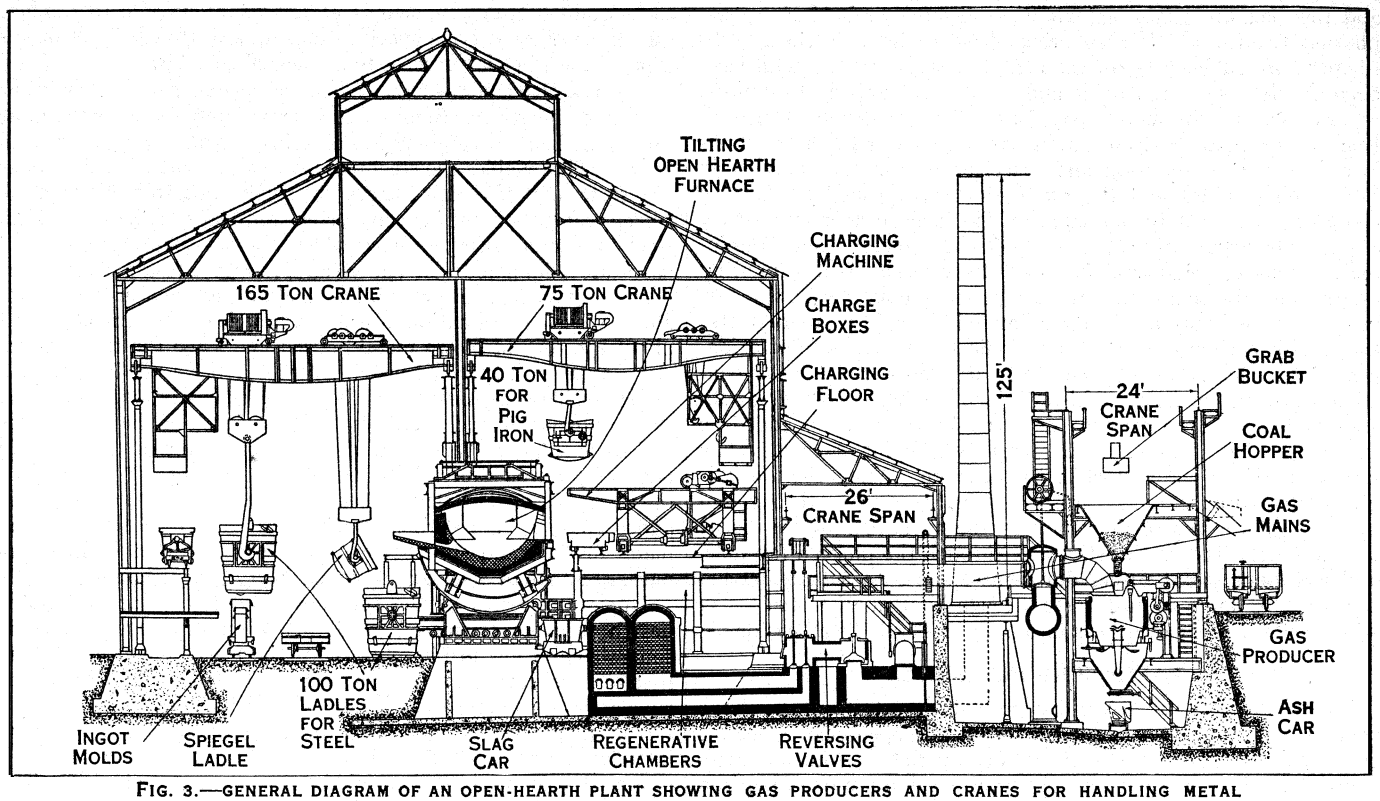


FIG. 3.—GENERAL DIAGRAM OF AN OPEN-HEARTH PLANT SHOWING GAS PRODUCERS AND CRANES FOR HANDLING METAL

with much exhausting labour. All solid materials are now loaded into charging boxes, cast steel trays about 24 in. wide and deep and about 4 ft. long, thus holding at least a ton of the bulkiest steel scrap. A complete charge for a furnace is assembled into 40 or 50 such boxes, placed on a train of small flat cars, and moved to a track running close to the furnace doors. On a wide gauge track alongside, the charging machine operates. Its ram engages an end socket on the box and is locked in. The ram then lifts the loaded box off the car, moves it forward through the open door into the furnace, slews it to either side and tips it upside down, discharging its contents in the correct place. These motions are then repeated in the reverse order. When the empty box is on the car, the charging machine moves sidewise, taking with it the entire train of loaded cars until the next full box is spotted directly in front of the proper door. This is then picked up, thrust into the furnace, and dumped. In this manner a 60-ton furnace can be loaded in less than an hour. Equipment must also be installed to pour the finished steel into ingot moulds, but this is an operation which, both in the principles involved, and in practice, is similar to casting a Bessemer heat, and will be described later.

Open-hearth Steel from Cold Metal.—The basic open-hearth process (1938) makes by far the most steel. Many steel-making furnaces are distant from blast furnaces, so they operate entirely on cold stock, and as noted, any proportion of pig and scrap may be charged, as economics require. This process as commonly practiced in a stationary furnace and its elementary chemistry are here briefly explained. After a furnace has been tapped and the bottom and banks repaired charging is begun. Plate scrap, if available, is spread out to protect the bottom, followed by several tons of limestone, depending upon the impurities to be removed from the pig and scrap. The furnace is then filled as full as possible, with scrap, pig iron and some iron ore; the doors are then closed, the flame given an excess of air and melting begins; as the mass melts and settles, the balance of the cold metal is added. Melting pig iron will trickle down over the white hot steel, still solid. Silicon and manganese in the pig iron droplets oxidize by the excess oxygen in the furnace atmosphere, and join with the iron oxide forming on the white hot steel and some of the lime on the bottom or furnace wall forming a slag. In four to five hours the molten metal is virtually free from silicon, and much manganese has also gone into the slag. Vigorous stirring is necessary as chemical reactions only occur at the surfaces where metal and slag are in mutual contact. This is effected principally by gases rising from the limestone, and some two hours after the metal is fluid it continues to break up, thus

$$CaCO_3 = CaO + CO_2$$

The gas coming to the surface in big bubbles causes a characteristic boil. The lime also floats up, joining the slag as a base, not only releasing some of the iron oxide contained therein for refining reactions, such as

$$2P + 5FeO = P_2O_5 + 5Fe$$

but also maintaining the basic slag necessary to dissolve and hold this phosphorus oxide. When the lime is all up further boiling in the bath is due to the chemical reaction between iron oxide and carbon (which has been going on continually but its mechanical effect somewhat overshadowed by the lime boil).

$$FeO + Fe_3C = 4Fe + CO$$

The iron oxide is dissolved by the metal from the slag. Bubbles of carbon monoxide gas evolved continue to keep the metal and slag in motion. The active refining reagent in the open-hearth furnace is the same as in the Bessemer and the earlier refining processes, namely iron oxide. but its origin is different. In the open-hearth process iron oxide is formed by oxidation of the steel during melting, picked up from the rustv scrap, and added as desired to the slag in the form of ore. During the late refining period. the furnaceman frequently takes a spoonful of metal from the bath, pours test ingots and breaks them, judging from the fracture the content in phosphorus and carbon. It is necessary to regulate the proceedings so that phosphorus in the metal shall be down to the desired minimum some time before the carbon is down. This relative elimination can be controlled by adjusting the temperature (reversing the flow of gases more frequently increases the heat), changing the slag by adding either lime or ore, increasing its fluidity by adding fluorspar (CaF) or increasing the carbon by adding some low-phosphorus pig iron. In about three hours the carbon boil should subside. the bath should be low in phosphorus,

and the slag essentially a high lime silicate—to hold the phosphorus; the furnace is then driven hard to increase the metal's temperature sufficiently for casting. The slag and the metal have been slowly losing iron oxide and carbon respectively by mutual interaction, and the metal gives up considerable gas held in solution. Since 1930 much attention has been given to the relationship between composition and viscosity of the slag existing in the refining stages and the quality of the finished steel. Slag composition is rapidly estimated on the furnace floor by pouring a small "pancake" of slag in a standardized manner and examining its surface, colour and fracture. Its viscosity is measured by the distance the slag flows down a pipe-stem mould. Likewise carbon in the steel may be closely estimated by rapid magnetic tests; the rate of carbon drop is also an indicator of the state of oxidation in the heat. High grade steels are deoxidized by the controlled slag in the furnace, after which further deoxidizing substances like ferro-manganese or ferro-silicon may be added to the metal bath, followed by various alloying elements like chromium if an alloy steel is to be made. When the word is given, the furnace crew thrusts a long heavy bar through an opening in the centre door, across the furnace into the bath; several battering-ram thrusts break through the plugged tap hole, and white-hot metal rushes down the spout into a ladle set beneath. This ladle is just large enough to hold the steel; slag which follows after overflows into a pit or slag ladle alongside.

VARIATIONS IN PROCESS

Use of Molten Pig.—Various methods deviate from the above routine and have been devised to adapt the open-hearth process to the economic conditions to be met by the steel-maker, especially as to the relative amount of scrap steel and molten pig iron available. These range from processes for handling a preponderance of scrap and a minor amount of molten pig iron (as is usual in America) to the Talbot process described below for handling up to 80% hot metal (as is practiced in England, 1939).

In American stationary furnaces of, say, 100 tons capacity the limestone and scrap are charged as indicated above and heated strongly until well melted. During this time the slag forms from oxidized iron and calcined lime. Within two hours all but the heaviest scrap has melted and molten pig iron is poured in. A rapid reaction starts between the iron oxide in slag and melted scrap and the carbon, phosphorus, and silicon in the molten pig iron. Carbon oxides boiling up through the slag cause it to froth and swell and much of this "flush slag" flows off through a hole in the back of the furnace well above the normal shore line. This slag carries a little sulphur, and much of the silicon, phosphorus and manganese in the pig iron, and the amount of finishing slag is correspondingly reduced.

Continuous Steel Making.—Benjamin Talbot first built furnaces for continuous production of steel at Pencoyd, Pa., in 1899, although the Talbot process is more popular in England (1939). Furnaces are of large capacity—200 to 300 tons of metal—and are mounted like a mixer on trunnions; they can be tilted forward and slag skimmed or metal poured through a spout, normally far above the liquid bath. Most of the finishing slag and about 10 tons of steel from the previous heat are retained in the furnace and on this is charged enough burnt lime and ore so the first slag can be removed when the metal is 0·30% carbon above that desired. After heating the slag and furnace for 2 hours scrap as available is charged, heated another 2 hours, and about three-quarters of the required molten pig iron is poured in. Reaction is vigorous for about 4 hours, and then the remainder of the hot metal is added. The bath quickly comes to a good boil and the slag is carefully skimmed off 1 hour later. This slag carries most of the phosphorus; it may analyze 17% P_2O_5 and is a valuable by-product. The finishing slag is then made up of lime and scale (iron oxide) and the bath worked until carbon, sulphur, and phosphorus in the metal are reduced to the required point, taking about 3 hours, whereupon ferro-manganese is added and the steel is poured into waiting ladles. The analysis can be "caught on the run," and held for adjustments, alloying, or making up a second refining slag. The process, therefore, in addition to consuming large proportions of hot metal, is able to produce quality steels of varying specifications at will, thus being a prototype of the electric furnace, to be described later.

Duplex Processes.--Other means of speeding the rather deliberate open-hearth reactions are used extensively, perhaps the most important being a combination of acid Bessemer and basic open hearth. This enables the steel-makers to start with a high sulphur ore, smelting it to a high silicon, low sulphur pig iron, blowing the silicon and carbon out in a converter, and transferring the molten steel to a large tilting furnace where the phosphorus, oxide and gases are eliminated. In American practice 250-ton tilting furnaces are used; 50 tons of molten steel are reserved in the hearth, a highly basic combination of ore and lime is charged, melted, and about 150 tons of blown metal poured in. When the temperature and slag are correctly adjusted, a ladle of basic pig iron from a mixer is charged. A strong carbon boil ensues immediately, and the slag foams up and overflows, carrying much of the phosphorus and some sulphur. When the first reaction quiets down, a second ladle of pig iron causes it to resume, and drives out the rest of the phosphorus. The slag is then skimmed off, enough pig iron is added to bring the carbon to the desired percentage, and the metal finished and superheated for pouring. From such a furnace, 200 tons of steel can be taken every 3 or 4 hours.

Duplex processes of the sort described but using two open-hearth furnaces originated in Germany and are used for irons somewhat too low in phosphorus for the basic converter. In the first furnace, run at a rather low temperature, the phosphorus and silicon are eliminated into a lime slag rich enough for use as a fertilizer. The furnace is tapped, the slag separated, and the metal introduced into another and hotter furnace, wherein awaits a proper slag for rapid carbon elimination. This is called the Bertrand-Thiel process; the Hoesch modification recharges the partly purified metal back into the furnace from which it has just been drained. Super-refining molten basic steel in an electric furnace is another variety of duplexing which has been practised in America; by eliminating sulphur and oxidizing particles, good steel is made, but the difficulty of co-ordinating operations to avoid idle stand-by of costly furnaces has prevented the wider adoption of duplex processes.

Acid Steel.—Furnaces made with siliceous bottoms and banks, the descendants of the original open-hearth furnaces, still exist in considerable number. They make steel under slags which are essentially mixtures of iron, manganese and silicon oxides, having well over 50% of the latter, and are so quite acid in nature. Such acid steel has an enviable reputation for quality, but since the furnace reactions remove neither sulphur nor phosphorus, the raw materials and fuel must be selected with much more care.

Pig and scrap, as available, are charged cold into the furnace, which has a higher roof to withstand the higher refining temperature; during melting, nine-tenths of the manganese and silicon are oxidized, and join with the rust and burned iron to form a slag. Carbon is eliminated slowly by reaction with the iron oxide in the slag; a little ore is added some two hours after the charge is well melted to keep this reaction going until the residual carbon in the metal equals that required in the steel being made. Temperature is driven higher and higher. Toward the end of this refining period—which may require seven hours—some manganese and silicon re-enters the metal, reduced from the slag by reversible chemical reactions, and are very effective in removing oxygen and other dissolved gases. At the end the metal is slowly losing carbon but gaining manganese and silicon. However, manganese is still too low for most steel specifications, so an appropriate amount of ferro-manganese is added some 20 min. before tapping. A complete cycle of operations may require up to 16 hours when making steels for ordnance. The superiority of acid open-hearth steel is due to the better grade of raw material used, the small amount of slag formed (perhaps 7% of the metal), the more deliberate working of the heat enabling the furnaceman to bring his metal to the right analysis without making large additions of alloys, and the ability to eliminate gases and non-metallic impurities from a super-heated fluid metal while it is still in the furnace.

ELECTRIC STEEL

Electric furnaces (*q.v.*) are usually round in plan, with low side walls, flat domed roofs and invert bottoms, built inside a stout bowl of steel plates, which in turn is attached to some tilting device. Side walls are pierced by one or more doors and a pouring spout. The side wall and bottom linings may be either acid—silica brick and fused siliceous material—or basic magnesite. (The acid furnace is confined generally to small installations in foundries, and is merely a melting and super-heating device, since the unique carbide slags to be described later cannot be formed inside a siliceous lining.) Roofs are of silica brick, and are pierced for carbon or graphite electrodes, one for each phase of current, of proper size to carry the electricity without undue resistance. Furnace capacities range from ¼ ton for small foundries, to 50 tons for super-refining liquid steel. Size is limited by the size of electrodes available; of the latter, a carbon 40 in. in diameter is the maximum; a 7-ton furnace would be about 12 ft. in outer diameter, with 13 in. side walls, and hearth 5½ ft. inside height. In operation, the electrodes are automatically adjusted so the lower ends are constantly a correct distance above the slag. Electric currents of large amperage arc cross this gap, flow through the slag to the metal and there neutralize equal currents of opposite phase led in through the other electrodes. Heat is generated principally by the resistance offered by the air gap and the slag layer to the flow of this current. The electrodes are consumed gradually, combining with oxygen of the air within the furnace, producing a carbon monoxide atmosphere, desirable for steel refining.

Advantages of Electric Heat.—No virtue is given to electric steel by the electricity. It is merely a convenient source of heat, under close control. The advantages of electric furnaces for steel malting are: (a) ability to generate a high temperature and thus cause certain desirable reactions to occur; (*b*) virtual absence of products of fuel combustion and their unwanted compounds of carbon, hydrogen, sulphur and oxygen; *(c)* the ability to remove a slag and make up new ones, thus controlling refining reactions; (d) the metal is hotter than the refractory, a prime advantage in cost over crucible melting; *(e)* less slagging of alloying elements, thus making for economy and control of chemical composition within narrow limits. Such advantages are illustrated in the process of super-refining molten metal from the open-hearth furnace; in such operations the basic electric furnace is a unit of a duplex or even a triplex process—the pig iron may be desiliconized in an acid converter, de-phosphorized in a basic open hearth, and de-oxidized and de-sulphurized in a basic electric furnace.

Super-refining Molten Steel.---Open-hearth steel is taken from the furnace when the carbon has dropped to the required figure, and a little ferro-silicon or aluminium added to the ladle to prevent further decarbonization during the transfer. In such condition the phosphorus and silicon are both very low—0.010% or less—while the sulphur depends upon the purity of the metal at the beginning, none being lost in the process so far, in fact the metal picks up a little from the furnace gases. If a nickel steel is to be made, the correct amount of shot nickel is added when this liquid metal is poured into the electric furnace. After the current has played long enough to remelt any crust of metal which may have chilled, a highly basic white slag is made up and melted, consisting mostly of burned lime with only enough silica sand and fluorspar to give it the proper fluidity. In quantity this would amount to about 3% of the metal. An excess of ground carbon is then shovelled in, the furnace closed, left under current for from 1½ to 5 hours, depending upon the quality of steel required, and the doors opened only for sampling or adjusting the slag. Under these conditions of a reducing atmosphere, a high lime slag, and intense heat, calcium carbide is formed by reaction between the lime and crushed carbon

$$CaO + 3C = CaC_2 + CO$$

Slag samples quenched in water give off much acetylene (*q.v.*) easily distinguished by its characteristic odour. Such a carbide slag not only reduces oxygen in the steel but is capable of abstracting the sulphur. The reaction for the latter may be something like this:

$$3MnS + 2CaO + CaC_2 = 3Mn + 3CaS + 2CO$$

By this means ordinary open-hearth charges which usually melt to 0·05% sulphur are reduced to one-half that amount in a four-hour cycle, while selected charges melting to 0·015% sulphur can be driven to less than 0·010% in a heat taking 8 hours. It will be observed from this reaction that some manganese is necessary. This will be residual in the open-hearth metal, for it has been found that if say 2% manganese is in the original pig iron, the resulting steel, containing 0·30 to 0·50 manganese will be of much better quality, sounder and cleaner, than from a low-manganese charge.

When the soapy slag stops its slight foaming, it is a sign that desulphurizing and deoxidizing are about completed, and the various alloys necessary to make the required analysis are added at intervals in order of their oxidizing power, namely, ferro-silicon first, then ferro-manganese, ierro-chromium, and finally ferro-vanadium. Carbon is picked up from the carbide slag and from these alloys. After all these alloys are melted and diffused the current is shut off and the metal lies quiet for 30 min. or more, to allow entrapped particles of slag to arise and the superheated metal to cool and liberate dissolved carbon monoxide gas. Slag is then most carefully skimmed, and the steel poured into a ladle which may contain a little carbon, ferro-silicon and ferro-zirconium. After 30 min. further cooling the metal is teemed into warm, scrupulously clean moulds with hot tops. A sectioned ingot will show no cavities as large as a pin head.

Quality of Deoxidized Steel.—Quality of such deoxidized and desulphurized steels rests in a number of characteristics, some not capable of evaluation, such as better response to heat treatment, less non-metallic inclusions, as shown under the microscope and after deep pickling in strong acid. A better gauge is the transverse properties. If a well made heat of basic open hearth steel is forged into a big gun, tension test pieces cut out of this forging will show high ductility if the piece is cut in a directon parallel to the axis of the gun. On the other hand if these test pieces are cut tangentially to the bore, the ultimate strength is satisfactory but the ductility is not much more than half the longitudinal piece. Unfortunately this transverse weakness is in the very direction which must bear the heaviest stress when the gun is fired. An accepted explanation of this phenomenon is that the work of forging ranges the non-metallic impurities into layers parallel to the faces of compression, and interrupts the metallic continuity. Obviously, the cleaner the steel the less would be the transverse weakness. For that reason important forgings, such as hollow tubes to resist internal pressure, are commonly made of acid open-hearth steel. Super-refined basic electric steel is even better, as shown by the following typical tests from big gun forgings of nickel steel:

	Longitudinal	Tangential
Ultimate strength, lb. per sq. in.	110,000	110,000
Elastic limit, lb. per sq. in.	58,000	58,000
Elongation in 2 in., %	56	42
Contraction in area, %	24	21

Melting Cold Scrap.—By far the larger number of electric furnaces are of small capacity for melting cold scrap. While it is possible to refine impure pig iron in either the acid or basic electric furnace, it has been generally found more economical to start with clean, relatively heavy, high manganese scrap and melt without additions of iron ore. In a basic furnace considerable lime would be charged into the empty furnace; melting is done under the heaviest power input practicable. The slag formed on the steel is always black from the rust and oxide formed during melting. This slag is removed as soon as the charge is melted, and some ground carbon electrode butts are shovelled into the furnace and flapped under the metal. As the carbon dissolves, it first tends to deoxidize the steel

$$FeO + C = Fe + CO$$

and the carbon monoxide gas comes up in bubbles. Some surplus carbon helps bring the carbon to the required analysis. Then a

white or carbide slag is made up, and the refining and alloying is done with current of lower voltage and as described above.

Induction Furnaces.—The 1939 substitute for the crucible melting hole is the high frequency induction furnace. The furnace case is a small cubical box which can be tilted about one upper edge. It contains a cylindrical spiral coil of water cooled copper tubing which carries alternating current at about 2,500 cycles per second. The coil is electrically and thermally insulated, and inside it is rammed a magnesite refractory to form a crucible, into which is charged selected steel and ferro-alloys for simple melting and mixing without refining. The intense alternating magnetic field set up inside the coil induces eddy or Foucault currents (*q.v.*) in this metal to heat and melt it. Electrodynamic movement of the bath keeps the metal well stirred, which is of advantage in making high alloys of heavy metals, such as high speed tool steel (*q.v.*), but tends to stir in particles of incidental oxide slag. As a simple melting furnace of rapid action the induction furnace has no equal.

Statistics show that electric steel has practically supplanted crucible steel in America, but has not been so successful in Great Britain. Italy being rich in water power, but very poor in fuel, has at least 200 electric furnaces with annual capacity of one million tons, but nearly all of them produce tonnage steels. Much controversy exists as to the relative quality produced by the two processes. It is probably true that there is little difference when selected raw material is charged, an expert furnaceman is employed, and equally careful pouring, forging and annealing practice is adhered to—in other words, when equal care is given to the respective heats. But steel from either process can be disappointing when conditions get out of control. The crucible is more convenient for smaller casts of plain high-carbon steels; the electric is more convenient for heavy ingots of lower carbon, higher alloy steels.

INGOTS

Gases in Liquid Metal.—Early attempts to make steel in England by Bessemer's process were failures because the metal when poured into ingot moulds boiled over and the remaining portion when solid would be full of blow-holes, like a Swiss cheese. Robert Mushet noted that the only apparent difference between sound ingots and the spongy ones was that the former were made of high-manganese pig iron and a little manganese remained in the steel; consequently he proposed adding some of the metal after the blow. Thus originated the practice already mentioned of adding spiegel or ferro-manganese to heats of steel made by any of the Bessemer or open-hearth modifications. Superheated liquid steel absorbs gases from the atmosphere or oxygen from the slag. This gas is only slowly evolved as the steel cools off, but it boils out vigorously just at the freezing point. In the crucible and acid open-hearth process much of this oxygen is eliminated by holding the melted metal quietly in the furnace until reactions between the siliceous linings and the metal allow the latter to absorb some silicon which in turn is very effective in removing dissolved or combined oxygen existing in the steel, and causing it to solidify quietly without effervescing, which imparts superior physical properties. This time-consuming reaction is avoided when producing cheaper steels in great tonnages by adding the degasifyers to the steel in the ladle, or even as it is poured into the ingot. Melted spiegel-eisen is used for medium carbon Bessemer steels. Since spiegel ordinarily contains 20% manganese and 5% carbon, it will be observed that sufficient manganese to quiet the steel will also introduce considerable carbon. Should this be too much for the desired grade of steel, ferro-manganese is used instead. Since a relatively small amount of this is required small pieces are placed in the ladle, and melted by the inrushing steel; if the metal on casting still seems too effervescent, a few aluminium shot are thrown into each ingot. The principal effect of each of these metals is to rob harmful iron oxide existing in the steel of its oxygen, thereby transferring it to MnO, SiO_2 or Al_2O_3 as the case may be. These oxides are highly insoluble in metal, and tend to accumulate into slag particles and float; but there is little opportunity for elimination when the reactions occur in the ladle or ingot mould. Entrapment of submicroscopic inclusions is not an unmitigated evil; under proper control the effect is to restrict crystallization of the steel during solidification and in later heat treatment, and such fine grained steel has superior toughness and most other physical properties (except depth of hardening).

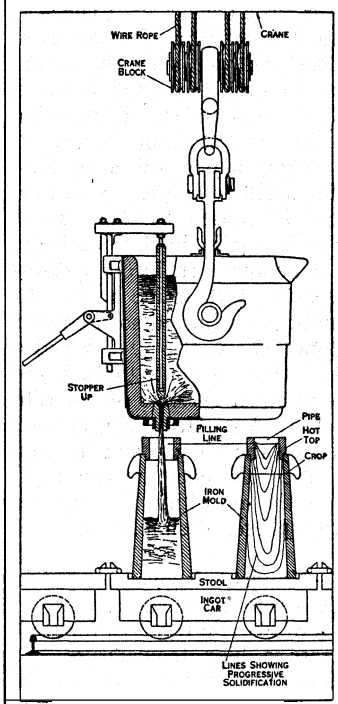

FIG. 4.—DIAGRAM SHOWING LADLE AND METHOD OF POURING INGOTS: AND LINES SHOWING PROGRESSIVE SOLIDIFICATION OF INGOTS

Teeming Practice.—It is usual practice to transfer steel from converter or open-hearth to ladle somewhat too hot to pour; also to use a ladle of correct size so most of the slag overflows. Ladles, therefore, contain from 5 to 200 tons of steel, depending on the furnace served (see fig. 4). They are strong steel pots lined with fire brick, and equipped with trunnions and shackles for crane transport. The hot metal is kept in the ladle sometimes as much as half an hour, to enable all trapped slag particles to float. Then the ladle is carried to the ingot moulds, and the metal teemed through a hole in the bottom. When one mould is filled, the metal stream is interrupted by lowering the stopper until the ladle may be moved to an empty mould. Splashing against the sides of the moulds must be avoided, for such splashings are the most general cause of surface defects on the finished articles.

Steel castings are ordinarily teemed in the same way; furnaces in steel foundries are usually very small as compared with furnaces serving rolling mills. 97% of all the steel made is cast into ingots.

Cavities in Ingots.—Well-killed steel contracts in volume when it changes from liquid to solid; consequently a mould poured level full will have a top cavity, or pipe, when solid. Good practice so proportions the chilling effect of the mould, the temperature of the steel and the rate of pouring that the ingot solidifies from the bottom up. A hot-top in the form of a firebrick collar, set on top of the mould, as shown, is a most useful device for keeping the top portion of the metal fluid until the last, and in condition to feed and fill the shrinkage cavity below (see fig. 4). A certain segregation or concentration of alloying elements also occurs toward the pipe; consequently all the defective top must be cropped as indicated and remelted as scrap. Segregation and piping is also minimized by casting ingots big-end-up and by slow pouring of rather cool metal. The latter is well accomplished by having several ingot-moulds on one stool, teeming into the central one, and allowing metal to rise in the others through connecting passages in the common base. Enough gas is left in most low carbon tonnage steels so a slight effervescence occurs in the mould, just enough to counteract the piping tendency. When properly made and cast, such ingots will have a flat top, a smooth solid surface, but a number of deepseated small blow holes. During subsequent rolling these are squeezed shut and the metal welds together more or less effectively. Metal of this sort is called "rimming" steel; the dense surface of the metallic ingot is an ideal start for thin sheet, which is almost all surface.

Stripping and Soaking.—Size of ingots depends upon the use to which the metal is to be put. Ingots of alloy steel and high grade tool steel sometimes weigh no more than 100 lb. Forging ingots are from two to five times the thickness of the biggest part of the resulting forging; those for rails, plates and structural shapes are adjusted to the size and capacity of rolling mill, and

the cross section of the desired product; for rolling mills they are generally square in cross section, with rounded corners, and about three times as high as thick. A common size is 2x2x6 ft. weighing about 6 tons. Forging ingots are frequently fluted hexagons or octagons in cross section The moulds are heavy-walled iron castings, made of low-phosphorus low-sulphur pig iron, such as is suitable for the acid Bessemer process, sprayed with lime wash or other coating. When the metal in the ingot has well solidified, the train of moulds is moved to a stripper, an overhead crane with a vertical plunger which can be forced down by suitable gearing on top of the ingot, holding it down against the stool. A pair of stirrups then loop over the ears on either side of the mould, and lift; if the inner surface of the mould is in good condition and smooth, no difficulty is had in thus removing the mould, and it is then placed on an empty car alongside. At this time the surface of the ingot is at a full red heat, yet the interior may still be white hot. To equalize this heat the ingot is placed in a soaking pit, a square fire brick chamber large enough to contain two to six ingots standing on end; an arched cover rolls aside for entrance. Auxiliary heat is supplied as necessary by a gas-air flame, operacing through regenerative chequer-work, ports and auxiliary control as described for open-hearth furnaces. Pit capacity for at least 100 ingots is required to maintain a steady supply of properly heated metal to a modern rolling mill.

ROLLING MILLS

Hot Working. — A spongy lump of wrought iron, hot from the furnace, requires forging in order to squeeze out much of the trapped slag, and to consolidate the metal. Even the best ingot of steel is improved by hot work, such as forging or pressing; its fracture is changed from a coarse crystalline cleavage like sugar to a mossy or fibrous appearance associated with greatly increased toughness; it also becomes more amenable to heat treatment. Formerly all this was done on the blacksmith's anvil. Massive gun tubes and armour-plates are forged slowly in hydraulic presses; heavy engine parts, axles and cranks are beaten out by steam-hammers; repetition tools, levers and machine parts are forged under drop-hammers. In every instance the aim is to convert a steel casting (ingot) into a special shape and with improved physical properties.

Modern machines and structures-even foods and personal conveniences — require large quantities of steel parts of uniform cross section, such as plates, bars, beams, rails, pipes, sheets, etc. These are made in rolling-mills where the work is performed by passing the red hot metal through one pair of heavy rollers after another, so grooved and spaced that each succeeding pass is smaller and more nearly the required final shape. While the products of a rolling mill vary widely in weight and shape, a common characteristic is that each piece is of uniform cross section from end to end, and is of a length limited only by the size of the original ingot, or by the size of the runout floor.

The word *mill* may mean the entire steel making plant, just one department, or one stand of rolls in the department. Complete departments have various names, such as rail mills, structural mills, plate mills, merchant bar mills, depending upon the product they most efficiently produce. Each such mill contains a number of roll-stands of decreasing size and power, from the blooming or cogging mills which do the heaviest work, down through the intermediate stands to the last pass, finishing mill or finishing stand, which impresses the exact final cross section.

There still exist many rolling-mills, some producing the highest type of tool steel, which start with a small piece of metal (a 150 lb. ingot or a chunky rolled bar called a billet) and produce rods, bars, hoops or flats a fraction of an inch thick. Metal is passed back and forth by tongs in the hands of skilled labourers. Such roll stands are usually arranged side by side and the hot bars are looped from stand to stand, entering from alternate sides, until the final shape is produced. Sometimes curved guides are installed to do the work of alternate workmen; as the size of the bars increases hand labour cannot cope with the situation. Most rolled shapes start from white hot ingots, perhaps six tons in weight, which are taken from soaking pits by a travelling crane, placed on the first of a series of "tables" — power driven roller conveyors — which transport the metal wherever a distant electric switch operator directs.

Blooming mills are usually arranged so the ingot is passed back and forth several times through the same roll stand. This requires a screw-down device and indicating dial on top of the housing for lowering and reversing the rolls progressively as the piece becomes smaller. The spindles connecting the rolls to the driving engine or motor are of most rugged construction, for upwards of 20,000 h.p. is transmitted at times.

Heating Furnaces. — In a modern rail-mill the ingot, having been reduced to a long bloom perhaps 8 in. square in cross section, has its ends sheared off to sound, unpiped metal by massive guillotine shears operated by hydraulic power, and is cut into such lengths that each billet will make one or two rails of required length and cross section; these are then reheated before further rolling; other mills which reheat cold billets require special furnaces, now usually gas or oil fired, frequently having waste heat boilers or recuperators (see also FURNACE, METALLURGICAL; ELECTRIC FURNACES). Furnaces have a long rectangular hearth, slightly inclined, as wide as the billet is long, and a low roof. Water-cooled skids carry the weight of the steel and prevent scraping on the brick furnace-bottom. At the cool end billets are pushed in sideways by a plunger, one by one, moving all ahead closer to the hot end. Every time a cold piece enters the furnace, a hot one is pushed out the other end on a roller table leading to a roll stand; other continuous furnaces have water-cooled rollers or other devices built into the bottoms for moving lighter pieces such as wire coils through them at a slow steady rate.

Rail Manufacture. — A reheated bloom in a rail-mill may then be given four more passes in another reversing mill, called the first roughing stand, passing then to the first finishing stand. This is three-high, *i.e.,* there are three rolls in a stand. The forward pass is through a groove cut in the lower and the middle roll; the receiving table is then elevated bodily and a backward pass is made between a groove cut in the middle and upper roll. Four such passes and a final one through a finishing stand completes the rail; a total of 11 passes and one reheating will convert an ingot into a rail weighing 100 lb. per yard. Structural shapes such as angles, channels and I-beams, are rolled in a similar routine. Frequently rail mills, by simple change in rolls, are made to produce structural steel when there is no market for rails. Special and extra heavy equipment is necessary to roll the massive H-beams with deep flanges so popular for building columns.

Plate manufacturing departments are less complicated than a rail mill, although the machinery may be more rugged. First the ingot — 6 to 10 tons or even heavier — is rolled to a flat slab in a blooming mill, sheared into pieces, and the slabs reheated. Further work is done by cylindrical (ungrooved) rolls. Sometimes a single reversing 2-high roll stand does all the work; at other times two three-high mills with elevating tables may be observed. On account of the enormous bending stresses carried by the rolls when rolling wide plates, many two-high reversing stands have been built as four-high mills, having two rather small working rolls, each backed up with a larger one for stiffness. Plates of more uniform thickness, edge to centre, may be made in this way. It should be observed that the action of a rolling-mill does not widen the piece very much — most of the change in volume results in increasing its length. Consequently a heavy slab is cut to a length which equals the width of the required plate, and it enters the plate rolls sideways. Cross rolling in this way results in a better plate; metal worked in only one direction acquires transverse weakness. This means that the tensile strength of test bars cut with their axes parallel with the direction of extension during rolling will be higher than when cut from the plate with axis in any other direction. Other interesting mechanical devices are included in a plate mill which cannot be described here in detail. Among them are plate straighteners, cooling beds, cross cut and edge shears, turnover devices, castor beds and magnetic grips. Side shearing on narrow plates may be avoided by using a universal mill, which is a roll stand to which is added a pair of stout

vertical rolls. The latter are adjustable, up to perhaps 48 in. apart, and are set a proper distance to keep the hot plastic plate the exact width during its formation.

MILLS FOR SEMI-FINISHED MATERIALS

Continuous Mills.—Four classes of semi-finished materials are manufactured in such tonnage that special mills are set up to produce them, namely: sheet bars, skelp, strip, and wire rods. These products are the raw material for special manufacturing plants often located at a distance from the steel furnaces. Sheet bars are worked into tinplate, galvanized, and uncoated sheet; pipe is made from skelp; strip is narrow sheet for hoops and bands; and rods are drawn into wire, from which all kinds of fencing, screening, cable, nails, and springs are made. Sheet bars and skelp are made in bar mills, frequently located immediately beyond a blooming mill, which take a 6 in. square bloom hot from the shear, and roll into the thin narrow plate without reheating. Such a plan requires the most rapid handling to complete the rolling before too much heat is radiated. This is done by placing a succession of two-high roll stands in tandem, within a few feet of each other, and guiding the bar automatically from one roll to the next. Since each pass elongates the piece, the speed of each roll is higher than the preceding, and the relation between speed and reduction must be nicely adjusted so the hot bar will neither buckle nor be stretched at any stage. A succession of eight or ten such rolls, with perhaps three pairs of vertical rolls to control the width—interspersed in the train—can produce standard width 8 in. sheet bars or skelp from 6 to 20 in. wide (suitable for forming into pipe up to 6 in. diameter), and from $\frac{1}{8}$ to $\frac{3}{8}$ in. thick, at the rate of 4,000 to 20,000 tons per week depending upon the sectional area of the bars manufactured. Since a mill of this sort can easily produce material far too long to ship, flying shears are set beyond the finishing roll to cut the bars to length. Many designs have been made, capable of square cutting a rapidly moving bar. Sheet bars are sometimes quenched by travelling down a long table under a series of water spray nozzles. Interesting piling devices are used.

Sheet Mills.—Sheets are $\frac{1}{8}$ in. thick or less, whereas plates have sufficient mass to retain heat until rolled to proper gauge, and a surface covered with mill scale is quite good enough for most purposes. Sheets, on account of their thinness and the excellent surface demanded by such finishing operations as galvanizing or lacquering, must be rolled in an entirely different manner. Many sheet mills are still operated by hand after the methods originated in Wales two centuries ago (see TIN) and have larger and more rugged equipment, generally producing material 18 to 30 gauge' thick, whereas tin plate is smaller in area and thinner—28 to 38 gauge. The 1930s saw a replacement of many hand mills by a few continuous sheet mills, especially in the American industry.

Sheet bars are cut with length slightly greater than the width of the required sheet, heated to a dull red 850° C, and rolled sideways through a two-high mill with massive cylindrical rolls, 32 in. diameter. One workman catches the bars as they come through and passes them back to another over the top roll; a third screws down the top roll gradually to continue the reduction. The crew passes two bars back and forth very dextrously; when these bars have been flattened to about 3/32 in. one is placed on top of the other, the top roll raised, and the pair rolled down until each is about twice as thick as the desired sheet. In the best practice, one pass is then given in the mill to be used for finishing, in order to "shape" the pack to this mill.

By this time, reheating is necessary; the pair is opened, that is the two sheets are separated, and placed in a furnace until the temperature is up to about 800° C. Low temperatures and a smoky flame are necessary to prevent surface oxidation in the furnace. A pair of these sheets are then further rolled to the required thickness in a finishing mill, more accurate in construction and requiring more skill to operate. For thin gauges, sheets are folded double and rolled in packs of four or even eight. Frequent opening and reheating is necessary in the latter stages of the process. They are then straightened and sheared to size.

Many surface finishes are required by customers who manufacture a multitude of objects of sheet metal. The sheets may be annealed either by being passed slowly through a long furnace with hot central zone—blue annealing—or by being piled in a tight box containing a prepared atmosphere to protect the steel from tarnish and heated for hours at a considerably lower temperature—box annealing; or the cold sheets may be given several passes through accurate rolls for a smooth surface and a somewhat stiffer temper. Interspersed with these operations, the oxide or mill scale may be removed by pickling (*q.v.*) in weak sulphuric acid. Finally the cleaned cold-rolled sheets may be dipped in white metal for a protective coat, wiped, cooled, polished and boxed. Coating with zinc is called galvanizing; tin or tin sheet is thin steel dipped in pure tin; terne sheet is dipped in a lead-tin alloy.

Strip and Continuous Sheets.—Desire to eliminate the large amount of labour required for sheet working by the above described process has led to the recent production of sheets in continuous mills. Since 1900 it had been common to roll strip up to 3 in. wide and 16 gauge or less in thickness, in very long coils in a series of roll stands placed close together; mills have been built for wider and wider strip-sheet, until sheet 8 ft. wide was produced commercially in America in 1939, but no thinner than 16 gauge. In a narrow strip, hoop or cotton-tie mill, a continuous heating furnace feeds flat bars about the width of the finished piece, endwise into the first of a series of six tongue and groove rolls, perhaps 10 in. diameter. One edger may be installed after the third roll, and the remainder then be flat rolls. Then the bar passes through a series of three very accurate finishing rolls, sometimes being bent sharply, scraped, and air blasted before entering the last roll to remove the scale. These finishing rolls are cylindrical, and the guides are shifted sidewise at frequent intervals, to prevent the chilled strip from wearing the roll-surface irregularly; speeds are watched closely; the first roughing roll is very slow, the last very fast; in fact the trailing end of the billet may still be in the furnace when the front end is being reeled, 200 ft. away, at the speed of 1,000 ft. per minute. One great advantage of such close-set continuous mills is that the time of passage from furnace to finishing roll is the same for all parts of the billet; consequently the temperature at the last pass is uniform, and the thickness after cooling is also quite uniform. Finished strip is automatically turned on edge, looped back and forth on a broad slow moving conveyor belt passing through a muffle; emerging it is cool enough for reeling, cutting to length and bundling. About 40 men are required to operate such a strip mill producing from 10 to 20 tons of strip per hour, depending upon its width and gauge. Such strip has a surface covered with mill scale, or if this is scraped off, a blued colour formed during slow cooling For higher finishes and stiffer tempers, the strip may be pickled and cold rolled rather slowly to accurate gauge and smooth surface.

In the new continuous sheet mills, slabs weighing up to a ton and a half, the product of a blooming mill, are reheated to the proper temperature and delivered to the first roll stand, where jets of high pressure, superheated steam strike the hot slab just as it enters the rolls, thus breaking loose most of the scale. This roll stand is set somewhat further from its successors than the space between later stands. Some of this table is utilized for a turning mechanism, so that the slab can be turned sidewise, since its original length should represent the width of the strip. Heavy machinery also holds the slab down while its edges are squeezed to the correct distance apart. The slab is also held here a little time to radiate down to the necessary temperature; the latter is fixed by the speed of the remaining stands and the desired delivery temperature. Once started on its way, the slab passes through three or four heavy, four-high roll stands comprising what is known as the roughing train, separated far enough so the slab is entirely free in its passage along the roller table from stand to stand. This roughing train will reduce the thickness of the $4\frac{1}{2}$ to 5-in, slab to somewhere around 1 in., and correspondingly increase its length. It is usual for these stands also to have vertical edging rolls set at their entering side to keep the width of the hot metal correct. The work rolls in all these four-high mills are relatively small in diameter and have very heavy, massive backing-up rolls. Next in train comes a series of six four-high stands set fairly close together, each one rotating

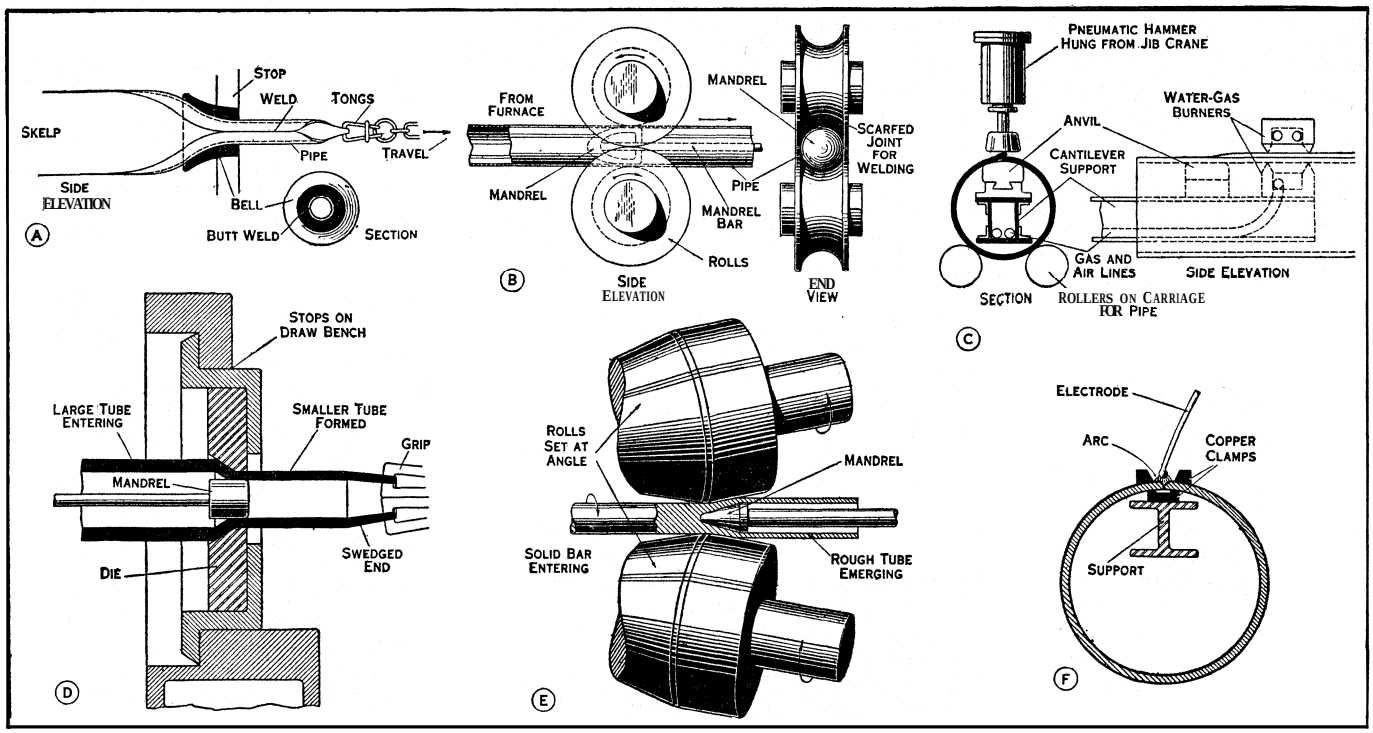

FIG. 5.— DIAGRAM ILLUSTRATING VARIOUS METHODS FOR MANUFACTURING PIPE. A. BUTT WELDING A 2 IN. PIPE: B. SIDE AND END VIEW OF LAP WELDING; C. HAMMER WELDING OF 30 IN. PIPE: D. DRAWING SEAMLESS PIPE: E. MANNESMAN METHOD; F. ARC WELDING OF 30 IN. PIPE

at a faster speed than its predecessor, the last one delivering sheet of required thickness from, say. $\frac{1}{4}$ in. down to $\frac{1}{16}$ in., at a speed of 30 miles an hour. The metal emerges from the last stand before the trailing end is clear of the first, so safe passage without breaking requires finger-tip control of the speed of the mills, as well as accurate and ready adjustment of the clearance between rolls—that is, the relative amount of reduction, stand to stand. All of these controls are electrical in nature and are centred in a pulpit where the operators are in full view of the entire operation. Temperature of delivery of the sheet is important for many applications. Instantaneous and automatic optical pyrometers, indicating and recording temperatures not only of the slab at the beginning, but of the finished sheet at the end, are essential items of equipment. Sometimes the hot-finished sheet is rapidly cooled by water sprays; at other times the sheet is delivered as hot as possible to the coiling devices and the tightly wound coil is cooled quite slowly.

This sheet-mill product may be cut or slit into such sizes as make it available for other operations, such as thin plate or thick sheet for tankage or barrels, or it may be slit into narrow strips suitable for making into pipe. However, if it is to be further rolled into thinner sheet, the mill scale is pickled off, and then the material is rolled through four-high cold rolling mills, usually set three in tandem. Reduced finally to the proper thickness and hardness, the coil is uncoiled through a leveller and automatic shear which cuts and piles the sheets, after which they are sent to the annealing department for proper annealing. This is now done in controlled atmosphere so that there is no scaling and even little discoloration. After a final pass through a four-high stand ("skin rolling and levelling"), the sheets are resquared, inspected, oiled, and shipped.

Pipe.—Skelp, the flat bars from which small sized pipe is made, is rolled in a continuous mill specially designed to produce bars true in thickness, width, and properly bevelled on the edges. Frequently the finishing stand is adjustable, and a skilled workman varies the roll spacing slightly in accordance with his estimate of the temperature of the metal issuing, thus compensating for the different amounts of contraction during cooling. Skelp is cut 20 ft. long, one end pointed, and then charged into a flat hearth, properly designed to produce a uniform white heat throughout; when reaching the welding temperature the metal appears to be covered with a shiny grease, which is molten iron oxide. The operator then catches the pointed end in tongs, and by means of a draw bench (see WIRE) draws the white hot bar through a welding bell (fig. 5-A) forming the flat bar into a tube and pressing the butted ends together into a true weld all in one operation. Further operations reduce the pipe, but only slightly, to the correct size, straighten it, remove the scale, shape and thread the ends, proof test it, and finally cover it with a protective coating.

Butt welding is done on pipe from $\frac{1}{8}$ to 3 in. nominal inside diameter. Common pipe from 2 to 18 in. is more usually made of flat plate by lap welding (see fig. 5-B). Plates are piled into a furnace, heated to a dull red, and run one by one through scarfing rolls, which form the necessary bevel on the edges for an overlapping seam. The hot steel is then drawn through a forming bell which curls it up into a tube (fig. 5-A). After reheating to the welding temperature this tube is caught between a pair of rolls and rolled over a manganese steel mandrel (fig. 5-B), and the joint welded by the high heat and great pressure at the point of contact. When the length has been rolled, the bar which has been holding the mandrel in position is withdrawn from the far end of the pipe. and the latter rolled away for the finishing operations already enumerated. It requires only a few seconds to weld a standard length pipe by either of these processes. Welded pipe over 30 in. in diameter is made by hammer welding or more recently by automatic arc-welding. In the former, the wide plate is curled on plate bending rolls and the overlapping joint heated and forged shut in sections. During the heating cycle two water-gas burners play a flame on a portion of the joint from both inside and outside; when the correct temperature is reached the lower burner is replaced by an anvil and the upper by a pneumatic hammer, and the hot spot welded and hammered down flat (fig. 5-C). The next section is similarly treated. After welding the length is re-rolled for shape and annealed, the ends sized and shaped, and the pieces tested and dipped in anti-corrosive liquid.

For arc-welding, the edges of the plate are planed to a bevelled V opening (fig. 5-F), the pipe bent to shape in rolls, clamped between long copper bars, and the bevel filled with metal from a slowly travelling wire, from which an electric arc is struck to the steel plate below. Details of this and other welding methods are given in the article on WELDING.

Seamless Tubing.— In America, seamless tubing is preferred for all purposes where the internal pressure is high and service severe, and a rapidly increasing amount of such pipe is being made in diameters up to 12 in. First, a round billet at full red heat is pierced by inclined rolls and mandrel. As sketched in fig. j-E, two 36 in. rolls of special shape are set side by side, with axes crossing and about 10° askew. The shape is such that the rolls grip the end of the ingot and spin it forward slowly, forcing it over a mandrel set between them. The operation is such that the mandrel seeks and maintains a truly axial position. After piercing the inner and outer surfaces are smoothed and the tube brought to exact size by several rollings over a mandrel, as in lap welding. Further operations from straightening to shipping are performed with considerable care. Not only is such pipe more reliable for the lack of any welded seam, but the piercing operation is so strenuous that nothing but metal of good quality can endure it. Therefore the tubing can safely withstand a considerably higher pressure than the best of welded pipe. Seamless tubes after cold drawing to thin walls are much used for structural members on bicycles, automobiles and aircraft, and for shaping into metal furniture and machine parts. Cold drawing is done as sketched (fig. 5-D). A tube somewhat too large and thick in wall has the end swaged down slightly. All oxide is then pickled off, the tube washed, dried and dipped in tallow or other lubricant. The pointed end is thrust through a round die, and gripped by drawbench tongs. Next, a mandrel is thrust through the tube from the far end until it has a position directly within the die, and then the tube drawn forcibly through the annular opening thus formed. In this way the outer and inner diameter may both be controlled. Each draw hardens the metal and makes it more brittle; after a few such passes, if the required size is not yet reached, the pipe is given a low temperature anneal to relieve the cold-working strains, and the process continued.

Rods and Wire.— As indicated above, wire rods are frequently rolled from 2 in. billets, 30 ft. long, on continuous mills, and the sixteenth or finishing pass delivers a 0.2 in. round to reels at a speed of 45 m. an hour. Such a mill will produce 15 tons per hour, with a complete labour force of 45 men. Other arrangements utilize a continuous mill for breaking down a 4 in. billet, and about a dozen loops fed by hand in a cross-country mill to finish. Rod reels are dumped automatically, and the rod cold-drawn through dies, with frequent annealings and other intermediate operations, into wire of various diameters, finishes and tempers. The operations are described more fully under WIRE. Most of this wire is stranded into cable or wire rope, woven into screens, netting, or fencing or made into nails. All such is done by automatic machinery so economically that the increase in cost of nails, for instance, over wire is 15 cents per 100 lb., which not only includes manufacture, but the cost of the keg as well.

CLASSIFICATION AND USES OF PLAIN CARBON STEELS

Production and Consumption.— Any classification which accounts for the destination of steel made by any combination of the above described processes must evidently be impossible on account of its complexity. As to process, it may be said that any of them can be made to produce steel which easily passes present commercial specifications, even for so severe a duty as railroad rails. The following figures show the distribution of American production of steel, 1938, according to ***The Iron Age:***

Sheet, strip and tinplate	41%
Bars	15%
Pipe	11%
Wire	9%
Plate	8%
Structural shapes	8%
Track material	5%
Miscellaneous	3%

In England the quantity of plates and track material is relatively larger, because of a more active ship-building industry and large exports respectively. The feature of the American industry is the large increase in sheet production, and the rapid decline of track material.

A similar classification of the chief lanes of consumption in the United States is given in the table which follows. It should be noted in this connection that in England and the Continent the proportion of exports is very much larger, and the relative position of automobiles and other machinery would probably be reversed. Figures are average for 1933–38 inclusive.

Industry	Proportion	Chief Purchases
Automotive	21%	Sheets, strip and bars
Building and construction	12%	Plates, structural shapes and reinforcing
Containers	10%	Sheet
Railroads	9%	Track material and plates
Exports	5%	..
Oil, gas, water	5%	Pipe
Machinery		Bars and sheets
Furnishings for buildings		Black plate and sheets
Agriculture	3%	Wire and galvanized sheet
Jobbers and distributors	15%	Wire, pipe, sheets, bars
Unclassified	12%	..

Grades **of** Carbon Steel.— Carbon is the principal alloying element used for hardening and strengthening iron. Consequently the utility of various iron-carbon alloys—the plain carbon steels which comprise such a large majority of the entire production—depends upon the amount of carbon present, and has led to the separation of the entire possible range into approximate grades: Ingot iron, made in a basic open-hearth furnace, has the lowest possible content of carbon and other alloying elements. It is used largely for sheets on account of its corrosion resistant properties. Extra soft or dead soft steel contains from 0.08 to 0.18% carbon, used where ductility, toughness, weldability or ease in cold working is desirable, and strength or stiffness a minor consideration, *i.e.,* for pipe, rivets, sheet, wire, and case hardened parts. Structural grade or mild steel contains from 0.15 to 0.25% carbon, used where a combination of strength and easy machineability is desired, for forging or flanging operations, *i.e.,* for buildings, bridges and railroad rolling stock, for boilers, drop forgings, and bolts. Medium grade contains 0.25 to 0.35% carbon and is even harder and stronger than mild steel, yet it may be hot-forged without difficulty, used for ship building, shafting, and forged machine parts. Medium hard steel contains from 0.35 to 0.65% carbon, and enters into the range where the final condition and reliability is much dependent upon the past mechanical and heat treatment; it is used for large forgings for locomotives and other prime movers, car axles, and in the higher carbons for railroad rails. Hard steel ranges from 0.65 to 0.85% carbon, and is used only after it is heat treated to a correct combination of strength and ductility, used for wrought steel wheels, locomotive tires, wood cutting tools, and sledges. Spring grades range from 0.85 to 1.05%, used in a heat treated condition, wherein a great range of hardness, resiliency and brittleness is possible, *i.e.,* automobile springs, cold chisels, rock drills and shear blades are made of these steels. High carbon tool steels range from 1.05 to 1.20%, used only after heat treatment for railroad springs, metal cutting and forming tools. A characteristic of these carbon steels is that each 0.01% of carbon increases the ultimate strength in the annealed condition by approximately 1,000 lbs. per sq.in., but at the expense of the ductility or toughness. Hardness also is increased.

Combinations of even higher strengths with considerable ductility and impact resistance may be had only in alloy steels, of which a number have been developed with special properties.

Use of alloy steels, which prior to 1910 was confined mostly to big guns, armour and projectiles, has spread rapidly into all metal working industries, among which the automotive leads. Production statistics are either lacking or uncertain because there is no agreement as to what constitutes an alloy steel. The trend (1939) is toward lower and lower contents of alloy made by basic open-hearth furnaces, operating under very special control for deoxidation and grain size. As pointed out in the article on STEELS, ALLOY, they are special steels, not merely a carbon steel to which

some alloys have been added. Production of such material is at least 3% of the total steel made (1939).

Nickel and *Chromium*.—Although there are infinite possibilities in alloying, by far the most important steels are those containing nickel and chromium, used for crank shafts. axles, gears and other automotive and machine parts. Relatively few analyses are in use, the present tendency being to minimize the number of alloy steels in process so as to avoid mixtures of the stock. The popular nickel steels contain up to 3·5% nickel and 0·10 to 0·50 carbon (Plate III., figs. 15 and 16). Chromium steels range from 0·60 to 1.50 chromium with the carbon in direct ratio from 0·15 to 1·10. Nickel-chromium steels are more numerous For machine parts, one series has nickel about 1·25%, chromium 0·6% and carbon 0·10 to 0·50; another has about 1·75% nickel, 1·0% chromium; a third has 3.5% nickel, chromium 1·5%. Nickel and chromium when added to steel increase its strength and hardness without a corresponding increase in brittleness. Nickel steels—not heat treated—are used for structural steel in long span bridges, and high strength boiler-plates; heat treated for gun tubes, engine forgings and castings, and shafting. Chromium steels are used for projectiles, for grinding rolls and for roller bearings, and with nickel or vanadium for armour plate and all sorts of heat treated machine parts, axles, and gears. Rustless irons and steels (*q.v.*) contain 12 to 18% chromium and up to 8% nickel.

Manganese is present in all steel, but when it adds up to between 1·0 and 2·0%, and carbon 0·30 to 0·50, the steel acquires special properties. These analyses are favoured in America for high strength castings, heat treated forgings, rifle barrels and for case hardening. So-called silicon structural steel used in long span bridges and for boiler plate, is really one of the lower manganese steels of this classification. The tough Hadfield manganese steel, used in castings for shock and wear resistance, contains 11 or 12% manganese and 1·0 to 1·2% carbon.

Vanadium is an element which has a powerful deoxidizing and scavenging effect; thus a vanadium-treatment on steel which shows very little of the element in the analysis makes for soundness, fine crystalline grain and reliability in forgings. From 0·5 to 2·0% is added along with other alloys to make high speed steels and tools for hot work.

Molybdenum is added to chromium, nickel, and chromium-nickel steels in from 0·2 to 0·3% to widen the range of heat treatment for given values, and to improve the forging and machining properties, and their resistance to creep when working at high temperature. Carbon-molybdenum steels of controlled grain size and hardenability are favoured by some American metallurgists.

High-speed *Steel*.—Carbon tool steels for cutting metals are heat treated by quenching from a high temperature, which gives them hardness, and then by reheating or tempering to a moderate degree to restore toughness. In use they must be operated at such low speeds that the friction between chip and tool-nose will not reheat the cutting edge above the drawing temperature, else the hardness and usefulness of the tool is destroyed. Better speeds could be made by using self-hardening tool steels, those which are hard after a slow cooling from a high temperature, such as the patented tungsten-manganese alloy invented by Robert Mushet in England sometime between 1860 and 1870, or the chromium-tungsten substitutes adapted by some American steel makers. During a 26-year research into the art of cutting metals, Frederick W. Taylor and Maunsel White discovered, 1898 to 1900, that if these steels were quenched from a sweating temperature, so high that it would utterly ruin a carbon steel, the hardness would be retained even when the cutting speed was so high that the nose of the tool and the chip leaving it were red hot. Modern high-speed steels possessing this property of red hardness fall into four general classes:

These are crucible or electric steels carefully forged to break up the crystals of complex carbides forming during the solidification of the ingot and distribute them evenly throughout the bar. A well annealed bar is not very hard (Brinell 240) and can be machined into a complex tool like a milling cutter, and then heat treated; pre-heat to 850° C, heat rapidly to 1,300° C, cool in oil or an air blast, giving a Brinell hardness of at least 600. Reheating 30 min. at 600° C is then necessary to give the quality of red hardness; the Brinell hardness is even higher and the toughness materially better. As an indication of the revolution which these steels have effected in machine shop practice, a plain carbon tool steel will cut 16 ft. per min. on a medium steel forging, an air hardening steel 26 ft. per min., the same after being given the high quench 60 ft. per min. and a modern high speed steel 100 ft. per min. or more, all cuts being of same depth and feed. and on the same material. Cobalt high speeds are for cutting extra hard or gritty substances.

Tungsten Steels.—Other alloys whose properties are due principally to tungsten, in addition to the air hardening tool steels and the high speed steels, are tool steels to which from 1 to 5% tungsten is added to improve the quality of the wood working or other tools which would be made of the plain carbon steels. They arc also good for making finishing cuts on metal after the most of it has been removed by deep cuts with high speed steel. Magnets are also made of steels with &% tungsten and 0·7% carbon, quenched but not tempered.

SOME FERRO-ALLOYS

Ferro-alloys are highly important and include those metallic substances used for finishing carbon steel and manufacturing alloy steel. Most of them are electric furnace alloys of iron and carbon plus the third distinguishing metal, manganese, silicon, chromium or some other, although for some purposes the carbon content must be as low as possible. For such specifications the alloys are made using either metallic aluminium or silicon for the reducing agent.

It was early discovered that manganese must be added to make sound steel by Bessemer's process. As already noted, the usual ferro-alloy for this purpose is spiegel-eisen, a blast furnace product made from iron ore sufficiently high in manganese to smelt into a pig iron containing 10 to 30% of that element, with carbon about 5%. Spiegel cannot be used for low carbon steels because the required amount of manganese carries with it too much carbon. For such purposes, ferro-manganese is used, containing nominally 80% manganese and 6¾% carbon. This is also a product of the blast furnace when smelting an ore containing 40 to 50% manganese, low in iron. Since manganese and iron are so alike chemically, the actions in the furnace are very similar to those previously described. The output in ferro-manganese from 50% ore is only about one third as much as though common pig iron were produced; the blast is 250° F hotter and the coke consumption twice as much; about ⅕ of the manganese is lost in the slag. While ferro-manganese can be made in an electric furnace of the pit type (*see* ferro-silicon) it cannot compete with the blast furnace product except under special economic conditions, as in Norway, or where carbon below 0·25% is required, as for high manganese alloy steels.

Ferro-silicon is the next most important alloy. A 12% silicon pig iron may be made in the blast furnace, but alloys higher in silicon are now used to deoxidize nearly all steel for castings, to quiet most tonnage steel from basic open-hearth furnaces, and to make several silicon alloy steels. Ferro-silicons are exclusively an electric furnace product and are made in several grades—jo, 75, 80, and 95%. Carbon is about 0·5%, phosphorus and sulphur less than 0.10%—the former particularly must be kept to the minimum to prevent the alloy from absorbing moisture from the air and generating poisonous phosgene gas (PH_3). A pit-type electric furnace is employed, rectangular in cross section, with bottom built of carbon blocks. Into this shaft are suspended three carbon electrodes, one for each phase of current; a granular mixture of pure quartzite, clean iron turnings and coke is shovelled into the open top, filling thr entire furnace Passage of current

from electrodes to furnace bottom gives the necessary heat for the coke to reduce silicon metal from the rock. Carbon monoxide produced by the reaction rises and burns at the top of the charge column, and a molten alloy of iron and silicon collects on the hearth, from which it is tapped periodically.

Ferro-chromium.—This is one of the earliest ferro-alloys produced in an electric furnace. At present the commercial alloys contain about 67% chromium. The so-called high carbon alloys range from 4 to 8% carbon by units, whereas the low carbon alloys necessary to make stainless irons range from 0·20 to 2·0% carbon by steps. Chromium metal up to 98% pure is also commercial. Ferro-chromiums are ordinarily made in closed furnaces of the Heroult type, with bottoms laid in carbon blocks. A charge of chromium ore, iron or iron ore, anthracite coal for reducing, and flux for slagging impurities, is mixed and shovelled in, the doors closed and electric current turned on. Carbon reduces the metallic oxides in the intense localized heat; at the finish the molten charge is poured into slabs, broken, analyzed and graded for shipment. To reduce high carbon, these varieties are remelted with concentrated chromium oxide, under a lime-fluorspar slag. Nickel is added to molten steel as shot metal, or a nickel-steel scrap may be used to make alloy steel—nickel having no tendency to enter the furnace slag.

Ferro-vanadium is one of the most difficult alloys to make, on account of the activity of the element. The pure metal is not commercial. B. D. Saklatwalla developed various means of commercial alloy production, using a mixture of vanadium oxide, iron oxide and powdered aluminium, either in crucibles by means of the thermit reaction, or in shaft furnaces with the assistance of the electric arc. At present the ore is smelted in a reverberatory furnace, and the vanadium concentrated in the slag. This slag is ground, mixed with carbon, iron scale and fluxes (glass cullet, lime and fluorspar) and fed in a fine stream into a covered furnace, directly through the arc between graphite electrodes, thus effecting the reduction almost instantly in the intense heat. Reduced alloy and slag collect in the hearth and are tapped three or four times a day. A common analysis contains 35% vanadium.

Ferro-tungsten.—Tungsten ore is widely distributed, and the concentrate comes to the refiner in such complex mixtures of minerals that the first step is frequently the production of the oxide WO_3 by chemical means (see **TUNGSTEN**). This oxide is easily reduced to metallic powder without melting by mixing with fine carbon, sealing in a crucible and heating to 1,300° C for several hours. Ferro-tungsten, which has become more popular for making high speed steel, may contain from 60 to 85% tungsten, and is made in single-phase electric shaft furnaces. The bottom is one terminal; the electrode set above is surrounded by a shaft of loose brickwork, and a mixture of oxide ore, iron and carbon is filled in. As the reduced alloy builds up on the hearth it chills into a thicker and thicker button, because it has an unusually high melting point; when this solid metallic mass has grown to a point where its electrical resistance interferes with operations, the temporary furnace is torn down and the sow crushed, analyzed and classified.

METALLOGRAPHY AND HEAT TREATMENT

General Structure of Steel.—Much may be discovered about the general structure of the metal by a close scrutiny with the naked eye, or with a little magnifying glass. Such studies (macroscopy) include examination of the finished surfaces, of freshly broken fractures, and of rough polished sections etched in various ways. Information gained from a freshly broken fracture has not yet been systematized and correlated with microscopic appearance except as to grain size of the steel after heat treatment. To be of value it requires a keen eye to note small differences, and much practice and everyday familiarity with the fracture of satisfactory metal. In the hands of a skilled inspector it is the first step in securing uniformity in raw materials.

General Structure may best be exhibited on a roughly polished surface by etching in freshly prepared ammonium persulphate solution (10% $(NH_4)_2S_2O_8$). It shows immediately differences in grain size caused by differences in heat treatment or other cause.

Deep *etching* is much favoured in America for acceptance tests on high grade steel. It shows any non-uniformity in chemical composition or general bad quality. The smooth sample is held in hot hydrochloric acid (diluted 50%) for about 30 min. Impure spots, blowholes or cracks are eaten more deeply than elsewhere, and the result is an irregularly pitted surface (Plate III., fig. 8). During solidification of a steel ingot, excess of sulphur compounds will collect toward the centre and top part, where they are trapped and remain during further rolling and manufacture. The distribution of sulphur compounds in a smooth section may be shown by pressing it firmly for about a minute against a sheet of photographic paper moistened with 2% sulphuric acid, then washing and fixing. The dark areas indicate the location of higher sulphur in the steel (Plate III., fig. 7). Phosphorus also accumulates around the borders of the large metallic crystals which form in the ingot, and during rolling or forging are pressed out into stringers or sheets in ruling directions. Ordinary plate or forging steel will always be found thus marked. In forging, these ***flow*** lines are arranged more or less parallel to the finished surface, and the dies are so constructed that the flow lines take an easy curve around corners. Any crinkling is associated with a weak brittle region. To show phosphorus segregations a polished surface is washed in alcohol, and immersed in 10% copper-ammonium chloride. A thin copper plate will coat out on those portions low in phosphorus, leaving high-phosphorus regions bright (Plate III, fig. 10).

The fact that the hardness, toughness and general desirability of a piece of steel could be profoundly modified by a simple heating and cooling has been known since time immemorial—in fact what we now know as steel was perhaps not recognized as having great merit until the fortunate discovery of heat treatment was made. This is a quite mysterious happening, this heat treatment, and it is not surprising that down through the long centuries when the art was guarded as a closed secret, many superstitions arose regarding the efficacy of certain heating fires and quenching fluids, and much quackery had free scope to practice its hocus-pocus. Within the past century the chemist and physicist have done much to clear up the mystery by analyzing the various operations; we now know the essential differences between the various steels, irons, fuels, atmospheres, and quenching fluids. Only since the beginning of the century, however, have intensive studies with the microscope, pyrometer, hardness and tension testing machines, brought forth a knowledge of the changes which go forward in steel or iron during a heating and cooling cycle, and working hypotheses of the causes of hardening (see **METALLOGRAPHY**). Logically, an ingot in a soaking pit prior to rolling, or a billet in a heating furnace prior to forging, may be said to be undergoing heat treatment, but from a workshop viewpoint the term is restricted to a heating and cooling to restore original ductility and workability in a partly finished piece, or a heating and cooling—sometimes repeated—to induce special properties in the finished article.

Furnaces (*q.v.*), in regard to size, depend upon the pieces to be treated and the temperature required. A well designed furnace is one which easily attains the necessary temperature, and maintains that heat uniformly in all parts, with an atmosphere which does not deteriorate the furnace, and yet has the desired effect or no effect, upon the metal being treated. Fuels may be coke or coal, gas, oil or electricity. No source of heat, pure heat, disassociated from the products of combustion, has any virtue over another source—it is merely a matter of which is the most convenient and economical. Gas and electricity are now favoured because of their ease of manipulation to give uniform temperature—choice depends upon the relative cost per thermal unit, and the atmosphere required. For instance, it is handiest to use electric resistors for heating elements in a furnace for annealing transformer sheets in a hydrogen atmosphere. Gas or oil fuel would probably be chosen for treatments on products such as roller bearings running into tons per day. Recuperators or regenerators are frequently installed to save heat. Mechanical devices for putting the metal in and taking it out, such as charging machines, furnace bottoms built on wheels or moved on rollers, revolving heating muffles and conveyors, are installed to save

labour wherever the weight of material receiving uniform treatment is very great. Temperature control is most important. Well conducted shops issue definite instructions on all important work giving the rate of increase in heat, duration at heat and speed of cooling. Continuous furnaces are devised to maintain this cycle automatically. Batch furnaces are controlled by hand, or by automatic control of the fuel burners through pyrometers (*q.v.*), which are installed in all furnaces, sometimes several in a single furnace, and indicate or make a permanent record of the temperature at all times. An important method of localized heating is by high frequency currents; pieces such as crankshafts are rapidly heated one at a time at only those bearing surfaces which are to be hardened.

Atmosphere within the furnace is important. In an open flame furnace scaling (or the production of oxide on the metal's surface) may be minimized by feeding rather less air than the gas or oil requires for complete combustion. This deficiency of oxygen means that little or none will be available to react with the hot metal In long heating of thin sheet, or long annealing of tool steel. where the surface must be preserved, the work is protected from the furnace atmosphere by closed boxes or tubes. Protective atmospheres have been highly developed in the 1930–40 decade. Steel and gas are heated together in a muffle, or heated without a muffle by electric resistors or by flames contained in alloy tubes. Atmospheres for bright annealing are relatively easy to prepare of flue gas, partially burned fuel gas, or even gas engine exhaust; due to the comparatively low annealing temperature—650' C—any mixture of an excess of carbon monoxide over carbon dioxide will protect the steel. It must be fairly dry to prevent tarnishing by steam on the cooling cycle. Protection during higher heating—850" C—for quenching is far more difficult because the reactions are much more rapid and the steel must neither oxidize nor must it gain or lose carbon. Such atmospheres are bone-dry and oxygen-free mixtures of hydrogen, nitrogen, and carbon monoxide; they may be prepared from burned natural gas (methane, CH_4) by removing excess oxygen by hot copper, washing out CO_2 with caustic, and absorbing moisture in activated alumina. On the other hand, certain reactions may be induced during heat treatment—for this purpose the material is packed in boxes with substances forming the necessary gaseous atmosphere, or the furnace is a closed muffle through which a stream of the proper gas slowly travels. Case hardening (*q.v.*), for instance, is done by packing the metal pieces in carbonaceous compounds and heating, or by piping in a gas which is principally carbon monoxide.

Quenching, to cool heated metal, may be done in various liquids, depending upon the speed required. All kinds of solutions of outlandish materials have been used, but there is no virtue in a quenching fluid except the ability to abstract heat quickly. In practice, the most drastic quench is given by a properly disposed nest of nozzles, spraying cold water at high pressure on the hot steel. Next comes a bath of iced brine; then cold water, then high flash point oil, then boiling water, then molten lead, then air blast, then quiet air, and even slower cooling may be done in 8 hours by burial in lime; a dying furnace may require from 24 hours up to seven days. Quenching baths require methods for circulating the medium, maintaining its correct temperature either by heating or refrigerating coils, and dashing it against the metal so no air or steam bubbles remain attached to the hot metal, else soft spots will occur on an otherwise hardened surface. Conveyors or other mechanical methods of getting the hot metal rapidly into the quench and removing it when cold, are installed to save labour. In order to understand what goes on during these heating and cooling cycles, an introduction to the science of metallography and the so-called iron-carbon equilibrium diagram is necessary.

Metallography (*q.v.*) is the study of the inner structure of metals and how this varies with the chemical composition of the alloy and its past heat treatment or the work that has been done on it. It also includes the study of the relationship between the inner structure of metal and the physical properties, such as strength, toughness, and hardness. In this study the use of a microscope is a long step in advance of the ancient practice of breaking the metal and looking at the fracture. It enables the student to magnify the apparent size of the grains a thousandfold. A sample of the piece under study is given a high polish, etched slightly in a suitable acid, and placed on a microscope stage with a special illuminating device for opaque objects (see MICROSCOPE). The resulting structure may by appropriate means be photographed for permanent record, and for study in connection with information on its past history, and its physical strength, hardness or electrical characteristics. Important physical properties affected by heat treatments include strength, toughness, hardness, electrical and magnetic characteristics, corrosion resistance. Of these, the first three arc most relied upon. Machines and methods for making tension tests and determining the ultimate strength, elastic limit and ductility are described under STRENGTH OF MATERIALS. Hardness is measured by the size of impression left by a steel ball or a diamond cone weighted down by a given load. Toughness or impact strength is measured by the amount of energy absorbed from a swinging hammer by the instantaneous fracture of a standardized notched test piece.

Evidence That Metal Is Crystalline.—Viewed through a microscope, an etched metal surface presents a mosaic patchwork of interlocking and nice-fitting grains (Plate III., figs. 12 and 17). Much evidence is at hand to support the idea that these granules, despite their irregular boundaries, are crystalline; *i.e.,* the ultimate atoms are in an orderly geometric arrangement of rows and ranks. The fact was finally proven by X-rays in a manner easiest explained by this analogy: If a street lamp is viewed through a window screen the brilliant centre appears to have a series of bright rays extending outward, caused by reflections of light from every wire so placed as to throw light back into the eye. The geometric pattern of rays is caused by the geometric arrangement of the wires; arguing by analogy, if the atoms of metal are arranged in definite geometric patterns, then an X-ray beam penetrating the crystal would be reflected in definite ways and emerge in a geometric pattern, in fact, a mathematician can predict the atomic spacing and arrangement from the diffraction pattern so produced. Thus it is found that wrought iron at room temperature is in the body centred cubic arrangement. That means that if the space occupied is subdivided by imaginary planes into a space-lattice of tiny cubes regularly placed on top and to both sides of each other, the iron atoms are located at the corner of each of these imaginary cubes, and each cube will have one atom in its centre.

INFORMATION FROM TEMPERATURE CHANGES

Allotropic Changes in Pure Iron.—Much information about metal can be gained by studying the rate at which its temperature changes during uniform cooling. As long as the temperature falls uniformly, the loss by radiation is accounted for by loss in sensible heat. But suppose the surroundings are unchanged yet the rate of cooling is arrested, or even reverses—evidently some chemical or physical change is taking place inside the metal which generates a portion of the heat which is being constantly radiated. Such spontaneous heat evolutions or absorptions, arrests in the time-temperature curves, in purest iron occur at 770, 910, 1,390 and 1,535° C. Pure iron or ferrite at room temperature consists of an aggregate of tiny crystals of so-called alpha iron, crystallized in body centred arrangement On heating, this ferrite gradually loses its magnetism, becoming practically non-magnetic at 770° C, but without changing its atomic arrangements. This non-magnetic alpha iron has been called beta iron, and was erroneously thought to be the cause of the hardening phenomenon—it being given a fictitious hardness. At 910° C alpha iron recrystallizes on heating with absorption of considerable heat and a contraction of 1½% in volume. The elementary cubes in the space lattice now have atoms at each corner and at the centre of each face, a face-centred cubic form known as gamma iron. At 1,390° the reverse change takes place: so-called delta iron existing between 1,390° and the melting point appears to be a form of non-magnetic alpha iron, stable at high temperature. At 1.535° the metal melts, with large absorption of heat and profound change in all physical

properties. Precisely the reverse changes occur on slow cooling, as noted in the following thermometric chart.

Temperature	Arrest	State
		Molten (amorphous)
1,535° C .	..	Melting and freezing point Delta iron (body centred cubic)
1,390° C .	A_4	Recrystallization Gamma iron (face centred cubic)
910° C .	A_3	Recrystallization Beta iron (non-magnetic alpha iron: body centred cubic)
770° C .	A_2	Magnetic point, no crystalline change Alpha iron (magnetic) (body centred cubic)

A_4 and A3 lag somewhat on reversing the direction, *i.e.,* occur at slightly lower temperature on cooling than the reverse change during heating.

Solidification **of** Steel.—It has been found that iron containing a little carbon starts to solidify on cooling at a lower temperature than 1,535° C (the melting point of pure iron) and furthermore that this depression in the freezing point is greater and greater the more and more carbon is in the melt. This is plotted graphically in line AB in fig. 6. Line AB is called the liquidus; at all temperatures and compositions above and to the right of AB the alloy is molten. Hot solid iron at 1,130° C will dissolve 1·7% carbon, and rather less as the temperature increases. This relationship is also plotted by the line AE, called the solidus. At all temperatures and compositions below and to the left of AEB the alloy is solid. The region between the liquidus and the solidus denotes that at those temperatures and compositions the alloy is in a mushy state, part solid, part liquid.

The way a 1% carbon steel solidifies is worthy of study. Its condition at any temperature may be investigated by drawing a vertical ordinate at the composition representing 1% carbon. The diagram shows immediately that the first solid material appears on cooling to 1,450° C (point m). This solid is not pure iron, but a solid solution of carbon in iron whose chemical composition is found at point n on the solidus (about 0·2%). This solid is much richer in iron than the melt, so its appearance leaves the melt richer in carbon, and it must be cooled further before more solid appears. Thus, by continuous solidification of iron poor in carbon and drop in temperature, the sample reaches let us say 1,400° C. At 1,400° C the melted portion has acquired a composition represented by point p (about 1·6% carbon), and the solid appearing from it is a solid solution containing 0·4% carbon (point q).

And so it goes: at 1,300° the remaining mother liquor has 2.7% carbon; the solidifying material has 0·8% carbon.

The first-formed solid material will act as a nucleus for the later which solidifies as the melt chills down. This causes the early-formed solid, low in carbon, to be in contact with later-formed solids higher in carbon. Yet at this lower temperature the material in the cores of the crystals has a greater capacity for carbon than it had before, since the solubility of carbon increases with decreasing temperature down to 1,130° C, and there is a pronounced tendency for carbon to pass from the high carbon melt, inward through the outer crystalline layers, until the carbon content of the solid solution becomes more nearly uniform. It requires a very slow cooling or a long annealing to cause entire equalization of carbon; the so-called solid solution alloys cast and cooled at normal rates, usually show a cored structure under the microscope, caused by systematic variations in chemical composition between the material first solidified and the last freezing mother liquid. Assuming that the cooling has been very slow, and the equalization of carbon in the solid portions perfect, the last of the mother liquor in the 1% steel disappears at 1,230° C (point r, fig. 6); the metal is entirely solid.

AUSTENITE

Solid Solution.—Since the word solution ordinarily connotes a liquid, the term solid solution appears to be a contradiction of terms. The solid solution of iron and carbon is so important that it has been given a-special name, austenite, in honour of the English metallurgist, Sir William Roberts-Austen. If any steel is homogenized by long heating at 1,130° C, the temperature of maximum solubility of carbon in gamma iron, quenched so rapidly as to prevent changes on cooling, etched, and examined under the microscope it will look like a pure metal (Plate III., fig. 3); *i.e.,* a series of abutting crystalline grains of uniform appearance—saving the slight coring which may remain after insufficient anneal, or some surplus material insoluble under any conditions. Thus the solid solution has some of the essential characteristics of a liquid solution—it is a uniform dispersion of atoms of one element amongst atoms of another, and the proportions may be anything within the limits of solubility. Austenite in fact is an aggregate of crystals of gamma iron; iron atoms are arranged in the face centred cubic system, within which are tucked away the carbon atoms here and there inside the space lattice.

Decomposition **of Austenite.**—Another similarity between the solid solution austenite and such liquid solutions as salt in water is that the mutual solubility of carbon in iron, or iron in carbon, whichever appears to be the excess element, changes with lowering temperature, and the then insoluble substance crystallizes out. Such changes can occur in the atomic arrangement in entirely solid metal. The latter is not a fixed and entirely rigid structure, except perhaps at absolute zero. The atoms, while they do not wander about at random, as in a liquid, are in a state of thermal agitation and are moving in small orbits or oscillating back and forth with more and more vigour as the temperature goes up. Under such circumstances considerable rearrangement may take place by interchange of position, or by stranger atoms slipping through the open spaces in the crystalline lattice. Such crystalline rearrangements generally occur in a reasonably small temperature interval, involve an evolution or absorption of heat, and are recorded on time-temperature or cooling curves.

Cooling curves on a low carbon steel show that the change occurring in pure iron at 910° C from gamma to alpha form is lowered progressively with the increasing carbon content. Furthermore a new and important evolution of heat occurs in all steels at about 690° C, increasing in intensity as the carbon goes up. These two temperature arrests, called A_3 and A_1 respectively, coincide at 0·9% carbon. At higher carbons two diverging temperature effects are again noted. All these facts are noted on fig. 6, the steel end of the iron-carbon equilibrium diagram, by the lines GSE and PSK. This is an underlined V, a shape familiar to the physical chemist as noting the break up of a solution into two mutually insoluble constituents. In the case of steel, the solution is austenite; the excess constituent first precipitated out in low carbon steels is iron, or ferrite, while that first appearing in the highest carbon steels is not carbon but an iron carbide, Fe_3C, called cementite. A 0·83% carbon steel corresponds to the eutectic. Since it appears in a solid solution it is termed a eutectoid. If examined under the microscope, a slowly cooled 0·83% carbon steel is made up of tiny flake-like crystals of iron and iron carbide, arranged in rough parallelism and having a pearly lustre. Hence its name pearlite (Plate III., fig. 13). A cooling eutectoid steel reaching 690° C is simultaneously saturated in both constituents—they separate out simultaneously, side by side, in closely intermixed crystals.

Structure of Low Carbon Steels.—The mechanism may be illustrated by studying a cooling steel containing 0·25% carbon (line t u). Pure iron starts to be precipitated when the temperature reaches 820° C (point v) and more and more pure iron crystallizes out as the temperature falls, leaving a mother substance richer and richer in carbon. This action continues until at 690° C the remaining solid solution has reached saturation (point S, 0.83% carbon, the eutectoid) and that portion then rearranges itself into pearlite. Plate III., fig. 12 shows the microstructure at the end. The larger clear crystalline grains are alpha iron; the gray specks are pearlite (high magnification is necessary to show the laminated structure). Medium carbon and hard steels have relatively less and less free ferrite, and more and more pearlite. A 0·83% carbon steel is all pearlite (Plate III., fig. 13). Slow cooled higher carbon steels (so-called "hyper-eutectoid" steels)

have excess cementite in white veinlets surrounding pearlite masses (Plate III., fig. 2). Reverse changes to those described above take place on heating; that is, a well crystallized slowly cooled steel again reverts to a uniform solid solution when heated above the line GSE.

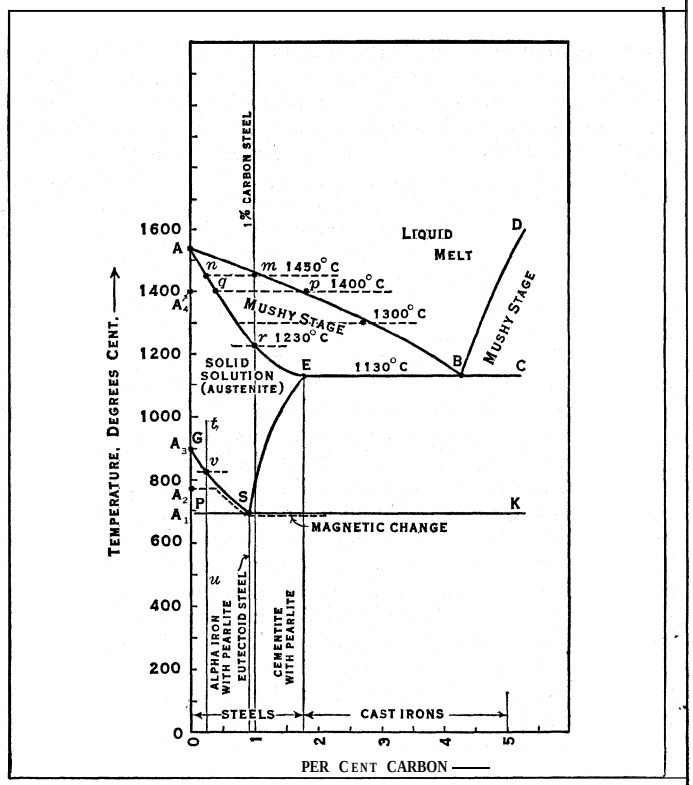

FIG. 6.— SIMPLIFIED EQUILIBRIUM DIAGRAM OF IRON AND CARBON (DOES NOT SHOW THE SLIGHT SOLUBILITY OF CARBON IN ALPHA IRON, OR THE DELTA IRON REGION ABOVE 1,390°C)

Structures in **Quenched** Steel. — The above described changes take place in a slowly cooled steel. If cooling is more rapid, time is not given for the atomic rearrangements necessary for such complete recrystallization, and certain intermediate microstructures may be observed. The most rapid quenching of austenite may be able to preserve this structure unchanged in the cold metal. In fact this can be done, especially in steels with considerable alloying elements like manganese or nickel. X-ray investigation of such a specimen of austenite proves that the metallic atoms build up a face-centred crystalline lattice characteristic of gamma iron. The carbon atoms are more or less uniformly distributed, but not combined in any definite compound. Such quenched manganese steels are exceedingly tough; while they are not so hard as other steels under the Brinell test, it is impossible to cut them with a chisel; they resist wear, scour, and impact well. High manganese steels are therefore suitable for such things as steam-shovel teeth and rail crossings.

High carbon steels, without alloys, can seldom be quenched rapidly enough to preserve very much pure austenite. Under the microscope a polished and etched surface appears to be criss-crossed with sharp needles (the lighter portions of Plate III., fig. 14). This structure has been given the name martensite; it is the hardest and most brittle condition of steel. X-ray studies show that the iron has completely transformed into a body-centred tetragonal crystalline lattice very similar to a lattice of alpha iron strained by trapped atoms of carbon; it also indicates that the new crystals are exceedingly small. far below the ability of the microscope to see. The needle-like markings are relics of the larger austenite grains rather than actual structures of martensite.

At the interior of a quenched high carbon steel specimen, where the cooling rate is slightly slower than on the surface, the martensite needles may be mixed with rounded areas which etch much more rapidly, appearing black in fact. This structure is called primary troostite (also shown in Plate III., fig. 14); it also appears in a lower carbon steel rapidly quenched. Primary troostite is very fine pearlite; none of the individual crystals have grown to a point where they can be seen even at 5,000 magnifications; however, the X-ray proves it to be an aggregate of excessively small crystals. Troostite, with hardness of **41** to **44** units on Rockwell "C" scale, is much softer than martensite (C-63 to C-65), but is noticeably less brittle.

Scientific studies since 1935 have shown that, while the temperature of transformation of the austenite solid solution into pearlite is lowered somewhat from 690° C as the rate of cooling is increased, and the result is finer and finer pearlite (primary troostite), this change in carbon and alloy steels always occurs at high temperatures — above 500° C. Time is required for the process, however, and if enough time is not given at those high temperatures during a rapid quench, then the austenite is retained unchanged to a low temperature, and transforms almost instantly into martensite (a solid solution of carbon in tetragonal ferrite) at 150 to 100° C. If carbon steels are quenched into a molten salt bath at some intermediate temperature, say 400° C, and held there long enough, the austenite leisurely transforms into another acicular microstructure whose exact nature is as yet unknown. In carbon steels this intermediate structure has medium hardness and superior toughness. In some alloy steels the intermediate structure appears during normal oil quenching, and its properties are not always so desirable.

If a quenched steel is moderately reheated (tempered or drawn) it loses a little of its hardness, but the added toughness is necessary for practical use. That is, tools are quenched and tempered. The microstructure is apparently unchanged, except that the acicular martensite etches much more rapidly. On reheating to higher and higher temperatures the atomic carbon first collects into submicroscopic crystals and the appearance under the microscope is uniformly structureless (secondary troostite), and later as the carbide crystals grow a cloudy microstructure, still unresolvable, appears and is called sorbite. If time and higher temperature below the transformation range (A_1) is sufficient, tiny globules of carbide appear throughout the entire mass, a structure known as spheroidized cementite. This is the most easily machineable condition for high carbon steels.

THEORY OF HARDENING AND TEMPERING

"Slip Interference."' — These various actions which go on within solid steel at moderate temperatures are of the greatest commercial importance, for they control the important operations of hardening and tempering steels. In the simplest example these consist of slowly heating the steel to a temperature somewhat above line GSE, holding it there long enough for it to become a uniform solid solution, then quenching it rapidly thus retarding the reverse reactions as much as possible, and finally reheating the quenched bar moderately to produce troostite or sorbite, still hard but much less brittle than the freshly quenched structures. The most widely accepted explanation of the hardening phenomenon is known as the ***slip*** *interference* theory, definitely formulated and systematized by the American metallurgists Zay Jeffries and R. S. Archer. It starts with the knowledge that metals are crystalline, and that metallic crystals when they are stressed beyond the elastic limit, do not tear apart irregularly, but one portion slides past another portion along definite crystalline planes without appearing to let go. Such motion is speedily jammed and stops because it tends to disarrange all the neighbouring crystals The slip plane also heals immediately. Much of the hardness of quenched steel is believed to be due to the sub-microscopic size of the constituent crystals; the boundaries of each one interfere with slip under stress in all the neighbours; since slip cannot occur, the metal resists deformation, and is therefore hard. In steel another hardening factor supplements this slip interference at the grain boundaries, namely, the presence of a great number of carbon atoms, cementite molecules or even tiniest cementite crystals uniformly dispersed through the ferrite grains Such particles harden the entire metal from two causes: first, they prevent the start of any slip between crystalline layers as would billions of

tiny staples in the leaves of a book; and second, the slips once started despite this hindrance must drag against a multitude of anchors.

Hardening by Cold Work.—Since a ductile metal like iron deforms plastically under cold work or stress beyond the elastic limit by internal slip along crystalline planes, it would appear that this slip has the effect of breaking up the original crystals into numbers of small ones. For that reason cold work hardens the metal; finer grained metals are harder. Under the microscope the slip planes are seen only in special circumstances, but the original grains appear to be flattened out and assume a shape more or less parallel to the extension. In extreme cases, as in wire for suspension bridge cables, a high carbon steel with original tensile strength of about 80,000 lb. per sq.in. can be cold worked into a condition where it will carry 220,000 lb. per sq.in. before rupture. Microstructure of such a wire parallel to the direction of drawing shows the original crystalline boundaries flattened out until the structure seems to be fibrous (Plate III., fig. 11).

Increase in hardness is accompanied by an increase in brittleness, so excessive cold work is liable to break the article, either during manufacture, or in its after history—season cracking. To avoid this danger, and to restore ductility, the piece may be annealed (*q.v.*) or reheated moderately to a point which does not affect the microscopic appearance yet the added atomic mobility at higher temperature permits such rearrangements as necessary to relieve internal stresses associated with work hardening.

Recrystallization.—A little higher heat on a cold worked piece of metal will cause the previous grain structure to be entirely replaced by a new arrangement. This is known as recrystallization. The recrystallization temperature varies with the amount of cold work previously done on the metal. Long stay at temperatures above this will cause the growth of large crystals. Such is to be avoided because it makes for a condition known as Stead's brittleness. Slip planes started across a large crystal find less supporting material at the grain boundaries, and the self-healing action ordinarily occurring during plastic deformation is absent; the big crystal splits along the cleavage plane.

Refining the Grain.—Recrystallization by moderate heat after cold work is to be disticguished from recrystallization on a higher heating to above the line GSE. The alpha iron then transforms into crystals of gamma iron. Apparently the new crystalline arrangement is almost entirely independent of the old; if the temperature is maintained for some time the new set of austenite crystals grow in average size as the temperature or time increases. On slow cooling through the transformation range these new austenite grains eject the excess constituent to the borders, and the kernels are the locus of the pearlite regions.

Thus by a heating and cooling through the transformation range, the grain size of steel can be changed, refined or enlarged, as desired. Since previous effects of work or hardening are wiped out by such an anneal, the process is frequently called normalizing.

Burning.—Excessive heating of steel ruins it by burning. A burnt steel is brittle and the brittleness cannot be removed by heat treatment. Microscopic examination shows that the grain size is unusually large, due to the high temperature experienced, and the grain boundaries contain considerable oxide. Burnt steel in fact has been heated beyond the solidus (line AE) and the high carbon regions in the austenite have actually melted. The melted metal absorbs furnace gases very quickly, which are responsible for the incurable damage done in the molten portions of the steel.

BIBLIOGRAPHY.—The fullest account of American practice is contained in J. M. Camp and C. B. Francis, *The Making, Shaping and Treating of Steel* (1939); for British and Continental *see* F. W. Harbord and J. W. Hall, *The Metallurgy of Steel* (1923); *H.* P. Tiemann, *Iron and Steel* (1933), a pocket dictionary of terms and a brief encyclopaedia of the whole subject; American Society for Metals, *Metals Handbook* (1939). Some fine text books cover only portions of the subject, such as Robert Forsythe, *The Blast Furnace and the Manufacture of Pig Iron* (1922); Walter Lister, *Practical Steelmaking* (1929); *A.* W. and Harry Brearley, *Ingots and Ingot Moulds* (1919); *D. K.* Bullens, *Steel and its Heat Treatment* (1939); Z. Jeffries and R. S. Archer, *The Science of Metals* (1939). Professional societies which devote much attention to the manufacture of iron and steel, and whose journals contain accounts and symposiums on the current state of the art are: (British) Iron and Steel Institute, American Iron and Steel Institute, and American Society for Metals. Leading journals of the trade are *The Iron Age,* New York; *Steel,* Cleveland, Ohio; *Iron and Coal Trades Review,* London; and *Stahl und Eisen,* Dusseldorf. (E. E. T.)

IRON AND STEEL: WORLD'S STATISTICS. In tracing the development of the world's iron and steel output it is necessary to commence with Great Britain, for although the output of pig iron in Great Britain was in 1938 only 8.4 per cent of the world's total and of steel only 9.9 per cent, nevertheless Great Britain was the birth-place of the modern iron and steel industry, and many of the developments connected with the industry originated there. Until 1871 the output of pig iron in Great Britain exceeded that of all other countries put together; in 1890 Great Britain was for the first time surpassed by the United States: in 1904 for the first time by Germany, and in 1921—owing to a coal stoppage—for the first time by France. In 1931 the output of Russia exceeded Great Britain for the first time.

According to Mushet the output of pig iron in Great Britain in 1720 was 17,350 tons but T. S. Ashton, in his Iron and Steel *in* the *Industrial* Revolution, gives reasons for thinking this too low, preferring the estimate of William Rea, an ironmaster of Monmouth, who put the output of pig iron at this period at about 25,000 tons per annum; he also points out that Scrivener's History (p. 57) wrongly gives 1740 as the date of Mushet's estimate, an error which has been followed by almost all writers since. The 25,000 tons produced in 1720 had risen to 68,300 tons by 1788; but, whereas the majority of the furnaces in 1720 had been charcoal, jj in 1788 were coke furnaces. It is not possible to describe the reactions of improvements in blast furnaces upon the demand for iron, nor of the demand for iron (created by engineering inventions) upon blast furnace improvements; suffice it to say that by 1840 production of pig iron had risen to 1,396,000 tons; by 1860 to 3,890,000 tons; and by 1880 to 7,750,000 tons. Raving nearly trebled in the 20 years between 1840 and 1860 and doubled between 1860 and 1880 the increase between 1880 and 1900, was no more than 16%, while the output in 1937—the highest post-war year—was actually less than in 1900.

It was not until the development of the pneumatic converter in 1856, a discovery claimed by both Sir Henry Bessemer, an Englishman, and William Kelly, an American, that the production of steel at relatively low prices was made possible. This was followed by the discovery of the open hearth process by Siemens Bros. in 1864–67. Between 1877 and 1883 another obstacle to low cost production of high grade steel was removed through the perfection by Sydney Gilchrist Thomas and his cousin, of a technique for removing phosphorus from steel during the processing period. The influence of these improvements on steel production is indicated by the rapid expansion of output in Great Britain. From 220,000 tons in 1870, it had grown to 4,900,000 tons by 1900. By 1920 it had almost doubled again, and in 1937, just four score years after the introduction of the pneumatic converter, it reached the all time peak of 12,960,000 tons.

It is impossible to trace, even in this broad outline, the progress of development in the other iron and steel producing countries. In all cases except where the industry is of comparatively recent growth, iron was first smelted with charcoal, and coke but slowly won its way: *e.g.,* mineral fuel was first used in France in 1782, but by 1819 only two furnaces were using coke out of a total of 350 (*Memoirs* of *the* Geological Survey of Great Britain, vol. i., pt. 1, 1856, quoted by Ashton): but in all countries the great bulk of the steel output is made by the Siemens process which, since its discovery, has been rapidly supplanting the pneumatic converter process because of its economy and regularity of operation. In 1880 open hearth production in Great Britain accounted for about 20% of the total output, but by 1936 it had grown to close to 95%.

Pig Iron: **World** Output.—It will be seen from the following table that in the 100 years ended 1910, the average increase in world production of pig iron in any decade mas 60%, while due to the dislocation caused by the World War, a loss of 3% was experienced in the 10 years ended 1920. However, in the decade ended 1930, the upward trend was resumed and an increase of

26% was recorded. A contributory cause of the slow growth since 1910 is that since the World War a greater proportion of steel scrap has been used in steel-making. The rate of progress of steel output has also been checked by the war, but, owing to the increased use of scrap, the increase in output in 1937 compared with 1910 (125%) is much greater than in the case of pig iron.

TABLE I. *World Output of Pig Iron at the End of Each Decade 1820 to 1920, in 1931, and Certain Years from 1920 to 1938.*

Year	Output: tons	Increase per cent per decade
1820	1,000,000	33*
1830	1,800,000	80
1840	2,700,000	50
1850	4,700,000	74
1860	7,220,000	54
1870	11,840,000	64
1880	18,160,000	53
1890	26,750,000	47
1900	39,810,000	49
1910	64,760,000	63
1915	59,700,000	..
1920	62,850,000	— 3†
1925	75,690,000	..
1929	97,410,000	..
1930	79,240,000	26
1935	73,100,000	..
1936	90,190,000	..
1937	101,188,000	..
1938	79,344,000	..

†Includes Luxembourg 1850 and 1860, and Austria in 1937 and 1938.
*Since 1920 Lorraine is included with France.

In 1913 the output of both pig iron and steel in Great Britain was higher than in any previous year, but the capacity of British steel works was not equal to the war demand for steel especially when the requirements of the allies, much of whose steel producing area was over-run, are taken into account. Considerations of time and man power made it impossible to expand the capacity for the manufacture of pig iron to the same extent as for the manufacture of steel, and British pig iron capacity was, therefore, only increased by about 1,000,000 tons per ann. (from 11,000,000 to 12,000,000) while steel capacity was increased by about 4,000,000 per ann. (from 8,000,000 to 12,000,000). The lack of balance thus resulting was met by restricting the use of pig iron for purposes other than for steel making, by the increased use of scrap, and by importation from America.

*Prior to 1920, Lorraine is included with Germany, but since that date with France. Austria is included with Germany from March, 1938.
†Includes Poland through 1919.

The British production of steel since the war has exceeded the output of 1917 only since 1934. In 1937, the year of the highest production of record, the output was 33% above the peak of the World War years. However, in the case of pig iron making, the record of 1917, 9,320,000 tons, has never been equalled in the post war years. In 1937, pig iron output was 9% below the 1917 total.

Iron and Steel Exports.— Table IV. which gives the exports of iron and steel (as far as possible according to the Board of Trade's classification) from chief producing countries shows that exports from Great Britain have not yet reached the record figure of 1913 when they amounted to nearly 5,000,000 tons. The best British post-war years have been 1923, when exports from European countries were curtailed owing to the Ruhr occupation, and 1927 when arrears accumulated during the coal stoppage of 1926 were being worked off. The decline in the British export trade has taken place in spite of great reduction in prices for, as shown by the Board of Trade's price index number, prices of iron and steel products have been falling since the end of 1920, and in March, 1928, prices were on the average only 13% above 1913.

*Includes Luxembourg and Saar in 1913 and Saar from Feb. 1935.
†Includes Saar from 925 to Feb. 1935.
‡Includes Luxembourg from May 1922.
§Fiscal year ended June 30, 1913.

After a world war, during which the great bulk of iron and steel produced was immediately consumed, it is clear that the potential demand for iron and steel must be considerable, but in the early post-war years most countries were too impoverished to make that demand effective, whilst the belligerent countries who before the war supplied capital for development were no longer able to do so on the same scale. As the world slowly recovered from the effects of the war and purchasing power increased the advantages enjoyed by European countries in their depreciated exchanges, longer working hours, lower standard of living, lower

transport charges, etc., enabled them to quote substantially lower prices than Great Britain and to supply an increasing proportion of the world's needs. The table therefore shows that, while the exports from Great Britain have declined, exports from the other European countries have increased.

As in the case of Great Britain so in France the year 1913 had been one of maximum production, and France produced 5,126,000 tons of pig iron and 4,613,700 tons of steel in that year. As a result of the war, Alsace and Lorraine were added to France and these provinces produced in 1913 3,809,400 tons of pig iron and 2,250,700 tons of steel. The total production of France, as now constituted, therefore in 1913 amounted to 8,935,400 tons of pig iron and 6,864,400 tons of steel. On the other hand, a great proportion of the area in which the iron and steel works were situated was either occupied by Germany or was within range of the German gunfire, so that 63 per cent of the French iron and steel industry was out of commission during the war. France attempted to compensate for this to some extent by building new works in the non-invaded area, and, as soon as the war was over, proceeded to rebuild the devastated areas so that the French iron and steel making capacity within the 1913 boundaries is now considerably in excess of pre-war, and in 1929 France produced 10,200,000 tons of pig iron and 9,550,000 tons of steel. This increased prociuction necessitates a much bigger export of iron and steel from France than formerly, and although the Peace Treaty and subsequent Franco-German agreements provided that a certain quantity of iron and steel should find an outlet in its former market in Gcrmany, France has still to market a great proportion of her output on the world's markets. and this is perhaps the biggest of many factors contributing to the internecine competition which has been experienced in the past few years. It will be seen from Table IV. that French exports rose to a peak of 5,602,500 tons in 1927 and have been steadily growing smaller since.

The production of pig iron in Belgium in 1913 amounted to 2,445,900 tons, and of steel ingots and castings to 2,428,100 tons; as in the case of most other producing countries this was very nearly equal to capacity. The effect of the reconstruction necessitated by the destruction of plant capacity in the World War has done much to augment the productive capacity of Belgium, and in 1937, 3,780,000 tons of pig iron and 3,810,000 tons of steel ingots were produced, or about 55% in excess of the 1913 output. A great proportion of Belgium's production must be exported, but a comparison with the pre-war years is not possible as Luxembourg is now included with Belgium, whereas prior to the war Luxembourg counted with Germany. The production of pig iron and steel in Germany in 1913 (as then constituted and excluding Luxembourg) amounted to 16,500,000 tons and 17,323,800 tons respectively. Germany was thus the second largest producer in the world. Having lost Lorraine, part of Silesia, and the Saar as a result of the war, an effort was made to expand the productive capacity within her contracted borders. This, together with the requirements of the armament and heavy construction program of 1936–38, resulted in a tremendous increase in production from the pre-war years. In 1938, Germany's peak year, output (including Saar) was 18,200,000 tons of pig iron and 22,600,000 tons of steel, an increase of 10% and 30% respectively over the 1913 figures.

The increase in production in Russia of both pig iron and steel since 1925 has probably never been equalled. In 1925 output of pig iron was 1,300,000 tons, while in 1938 it was 14,850,000 tons, an increase of 1,114%. Steel production in 1925 amounted to 1,840,000 tons, but by 1938 it had expanded to 18,410,000 tons, a gain of 1,110%. Thus in 13 years Russia rose from sixth in importance among world producers to a position of second only to the United States. This growth may be credited primarily to the tremendous effort to industrialize Russia since the overthrow of the Czar. This industrialization called for large tonnages of steel and the exploitation of Russia's natural resources to satisfy this need was a logical step. Despite this expansion in production, Russia's exports are negligible.

American Production.— The output of pig iron in America, the world's largest producer since 1897, was 30,966,000 tons in 1913 and of steel ingots 31,301,000 tons. The enormous contracts for munitions, machine tools, etc., placed by the Allies during the World War, as well as the demands for equipping her own army, necessitated the extension of existing iron and steel plants and the erection of new ones. After the war, the great increase in capacity was absorbed by the growing internal demand and in 1937 output of pig iron was 37,130,000 tons and of steel 50,570,000 tons.

With the development of alloy steels, which greatly widened the field of steel consumption, together with such refinements in production as the continuous sheet and strip mill which have acted to lower greatly the cost of steel, the saturation point of steel consumption seems as far away today as it was when the pneumatic converter was invented. However, new engineering materials such as the plastics, and new processes for producing and fabricating such non-ferrous metals as aluminium, magnesium. copper and zinc alloy die castings, bid fair to present in the future a formidable challenge to the steel industry's position. Yet, on the other hand, steel is supplanting wood on a large scale for such applications as small home building, interior constructions, etc., which may well counterbalance the effects of the greater use of plastics, etc. It may be reasonably assumed. however, that the low cost of steel will for a long time support its position as the basic material of the modern world (W. A PH)

IRONBARK, the name applied to species of *Eucalyptus* (*q.v.*) in Australia, from the hardness of the bark.

IRON CROSS. A German decoration, instituted in 1813 as a reward for distinguished service in the War of Liberation. (*See* NUMISMATICS; *Medals of Other Countries.*)

IRON IN ART. Iron work is a term used generally to denote anything made of iron, but specifically applied to the designing and handicraft of iron as a work of art.

HISTORY

The working of iron has engaged the activities of the human race from remote antiquity, especially in the continents of Europe and America. The metal ore exists in vast quantities in the soil, indeed there seems to be no limit to it, and each succeeding year records its discovery in some new place. The pure metal is obtained from the ore by the process of smelting, some primitive form of which was known in early times even by uncivilized races. It was not difficult to fill a cavity with ore and charcoal, and leave an opening for the wind to produce the currents necessary for fanning the flame and raising heat. Wood and charcoal were employed for producing the necessary heat, but in England, in 1611, a patent was taken out for smelting iron with coal, though 100 years passed before Abraham Darby, the first of that name, brought the process into common use. The result was in the form of rough bars of iron called pigs.

The working of iron is referred to in China some thousands of years before the Christian era, and it is found in India at a later date. Its use was known in Chaldaea, Assyria and ancient Egypt. References in the Old Testament suggest that the Hebrews also were acquainted with it. The Greeks are credited with the art of casting statues in iron. Later the Romans profited by the Greeks' knowledge. Currency bars of iron which have been found by the hundred in various parts of England prove that the Roman occupiers found iron very useful as a medium of commerce.

THE MEDIAEVAL PERIOD

England.— By the 10th century iron-working among the English was as fully developed as at any time during the next three centuries. It appealed to the sturdy English temperament as a difficult material calling for swift action; it suggested strength, stability and protection, all of which qualities were in those days not to be ignored. Its first use was purely protective; enemy attacks were frequent, and doors had to bc strengthened with massive iron-work inside and out. Window openings, especially those of the treasuries of mansions and cathedrals, were filled with strong interlacing bars of solid iron; a good example remains at Canterbury cathedral. When in course of time the need passed away, there came greater freedom of work and a

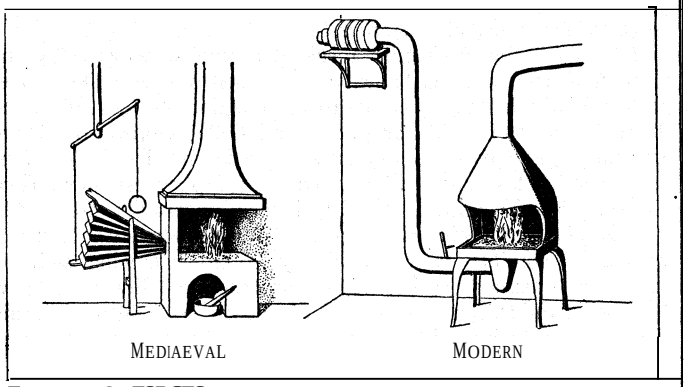
EXAMPLES OF RENAISSANCE IRONWORK

1. Iron gate and grille by Jean Lamour, at Nancy, France
2. Grille from northern Italy
3. Iron gates formerly at Devonshire House, Piccadilly, London
4. Lantern on the Strozzi Palace, Florence, by Niccolo Grossi (*Il Caparra*), an iron worker under the patronage of Lorenzo de Medici, end of 15th century
5. Ironwork railing from a balcony at Versailles, France. Late 18th century
6. Part of iron hinge work on central door, façade of the Cathedral of Notre Dame, Paris

definite intention of ornament. Throughout England, church doors are found with massive iron hinges, the bands worked in rich ornamental designs of scroll-work, many of them probably the work of local smiths. They vary from the plain hinge-band with crescent to the most elaborate filling of the door. Examples exist at Skipwith and Stillingfleet in Yorkshire, many in the Eastern counties and others in Gloucester, Somerset and the



FIGS. 1 & 2.—FORGES: BELLOWS OF MEDIAEVAL PERIOD, OPERATED BY HAND OR FOOT: THE MODERN HAS A MOTOR-DRIVEN AIR-PUMP

west Midlands. The next movement came with the erection of the great cathedrals and churches, whose shrines and treasures demanded protection. Winchester cathedral possesses the remains of one screen with a symmetrical arrangement of scroll-work. The grille above the tomb of Queen Eleanor at Westminster Abbey recalls the maker Thomas de Leghtone, a master-craftsman in iron who had succeeded another great smith, Henry of Lewes. Tombs were enclosed within railings of vertical bars with ornamental finials at intervals, such as that of the Black Prince at Canterbury. A third development appeared in the early years of the 14th century when the smith, working in cold iron, attempted to reproduce Gothic stone tracery in metal. This work was more like that of a joiner than of a smith, being often in small pieces chiselled and riveted, and fixed on a background of sheet-iron. A typical example is in Henry V.'s chantry at Westminster Abbey; but the most magnificent is the great grille at St. George's chapel, Windsor, made to protect the tomb of Edward IV. For many years it passed as the work of the Fleming, Quentin Matsys, but it is now known to have been executed by an Englishman, John Tresilian. Many small objects such as door-knockers, handles and escutcheons are to be found executed in the same manner. Smithing declined in England during the 16th century.
