COLEBROOKE to DAMASCIUS

COLEBROOKE, HENRY THOMAS (1765–1837), English orientalist, was born in London, June 15, 1765, and died March 18, 1837. He served in India as a civilian from 1782 to 1814, being a member of the Council of India for the last seven years of his service. After his return from India, he was a director of the Asiatic society. Colebrooke completed the translation of the *Digest of Hindu Laws*, begun by Sir William Jones, and wrote a *Sanskrit Grammar* (1805) and an *Essay on the Vedas* (1805), which was for a long time the standard work on the subject.

COLEMAN DU PONT ROAD, one of the most remarkable highways in the United States, conceived and built at his own expense and presented as a gift to the state of Delaware by Senator Coleman du Pont. It runs from Wilmington, Del. to the Maryland-Delaware state line at Selbyville, a distance of 98 mi. The original right-of-way, 200 ft. in width, was designed for a divided highway by-passing towns. This is believed to be the first highway to be built which was thus planned.

COLEMANITE, a hydrous calcium borate found in California as monoclinic crystals ($Ca_2B_6O_{11}5H_2O$). It contains 50.9% of boron trioxide, and is an important source of commercial borates and boracic acid. Beautifully developed crystals, up to two or three inches in length, encrust cavities in compact, white colemanite; they are colourless and transparent with brilliant lustre. There is a perfect cleavage parallel to the plane of symmetry of the crystals. Hardness 4–4½; sp. gr. 2.42. The mineral was first discovered in 1882 in Death valley, Inyo county, Calif., and in the following year it was found in greater abundance near Daggett, in San Bernardino county, Calif., forming with other borates and borosilicates a bed in sedimentary strata of sandstones and clays. *Priceite* and *pandermite* are hydrous calcium borates with very nearly the same composition as colemanite.

COLENSO, JOHN WILLIAM (1814–1883), English bishop of Natal, was born at St. Austell, Cornwall, on Jan. 24, 1814. In 1836 he was second wrangler and Smith's prizeman at Cambridge, and in 1837 he became fellow of St. John's. Two years later he went to Harrow as mathematical tutor, but the school was just then at the lowest ebb, and Colenso not only had few pupils, but lost most of his property by a fire. He went back to Cambridge, and in a short time paid off heavy debts by diligent tutoring and by the proceeds of his series of manuals of algebra (1841) and arithmetic (1843), which were adopted all over England. In 1846 he became rector of Forncett St. Mary, Norfolk, and in 1853 he was appointed bishop of Natal. He learned the Zulu language, of which he compiled a grammar and a dictionary, and translated the New Testament and other portions of Scripture into Zulu. He had already given evidence, in a volume of sermons dedicated to Maurice, that he was not satisfied with the traditional views about the Bible. The puzzling questions put to him by the Zulus strengthened him in this attitude and led him to make a critical examination of the Pentateuch. His conclusions, positive and negative, were published in a series of seven treatises on the Pentateuch, extending from 1862 to 1879, with the general title, *The Pentateuch and the Book of Joshua critically examined.*

While the controversy raged in England, the South African bishops, whose suspicions Colenso had already incurred by the liberality of his views respecting polygamy among native converts and by a commentary upon the Epistle to the Romans (1861), in which he combated the doctrine of eternal punishment, met, and pronounced his deposition (Dec. 1863). Colenso, who had refused to appear before their tribunal otherwise than as sending a protest by proxy, appealed to the privy council which pronounced that the metropolitan of Cape Town (Robert Gray) had no coercive jurisdiction and no authority to interfere with the bishop of Natal. No decision, therefore, was given upon the merits of the case. His adversaries, though unable to obtain his condemnation, succeeded in causing him to be generally inhibited from preaching in England, and Bishop Gray not only excommunicated him but consecrated a rival bishop for Natal (W. K. Macrorie), who, however, took his title from Maritzburg. Colenso returned to his diocese, and continued his work as a biblical commentator and translator. By his championship of the natives against Boer oppression and official encroachments he made more enemies among the colonists than he had ever made among the clergy. He died at Durban on June 20, 1883.

COLENSO, a village on the Tugela river in Natal, 16 mi. S. of Ladysmith, was the scene of a battle in the South African War (*q.v.*) on Dec. 15, 1899, between the Boers and the British force under Gen. Buller, which was endeavouring to relieve Ladysmith (*q.v.*). Buller, having assembled 20,000 men at Chieveley, moved forward, after two days' preliminary bombardment, to attack about an equal force of Boers under Louis Botha, who had entrenched themselves in a strong position on the north bank of the Tugela. Little was known by the British of the enemy positions or of the country they were to fight over. Two brigades were engaged, the one in a frontal attack at Colenso, the other 2 mi. farther west in what was intended to be a flank attack, but eventually also became frontal. The artillery supporting the right attack, coming into action within close range of the Boer positions, was quickly silenced; the infantry advance did not take place, and ten guns, despite repeated gallant attempts to bring them off, fell into Boer hands. The left brigade early lost direction and coming under concentric fire in a loop of the river suffered considerably and had to be withdrawn. Although little more than half his force had been engaged, Buller before mid-day issued orders to break off the action and return to camp. The so-called battle had, in fact, been little more than a reconnaissance in force, in which practically no loss had been inflicted on the Boers; but its moral effects, coming immediately after two other British defeats in the same week at Stormberg and Magersfontein, were considerable; Britain and the empire for the first time realized the true difficulty of effectively subduing the resistance of the South African republics, and were roused to efforts commensurate with the task. Pop. (1936) 1,123, including 443 whites.

COLEOPTERA, a term used in zoological classification for the true beetles which form one of the best defined and most natural orders of the Insecta. They vary very greatly in size and include some of the largest and also some of the most minute members of that class: thus *Dynastes hercules* attains a length of 155mm. (6in.) while there are members of the family Trichopterygidae that look like mere specks, less than ·5mm. long. The name (Gr. κολεός a sheath, and πτερά wings) is in allusion to the fore-wings which form horny or leathery sheaths or *elytra* which serve, when closed, to protect the membranous hind-wings which are folded beneath them. Their mouth-parts are adapted for biting and the prothorax is large and mobile. Beetles pass through a complete metamorphosis and their larvae are very varied in form, but generally possess legs or rudiments of them; only rarely are they footless. The above general definition will serve to recognize the majority of these insects of which approximately 180,000 species have been described. They form, it may be added, the largest single order in the whole animal kingdom: about 3,400 species occur in the British Isles and over 20,000 species are found in N. America. Perhaps the most characteristic feature of beetles is the solidarity of the integument exhibited in so many species, which is an important factor in protecting them against various enemies, and has evidently contributed much towards their dominance in the insect world. The habits of beetles are extremely varied, but they are more especially insects of the ground and either inhabit the soil or the various decaying animal and vegetable substances present. Consequently dung, carrion, vegetable refuse, rotting wood, and fungi all give sustenance to large numbers of these insects. On the other hand, many beetles, especially those of the metallic or other brilliant colours, are met with in association with growing vegetation and a considerable number are aquatic or sub-aquatic in habit.

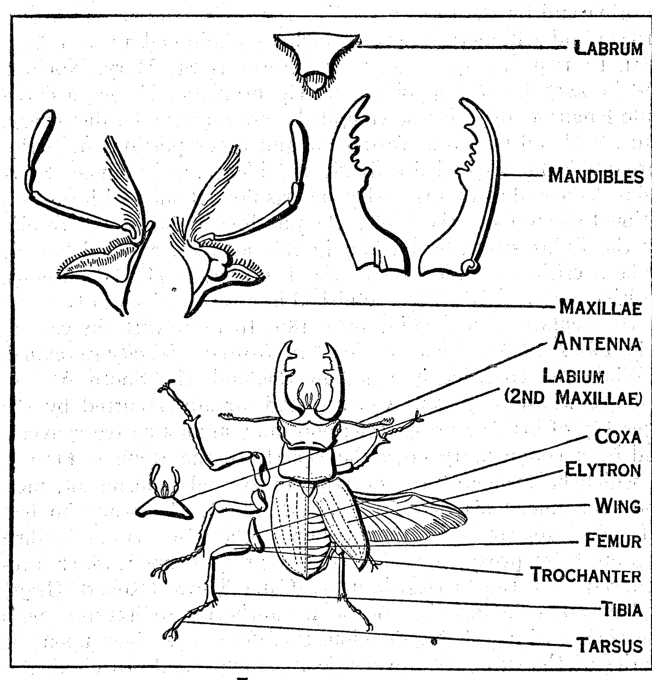

FIG. 1.—STAG BEETLE

The name is derived from the large, strong mandibles, found only in the male, which resemble horns of a stag

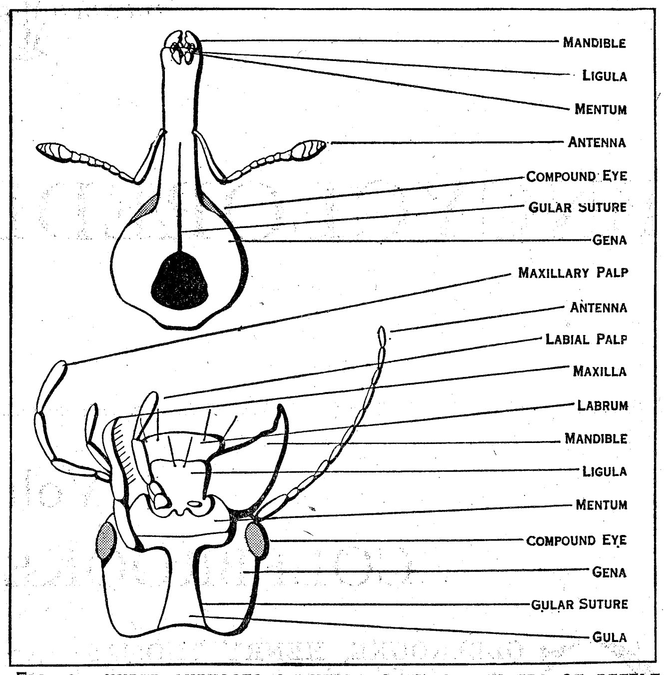

FIG. 2.—UNDER SURFACES OF HEADS OF TWO MEMBERS OF BEETLE FAMILY

Above, Weevil; below, Ground Beetle

General Structure.—The head is strongly chitinized and bears compound eyes but rarely ocelli: in most beetles a gular plate is present on the floor of the head, excepting weevils (fig. 2). The antennae vary greatly in character in different families: the mandibles are strong and very greatly developed in male stag-beetles (fig. 1) but as a rule they do not vary much in the two sexes: the maxillae consist of the typical parts, and the labium is characterized by its variability of form. The prothorax is a large shield forming the whole region between the head and the elytra, while the legs are generally adapted for running, more rarely for digging and, in water beetles, one or more pairs are flattened and oar-like for purposes of swimming. The elytra are the hardened, modified forewings and are protective rather than alary in function: they are variously sculptured and meet along the middle line of the body. The hind-wings (fig. 3) exhibit a characteristic venation which is of importance in classification: their most noteworthy feature is the presence or absence of a closed cell or oblongum. The number of segments in the abdomen is variable, ten being the maximum, and the first sternum is aborted: a true ovipositor is absent and the male genitalia are concealed.

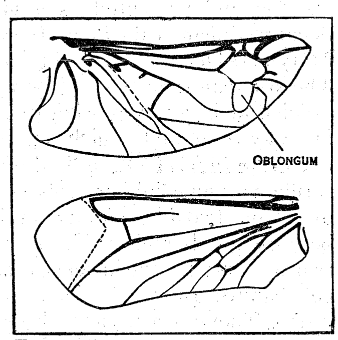

FIG. 3.—HIND-WING OF (ABOVE) WATER BEETLE, AND (BELOW), CLICK BEETLE, SHOWING DIFFERENCES IN THE ARRANGEMENT OF VEINS

Classification.—Many systems of classifying beetles have been proposed and one of the most satisfactory is that of Ganglbauer, who divides them into two main suborders and seven superfamilies, as below.

ADEPHAGA

Antennae usually thread-like: tarsi 5-jointed; hind wings with an oblongum and one or two cross-veins near middle (fig. 3): *first visible abdominal sternum completely divided by hind coxal cavities. Larvae predaceous, campodeiform* (fig. 23) *and usually with definite tarsi and paired claws.*

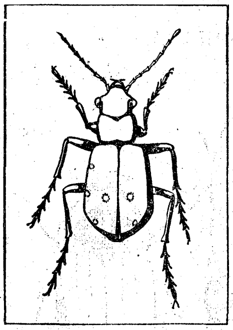

FIG. 4.—TIGER BEETLE
These beetles are fierce in nature, capturing other insects with their sharp mandibles

The Adephaga consist of a single superfamily, the *Caraboidea,* whose characters are as given above. Ten families are included here and the most important are as follows:

The *Cicindelidae* (fig. 4) are known as tiger beetles and rank among the most voracious of carnivorous insects. Their slender legs, acutely toothed mandibles, very prominent eyes and the presence of a jointed hook at the apex of the lacinia of the maxilla, are special distinguishing features. They are often brightly coloured and run and fly with great rapidity in sunshine. The species of *Cicindela* frequent sandy places, including the sea-shore, where their larvae construct deep burrows and feed upon other insects which they suddenly seize when near these retreats. About 1,800 species are known: four species inhabit the British Isles and 114 species occur in N. America, but the majority frequent hot countries.

The *Carabidae* (fig. 5) comprise the carnivorous ground beetles of which over 17,000 kinds are known. They are distinguished from the Cicindelidae by the absence of the jointed hook to the lacinia, and by the fact that the clypeus does not extend over the bases of the antennae. They mostly occur in the soil, under stones, in moss, under bark, etc., and are active runners: many species have hind wings reduced or absent, and the elytra soldered together. Since these beetles and their larvae prey upon other insects, worms, etc., they are distinctly useful to man: a few species may attack cereals and strawberries, but this is exceptional.

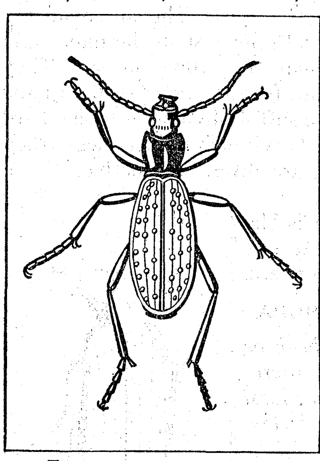

FIG. 5.—GROUND BEETLE
A member of the carnivorous family, *Carabidae;* ground beetles are found in the soil, under stones, or under bark

The *Dytiscidae* (fig. 6) are a large family of carnivorous water beetles. Their hind legs function as oars, being flattened and provided with long hairs. In the males of some genera three segments of the fore tarsi are expanded to form sucker pads which enable them to hold the females during pairing. Their larvae prey upon other forms of aquatic life including even tadpoles and small fish: their long sickle-like jaws are perforated by a fine canal through which the body-fluids of their victims are imbibed. The family is world-wide and includes about 2,200 species.

Other families include the *Gyrinidae* or whirligig beetles which swim on the surface of fresh water, and the curious *Paussidae* which inhabit ants' nests.

POLYPHAGA

Antennae and tarsi very variable: hind wings without cross-veins or oblongum (fig. 3): *first visible abdominal sternum not completely divided by hind coxal cavities. Larvae very variable in form and habit: tarsi wanting, claws single.*

SUPERFAMILY I. STAPHYLINOIDEA

Antennae simple or clubbed: venation of hind-wings without any closed cells, often greatly reduced. Larvae generally campodeiform.

The *Staphylinidae* (fig. 7) or rove-beetles amount to about 13,000 species, over 800 inhabiting the British Isles. They are easily distinguished by the very short elytra which usually leave

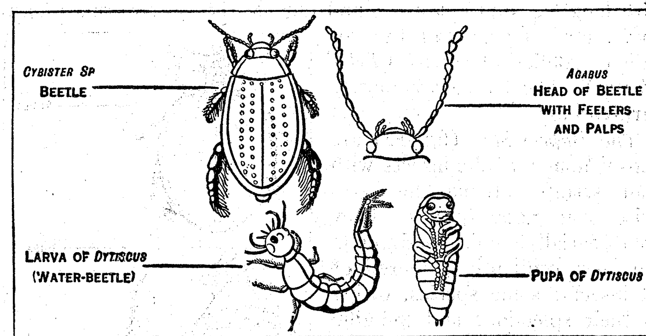

FIG. 6.—WATER BEETLE
In these aquatic beetles, the intermediate and hind legs are modified as swimming organs

the greater part of the abdomen uncovered. Both these beetles and their larvae inhabit the soil or decaying organic matter of many kinds: some are carnivorous and others feed on refuse.

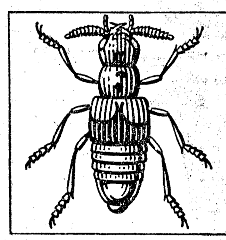

FIG. 7.—ROVE-BEETLE, A EUROPEAN MEMBER OF THE STAPHYLINIDAE GROUP

The *Silphidae* (fig. 8) include the carrion beetles and allies. The true burying beetles (*Necrophorus*) are large black or black and orange insects feeding upon small animal carcasses. The larvae of some species of *Silpha* prey upon snails or caterpillars, while those of *S. opaca* attack root crops.

The *Histeridae* are a large family of hard, shining beetles with elbowed, clubbed antennae: the elytra are shortened behind, leaving the last two body-segments exposed. *Hister* and its allies frequent dung and carrion while other genera live under bark. The larvae are carnivorous.

Among other families, mention must be made of the *Trichopterygidae* which are the most minute of all beetles.

SUPERFAMILY II. DIVERSICORNIA

Antennae generally clubbed or serrate: tarsi 1- to 5-jointed but not heteromerous. Larvae very varied.

This enormous division includes a great number of families and is to be regarded as a provisional group, including all those forms not belonging to other superfamilies: only a few of the important families can be mentioned here.

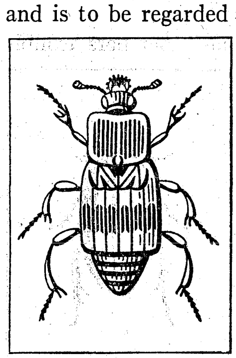

FIG. 8.—SEXTON BEETLE

The *Coccinellidae* (fig. 9) or ladybirds are rounded insects with the head concealed under the thorax: the antennae are feebly clubbed and the tarsi have three evident joints. Most of the species are brightly coloured and spotted, and since both the larvae and adults prey upon aphids and other soft-bodied insects, the family is highly beneficial to man. A small number, however, are injurious to vegetation, especially the squash-ladybird *Epilachna borealis* of the United States. More than 2,000 kinds of ladybirds are known and they occur in most parts of the world.

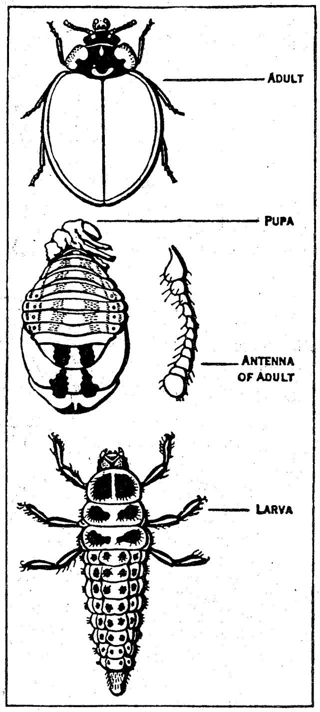
The *Dermestidae* are hard, dull-coloured insects with scaly or hairy elytra. Their larvae are active, hairy, with evident legs and feed upon dried animal matter, fur, hair, bacon, etc. Certain species have become widely spread through commerce and 16 occur in the British Isles.

The *Hydrophilidae* (fig. 10) are aquatic or sub-aquatic beetles numbering about 1,000 species. They are herbivorous in habit and can be recognized by the very long maxillary palpi which are often mistaken for antennae: the latter organs are very short and terminate in a hairy club. The large black *Hydrophilus piceus* when submerged, carries a supply of air beneath the elytra, and lays its eggs in a kind of cocoon attached to a leaf: its larva feeds upon other aquatic organisms.

The *Cantharidae* (fig. 11) are very soft-bodied elongate insects with long legs and antennae, and include the glow-worms (*Lampyris*, etc.) (*q.v.*) and the so-called soldier beetles (*Telephorus*). The larvae are mostly carnivorous.

The *Buprestidae* (fig. 12) are conspicuous metallic insects with short serrate antennae and comprise over 5,000 species. They are essentially tropical and among the most brilliantly coloured of all insects: some species, owing to their splendour and metallic lustre, are used in embroidery and jewellery. The beetles fly actively and inhabit forests where their larvae mostly live beneath the bark, wood and roots of trees.

The *Elateridae* or click beetles are a large and important family of wide distribution. By means of a peg and socket arrangement on the under side of the body, these insects are enabled to leap into the air with a clicking sound, hence their name. The larvae of certain species of *Agriotes*, and other genera, are known as wireworms (fig. 13) and are exceedingly destructive to cereals, grasses and root-crops, feeding actively on the underground parts of the plants. Included in this family are the "fire-flies" (*Pyrophorus*) of tropical America, which emit a bright light from localized areas on the thorax and the base of the abdomen.



AFTER WARLATT, BY COURTESY OF THE U.S. DEPARTMENT OF AGRICULTURE

FIG. 9.—LADYBIRD, SHOWING THE PUPA, LARVA, AND ADULT
The *Coccinellidae* family, to which the Ladybird belongs, lives mainly on plant lice

Among other families the *Anobiidae* or "death watch" beetles and the *Lyctidae* or powder post beetles should be mentioned.

SUPERFAMILY III. HETEROMERA

Fore- and middle tarsi 5-jointed, hind tarsi 4-jointed. Larvae campodeiform, or more usually an intermediate type.

The Heteromera include 17 families whose members exhibit great diversity of form and habit but all agree in the possession of the tarsal characters enumerated above. The two most important families are the following:

The *Tenebrionidae* are a very large group of beetles, variable in size and form, and number about 10,000 species. The familiar "black beetles" of the genus *Blaps* occur in cellars and outbuildings, and species of *Tenebrio* infest flour, meal and stored goods, their larvae being known as meal worms: most members of the family, however, occur on the ground, under stones and logs, or beneath bark.

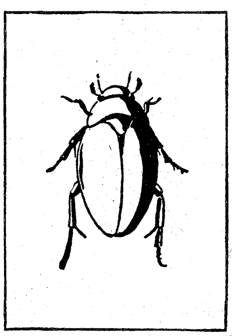


FIG. 10.—BLACK WATER BEETLE

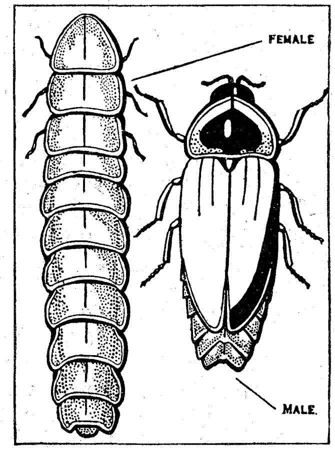
The *Melöidae* (fig. 14) comprise the blister beetles and oil beetles which are soft bodied insects with the elytra (often abbreviated) not fitting closely to the sides of the body, the head constricted behind forming a neck, and the claws of the feet cleft to the base. Their life-histories are very remarkable and the newly hatched larvae are active creatures known as triungulins. In *Melöe* and *Sitaris* these triungulins are dependent upon meeting certain wild bees, so, that they may be carried to their nests where they complete their development. Here they feed upon the eggs and stored honey or the latter only, and at each moult change their form and undergo a remarkable hypermetamorphosis (*see* INSECTS). The "spanish fly," *Lytta vesicatoria*, which yields cantharidin, is also a member of this family.

Mention should also be made of the *Rhipiphoridae* whose larvae are parasites of wasps, etc., and the *Pyrochroidae* which include the scarlet, or scarlet and black, cardinal beetles.

SUPERFAMILY IV. PHYTOPHAGA

Plant-feeding beetles with the antennae generally simple, less often pectinate or serrate: tarsi apparently 4-jointed, the 4th joint minute and concealed by the 3rd joint. Larvae eruciform with short or rudimentary legs.

The *Chrysomelidae* or leaf-beetles (fig. 15) number about 20,000 described species, being the second largest family of Coleoptera. These insects are usually bare and shining often with metallic colours, the antennae are of moderate length and are not embraced by the eyes around their points of origin from the head. Included in this family are such well known insects as the Colorado potato beetle and the asparagus beetle. In all cases the larvae and beetles feed on the leaves and other parts of plants: in the elongate metallic species of *Donacia* the larvae live submerged in the roots and stems of water plants.



FROM IMMS, "GENERAL TEXTBOOK OF ENTOMOLOGY" (METHUEN & CO.)

FIG. 11.—GLOW-WORM (LAMPROPHONUS TARDUS)

The *Cerambycidae* or longicorn beetles (fig. 16) are closely allied to the above family but are more rarely metallic and usually somewhat pubescent, elongate insects with the bases of the antennae more or less embraced by the eyes. The antennae are frequently elongate and slender, usually longest in the males and sometimes several times longer than the whole insect. They are mainly denizens of woods and forests, and about 13,000 species are known. Their larvae have soft fleshy bodies with a hard head and jaws, broad prothorax and very much reduced legs: they tunnel into the wood of trees and are often destructive. Some species live several years as larvae.

The other family of Phytophaga is the *Bruchidae* (or *Laridae*) whose larvae live in seeds, especially dried peas, beans, etc.

SUPERFAMILY V. RHYNCHOPHORA

Head generally produced into a beak or rostrum: gular plate absent and represented by a single mid-ventral suture: tarsi with four evident joints. Larvae legless and maggot-like.

The Rhynchophora are a vast assemblage of insects usually very easy to recognize and are all plant-feeders. They are divided into four main families of which the most important are the following:

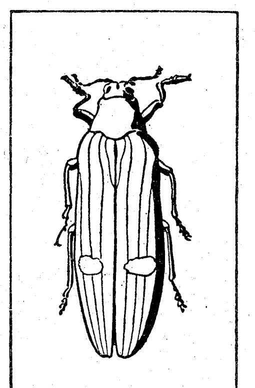


FIG. 12.—THE BUPRESTID BEETLE OF JAVA
The anterior wings of this beetle are used as ornaments of dress

The *Curculionidae* or weevils (figs. 17 and 2) include nearly 30,000 known species and great numbers still await discovery in tropical lands. They are usually recognized by the pronounced rostrum or beak, the clubbed elbowed antennae and the very reduced rigid palpi. The female often uses the rostrum as a boring instrument to prepare a place for egg-laying and the organ is usually longest in that sex. As a rule weevils (*q.v.*) are sombrely coloured but the tropical diamond beetles are beautiful insects. The family includes many destructive species including the cotton boll weevil, the grain weevils and the apple blossom weevil.

The *Scolytidae* (*Ipidae*) or bark beetles bore into the bark and wood of trees and are among the most serious enemies the forester has to contend with. They are hard, cylindrical insects devoid of a rostrum and with the tibiae armed with denticles (fig. 18). They construct galleries of very definite patterns beneath the bark, and their larvae closely resemble those of the weevils.

SUPERFAMILY VI. LAMELLICORNIA

Antennae clubbed, the club composed of plates or comb-like projections: legs stout and spiny, used for burrowing, tarsi 5-jointed. Larvae fleshy and crescentic with rather long legs.

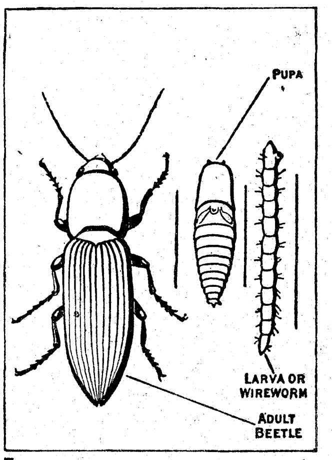

FIG. 13.—WIREWORM, THE LARVA OF CERTAIN CLICK BEETLES. IT IS DESTRUCTIVE TO ROOT CROPS

There are three families of Lamellicornia as follows:

The *Lucanidae* or stag beetles (fig. 19) are notable owing to the great development of the mandibles in the males, in which sex they are often antler-like in form: the use of these organs is problematical. The antennae are elbowed and the elytra cover the apex of the abdomen; their larvae inhabit decaying trees or their roots.

The *Passalidae* are confined to tropical forests: unlike the Lucanidae they have striated elytra and the jaws in the two sexes are alike. Their larvae live gregariously in wood and are tended by the parent beetles.

The *Scarabaeidae* (fig. 20) number over 14,000 species: the rose chafer, cockchafer and the "dor" beetles are familiar examples, while the sacred beetles or scarabs of ancient Egypt also find their place here. They are somewhat convex with very short antennae which are not elbowed, and the elytra do not cover the apex of the abdomen. The *Scarabaeus* has been studied by J. H. Fabre and the female beetles collect dung into balls which they roll along the ground and store in the earth as food for themselves and their larvae. The African goliath beetles (fig. 21) are among the largest of all insects. The larvae in this family feed upon dung, rotting wood, etc., or at the roots of plants: the latter habit prevails among cockchafers and great injury to crops may result.

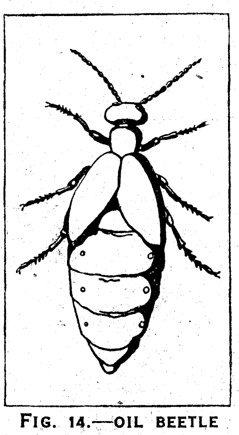

FIG. 14.—OIL BEETLE
The larvae of this group develop into mature growth only under nourishment derived from wild bees' eggs and honey

Reproduction and Development.—The eggs of beetles are laid in all kinds of places and most of them are ovoid without special features. Beetles are not very prolific and, although the oil beetles may lay several thousand eggs apiece, this is exceptional. By ladybirds the eggs are laid in batches on leaves, some water beetles enclose their eggs in a kind of cocoon, while many weevils lay them in deep holes, drilled by the rostrum of the female, in the food plants. All beetles undergo complete metamorphosis and their larvae vary greatly in character (fig. 22). They may be active and seek out their prey, as in the ground beetles, tiger beetles and ladybirds (figs. 22 and 23). Others, such as the chafers (fig. 22), have sluggish larvae, and live below ground or in rotting wood: although possessed of well formed legs they seldom seem to use them. In the weevils the larvae are legless maggots (fig. 22), remaining in close association with their food. When fully fed, beetle larvae transform into generally pale-coloured, very thin-skinned pupae which have the appendages free (fig. 17). Such pupae are commonly found without a special cocoon in the soil or in whatever material the larvae fed upon. In some cases earthen protective cells are constructed or a loose cocoon of wood or debris, while a few weevils form attractive net-like or seed-like cocoons attached to their food-plants.

As a general rule, beetles have a single generation in the year and many of them hibernate as adults under bark, in moss, etc. Some species, such as certain bean weevils and the cotton boll weevil, may complete their life-cycle in a few weeks, and there results a number of broods in the year: the same remark applies to certain beetles living under warm conditions in stored grain. On the other hand, the cockchafer and stag beetle require several years to complete their transformations. Certain beetles of parasitic habits undergo hypermetamorphosis (for definition *see* INSECTS). Thus, some of the Staphylinidae of the genus *Aleochara* hatch from the egg as active free larvae; which roam about and seek the puparia of certain kinds of flies. They bore their way into their hosts and transform into inert sluggish maggots with vestigial limbs. The same peculiarity is found in the Melöidae whose active newly hatched larvae are known as triungulins (*see* above).

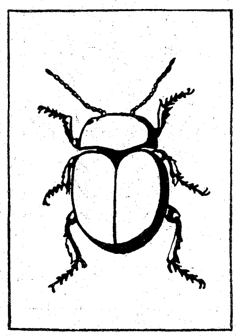

FIG. 15.—LEAF-BEETLE
These destructive beetles comprise about 20,000 species. The mandibles are strong, and adapted to a vegetable diet

Geographical Distribution. — Coleoptera are the most widely distributed of all large orders of insects and no other order has invaded the land, air and water to so great an extent. Many of the dominant families such as the Carabidae (ground beetles), Curculionidae (weevils) and Scarabaeidae (chafers) are almost as widely distributed as the order itself. On the other hand, the Dytiscidae (water beetles) are more abundant on the northern continents, while the Cicindelidae (tiger beetles), Buprestidae, Cerambycidae (longicorns) and Lucanidae (stag beetles) are essentially tropical families, becoming scarcer in more temperate zones. Some of the smaller families, however, are very restricted in their range, the Proterhinidae (closely allied to the weevils), for example, being almost confined to the Hawaiian Islands, and the aquatic family Amphizoidae only occurring in parts of N. America and Thibet. Certain species of beetles of diverse families appear more tolerant of climatic differences than others, and about 500 kinds are common to Europe, N. America and northern Asia. Many have become widely spread through the agency of man and over 100 species, more especially those affecting grain and other stored products, are now practically cosmopolitan. The study of island life yields some interesting features relative to the distribution of beetles. Thus, in the Madeira Islands, Wollaston found 580 species of Coleoptera, and of these, 266 kinds are peculiar to those islands, although allied to European species: in the Hawaiian Islands, Sharp mentions 428 species among which 352 species have not so far been found elsewhere. Thus the peculiar species must have formerly existed elsewhere, migrated to the islands mentioned, and since become extinct in their original homes, or they must have been evolved within the islands—the latter being the more probable.

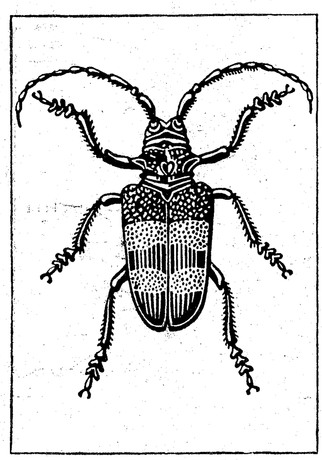

FIG. 16.—LONGICORN BEETLE, A MEMBER OF THE CERAMBYCIDAE FAMILY

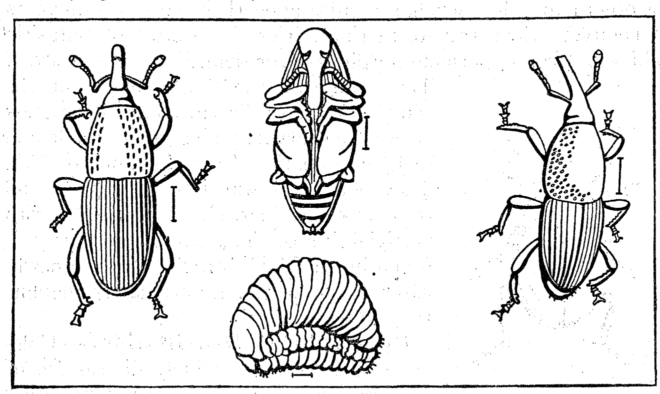
Geological Distribution.—The oldest known fossil beetles come from the Upper Permian beds of New South Wales and consist of elytra only: these remains have been referred to special families, unrepresented at the present day, and certain of them show affinities with the existing family Hydrophilidae. A great number of fossil remains of beetles have been found in the Upper Trias of Ipswich, Queensland, and in the Trias of Switzerland. Some of these Triassic fossils are leaf-beetles and weevils, while the English Purbeck beds have yielded remains of bark beetles. In the Tertiary rocks of Colorado and Florissant and in the Prussian amber (Oligocene) many fossils referable to living genera have been found, including about 400 species of weevils.

Natural History.—Beetles and their larvae live and feed in almost all the diverse ways found among insects. The carnivorous habit of seeking and devouring living prey occurs in the ground beetles, tiger beetles, ladybirds and in water-beetles of the family



BY COURTESY OF U.S. DEPT. OF AGRICULTURE, FROM CHITTENDEN, "YEARBOOK, 1894"

FIG. 17.—THE GRAIN WEEVIL, A SOURCE OF GREAT AGRICULTURAL LOSSES
Left: *Calandra granaria;* above, pupa; below, larva; right, *Calandra oryzae*

Dytiscidae. In these instances the beetles and their larvae have like habits. In certain rove beetles of the genus *Aleochara,* in the ground beetle *Lebia scapularis* and in the curious *Metaecus paradoxus* (fam. Rhipiphoridae) the larvae are true parasites and the beetles free-living—a habit that is rare among Coleoptera. The *Metaecus* occurs in Britain and its newly hatched larva is a minute black, active creature which, by some unknown means, finds its way into wasps' nests. Here it becomes an internal parasite of the wasp grub and subsequently bores its way out of its host, finally devouring the remains. A vast number of beetles and their larvae feed directly upon plants: this is the case with the whole family of the Chrysomelidae, or leaf beetles, and with the weevils. Others, such as the Cerambycidae (longicorns), Scolytidae (bark beetles) and Buprestidae, feed in the larval stages upon the wood or bark of trees. Wireworms, or injurious Elaterid larvae, and chafer larvae feed on the roots of various crops. Weevils have very diverse habits and no parts of plants from the roots to the seeds are exempt from the attacks of one or more species. There is again a great and diverse assembly of beetles, and more especially their larvae, which feed entirely upon decaying organic matter of various sorts. Thus the Silphidae include many carrion feeders and are well exemplified by the burying beetles; hosts of rove beetles frequent refuse of all kinds, and many Scarabaeidae live in dung. We have to add to these examples the many beetles and their larvae that live in grain and other stored products, and those attacking hides, furs, museum specimens, tobacco and drugs.

FIG. 18.—BARK BEETLE
The adult beetle tunnels beneath the bark to deposit her eggs, and the young beetle, on emerging, cuts fresh galleries off the original passage

Apart from the more usual habits it is interesting to note certain exceptional modes of life found among beetles. There are genera and even whole families that live in the nests of ants or of termites. There are others that inhabit the extensive limestone caves of Europe and North America, while certain blind ground beetles are only met with beneath huge boulders deeply embedded in the earth. There are also species that inhabit the sea-shore and are submerged by the tides.

Means of protection against enemies are very varied among Coleoptera. Some are cryptically coloured and closely resemble their surroundings: thus in the African longicorn *Petrognatha gigas* the whole upper surface resembles dead velvety moss, and its irregular antennae are very like dried tendrils or twigs. Many weevils fall and feign death at the least alarm and, folding their limbs close around the body, look like seeds or particles of soil, thus escaping observation. There are again beetles, especially those living in ants' nests, that resemble ants, and the common wasp beetle of Europe, both in its movements and colouration, closely resembles a wasp (for further instances of this kind *see* the article MIMICRY). There are other beetles which obtain some measure of protection possibly from their repellent appearance, or from their property of emitting evil-smelling or distasteful secretions, either in the form of exudations of blood from definite parts of the body, or as the product of special foetid glands. The bombardier beetles (fam. Carabidae) have the property of secreting an evil-smelling defensive fluid from the anal end of the body. In some cases this fluid volatilizes into a gas which appears like a minute jet of smoke when it comes into contact with the air, and its caustic properties act as a repellent to other insects or foes. Finally a number of beetles secure protection in virtue of their general agility of movement—thus, many ground beetles and tiger beetles run rapidly and the latter also take to the wing with great readiness, while the flea-beetles have remarkable powers of leaping.

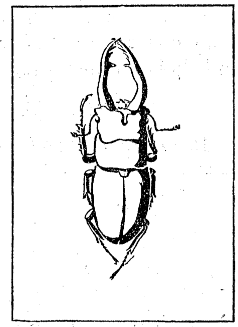

FIG. 19.—STAG BEETLE OF JAVA, SHOWING ANTLER-LIKE MANDIBLES

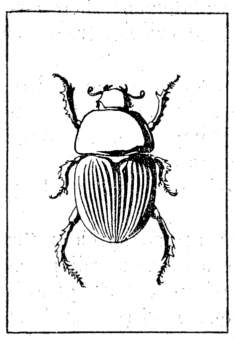

FIG. 20.—BRITISH "DOR" BEETLE
This member of the family *Scarabaeidae* flies in the evening with a loud humming flight, and its larva feeds upon dung

Many beetles are capable of sound-production which is usually brought about by the friction of one part of the body (the "scraper") against another part (the "file"). These stridulating organs have been studied by C. Darwin and more recently (1900) by C. J. Gahan: they are generally present in both sexes and probably serve for mutual sexual calling. In some beetles there is a file-like area on the head which is rasped by the anterior margin of the prothorax. Among the Cerambycidae (longicorns) the sound is produced either by rubbing the hind margin of the prothorax over a striated area on the mesothorax, or by rubbing the femora of the hind legs against the margins of the elytra. Stridulation, however, is not confined to adult beetles, but obtains in certain larvae also. Thus, in some larvae of the group Lamellicornia there is a series of ridges or tubercles on the coxae of the middle pair of legs and the hind legs are modified in various ways as rasping organs. In the cockchafer larva and larvae of other Scarabaeidae a ridged area on the mandible is rasped by a series of teeth on the maxillae. Stridulation in larvae is quite independent of sex and it has been suggested that it is to warn neighbouring larvae, inhabiting burrows in wood, etc., to avoid getting in each other's way.

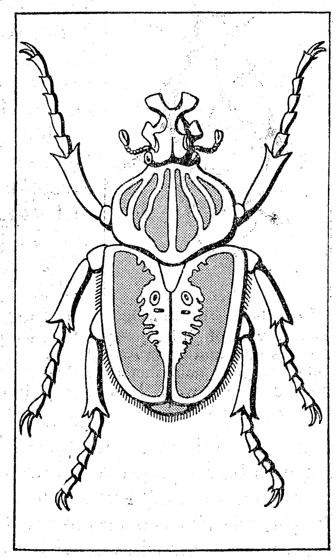

FIG. 21.—GOLIATH BEETLE

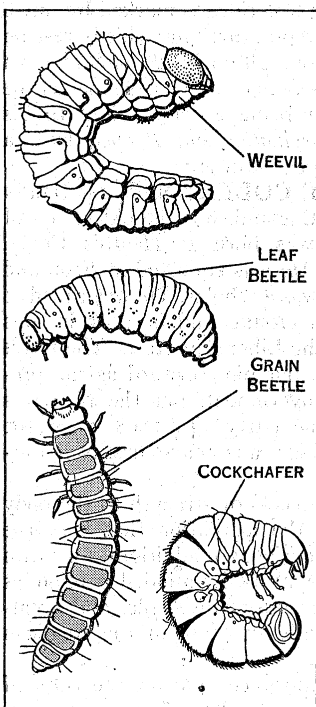
Apart from recognition by sound, some other beetles emit a bright light for the same purpose. The seat of the light is in special luminous organs which consist of an outer or light-producing layer, and an inner or reflector layer. The outer layer is supplied with oxygen by means of tracheae and the reflector layer contains many urate crystals which appear to act as a background, scattering the light and preventing its dispersion internally. The light is produced as the result of the oxidation of a compound *luciferin* in the presence of an enzyme-like substance *luciferase,* which takes place in the outer layer of the luminous organ. It has been suggested that this property does not reside in the actual cells of the tissue concerned, but is due to the presence therein of special luminous bacteria. Luminous beetles belong to the families Cantharidae and Elateridae and a familiar example of the first mentioned family is the common European glow-worm *Lampyris noctiluca,* whose wingless female emits a bright light near the hind end of the body: its winged male exhibits a much feebler luminosity. The luminous Elateridae include the fire-flies of the genera *Pyrophorus* and *Photophorus,* both sexes of which are winged and luminous.



FROM IMMS, "GENERAL TEXTBOOK OF ENTOMOLOGY" (METHUEN & CO.)

FIG. 22.—LARVAE OF VARIOUS SPECIES OF COLEOPTERA. ALL BEETLES UNDERGO COMPLETE METAMORPHOSIS

Economic Importance.—Beetles include among their species many that are injurious, either as larvae or often as adults also. Among those which attack farm crops, wireworms, or injurious larvae of certain click beetles are severe pests of the farmer. They are most prevalent in newly ploughed grassland and attack the supervening crops, particularly cereals and roots. Flea beetles (fam. Chrysomelidae) cause great injuries to plants of the turnip tribe, both the beetles and their larvae feeding upon the leaves and other parts. The asparagus beetle (*Crioceris asparagi*), belonging to the same family, is a familiar pest with growers of that vegetable in Europe and N. America (fig. 24). Related to it is the Colorado potato beetle (*Leptinotarsa decemlineata*) which is destructive to potato foliage in the eastern half of N. America: quite recently it has become established in the Bordeaux district of France. The Japanese beetle (*Popillia japonica*), one of the chafers, was accidentally introduced into New Jersey, from Japan, about 1916 and is extending its range in N. America where the beetle is injurious to the foliage of fruit and other trees, and its underground larvae damage lawns and golf greens. The common cockchafer (*Melolontha vulgaris*) and its allies are European pests whose larvae devour the roots of farm and other crops, the beetles feeding upon the foliage of trees. Many weevils are highly injurious: thus, the cotton boll weevil (*Anthonomus grandis*) is the most serious enemy of the American cotton crop. It entered Texas about 1892 from tropical America, subsequently infesting almost the whole cotton belt. In England, and other parts of Europe, its ally the apple blossom weevil (*A. pomorum*) prevents the formation of large quantities of fruit. The palm weevil (*Rhynchophorus ferrugineus*) infests toddy and cocoa-nut palms, and the pine weevil (*Hylobius abietis*) is extremely harmful to young conifers in Great Britain. Various members of the Scolytidae (bark beetles) are widespread pests of forest trees: one species (*Xyleborus fornicatus*) is the shot-hole borer of tea in Ceylon. Larvae of many Cerambycidae (longicorns) are also destructive to living and dead timber, while species of *Anobium* and *Xestobium* (death watch beetles) bore into furniture and the rafters of public buildings (fig. 25A): the powder-post beetles (Lyctidae) have very similar habits. Many beetles also attack stored grain, meal and other dried products, notably the granary weevils (*Calandra*) and the meal-worms and their allies (fam. Tenebrionidae).

FIG. 23.—THE LARVAE OF A GROUND BEETLE (CARABIDAE)

The larvae of ground beetles seek out their prey, while those of many other beetles are sluggish

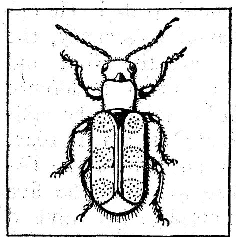

FIG. 24.—ASPARAGUS BEETLE, WHICH ATTACKS YOUNG ASPARAGUS SHOOTS, WHILE ITS LARVA DESTROYS THE SHOOTS, BERRIES AND SEEDS

The above remarks serve to show the many injurious species of Coleoptera; nevertheless, there are others which have been employed by man to his own benefit. The Australian ladybird (*Novius cardinalis*) has been imported into most citrus-growing countries of the world for the purpose of controlling the fluted scale which it attacks and destroys to a remarkable degree. Another Australian ladybird (*Cryptolaemus montrouzieri*) has a similar habit of preying upon mealy bugs (Coccidae), and its introduction into the Hawaiian Islands and California has achieved a remarkable degree of success. The European ground beetle *Calosoma sycophanta* has been introduced into N. America, where it preys upon the caterpillars of the gipsy moth and brown-tail moth. Mention must also be made of another type of useful beetle viz. the Spanish fly (*Lytta vesicatoria*) which yields cantharidin.

BIBLIOGRAPHY.—In addition to information given in general textbooks of entomology (*see* INSECTS) the volume by W. W. Fowler in *Fauna of British India: Coleoptera—General Introduction* etc. (1912), should be consulted. Among continental authorities, L. Ganglbauer's *Käfer von Mitteleuropa* (1892–1904) is a standard work. British beetles are described and figured in W. W. Fowler, *Coleoptera of the British Islands,* (1887–1913); a less expensive work, valuable for the British species, is E. Reitter, *Fauna Germanica: Käfer* (1908–16). For the North American species, J. L. Leconte and G. H. Horn *Classification of the Coleoptera of N. America* (Smithsonian Misc. Coll. xxxviii., 1883), although old, is an important general work; a more recent book for the ordinary student is W. G. Blatchley, *Coleoptera of Indiana* (1910).

Catalogues of the species of Coleoptera include the *Catalogus Coleopterorum Europeae* (1906) by L. Heyden, E. Reitter and J. Weise; C. W. Leng, *Catalogue of the Coleoptera of America* (1920; with supplement, 1927); and E. A. Newberry and W. E. Sharp, *An Exchange List of British Coleoptera* (1915).

Works on the natural history of beetles include L. C. Miall, *Natural History of Aquatic Insects* (1902) and J. H. Fabre, *Souvenirs Entomologiques* (1879–91), many of the latter being available in English. The stridulating organs are described by C. J. Gahan in *Trans. Entomological Soc. London* (1900), and the luminous organs by E. N. Harvey, *Nature of Animal Light* (1920). The larvae of beetles are beautifully figured by J. C. Schiödte in a series of papers in *Naturh. Tidsskr,* i.–xiii., (1861–72), a journal to be found in leading scientific libraries. A standard anatomical and biological work, based upon a study of the water beetle *Dytiscus,* is E. Korschelt, *Der Gelbrand* (1923), which is a mine of information for the special student, with copious bibliographical references. (A. D. I.)

Attacks wood, from the larval stages

COLEPEPER, JOHN COLEPEPER (or CULPEPPER), 1st BARON (d. 1660), English statesman, was the only son of Sir John Colepeper, of Wigsell, Sussex. He was elected member for

Kent in the Long parliament, when he took the popular side, speaking against monopolies on Nov. 9, 1640, being entrusted with the impeachment of Sir Robert Berkeley on Feb. 12, 1641, supporting Strafford's attainder, and being appointed to the committee of defence on Aug. 12, 1641. He separated, however, from the popular party on the Church question, fearing the effect of the revolutionary changes which were now contemplated. He opposed the London petition for the abolition of episcopacy, the project of religious union with the Scots, and the Root and Branch Bill, and on Sept. 1 he moved a resolution in defence of the prayer-book. In the following session he opposed the militia bill and the Grand Remonstrance, and finally on Jan. 2, 1642, he joined the king's party, taking office as chancellor of the Exchequer. He highly disapproved of the attempt upon the five members, which was made without his knowledge, but advised the enterprise against Hull. On Aug. 25, 1642, he appeared at the bar of the House of Commons to deliver the king's final proposals for peace, and was afterwards present at Edgehill. In December he was made by Charles master of the rolls. He was a leading member of the Oxford parliament, and was said, in opposition to the general opinion, to have counselled considerable concessions to secure peace. He received a peerage in 1644.

Colepeper was despatched with Hyde in charge of the prince of Wales to the West in March 1645, and after Charles's final defeat, embarked with the prince for Scilly, and thence to France. He strongly advocated the gaining over of the Scots by religious concessions, a policy supported by the queen and Mazarin, and urged this course upon the king. In 1648 he accompanied the prince in his unsuccessful naval expedition, and returned with him to The Hague, where violent altercations broke out among the royalist leaders, Colepeper going so far, on one occasion in the council, as to challenge Prince Rupert, and being himself severely assaulted in the streets by Sir Robert Walsh. He continued after the execution of the king to press the acceptance on Charles II. of the Scottish proposals. He was sent to Russia in 1650, where he obtained a loan of 20,000 roubles from the tsar, and, soon after his return, to Holland, to procure military assistance. By the treaty, agreed to between Cromwell and Mazarin, of Aug. 1654, Colepeper was obliged to leave France, and he appears henceforth to have resided in Flanders. He accompanied Charles II. to the south of France in Sept. 1659, at the time of the treaty of the Pyrenees. At the Restoration he returned to England, but only survived a few weeks, dying on June 11, 1660.

THOMAS COLEPEPER (d. 1719), son of the former, became governor of Virginia from 1680–83; the title became extinct on the death of his brother Cheney in 1725.

COLERAINE, seaport, market town and municipal borough, Co. Londonderry, Northern Ireland, on the Bann, 4 mi. from its mouth. Pop. (1937) 9,180. Area, 1.6 sq.mi. A bridge connects the town with its suburb, Waterside or Killowen, on the opposite bank of the river. The main town on the east bank radiates from a central square—the Diamond. A rath occupies Mount Sandel 1 mi. S.E. of the town and there was once a priory, monastery and castle. Coleraine owed its importance to the Irish society, which was incorporated under James I as the Company for the New Plantation of Ulster in 1613. This society founded and still maintains schools in the town. The linen trade is much reduced, the staple industries being shirt and collar making, whiskey distilling, ironfounding and salmon fishing. The harbours were much improved by grants from the Irish Society of London and the River Bann Navigation act, 1879.

COLERIDGE, HARTLEY (1796–1849), English man of letters, eldest son of the poet Samuel Taylor Coleridge, was born on Sept. 19, 1796, near Bristol. In 1815 he went to Oxford, as scholar of Merton College. His university career, however, was unfortunate. He gained an Oriel fellowship, but at the close of the probationary year (1820) was judged to have forfeited it. Hartley Coleridge then spent two years in London, where he wrote short poems for the *London Magazine,* afterwards he became for a short time partner in a school at Ambleside, and in 1830 began to do hack work for a Leeds publisher, Mr. F. E. Bingley. Bingley also printed a volume of his poems in 1833, and Coleridge lived in his house until the contract came to an end through the bankruptcy of the publisher. From this time, except for two short periods in 1837 and 1838 when he acted as master at Sedbergh grammar school, he lived quietly at Grasmere and (1840–1849) Rydal, spending his time in study and wanderings about the countryside. In the year 1839 appeared his edition of Massinger and Ford, with biographies of both dramatists. He died on Jan. 6, 1849. The prose style of Hartley Coleridge is marked by much finish and vivacity; but his literary reputation must chiefly rest on the sanity of his criticisms, and above all on his *Prometheus,* an unfinished lyric drama, and on his sonnets. As a sonneteer he achieved real excellence, the form being exactly suited to his sensitive genius. *Essays and Marginalia,* and *Poems,* with a memoir by his brother Derwent, appeared in 1851.

COLERIDGE, JOHN DUKE COLERIDGE, 1st BARON (1820–1894), lord chief justice of England, was the eldest son of Sir John Taylor Coleridge. He was born at Heath's Court, Ottery St. Mary, on Dec. 3, 1820. He was educated at Eton and Balliol college, Oxford, of which he was a scholar. He was called to the bar in 1846, went the western circuit, and in 1865 he was returned as member for Exeter in the Liberal interest. The heads of his party determined in 1867 to put him forward as the protagonist of their attack on the Government, but the plan was frustrated by opposition within the party. In 1868 when the Liberals returned to power Coleridge was made first solicitor-general and then attorney-general.

His arrival in parliament was an access of strength to the body of Oxford men who had attacked the legislation that kept the university under ecclesiastical domination. In addition to his own talents he carried weight with the clerically-minded section as the son of Sir John Coleridge, the godson of Keble, and great-nephew of the man who was an indirect cause of the Anglican revival of 1833—Coleridge the poet.

The Tichborne trial was the most conspicuous feature of Coleridge's later years at the bar, and tasked his powers as an advocate to the uttermost, though he was assisted by Charles (afterwards Lord) Bowen. In November 1873 Coleridge succeeded Sir W. Bovill as chief justice of the common pleas, and was immediately afterwards raised to the peerage as Baron Coleridge of Ottery St. Mary. In 1880 he was made lord chief justice.

In jury cases his quickness in apprehending facts and his lucidity in arranging them were very remarkable indeed. He was not one of the most learned of lawyers, but he was a great deal more learned than many people thought, and as an ecclesiastical lawyer had few superiors. His fault—natural in one who had been so successful as an advocate—was that of being too prone to take one side, and he allowed political or personal prepossessions to colour the tone of his remarks from the bench. Latterly his health failed, and he became somewhat indolent. On the whole, he was not so strong a man in a judicial capacity as Campbell or Cockburn; but it must be admitted that his scholarship, his refinement, his power of oratory, and his character raised the tone of the bench during his occupancy, and that if it has been adorned by greater judicial abilities, it has hardly ever known a greater combination of varied merits. Coleridge died on June 14, 1894.

Coleridge's addresses and papers have not been published. One of the best and most eminently characteristic of the man, was his inaugural address to the Philosophical Institution at Edinburgh in 1870; another was a paper on Wordsworth (1873). He was an exceptionally good letter-writer. Of travel he had very little experience. He had hardly been to Paris; once, quite near the end of his career, he spent a few days in Holland, and came back a willing slave to the genius of Rembrandt; but his longest absence from England was a visit, of a representative legal character, to the United States. He had an extraordinary store of anecdotes, which were nearly always connected with Eton, Oxford, the bar or the bench. His exquisite voice, considerable power of mimicry, and perfect method of narration added greatly to the charm. John Duke Coleridge was sarcastic and critical, and at times over-sensitive. But his strongest characteristics were love of liberty and justice. By birth and connection Conservative, he was a Liberal by conviction, and loyal to his party and its great leader, Gladstone.

His *Life and Correspondence,* ed. by E. H. Coleridge, was published in 1904; *see* further E. Manson, *Builders of our Law* (1904); for the history of the Coleridge family *see* Lord Coleridge, *The Story of a Devonshire House* (1907).

COLERIDGE, SIR JOHN TAYLOR (1790–1876), English judge, the second son of Captain James Coleridge, and nephew of the poet S. T. Coleridge, was born at Tiverton, Devon, and was educated at Corpus Christi college, Oxford, where he had a brilliant career. He graduated in 1812 and was soon after made a fellow of Exeter; in 1819 he was called to the bar at the Middle Temple and practised for some years on the western circuit. In 1825 he published his excellent edition of *Blackstone's Commentaries,* and in 1832 he was made a serjeant-at-law and recorder of Exeter. He was one of the judges of the king's bench from 1835 to 1858. In 1869 he produced his *Memoir of the Rev. John Keble,* a third edition of which was issued within a year. He died on Feb. 11, 1876, at Ottery St. Mary, Devon, leaving two sons and a daughter; the eldest son, John Duke, 1st Baron Coleridge (*q.v.*), became lord chief justice of England. Sir John Taylor Coleridge's brothers, James Duke and Henry Nelson (husband of Sara Coleridge), are referred to in other articles; his brother Francis George was the father of Arthur Duke Coleridge (b. 1830), clerk of assizes on the midland circuit and author of *Eton in the Forties,* whose daughter Mary E. Coleridge (1861–1907), was poet, novelist and critic. Mary Coleridge's posthumous *Gathered Leaves* (1910) contains a notice of her work by Edith Sichel.

COLERIDGE, SAMUEL TAYLOR (1772–1834), English poet and philosopher, was born on Oct. 21, 1772, at his father's vicarage of Ottery St. Mary, Devonshire. His father, the Rev. John Coleridge (1719–1781), described by the poet as "a perfect Parson Adams," was known for his scholarship, simplicity of character, and affectionate interest in the pupils of the grammar school, of which he was appointed master a few months before becoming vicar of the parish (1760). The poet was the youngest child of his second wife, Anne Bowdon (d. 1809), a woman of great good sense, who saw to it that Samuel should be educated for the church as his father intended, and as three of his elder brothers had been before him. On the death of his father an old pupil of the latter secured for Samuel a presentation to Christ's Hospital, where he continued for eight years. Of these school-days Charles Lamb has given delightful glimpses in the *Essays of Elia.* Formerly a fretful and timorous child, Samuel became a comparatively happy schoolboy, though often ailing. The headmaster, Boyer, a severe disciplinarian, pushed him watchfully. Some of his compositions in English verse written at 16 give evidence of the influence of Bowles, to which he has testified in his *Biographia Literaria.*

In Feb. 1791 he was entered as a sizar at Jesus college, Cambridge, and went into residence in October. A schoolfellow who followed him to the university has told how in the evenings, in his rooms, he and his friends would put aside their work to discuss as they appeared, the new pamphlets of Burke, which Coleridge absorbed immediately. At that stage he was warmly democratic. William Frend, a fellow of Jesus, accused of sedition and Unitarianism, was at this time tried and banished, though not technically expelled from Cambridge. Coleridge had imbibed his sentiments, and joined the ranks of his partisans. He grew discontented with university life, and in 1793, pressed by debt, went to London. A poem in the *Morning Chronicle* brought him a guinea, and when that was spent he enlisted in the 15th Dragoons under the name of Silas Tomkyn Comberbacke, revealing at once an absolute unfitness for an army career. Shortly afterwards an old school-fellow (G. L. Tuckett) heard of his whereabouts, and by the intervention of his brother, Captain James Coleridge, his discharge was procured. He returned for a short time to Cambridge, but quitted the university without a degree in 1794. In the same year he visited Oxford, and after a short tour in Wales went to Bristol, where he met Southey. The French Revolution had captivated Southey, and Coleridge received with rapture his new friend's scheme of Pantisocracy. On the banks of the Susquehanna was to be founded a brotherly community, where selfishness was to be extinguished, and the virtues were to reign supreme. No funds were forthcoming; and in 1795, to the chagrin of Coleridge, who seems to have bitterly blamed Southey, the scheme was dropped. In 1794 appeared *The Fall of Robespierre,* of which Coleridge wrote the first act and Southey the other two. At Bristol Coleridge formed the acquaintance of Joseph Cottle, the bookseller, who offered him thirty guineas for a volume of poems. In October of 1795 Coleridge married Sarah Fricker, and took up his residence at Clevedon on the Bristol channel. A few weeks afterwards Southey married a sister of Mrs. Coleridge, and on the same day quitted England for Portugal.

Coleridge began to lecture in Bristol on politics and religion. He embodied the first two lectures, which contained much invective against Pitt, in his first prose publication, *Conciones ad Populum* (1795). The first volume of *Poems* was published by Cottle early in 1796. Coleridge projected a periodical called *The Watchman,* and in 1796 undertook a journey, well described in the *Biographia Literaria,* to enlist subscribers. *The Watchman* had a brief life of two months, and at this time Coleridge began to think of becoming a Unitarian preacher. Hazlitt has recorded his very favourable impression of a remarkable sermon delivered at Shrewsbury; but there are other accounts of Coleridge's preaching not so enthusiastic. In the summer of 1795 he met for the first time the brother poet with whose name his own will be for ever associated. Wordsworth and his sister had established themselves at Racedown in the Dorsetshire hills, and here Coleridge visited them in 1797. The gifted Dorothy Wordsworth described Coleridge as "thin and pale, the lower part of the face not good, wide mouth, thick lips, not very good teeth, longish, loose, half-curling, rough, black hair,"—but all was forgotten in the magic charm of his utterance. Wordsworth, who declared: "The only wonderful man I ever knew was Coleridge," seems at once to have desired to see more of his new friend. He and his sister removed in July 1797 to Alfoxden, near Nether Stowey, to be in Coleridge's neighbourhood, and in the most delightful and unrestrained intercourse the friends spent many happy days.

One evening at Watchett on the Bristol Channel, *The Ancient Mariner* first took shape. Coleridge was anxious to embody a dream of a friend, and the suggestion of the shooting of the albatross came from Wordsworth, who gained the idea from Shelvocke's *Voyage* (1726). A joint volume was planned. Wordsworth was to show the real poetry that lies hidden in commonplace subjects, while Coleridge was to treat supernatural subjects to illustrate the common emotions of humanity. From this sprang the *Lyrical Ballads,* to which Coleridge contributed *The Ancient Mariner,* the *Nightingale* and two scenes from *Osorio,* and after much cogitation the book was published in 1798 at Bristol by Cottle. A second edition of the *Lyrical Ballads* in 1800 included another poem by Coleridge—*Love,* to which subsequently the subtitle was given of *An Introduction to the Tale of the Dark Ladie.* To the Stowey period belong also the tragedy of *Osorio* (afterwards known as *Remorse*), *Kubla Khan,* and the first part of *Christabel.* In 1798 an annuity, granted him by the brothers Wedgwood, led Coleridge to abandon his reluctantly formed intention of becoming a Unitarian minister. For many years he had desired to see the continent, and in September 1798, in company with Wordsworth and his sister, he left England for Hamburg. *Satyrane's Letters* (republished in *Biog. Lit.* 1817) give an account of the tour.

A new period in Coleridge's life now began. He soon left the Wordsworths to spend four months at Ratzeburg, whence he removed to Göttingen to attend lectures. During his stay of nine months in Germany, he made himself master of the language to such purpose that the translation of *Wallenstein* was actually accomplished in six weeks. During these years he wrote many newspaper articles and some poems, among them "Fire, Famine and Slaughter," for the *Morning Post.* He had vehemently opposed Pitt's policy, but a change came over his way of thought, and he found himself separated from Fox on the question of a struggle with Napoleon. He had lost his admiration for the revolutionists, as his "Ode to France" shows (*Morning Post,* April 16, 1798). Like many other Whigs, he felt that all questions of domestic policy must at a time of European peril be postponed. In the year 1800 he left London for the Lakes, where he wrote the second part of *Christabel.* In 1803 Southey became a joint lodger with Coleridge at Greta Hall, Keswick, of which in 1812 Southey became sole tenant and occupier.

In 1801 begins the period of Coleridge's life during which he sank more and more under the dominion of opium, in which he may have first indulged at Cambridge. Few things are so sad to read as the letters in which he details the consequences of his obsession. He was occasionally seen in London during the first years of the century, and wherever he appeared he was the delight of admiring circles. He toured in Scotland with the Wordsworths in 1803, visited Malta in 1804, when for ten months he acted as secretary to the governor, and stayed nearly eight months at Naples and Rome in 1805–06. In Rome he received a hint that his articles in the *Morning Post* had been brought to Napoleon's notice, and he made the voyage from Leghorn in an American ship. On a visit to Somersetshire in 1807 he met De Quincey for the first time, and the younger man's admiration was shown by a gift of £300, "from an unknown friend." In 1809 he started a magazine called *The Friend,* which continued only for eight months. At the same time he began to contribute to the *Courier.* In 1808 he lectured at the Royal Institution, but with little success, and three years later he gave his lectures on Shakespeare and other poets. These lectures attracted great attention and were followed by two other series. In 1812 his income from the Wedgwoods was reduced, and he settled the remainder on his wife. His friends were generous in assisting him with money, and eventually, in 1824, some of them obtained a grant of £100 a year for him during the lifetime of George IV., as one of the royal associates of the Society of Literature, while his children shared Southey's home at Keswick. But between 1812 and 1817 Coleridge made a good deal by his work, and was able to send money to his wife in addition to the annuity she received. The tragedy of *Remorse* was produced at Drury Lane in 1813, and met with considerable success.

Three years after this, having failed to conquer the opium habit, he determined to enter the family of James Gillman, who lived at Highgate. For the rest of his life he hardly ever left this home. During his residence there, *Christabel,* written many years before, and known to a favoured few, was first published in a volume with *Kubla Khan* and the *Pains of Sleep* in 1816. In 1816 and the following year, he gave his Lay Sermons to the world. *Sibylline Leaves* appeared in 1817; the *Biographia Literaria* and a revised edition of *The Friend* soon followed. Eight years afterwards his most popular prose work—the *Aids to Reflection*—first appeared. His last publication, in 1830, was the work on *Church and State.* It was not till 1840 that his *Confessions of an Inquiring Spirit,* his most seminal work, was posthumously published. In 1833 he appeared at the meeting of the British Association at Cambridge, but he died in the following year (July 25, 1834), and was buried in the churchyard close to the house of Gillman, where he had enjoyed every consolation which friendship and love could render. Coleridge died in the communion of the Church of England, of whose polity and teaching he had been for many years a loving admirer. An interesting letter to his god-child, written twelve days before his death, sums up his spiritual experience in a most touching form.

To the extraordinary influence which he exercised in conversation there are many testimonies. Many of the most remarkable among the younger men of that period resorted to Highgate as to the shrine of an oracle; and although one or two disparaging judgments, such as that of Carlyle, have been recorded, there can be no doubt that since Samuel Johnson there had been no such intellectual power in England. His nephew, Henry Nelson Coleridge, gathered together many specimens of the *Table Talk* of the few last years. Four volumes of *Literary Remains* were published after his death, and these, along with the chapters on the poetry of Wordsworth in the *Biographia Literaria,* may be said to exhibit the full range of Coleridge's power as a critic of poetry. In this region he stands supreme, ranking as the creator in England of that higher criticism which had already in Germany accomplished so much in the hands of Lessing and Goethe. The fragmentary series of his Shakespearian criticisms gives evidence of the truest insight, and an original appreciation of the judicial "sanity" which raises the greatest name in literature above even the highest of the poets who approached him.

As a poet Coleridge's own place in the great gallery of English poets is secure. Of no one can it be more emphatically said that at his highest he was "of imagination all compact." The whole soul of the poet is reflected in the *Ode to Dejection.* The well-known lines—

> O Lady! we receive but what we give,
> And in our life alone does nature live;
> Ours is her wedding garment, ours her shroud,

with the passage which follows, express more vividly, perhaps, than anything which Coleridge had written, the shaping and colouring function which he assigns, in the *Biographia Literaria,* to imagination. *Christabel* and the *Ancient Mariner* have so completely taken possession of the highest place, that it is needless to do more than allude to them. The supernatural has never received such treatment as in these two wonderful productions of his genius, and though the first of them remains a torso, it is the loveliest torso in the gallery of English literature. Although Coleridge had, for many years before his death, almost entirely forsaken poetry, the few fragments of work which remain, written in later years, show little trace of weakness, although they are wanting in the unearthly melody which imparts such a charm to *Kubla Khan, Love* and *Youth and Age.*

It is chiefly as a personality and as a thinker that Coleridge has incurred disparaging criticism. The infirmity of will and the "sloth" to which he sadly confessed have been the subject of many homilies; and even eulogists have to avow that his works in mass are a "collection of fragments," to say nothing of a hundred large plans never fulfilled. But in the light of the biographical study of the last generation, he can be seen as the victim of heredity and malady, his rare powers and his inefficiencies being alike innate, and the opium-eating a fatal consequence. That he laboured under a vital cardiac weakness seems certain. In his vivid accounts of his childhood he has revealed himself as a "dreamer," living in the world of his strange imagination, and singularly responsive through that faculty to every stimulus received from his manifold reading. His poetry and his philosophy are thus alike to be seen as shaped at once by his bias and his culture.

In his youth he was poetically dominated by Bowles, because Bowles was the first of the modern innovating poets who had come in his way. Of Blake and Burns, and even of Cowper, at that stage he knew nothing. An American student has latterly revealed how the *Ancient Mariner* was coloured in diction and in conception by his reading, and then perfected by his fine critical faculty. His philosophy may be viewed in the same fashion. All the notable ideas which came to him took possession in turn of his imgination, only to be transformed continuously. As he truly said of himself, his mind was always "energic," as distinguished from "energetic." Save in his many hours of misery or utter lassitude, it was constantly at work creatively on the material of his reading, and its uncontrolled play has yielded a remarkable harvest of criticism and speculation, couched in a prose stamped at once with intensive feeling and skill of phrase. Hence the stirring quality of his influence.

In the latter part of his life, and for the generation which followed, Coleridge was ranked by many young English churchmen of liberal views as the greatest religious thinker of their time. Among those he thus fascinated was the abnormal Edward Irving. As Carlyle has told in his *Life of Sterling,* the poet's distinction, in the eyes of his audience, lay in his having recovered and preserved his Christian faith after having passed through periods of rationalism and Unitarianism, and faced the full results of German criticism and philosophy. His opinions, however, were at all periods mutable, and it would be difficult to state them in any form that would hold good for the whole even of his later writings. He was, indeed, too receptive of thought impressions of all kinds to be a consistent systematizer. From his early Unitarianism he gradually moved towards pantheism, a way of thought to which he had shown remarkable leanings when, as a schoolboy, he discoursed of Neoplatonism to Charles Lamb. Early in life, too, he met with the doctrines of Jacob Behmen, of whom, in the *Biographia Literaria*, he speaks with affection and gratitude as having given him vital philosophic guidance. In the *Aids to Reflection* he disparages him. Between pantheism and Unitarianism he seems to have balanced till his thirty-fifth year, always tending towards the former in virtue of the recoil from "anthropomorphism," which originally took him to Unitarianism. In 1796, when he named his first child David Hartley, but would not have him baptized, he held by the "Christian materialism" of the writer in question, whom in his *Religious Musings* he terms "wisest of mortal kind."

When, again, he met Wordsworth in 1797, the two poets sympathetically discussed Spinoza, for whom Coleridge always retained an admiration; and when in 1798 he gave up his Unitarian preaching, he named his second child Berkeley, signifying a new allegiance, but still without accepting Christian rites otherwise than passively. Shortly afterwards he went to Germany, where he began to study Kant, and was much impressed by Lessing. In the *Biographia* he avows that the writings of Kant "more than any other work, at once invigorated and disciplined my understanding." But after his stay at Malta, he announced to his friends that he had given up his "Socinianism" (of which ever afterwards he spoke with asperity), professing a return to Christian faith, though still putting on it a mystical construction, as when he told Crabb Robinson that "Jesus Christ was a Platonic philosopher." At this stage he was in sympathy with the historico-rationalistic criticism of the Old Testament, as carried on in Germany. From about 1810 onwards, however, he openly professed Christian orthodoxy, while privately indicating views which cannot be so described. And even his published speculations were such as to draw from J. H. Newman a protest that they took "a liberty which no Christian can tolerate," and carried him to "conclusions which were often heathen rather than Christian."

The explanation seems to be that while on Christian grounds he repeatedly denounced pantheism as being in all its forms equivalent to atheism, he was latterly much swayed by the thought of Schelling in the pantheistic direction which was natural to him. It would seem that, in the extreme spiritual vicissitudes of his life, conscious alternately of personal weakness and of the largest speculative grasp, he often threw himself entirely on the consolations of evangelical faith, and at times reconstructed the cosmos for himself in terms of Neo-Platonism and the philosophy of Schelling. So great were his variations, even in his latter years, that he could speak to his friend Allsop in a highly latitudinarian sense. From Schelling, whom he praised as having developed Kant where Fichte failed to do so, he borrowed much and often, not only in the metaphysical sections of the *Biographia* but in his aesthetic lectures, and further in the cosmic speculations of the posthumous *Theory of Life*. On the first score he makes but an equivocal acknowledgment, claiming to have thought on Schelling's lines before reading him; but it has been shown by Hamilton and Ferrier that besides transcribing much from Schelling without avowal he silently appropriated the learning of Maass on philosophical history. In other directions he laid under tribute Herder and Lessing; yet all the while he cast severe imputations of plagiarism upon Hume and others. His own plagiarisms were doubtless facilitated by the physiological effects of opium.

Inasmuch as his philosophy satisfied neither the logical needs appealed to by Hegel nor the new demand for naturalistic induction, Coleridge, after arousing a great amount of philosophic interest in his own country in the second quarter of the century, has ceased to "make a school." Thus his significance in intellectual history remains that of a great stimulator. He undoubtedly did much to deepen and liberalize Christian thought in England, his influence being specially marked in the school of F. D. Maurice, and in the lives of men like John Sterling.

Of Coleridge's four children, two (Hartley and Sara) are separately noticed. His second child, Berkeley, died in infancy. The third, Derwent (1800–1883), a distinguished scholar and author, was master of Helston school, Cornwall (1825–1841), first principal of St. Mark's college, Chelsea (1841–1864), and rector of Hanwell (1864–1880); and his daughter Christabel (b. 1843) and son Ernest Hartley, both became well known in the world of letters, the former as a novelist, the latter as a biographer, editor and critic.

After Coleridge's death several of his works were edited by his nephew, Henry Nelson Coleridge, the husband of Sara, the poet's only daughter. In 1847 Sara Coleridge published the *Biographia Literaria,* enriched with annotations and biographical supplement, begun by her husband and finished by her. Three volumes of Coleridge's political writings, entitled *Essays on his Own Times,* were also published by Sara Coleridge in 1850. The standard life of Coleridge is that by J. Dykes Campbell (1894); his letters were edited by E. H. Coleridge (1895). The *Anima Poetae,* edited by the latter (1895) is a compilation from Coleridge's notebooks. The *Biographia Epistolaris,* edited by A. Turnbull (2 vols., 1911) is a reprint of the Biog. Supp. to the *Biographia Literaria,* with additional letters and elucidations. Of monographs on Coleridge the most important are that of H. D. Traill ("English Men of Letters" series) and that of Joseph Aynard, *La Vie d'un Poète—Coleridge* (Paris, 1907). The work of J. L. Lowes, *The Road to Xanadu, a Study in the Ways of the Imagination* (1927), is an important research. *See* also J. Charpentier, *Coleridge, the Sublime Somnambulist* (1929). (J. M. R.)

COLERIDGE, SARA (1802–1852), English author, the fourth child and only daughter of Samuel Taylor Coleridge and his wife Sarah Fricker of Bristol, was born on Dec. 23, 1802, at Greta Hall, Keswick. Here, after 1803, the Coleridges, Southey and his wife (Mrs. Coleridge's sister), and Mrs. Lovell (another sister), widow of Robert Lovell, the Quaker poet, all lived together; but Coleridge was often away from home; and "Uncle Southey" was a *paterfamilias*. The Wordsworths at Grasmere were their neighbours. Wordsworth, in his poem, the *Triad,* has left us a description, or "poetical glorification," as Sara Coleridge calls it, of the three girls—his own daughter Dora, Edith Southey and Sara Coleridge, the "last of the three, though eldest born." Greta Hall was Sara Coleridge's home until her marriage; and the little Lake colony seems to have been her only school. Guided by Southey she read by herself the chief Greek and Latin classics, and before she was 25 had learnt French, German, Italian and Spanish.

In 1822 Sara Coleridge published *Account of the Abipones,* a translation in three large volumes of Dobrizhoffer, undertaken in connection with Southey's *Tales of Paraguay,* which had been suggested to him by Dobrizhoffer's volumes. In 1825 her second work appeared, a translation from the mediaeval French of the "Loyal Serviteur," *The Right Joyous and Pleasant History of the Feats, Jests, and Prowesses of the Chevalier Bayard, the Good Knight without Fear and without Reproach: By the Loyal Servant.*

In Sept. 1829, at Crosthwaite church, Keswick, after an engagement of seven years' duration, Sara Coleridge was married to her cousin, Henry Nelson Coleridge (1798–1843), younger son of Captain James Coleridge (1760–1836). He was then a chancery barrister in London. In 1834 Mrs. Coleridge published her *Pretty Lessons in Verse for Good Children; with some Lessons in Latin in Easy Rhyme.* These were originally written for the instruction of her own children, and became very popular. In 1837 appeared *Phantasmion, a Fairy Tale.*

In 1843 Henry Coleridge died, leaving to his widow the unfinished task of editing her father's works. To these she added some compositions of her own, among which are the *Essay on Rationalism, with a special application to the Doctrine of Baptismal Regeneration,* appended to Coleridge's *Aids to Reflection;* a Preface to the *Essays on his Own Times, by S. T. Coleridge,* and the Supplement to the *Biographia Literaria.* During the last few years of her life Sara Coleridge was a confirmed invalid. Shortly before she died she amused herself by writing a little autobiography for her daughter. This, which reaches only to her ninth year, was completed by her daughter, and published in 1873, together with some of her letters, under the title *Memoirs and Letters of Sara Coleridge.* She died in London on May 3, 1852.

Her son, HERBERT COLERIDGE (1830–61), won a double first class in classics and mathematics at Oxford in 1852. He was secretary to a committee appointed by the Philological Society to consider the project of a standard English dictionary, a scheme of which the *New English Dictionary,* published by the Clarendon Press, was the ultimate outcome. His personal researches into the subject were contained in his *Glossarial Index to the Printed English Literature of the Thirteenth Century* (1859).

COLERIDGE-TAYLOR, SAMUEL (1875–1912), composer, was born in London on Aug. 15, 1875, the son of a West African doctor of medicine and an English mother. He sang in a church choir at Croydon, and studied the violin and composition at the Royal College of Music. His first important work was a symphony given at St. James's hall in 1896, but his reputation rests on his picturesque and melodious choral work, the trilogy of *Hiawatha.* This work was succeeded by many other choral works, none of which had quite the same success. He wrote some excellent incidental music for plays by Stephen Phillips: *Herod* (1900), *Ulysses* (1902), *Nero* (1906), and *Faust* (1908); also occasional music for *Othello.*

See W. C. Berwick Savers, *Samuel Coleridge-Taylor, Musician. His Life and Letters* (1915).

COLET, JOHN (1467?–1519), English divine and educationist, the eldest son of Sir Henry Colet (twice mayor of London), was born in London and educated at Oxford, probably at Magdalen college. When he took his M.A. in 1490 he already held the rectory of St. Mary, Dennington, Suffolk, and the vicarage of St. Dunstan's, Stepney, and was now collated rector of St. Nicholas, Thurning, Hunts. In 1493 he went to Paris and thence to Italy, studying canon and civil law, patristics and Greek. During his residence abroad he became acquainted with Budaeus (Guillaume Budé) and Erasmus, and with the teaching of Savonarola. On his return to England in 1496 he took orders, and began his Oxford lectures on the Pauline epistles. In replacing the old scholastic methods by a study of the personality and times of St. Paul, he began a new epoch in Biblical exegesis and greatly influenced Erasmus, who visited Oxford in 1498. Since 1494 he had been prebendary of York and canon of St. Martin le Grand, London. In 1502 he became prebendary of Salisbury, in 1505 prebendary of St. Paul's, and immediately afterwards dean of the same cathedral, having previously taken the degree of doctor of divinity. Here he continued his innovating Biblical lectures. About 1508, having inherited his father's wealth, Colet re-founded St. Paul's school where a good Christian education together with Greek and Latin was to be given to the 153 scholars. The celebrated grammarian William Lilly was the first master, and the company of mercers were (in 1510) appointed trustees, the first example of non-clerical management in education. The dean's liberal religious opinions led the clergy to deem him little better than a heretic; but William Warham, the archbishop, refused to prosecute him. Similarly Henry VIII. held him in high esteem despite his sermons against the French wars. In 1514 he made the Canterbury pilgrimage with Erasmus, and in 1515 preached at Wolsey's installation as cardinal. Colet died on Sept. 16, 1519.

Though a staunch Catholic, Colet disapproved of the sale of bishoprics, the custom of pluralities, Church lawyers and the worldliness of churchmen. He was not a great scholar, but by introducing the humanist movement he helped to discredit mediaeval thought. Among his works, first collectively published in 1867–76, are *Absolutissimus de octo orationis partium constructione libellus* (Antwerp, 1530), *Rudimenta Grammatices* (London, 1539), *Daily Devotions, Monition to a Godly Life, Epistolae ad Erasmum,* and Biblical commentaries.

See F. Seebohm, *The Oxford Reformers* (1887); J. H. Lupton, *Life of John Colet,* 2nd ed. (1909); art. in *The Times,* July 7, 1909.

COLET, LOUISE (1810–1876), French poet and novelist, was born at Aix of a Provençal family named Revoil. In 1835 she came to Paris with her husband Hippolyte Colet (1808–51), a composer of music and professor of harmony and counterpoint at the conservatoire. Louise Colet is perhaps best known for her intimate connection with some of her famous contemporaries, Abel Villemain, Gustave Flaubert and Victor Cousin. Only one of her many volumes of prose and verse is now of interest—*Lui: roman contemporain* (1859), the novel in which she told the story of her life. (*See* also Flaubert.)

COLEUS, a genus of ornamental herbaceous or shrubby plants of the mint family, natives of the tropics of the old world. They are much cultivated as bedding plants for the colour of their exceedingly varied, and often brilliant leaves. They can be wintered over as room plants if the house is not too hot and dry.

COLFAX, SCHUYLER (1823–1885), American political leader, vice-president of the United States from 1869–73, was born in New York city on March 23, 1823. His father died before the son's birth, and his mother subsequently married a Mr. Matthews. The son attended the public schools of New York until he was ten, and then became a clerk in his step-father's store, removing in 1836 with his mother and step-father to New Carlisle, Ind. In 1841 he removed to South Bend, where for eight years he was deputy auditor (his step-father being auditor) of St. Joseph county; in 1842–44 he was assistant enrolling clerk of the State senate and senate reporter for the *Indiana State Journal.* In 1845 he established the *St. Joseph Valley Register,* which he published for 18 years and made an influential Whig and later Republican journal. In 1850 he was a member of the State Constitutional Convention, and in 1854 took an active part in organizing the "Anti-Nebraska men" (later called Republicans) of his State, and was by them sent to Congress. Here he served with distinction from 1855 until 1869, the last six years as speaker of the House. At the close of the Civil War he was a leading member of the radical wing of the Republican Party, advocating the disfranchisement of all who had been prominent in the service of the Confederacy, and declaring that "loyalty must govern what loyalty has preserved." In 1868 he had presidential aspirations, and was not without supporters. He accepted, however, the Republican nomination as vice-president on a ticket headed by Gen. Grant, and was elected; but he failed in 1872 to secure renomination. During the political campaign of 1872 he was accused, with other prominent politicians, of being implicated in corrupt transactions with the Crédit Mobilier, and a congressional investigation brought out the fact that he had agreed to take 20 shares from this concern, and had probably received dividends amounting to $1,200. It also leaked out during the investigation that he had received in 1868, as a campaign contribution, a gift of $4,000 from a contractor who had supplied the Government with envelopes while Colfax was chairman of the post-office committee of the House. At the close of his term Colfax returned to private life under a cloud, and during the remainder of his lifetime earned a livelihood by delivering popular lectures. His interest in moral and social reforms is best exemplified by his lifelong labours for the cause of temperance. He died at Mankato, Minn., on Jan. 13, 1885.

See E. W. Martin, *The Life and Public Services of Schuyler Colfax* (1868) and O. J. Hollister, *Life of Schuyler Colfax* (1887).

COLIC, a term in medicine used outside England for any paroxysmal abdominal pain, but generally limited in England to a sudden sharp pain having its origin in the pelvis of the kidney, the ureter, gall-bladder, bile-ducts or intestine. There is a tendency, however, to restrict use of the word to a pain produced by the contraction of the muscular walls of any hollow viscus of which the aperture has become more or less occluded, temporarily or otherwise. For renal and biliary colic, *see* Kidney Diseases and Liver, only intestinal colic being treated here.

In infants, usually those who are "bottle-fed," colic is exceedingly common, and is shown by the drawing up of their legs, their restlessness and their continuous cries.

Among adults one of the most serious causes is lead-poisoning (*see* Lead-Poisoning). In Germany a similar colic resulting from the absorption of copper occurs.

The simplest form of colic is that arising from habitual constipation or from ingestion of indigestible food such as apples, pears or nuts, heavy pastry, meat pies and puddings, etc. Often it is associated with diarrhoea. It may accompany any form of enteritis or an intestinal malignant growth, and certain forms of influenza (*q.v.*) are ushered in by severe colic.

Intestinal colic is paroxysmal, and the pain is generally referred to the neighbourhood of the umbilicus. It varies greatly in intensity and is usually relieved by pressure; this point aids in the differential diagnosis between simple colic and peritonitis, the pain of the latter being increased by pressure.

Treatment.—In simple colic the patient must be confined to bed, hot fomentations applied to the abdomen and a purge administered, a few drops of laudanum being added when the pain is exceptionally severe. But the whole difficulty lies in making the differential diagnosis. Acute intestinal obstruction, appendicitis, peritonitis, gallstone, renal stone and the gastric crises of locomotor ataxy, must all be excluded.

COLIGNY, GASPARD DE CHATILLON, COMTE (1519–1572), admiral of France and Protestant leader, was born at Châtillon-sur-Loing on Feb. 16, 1519, the son of Gaspard de Coligny, known as the maréchal de Châtillon (d. 1522), marshal of France in 1516. By his wife, Louise de Montmorency, the marshal had three sons: Odet, cardinal de Châtillon; Gaspard, the admiral; and Francis, seigneur d'Andelot, all of whom played an important part in the first period of the Wars of Religion. At 22 young Gaspard came to court, and there contracted a friendship with Francis of Guise. In the campaign of 1543 Coligny was wounded at the sieges of Montmédy and Bains. In 1544 he served in the Italian campaign under the duke of Enghien, and was knighted on the field of Ceresole. Appointed colonel-general of the infantry (April 1547), he exhibited great capacity and intelligence as a military reformer. He was made admiral on the death of d'Annebaut (1552). In 1557 he defended St. Quentin with great courage and resolution; but the place was taken, and he was imprisoned in the stronghold of L'Ecluse. On payment of a ransom of 50,000 crowns he recovered his liberty. He had by this time become a Huguenot, through the influence of his brother d'Andelot—the first letter which Calvin addressed to him is dated Sept. 4, 1558—and he busied himself secretly with protecting his co-religionists, a colony of whom he sent to Brazil, whence they were afterwards expelled by the Portuguese.

On the death of Henry II. he demanded, in concert with Louis, prince of Condé, religious toleration and certain other reforms. In 1560, at the assembly of notables at Fontainebleau, the hostility between Coligny and Francis of Guise was declared. When the civil wars began in 1562, Coligny decided to take arms only after long hesitation, and he was always ready to negotiate. In none of these wars did he show superior genius, but he acted throughout with great prudence and extraordinary tenacity; he was "le héros de la mauvaise fortune." In 1569 the defeat and death of the prince of Condé at Jarnac left him sole leader of the Protestant armies. Victorious at Arnay-le-Duc, he secured in 1570 the pacification of St. Germain. Returning to the court in 1571, he grew rapidly in favour with Charles IX. As a means of emancipating the king from the tutelage of his mother and the faction of the Guises, the admiral proposed to him a descent on Spanish Flanders, with an army drawn from both sects and commanded by Charles in person. The king's regard for the admiral, and the bold front of the Huguenots, alarmed the queen-mother; and the massacre of St. Bartholomew was the consequence. On Aug. 22, 1572, Coligny was wounded by Maurevel, a bravo in the pay of the queen-mother and Guise. The king visited him, but the queen-mother prevented all private intercourse between them. On Aug. 24, the night of the massacre, he was attacked in his house, and a servant of the duke of Guise, generally known as Besme, murdered him and threw the body from a window into the courtyard at his master's feet. His papers were seized and burned by the queen-mother; among them, according to Brantôme, was a history of the Civil War, "très-beau et très-bien faict, et digne d'estre imprimé." His correspondence was edited in 1858 by Bourquelot.

By his wife, Charlotte de Laval, Coligny had several children, among them being Louise, who married first Charles de Téligny and afterwards William the Silent, prince of Orange, and Francis, admiral of Guienne, who was one of the devoted servants of Henry IV. Gaspard de Coligny (1584–1646), son of Francis, was marshal of France during the reign of Louis XIII.

See L. J. Delaborde, *Gaspard de Coligny* (1879–82); Erich Marcks, *Gaspard von Coligny, sein Leben und das Frankreich seiner Zeit* (Stuttgart, 1892); H. Patry, "Coligny et la Papauté," in the *Bulletin du protestantisme français* (1902); A. W. Whitehead, *Gaspard de Coligny, Admiral of France* (1904); and C. Merki, *L'Amiral de Coligny* (1909).

COLIIDAE: *see* COLY.

COLIJN, HENDRICK (1869–1944), Dutch politician, was born at Haarlemmer Meer, the Netherlands. After serving as a government official in the Netherlands Indies he returned to the Netherlands in 1909 and became a member of the Second Chamber. From 1911 to 1913 he was minister for war. In 1914 he became manager of the Batavian Oil Co., and from 1919 to 1922 was managing director of the Asiatic Petroleum Co. and director of the Royal Dutch Shell and Anglo-Saxon companies. In 1922, after the death of Abraham Kuyper, Colijn led the anti-revolutionary party. He was minister of finance in 1923, retaining this portfolio in the short-lived cabinet formed by him in 1925. He became prime minister and minister for the colonies in 1933. Also in 1933 he was chairman of the World Economic conference in London. Colijn was imprisoned by the Germans in World War II. His death was reported Sept. 16, 1944.

COLIMA, a small Pacific coast state of Mexico, lying between Jalisco on the N.W. and N., and Michoacan on the E. Including the Revilla Gigédo islands its area is only 2,009 sq.mi., which thus makes it the second smallest of the Mexican states. Pop. (1940) 78,806. The larger part of its territory is within the narrow, flat coastal plain, beyond which it rises toward the northeast into the foothills of the Sierra Madre, the higher masses of the range, including the Colima volcano, lying outside the state. It is drained by the Ameria and Coahuayana rivers and their affluents, which are largely used for irrigation. There are tidewater lagoons and morasses on the coast which accentuate its malarious character. One of the largest of these, Cuitlán, immediately south of Manzanillo, is the centre of a large salt-producing industry.

The soil is generally fertile and productive, but lack of transportation facilities has been a serious obstacle to any production greatly exceeding local demands. The dry and rainy seasons are sharply defined. The climate is hot, humid and malarious, becoming drier and more healthful on the higher mountain slopes of the interior.

Stock raising is an important industry in the higher parts of the state, but the horses, mules and cattle raised have been limited to local demands. Agriculture, however, is the principal occupation of the state, the more important products being sugar, rice, Indian corn, palm oil and coffee. The "Caracolillo" coffee, produced on the slopes of the mountains culminating in the volcano of Colima, is reputed the best in Mexico.

There are important mineral deposits in the state, including iron, copper and lead. Palm-leaf hats, hides and deerskins are exported in large quantities. A narrow-gauge railway had been in operation between the capital and Manzanillo for many years, and in 1907 a branch of the Mexican Central was completed between Guadalajara and the capital, and the narrow-gauge line to the coast was widened to the standard gauge. The capital of the state is Colima, pop. (1940) 22,601; other cities, with 1940 populations are Manzanillo (6,831); Tecomán (3,295); and Comala, 5 mi. from the capital (2,842).

COLIMA, a city of Mexico and capital of a state of the same name, 570 mi. (direct) W. by S. of Mexico City and about 36 mi. inland from the Pacific coast. Pop. (1940) 22,601. Colima is picturesquely situated on the Colima river, in a large fertile valley about 1,650 ft. above the sea, and lies in the midst of fine mountain scenery. About 30 mi. to the northeast the volcano of Colima, in the state of Jalisco, rises to an elevation of 12,685 ft.; it is the most westerly of the active volcanoes of Mexico. Colima enjoys a moderately cool and healthful climate, especially in the dry season (November to June). The city is regularly laid out and is in great part well built, with good public buildings, several churches, a theatre, two hospitals and a handsome market, completed in 1905. Tramways connect the central *plaza* with the railway station, cemetery, and the suburb of Villa de Alvarez, 2½ mi. distant. The local industries include cotton mills, an ice plant, corn-grinding mill and cigarette factories. The city is on the line of the Mexican National railway which connects Guadalajara with the port of Manzanillo. Colima was founded in 1522 by Gonzalo de Sandoval. It has not played a very prominent part in Mexican history because of its inaccessibility, and for the same reason has suffered less from revolutionary violence.

COLIN, ALEXANDRE (1526–1612), Flemish sculptor, was born at Malines. In 1563 he went, at the invitation of the Emperor Ferdinand I., to Innsbruck, to work on the magnificent monument which was being erected to Maximilian I. in the nave of the Franciscan church. Of the 24 marble alti-rilievi, representing the emperor's principal acts and victories, which adorn the sides of this tomb, 20 were executed by Colin, apparently in three years.

Colin, who was sculptor in ordinary both to the emperor and to his son, the Archduke Ferdinand of Tirol, did a great deal of work for his patrons at Innsbruck and in its neighbourhood, including the sepulchres of the archduke and his first wife, Philippine Welser, both in the same church as the Maximilian monument, and of Bishop Jean Nas.

COLISEUM: *see* COLOSSEUM.

COLL ISLAND: *see* HEBRIDES.

COLLAERT, HANS, Flemish engraver, son of Adrian Collaert, a draughtsman and engraver of repute, was born at Antwerp about 1545. After working some years in his father's studio, he went to Rome to perfect himself in his art. His engravings after Rubens are very highly esteemed. He left many works: among the best may be mentioned a "Life of St. Francis," 16 prints; a "Last Judgment," folio; "Monilium, Bullarum, Inauriumque Artificiosissimae Icones," 10 prints (1581); "The Dead Christ in his Mother's Lap"; "Marcus Curtius"; "Moses Striking the Rock," and "The Resurrection of Lazarus," after Lambert Lombard; "The Fathers of the Desert"; and "Biblia Sacra and the History of the Church," after Rubens.

COLLAPSE: *see* SHOCK AND COLLAPSE.

COLLAR, something worn or fastened round the neck, particularly a band of linen, lace or other material, which, under various shapes at different periods, has been worn by men and women to serve as a completion or finish to the neckband of a garment (*see* DRESS); also a chain, worn as a personal ornament, a badge of livery, a symbol of office or as part of the insignia of an order of knighthood, an application of the term with which the present article deals. The word is also applied to that part of the draught-harness of a horse which fits over the animal's neck, to which the traces are attached, and against which the strain of the drawing of the vehicle is exercised, and to a circular piece of metal passed round the joints of a rod or pipe, to prevent movement or to make the joint steam- or water-tight.

Necklaces with beads and jewels threaded thereon or the plain laces with a hanging ornament are among the common braveries of all times and countries. From these come the collar and the neck-chain. Torques or twisted collars of metal are found in burying-places of the barbarous people of northern Europe. British chiefs wore them, and gold torques were around the necks of the leaders of the first of the Saxon invaders of Britain, among whose descendants, however, the fashion seems to have languished. Edward the Confessor was buried with a neck-chain of gold 2ft. long, fastened with a jewelled locket and carrying an enamelled crucifix.

The extravagant age of Richard II. saw a great revival of the neck-chain, heavy links twisted of gold or silver. From this time onward neck chains, with or without pendant devices, were commonly worn by men and women of the richer sort. The men abandoned them in the time of Charles I.

Closely allied to the chain are the livery collars which appeared in the 14th century, worn by those who thus displayed their alliances or their fealty. Thus Charles V. of France in 1378 granted to his chamberlain Geoffrey de Belleville the right of bearing in all feasts and in all companies the collar of the *Cosse de Geneste* or Broomcod, a collar which was accepted and worn even by the English kings, Charles VI. sending such collars to Richard II. and to his three uncles. This French collar, a chain of couples of broom-cods linked by jewels, is seen in the contemporary portrait of Richard II. at Wilton. The like collar was worn by Henry IV. on the way to his crowning. Livery collars of the king of France, of Queen Anne and of the dukes of York and Lancaster are numbered with the royal plate and jewels which in the first year of Henry IV. had come to the king's hands. The inventory shows that Queen Anne's collar was made up of sprigs of rosemary garnished with pearls. The York collar had falcons and fetter-locks, and the Lancaster collar was doubtless that collar of Esses (or SS) used by the duke's son, Henry of Bolingbroke, as an earl, duke and king. This famous livery collar, which has never passed out of use, takes many forms, its Esses being sometimes linked together chainwise, and sometimes, in early examples, bestowed as the ornamental bosses of a garter-shaped strap-collar. The oldest effigy bearing it is that in Spratton church of Sir John Swinford (d. 1371). Swinford was a follower of John of Gaunt, and the date of his death easily disposes of the fancy that the Esses were devised by Henry IV. to stand for his motto or "word" of *Soverayne.* Many explanations are given of the origin of these letters, but none has as yet been established with sufficient proof. During the reigns of Henry IV., his son and grandson, the collar of Esses was a royal badge of the Lancastrian house and party, the white swan being its pendant. In one of Henry VI.'s own collars the S was joined to the Broomcod of the French device, thus symbolizing the king's claim to the two kingdoms.

The kings of the house of York and their chief followers wore the Yorkist collar of suns and roses, with the white lion of March, the Clare bull or Richard's white boar for a pendant device. Henry VII. brought back the collar of Esses, a portcullis or a rose hanging from it, although in a portrait of this king, now possessed by the Society of Antiquaries, his neck bears the *rose en soleil* alternating with knots, and his son, when young, had a collar of roses red and white. Besides these royal collars, the 14th and 15th centuries show many of private devices. A brass at Mildenhall shows a knight whose badge of a dog or wolf circled by a crown hangs from a collar with edges suggesting a pruned bough or the ragged staff. Thomas of Markenfield (d. *c.* 1415) on his effigy has a strange collar of park palings with a badge of a hart in a park, and the Lord Berkeley (d. 1392) wears one set with mermaids.

Collars of various devices are now worn by the grand crosses of the European orders of knighthood. The custom was begun by Philip of Burgundy, who gave his knights of the Golden Fleece, an order founded on Feb. 10, 1429–30, badges of a golden fleece hung from that collar of flints, steels and sparks which is seen in so many old Flemish portraits. To this day it remains the most beautiful of all the collars, keeping in the main the lines of its Flemish designer, although a vulgar fancy sometimes destroys the symbolism of the golden fleece by changing it for an unmeaning fleece of diamonds. Following this new fashion, Louis XI. of France, when instituting his order of St. Michael in 1469, gave the knights collars of scallop shells linked on a chain. The chain was doubled by Charles VIII., and the pattern suffered other changes before the order lapsed in 1830. Until the reign of Henry VIII., the Garter, most ancient of the great knightly orders, had no collar. But the Tudor king must needs match in all things with Continental sovereigns, and the present collar of the Garter knights, with its golden knots and its buckled garters enclosing white roses set on red roses, has its origin in the Tudor age. The collar of the Thistle with the thistles and rue-sprigs is as old as the reign of James II. The Bath collar, in its first form of white knots linking closed crowns to roses and thistles issuing from sceptres, dates from 1725, up to which time the knights of the Bath had hung their medallion from a ribbon. (*See* KNIGHTHOOD AND CHIVALRY.)

Founding the order of the Saint Esprit in 1578, Henry III. of France devised a collar of enflamed fleur-de-lis and cyphers of H and L, a fashion which was soon afterwards varied by Henry his successor. Elephants have been always borne on the collar of the Elephant founded in Denmark in 1478, the other links of which have taken many shapes. Another Danish order, the Dan-ne-brog, said to be "re-instituted" by Christian V. in 1671, has a collar of crosses formy alternating with the crowned letters C and W, the latter standing for Waldemar the Victorious, whom a legend of no value described as founding the order in 1219. Of other European orders, that of St Andrew, founded by Peter of Russia in 1698, had eagles and Andrew crosses and cyphers, while the Black Eagle of Prussia had the Prussian eagle with thunderbolts in its claws beside roundels charged with ciphers of the letters F.R.

Plain collars of Esses are now worn in Great Britain by kings-of-arms, heralds and serjeants-at-arms. Certain legal dignitaries have worn them since the 16th century, the collar of the lord chief-justice having knots and roses between the letters. Henry IV.'s parliament in his second year restricted the free use of the king's livery collar to his sons and to all dukes, earls, barons and bannerets, while simple knights and squires might use it when in the royal presence or in going to and from the hostel of the king. The giving of a livery collar by the king made a squire of a man even as the stroke of the royal sword made him a knight. Collars of Esses are sometimes seen on the necks of ladies.

Since 1545 the lord mayor of London has worn a royal livery collar of Esses. This collar, however, has its origin in no royal favour, Sir John Alen, thrice a lord mayor, having bequeathed it to the then lord mayor and his successors "to use and occupie yerely at and uppon principall and festivall dayes." It was enlarged in 1567, and in its present shape has 28 Esses alternating with knots and roses and joined with a portcullis. Lord mayors of York use a plain gold chain of a triple row of links given in 1670; this chain, since the day when certain links were found wanting, is weighed on its return by the outgoing mayor. In Ireland the lord mayor of Dublin wears a collar given by Charles II., while Cork's mayor has another which the Cork council bought of a silversmith in 1755, stipulating that it should be like the Dublin one. The lady mayoress of York wears a plain chain given with that of the lord mayor in 1670, and, like his, weighed on its return to official keeping. For some 230 years the mayoress of Kingston-on-Hull enjoyed a like ornament until a thrifty council in 1835 sold her chain as a useless thing. (O. B.; X.)

COLLARDS or **COLLARD,** (*Brassica oleracea* form *acephala*) bears the same botanical name as kale, from which it differs only in leaf characters. The leaves are like those of common cabbage, forming a large, prolific rosette like a cabbage plant that is approaching the formation of a head, but never forming a true head. Even when fully grown the plants may be left unprotected in the garden, through the winter, in the southern half of the United States. The larger leaves may be removed for use singly as the stem elongates, or the entire rosette may be harvested. The plant is a prolific source of nutritionally important minerals, and vitamins A and C. It is widely adapted, easily grown, and is probably the least exacting of any of the Crucifers in its requirements for successful seed production. Seed is sown in August or September and the plants thinned to stand about 1 ft. apart in rows 2 to 3 ft. apart. (*See* CABBAGE.) (V. R. B.)

COLLATERAL, a term used in law in several senses. *Collateral relationship* means the relationship between persons who are descended from the same stock or ancestor, but in a different line; as opposed to *lineal,* which is the relationship between ascendants and descendants in a direct line, as between father and son, grandfather and grandson. A *collateral agreement* is an agreement made contemporaneously with a written contract as part of the transaction, but without being incorporated with it. *Collateral facts,* in evidence, are those facts which do not bear directly on the matters in dispute. *Collateral security* is an additional security for the safety of the mortgagee, *e.g.,* a deed of guaranty, or property deposited, to secure the fulfilment of an obligation.

Collateral, in banking is the security which a borrower gives over to a lender as a pledge to guarantee the payment of the debt. If the debt is paid when and as agreed upon, the collateral is returned to the borrower but if default in payment is made the lender has the right to sell the collateral and from the proceeds retain the amount due for principal and interest, returning the remainder, if any, to the borrower. Almost any kind of property which is saleable may be used as collateral but as a matter of practice only certain types are generally acceptable to the lending banks.

The "financial type" of collateral is one of the greatest in importance. Certificates of stock in business corporations are accepted as collateral if they are marketable and give evidence that they will remain so till the expiration of the time of the loan. Corporate, municipal or government bonds are acceptable if they are sound and marketable. Securities which are listed on the Stock Exchange are much preferred as collateral over unlisted and outside market securities because of their exceptional marketability. The borrower usually has the privilege of substituting other collateral for that already pledged provided the new collateral is satisfactory to the lender. This privilege of exchanging collateral is especially important and necessary in the case of the investment banker who is constantly buying and selling and thus changing his securities, and in the case of the stock-broker who is continuously dealing for his clients. The "merchandise type" of collateral consists of negotiable warehouse receipts, negotiable bills of lading and trust receipts. Other collateral may be classed as "personal type," under which are included deeds, deeds of trust, mortgages, leases and similar rights in good real estate; deeds, deeds of trust, bills of sale and similar rights in movable goods capable of transfer, such as portable machinery, furniture, livestock, crops and many similar things. Savings bank pass-books, which serve as vouchers or receipts for deposits made, and without the presentation of which withdrawals cannot be made, are often assigned to a bank as collateral for loans. Banks will demand that the market value of the collateral exceed the amount of the loan so as to safeguard the bank in case of possible shrinkage of the value of the collateral. The excess margin usually required is about 20%, and when, through decrease in value of collateral, it falls below this percentage the bank can, under its customary agreement, require the borrower to deposit additional collateral equal in value to the decline, or to pay off a part of the loan so that the present collateral will again supply the required margin. On a large loan bankers demand "mixed collateral," consisting probably of railroad, industrial and other securities, rather than "straight collateral," consisting of securities of only one class. Likewise they do not grant too many small loans, each secured by the same type of collateral. Extremely high-priced stocks with wide market fluctuations are not considered desirable. Odd lots, *i.e.,* batches of less than 100 shares of any stock, are unpopular because they are harder to keep track of and rather troublesome to market if a sale becomes necessary. Where corporate securities are used as collateral they should be conservative, rather than speculative issues; active on the market rather than inactive; and should have good delivery, that is, be negotiable in form and indorsed in blank by the borrower. Property other than securities is not acceptable unless it has a determinable value and a potential market.

COLLATIA, an ancient town of Latium, 10m. E. by N. of Rome, by the Via Collatina. Later it became a mere village. It is the legendary scene of the rape of Lucretia. The site is on the hill now occupied by the large mediaeval fortified farmhouse of Lunghezza, immediately south of the Anio.

COLLATION, the bringing together of things for the purpose of comparison, and thus the critical examination of the texts of documents or mss. (Lat. *collatio* from *conferre,* to bring together or compare); also used in printing and bookbinding for the register of the "signatures," the number of quires and leaves in each quire of a book or ms. In Roman and Scots law "collation" answers to the English law term "hotch-pot" (*q.v.*). From another meaning of the Latin word, a consultation or conference, and so a treatise, comes the title of a work of Johannes Cassianus (*q.v.*), the *Conferences of the Fathers* (*Collationes Patrum*). Readings from such works were customary in monasteries. By the rule of St. Benedict it is ordered that after supper *collationes,* passages from the lives of the Fathers, etc., should be read. On fast days it was usual in monasteries to have a light meal after the *Collatio,* hence the meal itself came to be called "collation," a term now used of any light repast.

COLLÉ, CHARLES (1709–1783), French dramatist and song-writer, the son of a notary, was born in Paris. In 1729 he became a member of the famous "Caveau," which numbered among its members Helvétius, Charles Duclos, Pierre Joseph Bernard, called Gentil-Bernard, Jean Philippe Rameau, Alexis Piron and the two Crébillons. The society was dissolved in 1739, and was not reconstituted till 20 years afterwards. His first comedy, *La Vérité dans le vin,* appeared in 1747. The greater part of his genre pieces, *Théâtre de Société* (3 vols., 1777) were composed for the regent, Orleans, who was a good comedy actor, especially in low life parts. In 1774 appeared *La Partie de chasse de Henri Quatre* (partly taken from Dodsley's *King and the Miller of Mansfield*), Collé's last and best play. From 1748 to 1772, besides these and a multitude of songs, Collé was writing his *Journal,* a curious collection of literary and personal strictures on his boon companions as well as on their enemies, on Piron as on Voltaire, on La Harpe as on Corneille. The subjects of his lyrics are love and wine; occasionally, however, as in the famous lyric (1756) on the capture of Port Mahon, for which the author received a pension, the note of patriotism is struck.

See H. Bonhomme's edition (1868) of the *Journal et Mémoires* (1748–72); Grimm's *Correspondance;* and C. A. Sainte-Beuve, *Nouveaux lundis,* vol. vii.

COLLECTIVISM, a theory that society and industry should be based upon the collective, or national, ownership of land and capital, *i.e.,* of the means of production, distribution and exchange. Under such a system, the private ownership of capital would be abolished, but private property in personal goods would remain. Thus, the cotton-mills would be owned collectively by the nation, and the products of the cotton mills would be dealt in collectively by the nation, but the consumer who bought the collectively produced cotton products would own them as his inalienable personal property. Collectivism is thus not the common ownership of wealth, but the common ownership of the means of producing wealth. For a full discussion of the points involved *see* SOCIALISM.

COLLECTOR, a term used for various officials, and particularly in India for the chief administrative official of a district. The title is confined to the regulation provinces; in the non-regulation provinces the same duties are discharged by the deputy-commissioner (*see* COMMISSIONER).

COLLEGE (*Collegium*), in Roman law, a number of persons associated together by the possession of common functions—a body of colleagues; in many respects the collegium was what we should now call a corporation (*q.v.*). Collegia might exist for purposes of trade like the English gilds, or for religious purposes (*e.g.,* the college of augurs, etc.), or for political purposes; *e.g., tribunorum plebis collegia.* By the Roman law a collegium must have at least three members. The name is now usually applied to educational corporations, such as the colleges of Oxford and Cambridge, with which, in the numerous English statutes relating to colleges, the colleges of Winchester and Eton are usually associated. These colleges are in the eye of the law eleemosynary corporations. In some of the earlier statutes of Elizabeth they are spoken of as having an ecclesiastical character, but the doctrine of the common law since the Reformation has been that they are purely lay corporations, notwithstanding that most or all of their members may be persons in priest's orders.

Colleges appear to have grown out of the voluntary association of students and teachers at the university. According to some accounts these must at one time have been numerous and flourishing beyond anything we are now acquainted with. We are told, for example, of 300 halls or societies at Oxford, and 30,000 students. In early times there seems to have been a strong desire to confine the scholars to certain licensed houses beyond the influence of the townspeople. Men of wealth and culture, and notably the political bishops and chancellors of England, obtained charters from the Crown for the incorporation of societies of scholars, and these in time became exclusively the places of abode for students attending the university. At the same time the corporations thus founded were not necessarily attached to the locality of the university. The early statutes of Merton college, for example, allow the residence of the college to be shifted as occasion required; and the foundations of Wolsey at Oxford and Ipswich seem to have been the same in intention. In later times (until the introduction of non-collegiate students) the university and the colleges became coextensive; every member of the university had to attach himself to some college or hall, and every person admitted to a college or hall was obliged to matriculate himself in the university.

The fellowships, scholarships, etc., of colleges were until a comparatively recent date subject to various restrictions. Birth in a particular county, education at a particular school, relationship to the founder and holy orders, are amongst the most usual of the conditions giving a preferential or conclusive claim to the emoluments. Most of these restrictions have been swept away.

The American college has no exact counterpart in the educational system of other countries. It was developed from the European systems and particularly from the British Universities. While the older colleges such as Harvard, Princeton and Yale are in primary form of organization quite similar to the Universities of Oxford and Cambridge, the representative American college is an institution with adaptations widely different from the older schools. The three commonly accepted divisions of education in the United States, primary, secondary and higher stages, are fully recognized but are not rigorously followed. The typical American college is a composite institution, in part secondary and in part higher in its organization. It normally consists of a four-year course of study leading to a bachelor's degree. The many tendencies at present existing in American institutions of higher education are discussed under UNIVERSITIES; EDUCATION; SCHOOLS.

The term "college" (like "academy") is also applied to various institutions; *e.g.,* to colleges of physicians and surgeons, and to the electoral college in the United States presidential elections, etc.

For the Sacred College, *see* CARDINAL.

COL LEGNO (It.), "with the wood," a direction in music signifying that the notes so marked are to be played, not in the usual way, but by striking the strings with the stick of the bow.

COLLEONI, BARTOLOMMEO (1400–1475), Italian soldier of fortune, served the Venetian republic for many years under Gonzaga and Francesco Sforza. He defeated the Milanese at the battles of Brescia, Verona and on Lake Garda. He transferred his services to the Milanese in 1443, but the suspicious nature of Visconti was awakened by his conduct, and he was imprisoned at Monza until the duke died in 1447. He left the Milanese service in 1448, and returned to that of Venice; but dissatisfied at not having been appointed captain-general he again entered the Milanese service.

The offer of increased pay brought him back once more to Venice, and in 1455 he was appointed captain-general for life. He died in 1475.

BIBLIOGRAPHY.—For an account of Colleoni's wars, S. Romanin, *Storia documentata di Venezia* vol. iv. (Venice, 1855), and other histories of Venice; *see* also G. M. Bonomi, *Il Castello di Caverrago e i conti Martinengo Colleoni* (Bergamo, 1884); O. Browning, *Life of Bartolommeo Colleoni* (1891); B. Belotti, *La Vita di Bartolommeo Colleoni* (Bergamo, 1923).

COLLETTA, PIETRO (1775–1831), Neapolitan general and historian, served in the Neapolitan artillery against the French in 1798. He adhered to the Parthenopean republic, and on the surrender of Naples was imprisoned, but, more fortunate than many of his comrades, he was pardoned. When Joseph Bonaparte seized the Neapolitan throne in 1806, Colletta was reinstated in his rank and in 1812 he was promoted general. On the return of Ferdinand, Colletta not only retained his rank, but was given command of a division. When the revolution broke out in 1820, Colletta put down the separatist movement in Sicily with great severity. On the re-establishment of autocracy (1821) he was exiled to Brunn in Moravia, but two years later he returned to Florence, where he wrote his *Storia del reame di Napoli* (1st ed. Capolago, 1834). This work, which deals with the period 1734–1825, is still the standard history of the subject, despite its manifest bias.

See Gino Capponi's memoir in *Storia del reame di Napoli* (2nd ed. Florence, 1848).

COLLEY, SIR GEORGE POMEROY (1835–1881), British general, third son of George Pomeroy Colley, of Rathangan, Co. Kildare, Ireland, was born on Nov. 1, 1835. Entering the 2nd Queen's Regiment in 1852, he served in South Africa (1854–60), and in the Anglo-French expedition to China (1860). In 1870 he went to the War Office to assist in the preparation of Lord Cardwell's measures of army reform, and in 1871 was appointed professor of military administration at the Staff college. Joining Sir Garnet Wolseley at the Gold Coast in 1873, he took charge of the transport in the Ashanti expedition. On his return from Natal where he had accompanied Wolseley in 1875 he was appointed military secretary, and in 1877 private secretary, to Lord Lytton, governor-general of India. In 1879 he joined Wolseley as chief of the staff and brigadier-general in south-east Africa, but on the murder of Cavagnari at Kabul, returned to India. In 1880 he succeeded Wolseley in south-east Africa as high commissioner, and conducted the operations against the rebel Boers. Defeated at Laing's Nek and at the Ingogo river, he was killed at Majuba hill on Feb. 27, 1881.

See W. F. Butler, *Life of Sir George Pomeroy Colley* (1899).

COLLIER, ARTHUR (1680–1732), English philosopher, was born at the rectory of Steeple Langford, Wiltshire, and educated at Oxford. In 1704 he was presented to the family living of Langford Magna and held it to his death. His philosophical opinions grew out of a diligent study of Descartes and Malebranche. He makes no reference to Locke, and shows no knowledge of his works. His chief work appeared in 1713, under the title *Clavis Universalis,* or a *New Inquiry after Truth,* being a *Demonstration of the Non-Existence or Impossibility of an External World* (printed privately, Edinburgh, 1836, and reprinted in *Metaphysical Tracts* [1837] edited by Sam. Parr).

His views are grounded on two presuppositions: first, the utter aversion of common sense to any theory of representative perception; second, the opinion shared with Berkeley, that the difference between imagination and sense perception is only one of degree. The former is the basis of the negative part of his argument; the latter supplies him with all the positive account he has to give, and that is meagre enough. The *Clavis* consists of two parts. After explaining that he will use the term "external world" in the sense of absolute, self-existent, independent matter, he attempts in the first part to prove that the visible world is not external, by showing—first, that the seeming externality of a visible object is no proof of real externality; and second, that a visible object, as such, is not external. The second part of the book is taken up with a number of metaphysical arguments to prove the impossibility of an external world. From the hypothesis of an external world a series of contradictions are deduced, such as that the world is both finite and infinite, is movable and immovable, etc.; and finally, Aristotle and various other philosophers are quoted, to show that the external matter they dealt with, as mere potentiality, is just nothing at all. As cause of our sensations and ground of our belief in externality, Collier substituted for an unintelligible material substance an equally unintelligible operation of divine power. In philosophy he is a curiosity, and nothing more.

In theology Collier was an adherent of the High Church party, though his views were by no means orthodox. In the Jacobite *Mist's Journal* he attacked Bishop Hoadly's defence of sincere errors. His views on the problems of Arianism, and his attempt to reconcile it with orthodox theology, are contained in *A Specimen of True Philosophy* (1730, reprinted in *Metaphysical Tracts,* 1837) and *Logology, or a Treatise on the Logos in Seven Sermons on John i.* 1, 2, 3, 14 (1732, analysed in *Metaph. Tracts*). These may be compared with Berkeley's *Siris.*

See Robt. Benson, *Memoirs of the Life and Writings of Arthur Collier* (1837); Sir W. Hamilton, *Discussions* (1852); A. C. Fraser, ed. of *Berkeley's Works* (1871); G. Lyon, "Un Idealiste anglais au XVIIIe siècle," in *Rev. philos.* (1880), x. 375.

COLLIER, JEREMY (1650–1726), English nonjuring divine, was born at Stow-with-Quy, Cambridgeshire, on Sept. 23 1650. He was educated at Ipswich free school, of which his father was master, and at Caius college, Cambridge, He was appointed in 1679 to the small rectory of Ampton, near Bury St. Edmunds, and in 1685 he was made lecturer of Gray's Inn. He was a nonjuror, and at the Revolution he was sent to Newgate for writing in favour of James II. a tract entitled *The Desertion discuss'd in a Letter to a Country Gentleman* (1688), in answer to Bishop Burnet's defence of King William's position. He was released after some months of imprisonment, without trial, but in 1692 he was again in prison under suspicion of treasonable correspondence with James. His scruples forbade him to acknowledge the jurisdiction of the court by accepting bail, but he was soon released. In 1696 for his boldness in granting absolution on the scaffold to Sir John Friend and Sir William Parkyns, who had attempted to assassinate William, he was obliged to flee, and for the rest of his life continued under sentence of outlawry.

When the storm had blown over, he returned to London. In 1697 appeared the first volume of his *Essays on Several Moral Subjects,* to which a second was added in 1705, and a third in 1709. In 1698 Collier produced his famous *Short View of the Immorality and Profaneness of the English Stage. . . .* He attacked the immorality of the contemporary stage, supporting his contentions by references to the comparative decency of Latin and Greek drama, the profane language of the plays, the abuse of the clergy common in the drama, the encouragement of vice by representing the vicious characters as admirable and successful; and supported his general position by the analysis of particular plays, Dryden's *Amphitryon,* Vanbrugh's *Relapse* and D'Urfey's *Don Quixote.* Collier had no artistic appreciation of the subject he discussed, and he mistook cause for effect in asserting that the decline in public morality was the result of the flagrant indecency of the stage. He owed a good deal to Thomas Rymer's *Tragedies of the Lost Age* printed 20 years before. Dryden contented himself with protesting against Collier's insolence; but Congreve made an angry reply; Vanbrugh and others followed. Collier defended himself in numerous tracts: a *Defence* (1699), a *Second Defence* (1700), and *Mr. Collier's Dissuasive from the Playhouse, in a Letter to a Person of Quality* (1703), and a *Further Vindication* (1708). The fight lasted in all about ten years. The actual effect on the stage of Collier's onslaught has been much exaggerated by historians. The dramatists were incensed, but they did not mend their ways.

From 1701 to 1721 Collier was employed on his *Great Historical, Geographical, Genealogical, and Poetical Dictionary,* founded on, and partly translated from, Louis Moréri's *Dictionnaire historique,* and in the compilation and issue of the two volumes folio of his own *Ecclesiastical History of Great Britain from the first planting of Christianity to the end of the reign of Charles II.* (1708–14). The latter work was attacked by Burnet and others, but the author showed himself as keen a controversialist as ever. Many attempts were made to shake his fidelity to the lost cause of the Stuarts, but he continued indomitable to the end. In 1712 George Hickes was the only survivor of the nonjuring bishops, and in the next year Collier was consecrated. He had a share in an attempt made towards union with the Greek Church. He had a long correspondence with the Orthodox authorities, his last letters on the subject being written in 1725. Collier preferred the version of the *Book of Common Prayer* issued in 1549, and regretted that certain practices and petitions there enjoined were omitted in later editions. His first tract on the subject, *Reasons for Restoring some Prayers* (1717), was followed by others. In 1718 was published a new *Communion Office taken partly from Primitive Liturgies and partly from the first English Reformed Common Prayer Book . . .* which embodied the changes desired by Collier. The controversy that ensued made a split in the nonjuring communion. His last work was a volume of *Practical Discourses,* published in 1725. He died April 26 1726.

Bibliography.—There is an excellent account of Collier in A. Kippis's *Biographia Britannica,* vol. iv. (1789), where some sensible observations by the editor are added to the original biography. A full list of Collier's writings is given by the Rev. William Hunt in the article in the *Dictionary of National Biography.* For particulars of Collier's history as a nonjuring bishop, *see* Thomas Lathbury, *A History of the Nonjurors . . .* (1845). There is an excellent account of the *Short View* and the controversy arising from it in A. Beljame's *Le Public et les hommes de lettres en Angleterre au XVIIIe siècle* (2nd ed., 1897), pp. 244–263.

COLLIER, HON. JOHN (1850–1934), British painter, son of the 1st Lord Monkswell, was born in London on Jan. 27, 1850, and educated at Eton. He studied painting at the Slade school, London, and in Paris, Heidelberg and Munich. He enjoyed great popularity with the public as a painter of what were styled "problem pictures" or pictures depicting some highly dramatic incident; but his best work was done in portraiture. His portraits include "His Majesty the King when Duke of York" (1901), "Professor E. Ray Lankester" (1906), "Professor Huxley" (1891) and "H. Pelissier" (1909).

COLLIER, JOHN PAYNE (1789–1883), English Shakespearian critic, was born in London, on Jan. 11, 1789. The son of a journalist, he was on the staff of the *Morning Chronicle* and then of *The Times* for some time. He entered the Middle Temple in 1811, but was not called to the bar until 1829. The delay was partly due to his indiscretion in publishing the *Criticisms on the Bar* (1819) by "Amicus Curiae." Collier's first important work for the English drama was a new edition of Dodsley's *Old Plays* (1825–27), and a supplementary volume, *Five Old Plays* (1833). In 1831 appeared his *History of English Dramatic Poetry and Annals of the Stage to the Restoration.* He then became librarian to the duke of Devonshire, and gained access to the chief collections of early English literature throughout the kingdom, especially to the treasures of Bridgewater House. From 1835 to 1839 he published *New Facts, New Particulars and Further Particulars* respecting Shakespeare, and in 1852 the famous *Perkins Folio,* a copy of the second folio (1632), so-called from a name written on the title page. On this book were numerous Ms. emendations of Shakespeare said by Collier to be from the hand of "an old corrector." He published these corrections as *Notes and Emendations to the Text of Shakespeare* (1852), and incorporated them in his edition (1853) of Shakespeare. Their authenticity was disputed by S. W. Singer in *The Text of Shakespeare Vindicated* (1853) and by E. A. Brae in *Literary Cookery* (1855) on internal evidence; and when in 1859 the folio was submitted by its owner, the duke of Devonshire, to experts at the British museum, the emendations were incontestably proved to be forgeries of modern date. Collier was exposed by Mr. Nicholas Hamilton in his *Inquiry* (1860). The point whether he was deceiver or deceived was left undecided, but the falsifications of which he was unquestionably guilty among the Mss. at Dulwich college have left little doubt. He forged the name of Shakespeare in a genuine letter at Dulwich, and the spurious entries in Edward Alleyn's *Diary* were proved to be by Collier's hand when the sale of his library in 1884 gave access to a transcript he had made of the *Diary* with interlineations corresponding with the Dulwich forgeries. No statement of his can be accepted without verification, and no manuscript he has handled without careful examination, but he did much useful work. He compiled a valuable *Bibliographical and Critical Account of the Rarest Books in the English Language* (1865); he reprinted a great number of early English tracts of extreme rarity. His *Old Man's Diary* (1871–72) is an interesting record. He died at Maidenhead on Sept. 17, 1883.

For an account of the discussion raised by Collier's emendations *see* C. M. Ingleby, *Complete View of the Shakespeare Controversy* (1861). *See* also H. B. Wheatley, *Life of J. P. Collier* (London, 1884).

COLLIER: see HEWER.

COLLIMATOR, a lens (*q.v.*) placed at a distance equal to its focal length from the luminous object under examination; the rays proceeding from the lens are thus rendered parallel, which is equivalent to the removal of the luminous object under examination to an infinite distance, without the loss of light intensity which such a procedure entails.

In measurements in geometrical and physical optics and spectroscopy (*q.v.*) certain technical advantages require this collimation of the light. In these cases the collimator is usually a telescope with a slit at the principal focal length from the lens. Light from the luminous source is focused on this slit by a lens of similar focal length and the slit then serves as the luminous object of the optical system.

COLLIN, HEINRICH JOSEPH VON (1771–1811), Austrian dramatist, was born in Vienna on Dec. 26, 1771. In 1805 and in 1809, when Austria was under the heel of Napoleon, Collin, who was a civil servant, was entrusted with important political missions. He died on July 28, 1811. His tragedy, *Regulus* (1801), was written in strict classical form in conformity with French taste. But in his later dramas, *Coriolan* (1804), the overture to which was composed by Beethoven, *Polyxena* (1804), *Balboa* (1806), *Bianca della Porta* (1808), he made some attempt to reconcile the pseudo-classic type of tragedy with that of Shakespeare and the German romanticists. As a lyric poet (*Gedichte,* collected 1812), Collin has left a collection of stirring *Wehrmannslieder* for the fighters in the cause of Austrian freedom, as well as some excellent ballads (*Kaiser Max auf der Martinswand, Herzog Leupold vor Solothurn*). His younger brother Matthaüs von Collin (1779–1824) was in sympathy with the Romantic movement, and as editor of the *Wiener Jahrbücher für Literatur,* was a potent force in the literary life of Vienna. His dramas on themes from Austrian national history (*Belas Krieg mit dem Vater,* 1808, *Der Tod Friedrichs des Streitbaren,* 1813) may be regarded as the precursors of Franz Grillparzer's historical tragedies.

H. J. von Collin's *Gesammelte Werke* appeared in 6 vols. (1812–14). *See* an excellent monograph by F. Laban (1879); also A. Hauffen, *Das Drama der klassischen Periode,* ii, 2 (1891).

Matthaüs von Collin's *Dramatische Dichtungen* were published in 4 vols. (1815–17); his *Nachgelassene Schriften,* edited by J. von Hammer, in 2 vols. (1827). A study of his life and work by J. Wihan will be found in *Euphorion,* Ergänzungsheft (1901).

COLLIN D'HARLEVILLE, JEAN FRANÇOIS (1755–1806), French dramatist, was born at Mévoisins, near Maintenon (Eure-et-Loire), on May 30, 1755. His best plays are *L'Optimiste, ou l'homme toujours content* (1788), and *Le Vieux Célibataire* (1793). Collin was one of the original members of the Institute of France, and died in Paris on Feb. 24, 1806.

The 1822 edition of his *Théâtre et poésies fugitives* contains a notice by his friend the dramatist Andrieux. His *Théâtre* was also edited by L. Moland in 1876; and by Édouard Thierry in 1882.

COLLING, ROBERT (1749–1820), and **CHARLES** (1751–1836), English stock breeders, famous for their improvement of the Shorthorn breed of cattle, were the sons of Charles Colling, a farmer of Ketton, near Darlington, where Charles continued to farm, while Robert took a farm at Barmpton. An animal which Robert bought on Charles' advice for £8 and afterward sold to his brother, became known as the celebrated "Hubback," a bull which formed the basis of both the Ketton and Barmpton herds. The two brothers pursued the same system of "in and in" breeding which they had learned from Robert Bakewell (*q.v.*), and both the Ketton and the Barmpton herds were sold by auction in the autumn of 1810. Robert Colling died at Barmpton on March 7, 1820. Charles Colling died on Jan. 16, 1836. (*See* AGRICULTURE: A GENERAL SURVEY; CATTLE.)

COLLINGS, JESSE (1831–1920), British politician, was born at Littleham, Exmouth, Devon, on Jan. 9, 1831. In 1866 he settled in Birmingham, where he was intimately associated with Joseph Chamberlain, and in 1878 was elected mayor of Birmingham. In 1880 he entered parliament as Liberal member for Ipswich, and became a famous advocate of the Radical land policy, associated with the phrase "three acres and a cow." In 1886 he became parliamentary secretary to the local government board, but resigned with Chamberlain over William Gladstone's home rule policy. In 1895 Collings became under-secretary to the home office, retaining the post till 1902. He resigned his seat in parliament in 1918, and died at Edgbaston on Nov. 20, 1920. He was the founder (1872) of the Rural Labourers' league. His works are: *Land Reform* (1906); *The Colonisation of Rural Britain* (1914, 2 vols.); and *Autobiography* (1920).

COLLINGSWOOD, a borough of Camden county (N.J.), U.S.A., 3 mi. S.E. of Camden on the Pennsylvania railroad. It has some manufactures, including loom works and printing, but is primarily a suburban residence town, with a population of 8,714 in 1920, and 12,685 (federal census) in 1940. A commission form of government was adopted in 1917.

COLLINGWOOD, CUTHBERT COLLINGWOOD, BARON (1750–1810), British naval commander, was born at Newcastle-on-Tyne on Sept. 26, 1750, educated at a grammar school, and when eleven years old was sent to sea in the frigate *Shannon* in the care of his cousin, Captain Braithwaite. He served for some years on the home station with this officer and also under Admiral Roddam. In 1774 he served on the North American station under Admiral Graves, and was in the naval brigade that saw service at the battle of Bunker's Hill, here winning his lieutenancy (June 17, 1775). In the following year he was lieutenant of the sloop *Hornet* in the West Indies, and thereafter began his close association with Nelson whose proximity generally seems to have inspired him to his most brilliant work. He followed Nelson as first lieutenant of the *Lowestoft,* as Commander of the *Badger,* and post-captain of the frigate *Hinchinbrook* (March 1780). Immediately afterwards he was one of those employed under Nelson in the San Juan expedition which failed owing to the appalling climate which killed nine-tenths of the personnel. After commanding another frigate and the *Sampson* Collingwood found himself again with Nelson in the West Indies, this time in the frigate *Mediator.* He remained there three years and was present during the quarrel between Nelson and the commander-in-chief concerning the severity with which the navigation laws ought to be enforced against the late American colonists, agreeing with Nelson, with whom he was by now on most intimate terms, that no leniency should be exercised.

In 1786 Collingwood returned home and, with the exception of one brief command, remained there till 1792, marrying in 1791 the grand-daughter of one of his old commanders, Admiral Roddam. On the outbreak of war, he was appointed Flag-Captain to Rear-Admiral Bowyer in the *Prince,* and with him he shifted to the *Barfleur* and took part in Howe's victory on the "Glorious 1st of June," 1794. In August 1795 he was appointed to the *Excellent* for his first experience of the Mediterranean station; he was engaged in the blockade of Toulon and took a conspicuous part in Jervis's great victory off St. Vincent (Feb. 1797). As Jervis pierced the Spanish line, the *Excellent* was the rearmost ship in his fleet and when Nelson had, without orders, taken his ship from the line to oppose the Spaniards that seemed likely to escape, it was to Collingwood that Jervis signalled orders to go to his friend's assistance. He and Nelson thus found themselves greatly outnumbered until other ships, in the ordinary course, arrived to help,—a situation offering scope for heroic deeds of which both took full advantage. The Spanish flight was held up and two ships struck to the *Excellent.* In 1799 Collingwood became Rear-Admiral, and he was at sea in the *Triumph* and other ships until the peace of Amiens gave him some respite.

On the renewal of war in 1803, Collingwood was at once employed, and he continued in active service until his death. He began in the Channel fleet under Cornwallis which was blockading Brest. He remained there until May 1805 (having in the meantime been promoted to Vice-Admiral in May 1804), when he was given command of a small squadron which was intended to reinforce the Mediterranean fleet under Nelson. He placed himself off Cadiz when Villeneuve, after his return from the West Indies, made that port, and there he was joined by Nelson, so becoming second-in-command at Trafalgar. In this battle he carried out brilliantly the part assigned to him by the commander-in-chief. With 15 ships he was to attack the rear 11 of the enemy, breaking through and fighting from to leeward so as to prevent their escape, Nelson with 12 ships undertaking that the enemy's van and centre should not interfere with him. Collingwood carried his detachment into action in line of bearing—his own contribution to the tactics of the battle—but, owing to the irregularity of the allied line, became engaged with 16, instead of 11, ships. As, however, he demolished them with ease, this was positively a gain. His own ship, the *Royal Sovereign,* being a very fast sailer, was in action some 20 minutes before the rest of his detachment, and was consequently surrounded by enemies, but she got free and caused the Spanish flagship to strike to her. On Nelson's death, the command passed to Collingwood, and he had the difficult task of conserving the fleet and its prizes during the storm which followed. For his services in the battle he was created Baron Collingwood of Coldburne and Heathpool, and granted a pension of £2000 a year.

The very completeness of Trafalgar prevented Nelson's immediate followers from achieving any comparable success. Collingwood received the Mediterranean command and held it, with distinction, till his death, but the French were not easily induced to leave port, and on the only occasion that he had a chance of catching them he was hampered by lack of intelligence of their movements. Collingwood was not only a distinguished officer in the ordinary sense, he was also a gunnery expert, a man of great political insight and diplomatic ability, a humanist, objecting strongly to the cruder methods of maintaining discipline customary in his time, and a letter-writer of the first class. He died while on the way home, on March 7, 1810. His health had long been declining, but the Admiralty had been loath to dispense with the services of such a popular and versatile officer. He was, very fittingly, laid to rest in St. Paul's by Nelson's side.

See G. C. M. Collingwood, *Selection from the Public and Private Correspondence of Lord Collingwood* (1828); W. Clark Russell, *Life of Admiral Collingwood* (1891); Admiralty Committee Report, *Evidence relating to the Tactics employed by Nelson at the Battle of Trafalgar* (1913). (G. A. R. C.; J. G. B.)

COLLINGWOOD, a city of Bourke county, Victoria, Australia, a suburb of Melbourne on the N.E., on the Yarra river. Pop. (1933) was 30,665. It was the first town in Victoria incorporated after Melbourne and Geelong. It is now well within Greater Melbourne, and less than 2 mi. from the centre.

COLLINGWOOD, a town of Simcoe county, Ontario, Canada, 90m. N.N.W. of Toronto, on Georgian bay, and on the Canadian National railway. Pop. (1941) 6,270. It has steamer communication with all Lake and St. Lawrence ports. It contains a large stone dry-dock and shipyard, pork factory, and saw and planing mills, and has a large lumber, grain and produce export trade, besides a shipbuilding plant and steel works.

COLLINS, ANTHONY (1676–1729), English deist, was born at Heston, near Hounslow in Middlesex, on June 21, 1676. He was educated at Eton and King's college, Cambridge. The most interesting episode of his life was his intimacy with Locke, who in his letters speaks of him with affection and admiration. He died at his house in Harley street, London, on Dec. 13, 1729.

His writings are important as gathering together the results of previous English Freethinkers. In spite of unorthodoxy Collins was not an atheist or even an agnostic. In his own words, "Ignorance is the foundation of atheism and freethinking the cure of it" (*Discourse of Freethinking,* 105).

His first work of note was his *Essay concerning the Use of Reason in Propositions the Evidence whereof depends on Human Testimony* (1707), in which he rejected the distinction between *above* reason and *contrary to* reason, and demanded that revelation should conform to man's natural ideas of God. Like all his works, it was published anonymously. Six years later appeared his chief work, *A Discourse of Freethinking, occasioned by the Rise and Growth of a Sect called Freethinkers* (1713). In spite of its indiscriminate attack on the priests, the book contends for no more than every Protestant must allow. In England this essay, which was regarded and treated as a plea for deism, made a great sensation, calling forth several replies, among others from William Whiston, Bishop Hare, Bishop Hoadly, and Richard Bentley. Swift, also, being satirically referred to in the book, made it the subject of a caricature.

In 1724 Collins published his *Discourse of the Grounds and Reasons of the Christian Religion,* with *An Apology for Free Debate and Liberty of Writing* prefixed. Ostensibly, it is written in opposition to Whiston's attempt to show that the books of the Old Testament did originally contain prophecies of events in the New Testament, which had been eliminated or corrupted by the Jews, and to prove that the fulfilment of prophecy by the events of Christ's life is all "secondary, secret, allegorical and mystical," since the original and literal reference is always to some other fact. Since, further, according to him the fulfilment of prophecy is the only valid proof of Christianity, he thus secretly aims a blow at Christianity as a revelation. No less than 35 answers were directed against this book, the most noteworthy of which were those of Bishop Edward Chandler, Arthur Sykes and Samuel Clarke. To these Collins replied by his *Scheme of Literal Prophecy Considered* (1727). An appendix contends against Whiston that the book of *Daniel* was forged in the time of Antiochus Epiphanes (*see* DEISM).

In philosophy, Collins, is a defender of Necessitarianism. His brief *Inquiry Concerning Human Liberty* (1715) has not been excelled, at all events in its main outlines, as a statement of the determinist standpoint. Attacked by Samuel Clarke he replied after Clarke's death with *Liberty and Necessity* (1729).

Besides these works he wrote *A Letter to Mr. Dodwell,* arguing that it is conceivable that the soul may be material, and, secondly, that if the soul be immaterial it does not follow, as Clarke had contended, that it is immortal; *Vindication of the Divine Attributes* (1710); *Priestcraft in Perfection* (1709).

See Kippis, *Biographia Britannica;* G. Lechler, *Geschichte des englischen Deismus* (1841); J. Hunt, *Religious Thought in England,* ii. (1871); Leslie Stephen, *English Thought in the 18th Century,* i. (1881); A. W. Benn, *Hist. of English Rationalism in the 19th Century* (1906); J. M. Robertson, *Short History of Freethought* (1906); and *Deism.*

COLLINS, JOHN CHURTON (1848–1908), English literary critic, was born March 26 1848 at Bourton on the Water, Gloucestershire, and died at Lowestoft Sept. 15 1908. He was educated at King Edward's school, Birmingham, and Balliol college, Oxford. In 1904 he was appointed professor of English literature at Birmingham.

His works include: *Bolingbroke and Voltaire in England* (1886), a *Study of English Literature* (1891), a study of *Dean Swift* (1893), *Essays and Studies* (1895), *Ephemera Critica* (1901), *Essays in Poetry and Criticism* (1905), and *Rousseau and Voltaire* (1908), his original essays being sharply controversial in tone, but full of knowledge.

COLLINS, MICHAEL (1890–1922), Irish politician, was born near Clonakilty in County Cork, the eighth child of John Collins, a prosperous farmer who, at 62, married Kate O'Brien, his junior by 40 years. Michael Collins entered the second division of the British civil service and went to London as a junior postal clerk in 1907. After two years he left the civil service to be clerk in an accountant's office. During this period he joined the Irish Republican brotherhood.

At the beginning of 1916 Collins returned to Ireland, joined the Irish volunteers in Dublin, and was one of those who fought under Pearse in the general post office during Easter week. He escaped being taken under arms, but later was arrested and sent with the great body of suspects to the detention camp at Frongoch. Released with the rest in July 1917, he was returned at the general election in Dec. 1918 as Sinn Fein member for County Cork. Out of 73 elected only 29 were present when they met in the Mansion house and declared for the Irish Republic. E. de Valera, their elected president, was in gaol, so was the vice-president, Arthur Griffith. All effective decisions were taken by the men who were clever enough to avoid arrest. These were Collins, Cathal Brugha and the headquarter staff of the Irish volunteers.

Brugha (Charles Burgess), as minister of defence in de Valera's Republican Ministry, was head of the Irish volunteers, known later as the I.R.A. (Irish Republican Army). In this military organization Collins was head of the intelligence department; but in the administration as a whole he was minister of finance. In this dual capacity Collins controlled the entire correspondence of the movement. All enterprises were considered, financed, and many were carried out by him. In March 1919 he and Harry Boland arranged the escape of de Valera from Lincoln gaol. How far he was responsible for the spread of the guerrilla war cannot now be ascertained. But by 1920 his name, first gradually and then universally, had become known as that of the man most wanted by the British authorities. A reward of £10,000 was offered for his arrest, and pictures of him were published. Yet he used no disguise, went about Dublin alone on a bicycle and frequently made appointments for an interview in the public streets. He demoralized the British secret service and created a most effective spy system of his own.

At the close of 1920 secret negotiations, conducted through the Australian Archbishop Clune, were held with Collins, who afterwards maintained that all the concessions obtained six months later could have been secured then but for the action of a county council which called for cessation of hostilities. This, he held, encouraged the British to insist on a surrender of arms, upon which demand the negotiations broke down. In July 1921 when the truce with Britain was proclaimed, Collins for the first time became directly known to the Irish public. No other figure was so popular. When the negotiations between de Valera and Lloyd George failed to reach any conclusion, Griffith, Collins and three others were appointed to renew the attempt. Collins, by his genial personality, undoubtedly smoothed over many of the difficulties, and though in principle a republican he knew when the utmost possible had been gained. Griffith alone could not have forced the Dail to accept the treaty against de Valera's opposition; this achievement was mainly due to the magnetic personality of the younger man. When the result of the voting showed the narrow margin of seven for acceptance, Collins instantly rose and gravely warned the assembly of the anarchy that might follow dissension. He proposed a joint committee of public order, but the proposal was rejected. In the debate he had declared that he accepted the treaty as a stepping stone to a republic, but he was careful both in his speech and his published volume, *The Path to Freedom,* to disavow any desire to force a separation which would injure Britain or leave her exposed. In his opinion, the Dominions were destined to detach themselves naturally and without a wrench, like ripened fruit.

The first result of the Dail's decision was confusion. Griffith was elected president, not of the Free State but of the Irish Republic. Collins was appointed chairman of the provisional Government. But administration in the ordinary sense was impossible. Civil life had been destroyed in the guerrilla war; the police were now necessarily disbanded, since the struggle had left a blood feud between them and the people; the British garrison was evacuating the country, and the Irish army, still considered the army of the Republic, was deeply disaffected.

Collins's first object was to reach a settlement with Ulster. He therefore entered into personal negotiations with Sir James Craig, (Lord Craigavon) premier of Northern Ireland. No settlement was reached, largely because of the imminence of civil war in the South. Mutiny broke out in the army, and Collins, hoping against hope to avoid civil strife, refrained from drastic action. He was instrumental in postponing the general election (stipulated for under the treaty), and when at last a date for it was fixed in June he entered at the eleventh hour into a compact with de Valera by which he and the Republican leader agreed to appeal for the unopposed return of candidates jointly nominated by them. This would have given a very large representation to opponents of the treaty. But when independent candidates were put forward, Collins at the last moment advised his countrymen to vote as they wished. This he knew would mean the acceptance of the treaty. At the elections the republicans were heavily beaten and the Irish Government, challenged by force even in the capital, decided to use force in return.

Civil war began; and Collins, assuming chief command, flung himself into the struggle with all his energy. Opposition was crushed in Dublin and all the large towns. Suddenly, on Aug. 12, Griffith fell dead and Collins became at once head of the State and of the army. The newly enrolled forces needed impetus and he went down to give it to them by his presence in Munster, where the chief resistance lay. On Aug. 22, 1922, motoring with a strong escort from Skibbereen to Cork, his party was ambushed, and in the skirmish he was shot through the head. No man since Parnell had so caught the imagination of Ireland. Perhaps the moment of his death was fortunate, for he died when victory was more apparent than real, and he was spared the task of executing those who had been his comrades. But his work stands, and he emerges from the struggle with a reputation less tarnished than some of his contemporaries. (S. G.)

COLLINS, MORTIMER (1827–1876), English writer, was born in Plymouth June 29 1827, and died July 28 1876. His longest and best sustained poem is *The British Birds, a Com-*

munication from the Ghost of Aristophanes* (1872). He also wrote several novels, the best of which is perhaps *Sweet Anne Page* (1868).

COLLINS, WILLIAM (1721–1759), English poet, was born on Dec. 25, 1721. He divides with Gray the glory of being the greatest English lyrist of the 18th century. After some childish studies in Chichester, of which his father, a rich hatter, was the mayor, he was sent, in Jan. 1733, to Winchester college, where Whitehead and Joseph Warton were his school-fellows.

In 1734 the young poet published his first verses, in a sixpenny pamphlet, on *The Royal Nuptials,* of which, however, no copy has come down to us; another poem, probably satiric, called *The Battle of the Schoolbooks,* was written about this time, and has also been lost. Fired by his poetic fellows to further feats in verse, Collins produced, in his 17th year, those *Persian Eclogues* which were the only writings of his that were valued by the world during his own lifetime. They were not printed for some years, and meanwhile Collins sent, in Oct. 1739, some verses to the *Gentleman's Magazine,* which attracted the notice and admiration of Johnson, then still young and uninfluential. In March 1740 he was admitted a commoner of Queen's college, Oxford, but did not go up to Oxford until July 1741, when he obtained a demyship at Magdalen college. At Oxford he continued his affectionate intimacy with the Wartons, and gained the friendship of Gilbert White. Early in 1742 the *Persian Eclogues* appeared in London. They were four in number, and formed a modest pamphlet of not more than 300 lines in all. In a later edition, of 1759, the title was changed to *Oriental Eclogues.*

A few days after taking his degree in 1743 Collins published his second work, *Verses humbly addressed to Sir Thomas Hanmer.* This poem, written in heroic couplets, shows a great advance in individuality, and resembles, in its habit of personifying qualities of the mind, the riper lyrics of its author. For the rest, it is an enthusiastic review of poetry, culminating in a laudation of Shakespeare. A second edition of it, differing considerably from the first, was published in the following year. To this edition was added the *Song from Cymbeline* in its original form, which was not strictly adhered to by the editor, Cave, when he published it in the *Gentleman's Magazine* for Oct. 1749. Collins's indolence, which had been no less marked at the university than his genius, combined with a fatal irresolution to make it extremely difficult to choose for him a path in life. The army and the church were successively suggested and rejected; and he finally arrived in London, bent on enjoying a small property as an independent man about town. He made the acquaintance of Johnson and others, and was urged by those friends to undertake various important writings—a *History of the Revival of Learning,* several tragedies and a version of Aristotle's *Poetics,* among others—all of which he began but lacked force of will to continue. He soon squandered his means, plunging, with most disastrous effects, into profligate excesses.

It was at this time, however, that he composed his matchless *Odes*—12 in number—which appeared on Dec. 12, 1746, dated 1747. Collins's little volume fell dead from the press, but it won him the admiration and friendship of the poet Thomson, with whom, until the death of the latter in 1748, he lived on terms of affectionate intimacy. In 1749 Collins was raised beyond the fear of poverty by the death of his uncle, Colonel Martyn, who left him about £2,000, and he left London to settle in his native city. He had hardly begun to taste the sweets of a life devoted to literature and quiet, before the weakness of his will began to develop in the direction of insanity, and he hurried abroad to attempt to dispel the gathering gloom by travel. In the interval he had published a short piece of consummate grace and beauty—the *Elegy on Thomson,* in 1749. In the beginning of 1750 he composed the *Ode on the Popular Superstitions of the Highlands,* which was dedicated to the author of *Douglas,* and not printed till long after the death of Collins, and an *Ode on the Music of the Grecian Theatre,* which no longer exists. With this poem his literary career closes, although he lingered in great misery for nearly nine years. From Gilbert White, who jotted down some pages of invaluable recollections of Collins in 1781, and from other friends, we learn that his madness was occasionally violent, and that he was confined for a time in an asylum at Oxford. But for the most part he resided at Chichester, suffering from extreme debility of body when the mind was clear, and incapable of any regular occupation. In this miserable condition he passed out of sight of all his friends, and in 1756 it was supposed, even by Johnson, that he was dead; in point of fact, however, his sufferings did not cease until June 12, 1759. No journal or magazine recorded the death of the forgotten poet, though Goldsmith, only two months before, had begun the laudation which was soon to become universal.

No English poet so great as Collins has left so small a bulk of writings. Not more than 1,500 lines of his have been handed down to us. His odes are the most sculpturesque and faultless in the language. They lack fire, but in charm and precision of diction, exquisite propriety of form and lofty poetic suggestion, they stand unrivalled. The ode named *The Passions* is the most popular; that *To Evening* is the classical example of perfect unrhymed verse. In this, and the *Ode to Simplicity,* one seems to be handling an antique vase of matchless delicacy and elegance. In his descriptions of nature it is unquestionable that he owed something to the influence of Thomson. Distinction may be said to be the crowning grace of the style of Collins; its leading peculiarity is the incessant personification of some quality of the character. In the *Ode on Popular Superstitions* he produced a still nobler work; this poem, the most considerable in size which has been preserved, contains passages which are beyond question unrivalled for rich melancholy fullness, in the literature between Milton and Keats.

See his life in Johnson's *Lives of the Poets* and the biography by M. Thomas (1853). There is a bibliography of his writings in *Seven 18th Century Bibliographies* by I. A. Williams (1924). (E. G.)

COLLINS, WILLIAM WILKIE (1824–1889), English novelist, elder son of William Collins, R.A. (1787–1847), the landscape painter, was born in London on Jan. 8, 1824, and died there on Sept. 23, 1889. He was educated at a private school in Highbury, and when only a small boy of twelve was taken by his parents to Italy, where the family lived three years. On his return he was articled to a firm in the tea trade, but later abandoned that business for the law, and was entered at Lincoln's Inn in 1846, being called to the Bar three years later. He took little interest, however, in his new career. On his father's death in 1847, Collins made his first essay in literature with *The Life of William Collins* (1848). In 1850 he published his first novel, *Antonina, or The Fall of Rome,* which was clearly inspired by his life in Italy. *Basil* appeared in 1852, and *Hide and Seek* in 1854. About this time Collins made the acquaintance of Charles Dickens, and began to contribute to *Household Words,* where *After Dark* (1856) and *The Dead Secret* (1857) ran serially. Among his most successful subsequent books were *The Woman in White* (1860), *No Name* (1862), *Armadale* (1866), and *The Moonstone* (1868). After *The New Magdalen* (1873) his ingenuity seemed to become exhausted.

Collins' popularity was great in his own day. He subsequently shared the temporary eclipse of most of the Victorian authors, but regained some of his vogue through the increasing popularity of mystery stories in the early years of the twentieth century. His style approximates, at its worst, to the melodramatic, and he sometimes exhibits all the violence and crudity of the "penny gaff." But he was undeniably a first-class story-teller, a master of situation and effect. His method of telling a story through the mouths of several characters, though sometimes criticised, has been imitated with success by subsequent writers of similar stories, such as Bram Stoker in *Dracula,* and is certainly well adapted to the progressive elucidation of a mystery. Some of his characters are not only real but uncommon. Later admirers of "Professor Moriarty" and "Arsène Lupin" could find a peer and in many respects a superior to these and similar personages in Count Fosco in *The Woman in White,* who is the spiritual parent of scores of subtly humorous sardonic villains.

COLLINSVILLE, a city of south-western Illinois, U.S.A., on the Pennsylvania Railroad, 12m. E.N.E. of St. Louis. The population in 1930 was 9,235; 1940, 9,767 by the federal census. It is in a coal-mining and farming region; has a dress factory, flour mills, a large poster-printing plant, a tomato products factory, and manufactures pressed bricks and cowbells. It was settled about 1810 and incorporated as a city in 1873.

COLLODION, a colourless, viscid fluid, made by dissolving gun-cotton and the other varieties of pyroxylin in a mixture of alcohol and ether. It was discovered in 1846 by Louis Nicolas Ménard in Paris, and independently in 1848 by Dr. J. Parkers Maynard in Boston. The quality of collodion differs according to the proportions of alcohol and ether and the nature of the pyroxylin it contains. Collodion in which there is a great excess of ether gives by its evaporation a very tough film; the film left by collodion containing a large quantity of alcohol is soft and easily torn. Under the microscope, the film produced by collodion of good quality appears translucent and colourless. To preserve collodion it should be kept cool and out of the action of the light. For the iodizing of collodion, ammonium bromide and iodide, and the iodides of calcium and cadmium are the agents employed. (*See* PHOTOGRAPHY.) Collodion is used in surgery since, when painted on the skin, it rapidly dries to a thin contractile film, affording both pressure and protection. Flexible collodion, containing Canada balsam and castor oil, does not crack, but, on the other hand, does not contract. M. E. Gripon found (*Compt. rend.,* 1875) that collodion membranes, like glass, reflect light and polarize it both by refraction and reflection; they also transmit a very much larger proportion of radiant heat, for the study of which they are preferable to mica.

BIBLIOGRAPHY.—Medical uses of collodion: W. H. Martindale & W. W. Westcott, *Extra Pharmacopeia* (1924, 1925; 19th ed. vol. i., 1928); Photographic use of collodion: T. E. Thorpe, *Dictionary of Applied Chemistry,* vol. v. (1924).

COLLOIDS. In a paper entitled "Liquid Diffusion applied to Analysis" published in 1861 in the *Philosophical Transactions,* Thomas Graham (*q.v.*) described the results of an investigation carried out with very simple means. Aqueous solutions were placed in a cylindrical vessel the bottom of which was formed by a piece of animal membrane, like pig's bladder, or by the recently invented parchment paper, and the membrane immersed in water. The amount of dissolved substance which diffused into the outer water was determined from time to time. Graham found that the numerous substances examined fell into two classes: those which diffused in appreciable amounts and those which hardly passed through the membrane in perceptible quantities. The former were without exception substances known to crystallize from their solutions, like various salts or sugar, while the latter, among which were albumin, gum arabic or gelatin, had never been known as crystals. Graham accordingly called the first class *crystalloids* and the second class *colloids* (from *colla,* glue).

Graham made the further discovery that a number of substances known to be insoluble in water could, by appropriate procedure, be brought into a state of solution. Thus prussian blue, the well-known pigment, is quite insoluble in water, but dissolves in a solution of oxalic acid. If such a solution is placed in Graham's apparatus, the oxalic acid diffuses into the outside water and the prussian blue remains behind, but still forms what appears a perfectly clear solution, and thus behaves like Graham's other colloids. He called this method of separating crystalloid from colloid constituents *"dialysis"* and the apparatus used for it a *"dialyser,"* terms still in use.

Graham studied by the same method a number of similar preparations, one of which only need be mentioned. If a dilute solution of sodium silicate (the "waterglass" of commerce) is poured into dilute hydrochloric acid, silicic acid and sodium chloride are formed. If this mixture is now dialysed, the sodium chloride passes out and a perfectly clear and colourless solution of silicic acid remains in the dialyser, although this substance, which occurs in great quantities in nature, is almost completely insoluble in water. Both this solution and that of prussian blue, however, exhibit very striking differences from ordinary solutions of crystalloids beyond the fundamental one of not passing through the dialysing membrane. On addition of a few drops of any acid or salt solution the prussian blue is immediately coagulated and in a short while settles out as a flocculent precipitate, leaving the liquid quite clear and colourless. The silicic acid solution even undergoes a spontaneous change on keeping: it gradually becomes more and more viscous, develops a bluish opalescence and finally sets to a jelly; the change can be enormously accelerated by the addition of a few drops of ammonia or even by bubbling carbon dioxide gas through the solution. Both these transformations are *irreversible:* neither the precipitate of prussian blue nor the jelly of silicic acid can be re-transformed into the original solution by washing or the like.

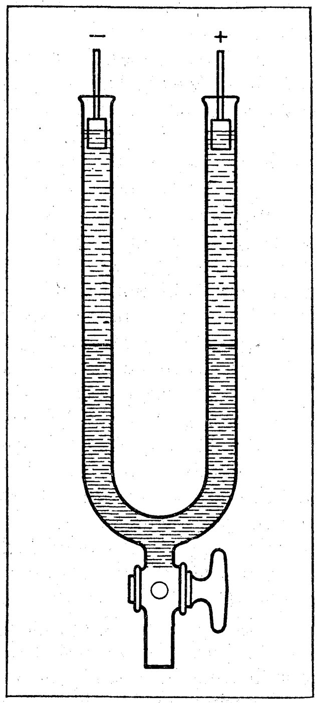

FIG. 1.—CATAPHORESIS TUBE FOR COLLOIDAL SOLUTIONS DEMONSTRATING THAT THE BOUNDARY BETWEEN COLLOIDAL SOLUTION AND WATER MOVES TOWARDS THE POLE WITH THE OPPOSITE SIGN TO THAT OF THE ELECTRIC CHARGE ON THE COLLOIDAL PARTICLES

Graham gave the convenient name of *sol* to a solution which did not dialyse, and the name of *gel* to its product of transformation; both terms have come into general use and will be employed in the rest of this article.

Earlier Observations.—Graham's method of preparing sols or colloidal solutions of many substances known to be insoluble was new and fundamental, but numbers of such apparent solutions had been observed long before him. Berzelius (*q.v.*) had already noticed that silicic acid, sulphur and several metallic sulphides formed such solutions in certain conditions; Francesco Selmi (1817–81) had investigated prussian blue and sulphur sols and expressed very modern views on the constitution of these "pseudo-solutions," as he called them, and many other isolated observations are on record.

Of particular interest is the first systematic investigation of what is now called colloidal gold or gold sol, a preparation which has been of immense importance in the study of colloids. It was known already to the alchemists of the 17th century that very dilute gold chloride solutions, when treated with reducing agents, turned red or purple. In a paper entitled "On the experimental relations of gold (and other metals) to light" published in the *Philosophical Transactions* in 1857, Faraday described such ruby and purple fluids obtained with various reducing agents and gave an extremely complete account of their properties. They were at once turned blue and eventually precipitated by traces of electrolytes; this change, which was irreversible, was even produced after a time by the minute amount of matter dissolved out of the glass vessels. Faraday expressed the definite view that the gold in these liquids was present in the form of extremely minute particles, much too small to be visible in the microscope; their presence could, however, be made evident "by gathering the rays of the sun into a cone by a lens and sending the part of the cone near the focus into the fluid"; the cone becomes visible which it would not be in a liquid entirely free from suspended particles.

This method of illumination was later used extensively by Tyndall and is generally known as the *Tyndall cone;* it has become one of the most delicate means of making small particles collectively visible in liquids or gases.

The Invention of the Ultra-Microscope.—Faraday's paper was almost completely overlooked for about fifty years. Towards the end of the last century R. Zsigmondy (now professor at Göttingen) prepared "ruby liquids" similar to those of Faraday by a new method of reduction, which he at first described as "aqueous solutions of metallic gold." The question of their constitution—and that of most other sols—was however eventually solved by means of the "Ultra-microscope" (*see* MICROSCOPE), designed by Zsigmondy and H. Siedentopf (the scientific adviser of the firm of Carl Zeiss) in 1903. In this instrument a small, but extremely intense, Tyndall cone is projected into the liquid and is viewed at a right angle to its axis with a microscope. Particles which, for reasons inherent in the formation of microscopic images, cannot be seen in the ordinary microscope on account of their small size, become visible in the ultra-microscope as bright discs on a dark ground. The apparent size of the discs is no measure of the actual size of the particles which can, however, be calculated from the number counted in a known volume of illuminated liquid and from the known concentration.

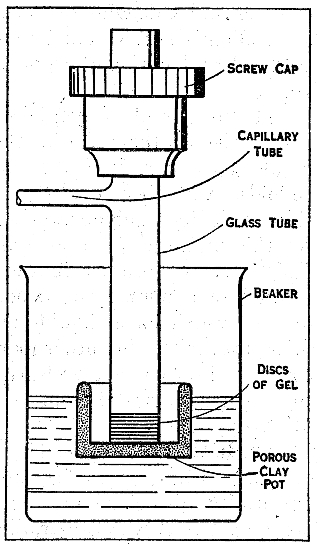

FIG. 2.—APPARATUS FOR DETERMINING THE DEGREE OF SWELLING OF INDIA RUBBER IN VARIOUS SOLVENTS

A very large number of sols have been examined with the ultra-microscope since its invention and have been found to contain particles of very various sizes, the *upper limit* of which is roughly 100–150$\mu\mu$ ($\mu\mu$= one-millionth of a millimetre; this is the usual unit of ultra-microscopic measurements). The lower limit of visibility depends, apart from the intensity of the illumination, on the size of the particle and on the optical difference between its substance and that of the liquid; the difference is greatest with metallic particles, and, with sunlight as the source of illumination, gold particles of about 5 $\mu\mu$ can just be made visible.

The presence of particles within the range described and thus very much larger than even complicated molecules is the characteristic of all colloidal solutions. Some substances, like albumin, gum arabic in cold and gelatin in warm water, are spontaneously *dispersed,* as the usual term is, into particles of such size; inorganic compounds such as have been mentioned, and very many others, must be produced by reactions which, by suitable choice of concentration, temperature and other factors, are so controlled that the particles formed cannot grow beyond the limit of colloïdal sizes. This result has now been achieved in many hundreds of cases, and it is clear that Graham's distinction between colloids and crystalloids as two different *kinds* of matter is no longer tenable. Sulphur crystallizes from solution in carbon disulphide, while common salt does so from aqueous solution; sols of sulphur in water and of salt in several organic liquids can, however, be prepared by a variety of methods. Although the term "colloid" is used for convenience, it now means, not a peculiar type of matter, but merely matter which is, or can be made to appear in, a particular state of subdivision. Some substances, which were among those investigated by Graham, invariably and spontaneously assume this state when brought into contact with a suitable liquid, while others have to be produced in conditions so controlled that the required subdivision is brought about.

Brownian Movement and Stability.—When particles can be observed at all they are always seen to be in constant motion of a very peculiar kind; they quiver and describe irregular paths, the distances traversed by small particles sometimes amounting to several times their diameter. The motion is not confined to ultra-microscopic particles, but was first observed in 1827 by Robert Brown, the botanist, with microscopic particles (pollen grains). The motion, which is called the *Brownian movement* (*q.v.*) is now known to be caused by the impact of the molecules of the surrounding liquid on the particle, and its amplitude increases as the size of the particle decreases. The impacts take place in all directions and the fraction of component which acts vertically upwards is sufficient to counteract gravity and to keep the particles from settling out in the course of time; in the absence of the Brownian movement even ultra-microscopic particles would shew appreciable sedimentation within a few hours or days.

Although the particles move in all directions they never, in a stable sol, are observed to collide with one another. Since there is nothing in the nature of the movement itself to render such collisions impossible, there must be something in the particles themselves which prevents collision. What this factor is will become clear when we have considered the classification of sols.

Classification of Sols.—In spite of the great diversity of behaviour exhibited by individual sols two main types can be clearly distinguished, one resembling the Prussian Blue or the gold sol, the other the gum arabic or albumin sol. The first type is generally very dilute and strikingly sensitive to small concentrations of electrolytes, which produce immediate coagulation followed by settling out of the dispersed substance. The coagulum in the great majority of cases cannot be made to pass into colloidal solution again. On the other hand sols of the second type, *e.g.* of albumin, are not perceptibly affected by small electrolyte concentrations; very high concentrations, such as saturation with ammonium sulphate, cause coagulation, but with this and some other salts the coagulation is reversible and the albumin disperses again when the salt is removed by dialysis. A somewhat similar effect is produced by alcohol or acetone, organic liquids which strongly attract water.

Colloids of the first class are called *lyophobic* and those of the second *lyophilic, i.e.,* translated literally, such as hate and such as like the state of solution, the classification of Prof. Herbert Freundlich (1880–1941) and many authors. Prof. Wolfgang Ostwald of Leipzig distinguished *suspensoids* and *emulsoids;* these classes coincide roughly, though not quite exactly, with the lyophobic and lyophilic respectively. These terms imply that the one class resembles suspensions, the usual description of a liquid in which solid particles are distributed, while the other resembles emulsions, which contain globules of one liquid distributed in another. The assumption that the particles in this class are liquid rests on inferences which are not generally accepted.

The **Lyophobic** or suspensoid sols shew a much more uniform behaviour than the lyophilic ones and may therefore be described first. They are all fairly dilute, concentrations of a few per cent being rarely exceeded, clear or slightly opalescent; their colour may vary widely for a given substance: thus gold sols may be red, purple or blue, and silver sols any colour from blue through purple and red to yellow. Their common and most striking characteristic, the sensitiveness to electrolytes, has already been mentioned repeatedly. A further property common to all of them, whatever the chemical nature of the dispersed substance, is the existence of a difference of electric potential between the surface of the particles and the surrounding liquid. The consequence is that in an electric field they move towards one pole, as was first shewn (for arsenic trisulphide sol) by S. Linder and H. Picton, working in Ramsay's laboratory in 1892. This phenomenon, known as *cataphoresis,* is demonstrated in the simple apparatus illustrated in Fig. 1. The lower portion of the U-tube is filled with the sol to be investigated, while the limbs contain distilled water, into which dip two electrodes. When these are connected to an electric supply, the particles move towards the electrode of the sign opposite to that on their surface, and, if the sol is coloured, the boundary between it and the water above can be seen to move accordingly. It can now be shewn that the existence of the charge at the surface of the particles is necessary for the stability of the sol. By careful addition of electrolyte in small amounts the charge on the particles can be neutralized, which shews itself by their no longer travelling in the electric field; when this point is reached, or even before the potential difference is quite reduced to zero, the sol becomes unstable and eventually precipitates. The particles which, notwithstanding the Brownian movement, did not collide while charged, now come into collision, adhere to one another and finally form aggregates sufficiently large to settle out.

Many theories, which cannot be discussed here, have been advanced to explain the origin of the potential difference, why it prevents collision is still obscure, although the facts are clearly established.

The great majority of lyophobic sols, like those of sulphur, the sulphides, ferrocyanides, gold, silver, platinum, etc. contain particles which are negatively charged towards the liquid and travel to the anode; the particles of a number of oxide sols, like those of iron, chromium, aluminium and cerium, are positive and travel to the cathode.

Electrolyte Coagulation.—The concentration of electrolytes required to bring about coagulation of a lyophobic sol (arsenic trisulphide) was investigated for the first time by Hans Schulze in 1882. He found that the concentration of salt depended on the nature of its metal or, as we now say, its cation and to a very marked degree on its valency. Potassium salts, with a univalent cation, had to be used in concentrations 40–50 times as great as the corresponding salts of bivalent cations like magnesium or barium, and in concentrations about 500 times as great as the corresponding salts of a tervalent cation like aluminium. The coagulation of the arsenic trisulphide sol, with negative particles, was again studied with great thoroughness by Linder and Picton, who confirmed Schulze's results and extended his rule by examining the ferric oxide sol, the particles of which are positive. They found that in this case the valency of the acid or anion was the determining factor. A very considerable amount of study has since been devoted to the phenomenon, which substantially confirms the findings of the pioneer workers; the valency of the ion of the sign opposite to that of the sol particles determines the concentration required to produce coagulation, but the ion which has the same sign makes itself felt by a slight antagonistic effect: thus potassium chloride or nitrate will coagulate a negative sol in somewhat lower concentration than potassium sulphate or citrate.

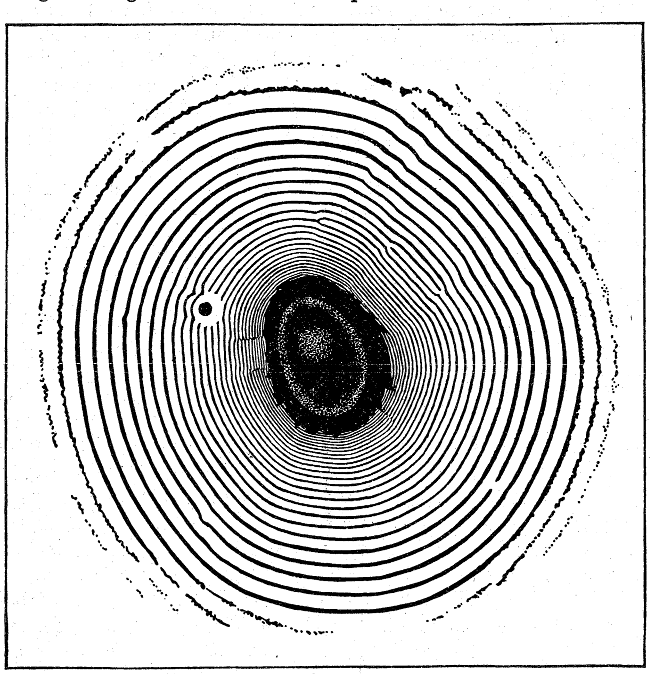

FIG. 3.—LIESEGANG RINGS OF SILVER CHROMATE WHICH STRIKINGLY RESEMBLE THE BANDING IN MANY MINERALS, SUCH AS AGATE, AND ARE BELIEVED TO EXPLAIN ITS FORMATION

It has been mentioned as one of the chief characteristics of the second or lyophilic class of colloids that they are little affected by low electrolyte concentrations. If a lyophilic colloid in small amount is added to a lyophobic sol it imparts to it this enhanced resistance to electrolytes or, as it is usually called, "protects" it. This protective action had been observed already by Faraday, who noticed that the addition of "a little jelly" made his ruby fluids much more stable. Gelatin is, indeed, one of the most effective protective agents for gold sols; a few milligrammes per litre prevent coagulation by salt concentrations many times higher than those which precipitate the unprotected sol. Gum arabic, albumin and its products of decomposition as well as tannin act in the same way. Various body fluids contain mixtures of proteins which act as protective colloids; in the cerebro-spinal fluid the protective effect is altered by various diseases and a diagnosis can be made by coagulating, by a standard sodium chloride solution, mixtures of the fluid with standard gold sol and noting the colour change produced (Lange's test, 1912).

The suspensoid of lyophobic sols are all laboratory products and, while of the greatest theoretical interest, do not play as important a part in nature or in the arts as do the lyophilic colloids. A number of sols, *e.g.* of ferric oxide, manganese dioxide, silver, selenium, sulphur, etc., are used in medicine; all sols made for this purpose are protected. Sols of graphite in water or oil find extensive use as lubricants. Coagulation by electrolytes is used in a number of processes to precipitate finely divided matter suspended in liquids and, indeed, occurs on a huge scale in nature; clay and other particles carried down by rivers are coagulated on contact with salt water and are deposited to form such deltas as are present at the mouths of the Nile and the Mississippi.

Lyophilic Colloids.—The lyophobic colloids, however different their chemical constitution, shew on the whole a remarkable uniformity of behaviour. The lyophilic colloids, on the other hand, exhibit very considerable variety and have no such striking feature in common as the electrolyte coagulation characteristic of all lyophobic sols. Nevertheless a fundamental similarity can be perceived when the properties of a few representatives of the group are surveyed and compared.

Albumin.—White of egg is a mixture of several proteins (*q.v.*) the most important of which, albumin, can be isolated by a simple procedure. The white is beaten to a froth, the clear liquid which drains from it suitably diluted, and sufficient ammonium sulphate is added to form a half-saturated solution. A precipitate forms, consisting of globulin, another protein, while the liquid contains albumin and ammonium sulphate, which can be removed by dialysis. The remaining sol of natural albumin can be shewn to contain negatively charged particles; on the gradual addition of acid it loses the charge and at a fairly constant acid concentration becomes neutral or "iso-electric" (Hardy, 1900).

Addition of neutral salts produces coagulation, but the concentrations required are enormously greater than those required for the precipitation of lyophobic sols, and in many cases, *e.g.* ammonium sulphate, amount to saturation. Salts fall into three classes according to their cation: salts of the alkalis form reversible coagula, which on dilution or dialysing out the salt disperse again; salts of the alkaline earths in about the same concentrations produce precipitates which are at first reversible but soon become permanently insoluble, while, finally, salts of the heavy metals produce irreversible precipitates in much smaller concentrations.

If salts of the first class with the same cation, say potassium or ammonium, are compared, it is found that the concentration required to precipitate or, as it is often called, "salt out" natural albumin depends markedly on the anion or acid. If the salts are arranged in increasing order of the concentrations required to produce coagulation, *i.e.* in decreasing order of their efficacy, the following sequence of anions is found:

Citrate—Tartrate—Sulphate—Acetate—Chloride—
Nitrate—Chlorate—(Iodide—Thiocyanate)

The salts of the two anions in parenthesis do not salt out even in saturated solutions. This sequence, which is of fundamental importance in the theory of lyophilic sols, was found by Hofmeister (Professor at Strasbourg) in 1888 and is generally called after him.

Albumin, like the majority of aqueous lyophilic sols, is also precipitated by alcohol; the concentration required is smallest at the iso-electric point, a significant fact to which reference will be made again.

Albumin finally undergoes a specific change familiar to everyone when heated for some time above 65° C: it coagulates irreversibly. When concentrated it forms a stiff white gel (boiled white of egg), when dilute an opalescent sol which has distinctly lyophobic character and is precipitated by low electrolyte concentrations.

Another protein, glutin, is the principal constituent of a lyophilic colloid well known to most people, gelatin. If the sheet or powder, as which it occurs in commerce, is placed in cold water, it swells until it has taken up six to ten times its weight of water. On warming to about 30° the gel disperses to form a faintly turbid sol which remains liquid above about 25° and on cooling "sets" to a jelly, the change being completely reversible.

High salt concentrations produce a stringy coagulum from the sol, and alcohol also precipitates gelatin. The most striking effect of salts, however, is shown in the viscosity of the sol and in the sol-gel transformation or setting. Here the Hofmeister series of anions appears again quite unmistakably: the salts at the beginning of the series make the sol more viscous, favour setting so that it takes place at higher temperature, and produce a stiffer jelly; these effects decrease towards the end of the series and the last members, iodide and thiocyanate, lower the viscosity of the sol, retard setting and, in sufficient concentrations, even prevent it altogether.

A substance shewing a behaviour quite parallel to that of gelatin, though differing from it profoundly in chemical constitution, is agar, much used as a culture medium in bacteriology. It is prepared from a number of Japanese seaweeds and occurs in commerce as shreds or powder, the principal constituent of which is a carbohydrate (*q.v.*). In cold water the substance swells and on heating to boiling point forms a sol, which on cooling to about 30° sets to a jelly at concentrations as low as 0·2%. The effect of the Hofmeister series is again exactly the same as on gelatin, which excludes the possibility of ascribing it to any sort of chemical action; the anions at the beginning favour setting, while those at the end retard or prevent it.

At sufficiently low concentrations the agar sol does not set to a jelly, and such dilute sols have been the subject of theoretical investigations of much importance (by Prof. Kruyt of Utrecht and his pupils) which afford an insight into the character of lyophilic sols in general.

Agar sol, like many others of this class, is an almost clear liquid and shews no particles in the ultra-microscope, but only a diffuse cone of light. It has already been emphasized that two factors determine the possibility of making ultra-microscopic particles visible, sufficient intensity of illumination being assumed: the size and the optical difference between particles and medium. It is the latter which is small in lyophilic sols, in which however the existence of particles falling within the colloidal range can be demonstrated, and their size estimated, by indirect methods which cannot be discussed here. A starch sol, *e.g.*, which in many respects resembles the agar sol closely, contains particles of about $14\mu\mu$ diameter. From the number of particles and the known quantity of *dry* starch used in making the sol it can however be calculated that this would account for particles of about $6\mu\mu$ diameter only, so that we must conclude the starch to be somehow associated with sufficient water to make up the larger volume, *i.e.* one part of starch with about eleven of water. Such hydrated—as the usual term is—particles are present in all lyophilic sols.

The particles of the agar sol are negatively charged, and the charge can be neutralized by small additions of electrolytes of the same order of concentration as are necessary for the coagulation of lyophobic sols. The agar sol however shews no perceptible change when this has been done, so that there must be some factor other than, or additional to, the electric charge which keeps it stable. This factor is the hydration or water associated with the particles, as can be shewn by adding some liquid which strongly attracts water, such as alcohol or acetone, to the sol which has been rendered electrically neutral by small electrolyte concentrations: coagulation takes place as soon as sufficient alcohol has been added to produce dehydration, *i.e.* withdrawal of water from the particles. The inverse order of procedure confirms the result just described; on addition of alcohol to agar sol without electrolyte the clear liquid becomes opalescent and shews copious particles in the ultra-microscope. The withdrawal of water from them increases the optical difference between them and the surrounding liquid, so that, although smaller, they become visible. The sol has, in fact, been transformed into a lyophobic sol, but is still stable because it retains its electric charge; this can be neutralized in the usual way by small additions of electrolytes, which again bring about coagulation.

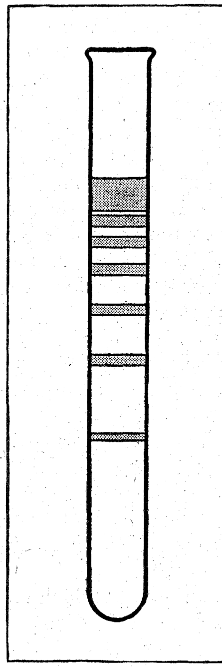

FIG. 4.—STRATIFICATION OF MAGNESIUM HYDROXIDE, SHOWING THE CLEAR SPACES BETWEEN THE STRATA

There are thus two factors which maintain the stability of the lyophilic sols, electric charge and hydration, and both have to be removed to bring about precipitation. Removal of the charge alone or dehydration alone alters the character of the sol but leaves the altered sols stable.

These considerations also elucidate satisfactorily the meaning of the Hofmeister series, which has been mentioned several times. The action of salts in *e.g.* salting out albumin is twofold: the first small addition neutralizes the charge, while the further large amounts required for coagulation act, like alcohol, by reducing the hydration of the particles. It is well known that the ions, into which the salts dissociate, are themselves hydrated, *i.e.* attach water molecules to themselves, to very different degrees and in proportion to this degree of hydration withdraw water from the colloid particles. The ions also have an effect on the water, to which brief reference only is possible: water at ordinary temperature is known to contain multiple or associated molecules, and its solvent properties are dependent on the proportion of those of the "degree of association." The degree of association itself is proved to be affected by the presence of the ions of the Hofmeister series.

We have so far spoken of lyophilic colloids in water only, and experimental investigation has, until recent times, been largely confined to them and more particularly to the proteins. The reason is the enormous importance of the proteins in living organisms; to take a single example, blood or, more exactly, the serum in which the red and white corpuscles are suspended, is a sol containing a mixture of several proteins with different properties which have been gradually elucidated by the methods of colloid chemistry. There are however many lyophilic sols of the greatest importance in the arts, in which the medium is not water but an organic liquid or a whole group of such. Thus india rubber forms sols in many hydrocarbons like petroleum ether, benzene or toluene, and also in substituted hydrocarbons like carbon tetrachloride or tetrachloro-ethane; the rubber solution used for mending tyres is a familiar example. Cellulose nitrates (one of which is gun-cotton) form sols in many organic solvents, such as acetone, glacial acetic acid, amyl acetate and in a mixture of ether and alcohol, though not in either of them separately. Cellulose acetate likewise forms sols in organic solvents and is now one of the materials for the manufacture of artificial silk, as is another derivative of cellulose, viscose or cellulose xanthate. It may be of interest to mention in this connection that cellulose itself, though not dispersed either by water alone or by any organic solvent, forms sols in various concentrated salt solutions when digested under pressure.

The most striking and obvious characteristic of the lyophilic sols in organic solvents is undoubtedly their very high viscosity at low concentrations. A sol containing 1 gm. of rubber in 100 cc. of benzene may have a viscosity 50–80 times as high as that of the solvent, while sols of certain brands of cellulose nitrate in acetone at the same concentration have viscosities many hundred times that of the solvent. For comparison it may be worth mentioning that a 40% sugar solution has a viscosity only 7·47 times as high as that of water at 15°. As there is generally a whole series of organic solvents available for every colloid of this class, it is possible to compare the viscosities produced by equal concentrations in a number of them, when it is found that they vary considerably in different liquids, a fact the significance of which will be discussed below.

The conditions which determine the stability of sols in organic solvents have not been studied to the same extent as those in aqueous sols. It is however fairly certain that electric charges, if present at all, do not play any great part, and that the principal or only factor is solvation, *i.e.* some sort of combination with the liquid, by which a great portion of it is held by the particles just as water is held by the agar or starch particles. No particles can be seen in benzene-rubber sol, but they become visible after the addition of alcohol, which withdraws benzene from them as it withdraws water from agar particles.

Gels.—Reference has already been made to the products of—reversible or irreversible—transformation of sols, to which Graham gave the name of *gels*. The gels of the lyophilic sols, to which the term has now become more or less confined, are of particular interest and importance; one of the typical forms is the gel of gelatin, familiar to everyone in the shape of table jellies. These contain 5–6% of the dry substance and thus exhibit at once the most striking characteristic of gels: that they retain their shape and behave up to a point like solids, although consisting very largely of liquid.

Gelatin gel is reversible: on warming it "melts" to sol, which on cooling sets again to gel. If the temperature is not raised above the melting point it can be dried without passing through the sol state until it contains in ordinary atmospheric conditions about 15% of water; the sheets or powder of commerce are such dry gel. A piece of this dry gel, placed in cold water, takes it up and swells, until the quantity taken up reaches 8–10 times its own weight, when the process stops. In thus swelling, the gel exerts considerable force, which can be measured by placing it in an enclosure permeable to water, but impermeable to the gel. An apparatus of this description (Posnjak, 1912) is shewn in sectional elevation in fig. 2. A cylindrical glass tube is luted at the lower end into a porous clay pot, while the upper end is closed by a screw cap. Discs of the gel to be examined, of exactly the same diameter as the inside of the tube, are placed on the bottom of the porous pot, and the whole tube is then filled with mercury, which reaches into the calibrated capillary tube. This is connected to a pressure gauge and a steel bottle containing compressed gas, by means of which any desired pressure up to about 6 atmospheres can be put on the mercury and through it on the gel. The lower end of the tube is placed in a vessel containing water, which passes through the porous clay cell to the gel, and the increase in volume of the latter can be calculated from the displacement of the mercury column in the capillary. In this way it has been found that gelatin, in taking up about half its weight of water, can overcome a pressure of about 5 atmospheres; in other words, this pressure has to be exerted on it to prevent it from swelling further. The first portions of water have the greatest effect, but when the gel has taken up over twice its weight of water it still exerts a pressure of about 0·5 atmospheres.

The swelling of gelatin is very greatly affected by electrolytes; all acids in low concentrations increase it markedly, but have the opposite effect when an optimum concentration has been exceeded. The effect of salts is still more complicated and cannot be briefly summarized here.

It may be mentioned here in parenthesis that a large number of organic tissues share with simple gels the property of swelling in water; the swelling of wood even in moist air, that of dry peas in water, etc. and the great forces exerted in these processes are everyday examples. The proper water content (or degree of swelling) of such living tissues as consist of proteins depends, like that of gelatin, on the electrolyte content and especially on the reaction, which healthy organisms regulate within very narrow limits.

As mentioned, gelatin gels containing as little as 5% of dry substance retain their shape, while those of 10–15% are sufficiently strong to permit a study of their elastic properties. Their Young's modulus has been determined by several observers and has been found to be of the order of grammes per sq. cm. and roughly proportional to the square of the gelatin content. Further investigation shews that the gel combines in a curious way the properties of the solid and liquid state. The volume remains almost exactly constant during deformation, a behaviour caused by the low compressibility of the liquid portion; if the deformation is maintained beyond a short time, the gel yields and the force required to maintain a given deformation, say a given elongation in a stretched rod, becomes less and less with time. Gels free from strain are, like liquids, optically isotropic, but when strained become double refracting (*see* LIGHT), as is revealed by examination in polarized light. When the stress is applied for a considerable time, and especially if the gel is dried while stressed, the double refraction remains permanent; it is a curious and significant fact that many structural elements of organisms, which consist of gels or mixtures of such, always exhibit double refraction.

A gel very similar to gelatin gel is that of agar, which has received comparatively little study so far. The gelatinizing properties of agar are much more marked than those of gelatin: a concentration of 1% is sufficient to form a fairly stiff gel. Owing to this property and to its being tasteless, as well as difficult to detect by chemical tests, agar has been much used for adulterating jams and jellies.

Lyophilic gels in which the liquid constituent is an organic solvent are also numerous and interesting. Cellulose acetate and benzyl alcohol behave exactly like gelatin and water: the acetate swells in the cols solvent, disperses on warming to about 40° to form a sol, which on cooling sets to a jelly resembling gelatin gel in appearance and elastic properties. Both natural and vulcanized rubber swell in hydrocarbons, although the latter does not form sols. The volumes of liquid taken up and the pressures generated are much greater than with gelatin: rubber, when it has taken up about 3.5 times its weight of benzene, still exerts a pressure of over 5 atmospheres. Rubber swells in a great number of organic liquids, but to very different degrees, which have been determined by several observers, who find that *e.g.* the quantity of carbon tetrachloride or of chloroform taken up is almost double that of benzene or toluene. Here a remarkable parallelism with the viscosity of sols shews itself: sols of equal concentration in carbon tetrachloride or chloroform are much more viscous than those in benzene. The inference is natural that the sol particles themselves are more "swollen" in the solvents containing chlorin than in the simple hydrocarbons, which would explain the higher viscosity of the sols in the former.

The gels described so far dry without the formation of any pores or voids; at no stage will they imbibe liquids other than those which have the specific effect of causing swelling. No organic liquid will penetrate into dry gelatin, nor water or aqueous solutions into dry rubber. A different behaviour is shewn by a number of gels, the most important representative of which is that of silicic acid. It has already been mentioned that this gel forms, spontaneously or on addition of electrolytes, from the sol and that it is a transparent or translucent mass with bluish opalescence. Unlike gelatin gel it cannot be deformed, but is brittle. Gels containing about 90% of water can be handled and keep their shape; on drying they shrink considerably and finally turn to a perfectly transparent mass resembling glass, but much lighter. If the gel is placed in water during any stage of the drying process it does not take up water and swell; it is therefore generally described as a *rigid* gel, in contradistinction to the type represented by gelatin and rubber, which are known as *elastic* gels.

When the gel has reached the glassy stage it still contains some water, which can be removed over concentrated sulphuric acid or at higher temperature; in this final drying, however, the volume undergoes no further reduction. The gel has now become a porous mass and the last stage of drying merely removes water contained in the pores. The existence of the pores can be easily demonstrated by immersing the gel in a liquid: air bubbles escape and the gel imbibes the liquid, of course without change of volume. The pores can be shewn by methods which cannot be described here to be of ultra-microscopic diameter. A gel resembling these artificially prepared ones is found in the internodial spaces of the bamboo; the optical properties of this substance, which is known as tabasheer and credited with curative properties, were investigated by Sir David Brewster (1819). Various forms of silica found in nature, such as opal and agate, probably originated from gels dehydrated under considerable pressure. Moist silicic acid gel has been found in fissures during the construction of the Simplon tunnel, and in mining operations in Australia.

Gelatin gel can be transformed into a rigid gel by the action of various agents, the most energetic of which is formaldehyde. The gel thus treated is quite brittle and no longer swells in water, nor disperses when the temperature is raised.

Diffusion and Reactions in Gels.—A further property of gels traceable to their high content of liquid is the small resistance which they offer to the diffusion of dissolved substances. This can be shewn by half filling test tubes with say 5% gelatin, allowing it to set and then pouring on the gel solutions of coloured salts or some of the simpler dyes, like fuchsin or fluorescein; the colour will be seen to penetrate fairly rapidly into the jelly. Graham, who carried out the first quantitative investigations on the rate of diffusion of a number of substances, found that it was not much lower in dilute gels than in the pure solvent and many measurements have been carried out in such, as the difficulties arising from vibration and convection are eliminated. In more concentrated gels, however, the rate of diffusion is markedly reduced. Colloidal solutions, which do not pass through membranes, do not diffuse into gels either, and the simple test described above can therefore be used—instead of dialysis—for deciding whether a given solution is colloidal. If a gold or other coloured sol is placed on the gelatin gel, no trace of colour shews in the latter even after days.

Since dissolved substances diffuse readily into gels, it is possible to allow reactions between two of them to proceed in such media either by letting the two solutions diffuse into a cylinder of the gel from opposite directions, or else by dissolving one of the substances in the gel itself and placing an aqueous solution of the other on it. The results are of considerable interest when one of the products of the reaction is an insoluble precipitate: as the solutions mix very gradually and as the first particles of precipitate are held fixed by the gel, thus acting as nuclei for further material, the conditions are favourable for the formation of large crystals. Many substances which are precipitated from aqueous solutions as microscopic particles only, can be obtained as large crystals when the reaction is produced in a gel, especially that of silicic acid; even metals can be obtained in well developed crystals of several mm. *e.g.* as glistening tetrahedra and gold as brilliant hexagonal plates.

The Liesegang Phenomenon.—An extremely curious phenomenon, generally called after its discoverer, R. E. Liesegang (Frankfurt), is observed with certain reactions. The original experiment is as follows: a thin layer of gelatin gel containing a little potassium dichromate is prepared on a glass plate, and a drop of strong silver nitrate solution placed in the centre. The silver nitrate at once diffuses into the gel and reacts with the dichromate, forming dark red, insoluble silver chromate and potassium nitrate. Diffusion proceeds continuously and it would seem that the precipitation of silver chromate should likewise be continuous and should lead to the formation of a gradually widening band of precipitate round the original drop. What actually happens, however, is that the chromate appears in a number of concentric rings separated by clear intervals, which become wider as the distance from the centre increases. (Fig. 3.) Similar results can be obtained by placing gel containing one substance in the lower half of test tubes and pouring the solution of the other substance on it, in which case parallel strata of precipitate are formed at increasing distances from each other. Fig. 4 shews diagrammatically the position of strata of magnesium hydroxide produced by letting a solution of ammonia diffuse into a gelatin gel containing magnesium chloride; the spaces between the strata are perfectly clear.

Many other reactions have been found, in carefully adjusted concentrations, to give similar stratifications, and investigation has also shewn that the gel does not take a passive part only, by securing quiet diffusion and fixing the precipitate where it is formed, but has a specific effect. Thus lead iodide and lead chromate form beautiful stratifications in agar, but not in gelatin, while on the other hand silver chromate forms them in gelatin, but not in agar.

Various interesting theories have been propounded to explain the phenomenon, none of which has found general acceptance or covers all the facts; in particular, most of them fail to explain the very marked specific effect of the gel.

Syneresis.—All gels at certain concentrations, specific for each substance, shew a characteristic phenomenon: they spontaneously contract with exudation of liquid. Graham, who first described this behaviour, called it *syneresis* (from the same Greek root as heresy, a separation or splitting off). Silicic acid shows it at high concentrations; sols can be prepared which set within a minute to gels apparently dry on the surface and adhering to the vessel. After about ten minutes the surface is covered with minute drops of liquid and in an hour so much liquid has exuded between the walls of the vessel and the gel that the latter can be tipped out. Gelatin and agar, on the other hand, exhibit syneresis at low concentrations only; so do some gels with organic solvents, like that of vulcanized india rubber, which contracts to 1/10 of its volume in a few days. The syneretic liquid is not pure solvent but always contains some colloid.

The Sol-Gel Transformation.—The formation of a gel, with some of the properties of a solid, from a sol which may contain as little as 0·5% of dry matter (agar) is an extremely striking change, which has very naturally been the subject of much speculation. Most gels are not differentiated in the ultra-microscope, so that theory has to rely on inferences from their known properties. The most generally received opinion is that the particles somehow join up to form chains and a network, or "ramifying aggregates," which some investigators (McBain) assume to be, to some extent, present already in the sol and to account for its viscosity. It is also probable that such a linking-up is accompanied by some change in the hydration of the particles. In any case, there must almost certainly be continuous liquid paths through a gel, to account for the ease with which diffusion proceeds through it.

Colloids in Nature and the Arts.—This necessarily brief account of the chief properties of a few typical colloids would be incomplete without a few words on the part played by colloids in nature and in the arts. Their importance in nature it is impossible to exaggerate: all organisms consist very largely of colloidal material, or more precisely of complicated mixtures and intricate structures composed of such. While the simple sols and gels of the laboratory are but the crudest models of even the simplest organic structures, the knowledge gained from their study is providing, if not a solution, new and promising methods of attack on problems which have proved intractable by the methods of physical chemistry. The selective permeability of cell membranes, *e.g.* to different ions is one of these problems, which any theory of solutions fails to explain, but for which known properties of colloidal systems provide at least a parallel.

As regards the arts, many of the oldest, like bread making, tanning, ceramics or dyeing, employ typically colloidal material and have empirically attained a high degree of perfection. In these the part of science is to find rational explanations of methods discovered by accident and improved by trial and error, and colloid science is playing this part successfully. The study of gelatin has thrown a great deal of light on obscure features of the tanning process; a study of the electric charges on dye particles and fibres has elucidated methods of dyeing, and so on. The industries just mentioned are of prehistoric origin, but even the processes which go on in so modern and astonishingly perfect a product as the photographic dry plate remained very obscure until the behaviour of colloidal silver and silver compounds embedded in a gel received systematic investigation.

More recent industries, the rise of which has coincided with the modern development of colloid chemistry, like the artificial silk and the rubber industry, have benefited much more directly. Some of the most important new developments, especially in the manufacture of rubber goods, are direct applications of theoretical knowledge. It may be mentioned that a recently published work dealing with colloids in the arts runs to over a thousand pages.

COLLOT D'HERBOIS, JEAN MARIE (1750–1796), French revolutionist, was a Parisian by birth and an actor by profession. He became director of the playhouse at Geneva. By the publication of *L'Almanach du Père Gérard* (1791), a little book setting forth, in homely style, the advantages of a constitutional monarchy, he suddenly acquired fame. He intervened on behalf of the Swiss of the Château-Vieux regiment, condemned to the galleys for mutiny at Nancy, and secured their liberation. He was a member of the Commune of Paris on Aug. 10, 1792, and was elected deputy for Paris to the convention, where he was the first to demand the abolition of royalty (on Sept. 21, 1792), and he voted the death of Louis XVI. *"sans sursis."* After the *coup d'état* of May 31, 1793, he made himself conspicuous by his pitiless pursuit of the defeated Girondins. In June he was made president of the convention; and in September became a member of the committee of public safety. The convention sent him, on Oct. 30, 1793, to suppress the revolt of Lyons. There he introduced the Terror in its most terrible form.

In May 1794 an attempt was made to assassinate Collot; but it only increased his popularity, and this won him the hatred of Robespierre, against whom he took sides on the 9th Thermidor, when he presided over the convention during a part of the session. During the Thermidorian reaction he was one of the first to be accused of complicity with the fallen leader but was acquitted. Denounced a second time, he defended himself by pleading that he had acted for the cause of the Revolution but was condemned to transportation to Cayenne (March 1795), where he died on Jan. 8, 1796. Collot d'Herbois wrote and adapted from the English and Spanish many plays, one of which, *Le Paysan magistrat,* kept the stage for several years.

See F. A. Aulard, *Les Orateurs de la Législative et de la Convention,* t. ii pp. 501–512 (1885–86). The principal documents relative to the trial of Collot d'Herbois, Barère, and Billaud-Varenne are indicated in Aulard, *Recueil des actes du comité de salut public,* t. i pp. 5 and 6.

COLLOTYPE. A photomechanical printing process for reproducing illustration copy with fine detail, practical only for runs of limited quantity. It is a planographic process, derived from the application of photography to lithographic printing. It was first developed on a practical scale in France, about 1865, by T. du Motay and C. R. Maréchal. The first collotype printing in the U.S. was done by Ernest Edwards in Boston in 1872.

Collotype differs from other reproductive processes in that the image is not broken up by any form of screen. From the original copy is made a continuous tone photographic negative with the image reversed by a prism. From the negatives are made blueprint proofs, which are pasted up to show their position on the sheet. Printing areas are cut out of a mask of opaque paper and the negatives mounted on this mask in position.

The printing plate for flatbed printing is a sheet of plate glass about ½ in. thick, which is first coated with a substratum solution with a high affinity for glass. The plates are dried in an oven, levelled and preheated to the temperature of the sensitized coating solution. This latter, made up of gelatin, water and a bichromate sensitizer, is flowed onto the plate and drawn across the surface. The plate is then subjected to higher heat in the oven, until all moisture is driven off. As the coating dries it becomes sensitive to light. The assembled masked negatives are then printed down on the plate. Light coming through the negatives reduces the capacity of the gelatin film to absorb moisture. After exposure to light, the plate is washed to remove the remaining sensitizing agent, the surface hardened with an alum solution, and then soaked in a water and glycerine solution. The gelatin film absorbs this solution selectively in proportion to the exposure, which causes the plate to accept or reject printing ink in proportion to the amount of solution absorbed. The plate is clamped to the bed of a flatbed press, similar to a stone lithographic press. The inking rollers which pass first over the plate, applying a stiff, greasy ink, are of leather with the flesh side out. Composition rollers follow to smooth out the image.

As sheets come off the press, they are slipsheeted, because of the heavy film of an ink which dries slowly. The speed of flatbed collotype printing is slow, about 200 impressions per hour. An average day's product on a press will not much exceed 1,000 sheets. The cost of platemaking, however, is low, making the process economical for relatively short runs of fine illustrations. For greater production metal sheets can be coated with the gelatin emulsion and printed on a direct rotary or offset press.

Fine colour printing by the collotype process has been done in England and Austria. Excellent single-colour full-tone reproductions are made in the U. S. Other names by which the process is known are albertype, autotype, phototype, heliotype, Lichtdruck, photocollotype, photogelatin, or simply gelatin printing. (D. C. McM.)

COLLUSION. In judicial proceedings, and particularly in matrimonial causes (*see* DIVORCE), collusion is a deceitful agreement between two or more persons, or between one of them and a third party, to bring an action against the other and obtain a judicial remedy which would not otherwise have been obtainable.

COLMAN, SAINT (d. 676), bishop of Lindisfarne (661), was an Irish monk at Iona. He attended the synod of Whitby in 664, when the dispute between the Roman and the Celtic parties on the date of Easter was considered. He upheld the Celtic usages, but King Oswy decided against him. After this event Colman returned to Iona, and then with many of the Columban clergy went to Ireland. He settled on Inishbofin, where he built a monastery and where he died on Aug. 8, 676.

Colman must be distinguished from St. Colman of Cloyne (*c.* 522–600), an Irish saint, who became a Christian about 570; and also from another Irishman, St. Colman Ela (553–610), a kinsman of St. Columba.

COLMAN, GEORGE (1732–1794), English dramatist and essayist, usually called "the Elder," and sometimes "George the First," to distinguish him from his son, was born in 1732 at Florence, where his father was resident at the court of the grand duke of Tuscany. Colman's father died within a year of his son's birth, and the boy's education was undertaken by William Pulteney, afterwards Lord Bath, whose wife was Mrs. Colman's sister. He was sent to Westminster school and then to Christ Church, Oxford. Here he made the acquaintance of Bonnell Thornton, the parodist, and founded *The Connoisseur* (1754–56), a periodical which reached its 140th number. He left Oxford in 1755 and was called to the bar at Lincoln's Inn in 1757.

In 1760 he produced his first play, *Polly Honeycomb,* which mocked at the sentimentalities of the popular novel. In 1761 *The Jealous Wife,* a comedy partly founded on *Tom Jones,* made

Colman famous. *The Jealous Wife* is one of the earliest instances of the successful dramatisation of a novelist's material, and is genuine comedy. The death of Lord Bath in 1764 placed Colman in possession of independent means. In 1765 appeared his metrical translation of the plays of Terence, and in 1766 he produced *The Clandestine Marriage,* jointly with Garrick. In the next year he purchased a fourth share in the Covent Garden theatre. Colman was acting manager of Covent Garden for seven years, and during that period he produced many pieces of his own and several "adapted" plays of Shakespeare. In 1774 he sold his share in the playhouse, which had involved him in much litigation with his partners, to Leake; and three years later he purchased of Samuel Foote, then broken in health and spirits, the little theatre in the Haymarket. He was attacked with paralysis in 1785; in 1789 his brain became affected, and he died on Aug. 14, 1794. Besides the works already cited, Colman was author of adaptations of Beaumont and Fletcher's *Bonduca,* Ben Jonson's *Epicoene,* Milton's *Comus,* and of other plays. He also produced an edition of the works of Beaumont and Fletcher (1778), a version of the *Ars Poëtica* of Horace, an excellent translation from the *Mercator* of Plautus for Bonnell Thornton's edition (1769–72), some thirty plays, many parodies and occasional pieces. An incomplete edition of his dramatic works was published in 1777 in four volumes.

COLMAN, GEORGE (1762–1836), "the Younger," son of the above, was born on Oct. 21, 1762. He passed from Westminster school to Christ Church, Oxford, and King's college, Aberdeen, and was finally entered as a student at Lincoln's Inn, London. In 1782 he produced, at his father's playhouse in the Haymarket, his first play, *The Female Dramatist,* for which Smollett's *Roderick Random* supplied the material. It was unanimously condemned, but *Two to One* (1784) was entirely successful. It was followed by *Turk and no Turk* (1785), a musical comedy; *Inkle and Yarico* (1787), an opera; *Ways and Means* (1788); *The Iron Chest* (1796), taken from William Godwin's *Adventures of Caleb Williams; The Poor Gentleman* (1802); *John Bull, or an Englishman's Fireside* (1803), his most successful piece; *The Heir at Law* (1808), which enriched the stage with one immortal character, "Dr. Pangloss," and numerous other pieces, many of them adapted from the French.

The failing health of the elder Colman obliged him to relinquish the management of the Haymarket theatre in 1789, when the younger George succeeded him, at a yearly salary of £600. On the death of his father, he was involved in litigation with Thomas Harris, and was forced to take sanctuary within the Rules of the King's Bench. Here he resided for many years continuing to direct the affairs of his theatre. Released at last through the kindness of George IV., who had appointed him exon of the Yeomen of the Guard, he was made examiner of plays by the duke of Montrose, then lord chamberlain.

Colman died in Brompton, London, on Oct. 17, 1836. He had, as early as 1784, contracted a runaway marriage with an actress, Clara Morris, to whose brother, David Morris, he eventually disposed of his share in the Haymarket theatre. Many of the leading parts in his plays were written especially for Mrs. Gibbs (*née* Logan), whom he was said to have married secretly after the death of his first wife.

See the second George Colman's memoirs of his early life, entitled *Random Records* (1830) and R. B. Peake, *Memoirs of the Colman Family* (1842).

COLMAN, SAMUEL (1832–1920), American landscape painter, was born at Portland (Me.), March 4, 1832. He was a pupil of Ashur B. Durand in New York, and in 1860–62 studied in Spain, Italy, France, and England. In 1871–76 he was again in Europe. In 1860, with James D. Smilie, he founded the American Water Colour Society, and became its first president (1866–67), his own water-colour paintings being particularly fine. He was elected a member of the National Academy of Design in 1862. Among his works are "The Ships of the Western Plains," in the Union League Club, New York; and "The Spanish Peaks, Colorado," in the Metropolitan Museum, New York. He died in New York city, March 27, 1920.

COLMAR, a town of France, capital of the department of Haut-Rhin, on the Logelbach and Lauch, tributaries of the Ill, 40 m. S.S.W. of Strasbourg on the main railway to Basle. Population (1936) 49,041.

Colmar (probably the *columbarium* of the Romans) is first mentioned, as a royal *villa,* in a charter of 823. It was raised to the status of a town and surrounded with walls by Wölfelin, advocate (*Landvogt*) of the emperor Frederick II in Alsace. In 1226 it became an imperial city, and the civic rights (*Stadtrecht*) conferred on it in 1274 by Rudolph of Habsburg became the model for those of many other cities. A long struggle between democratic gilds and aristocratic "families" ended in 1347 in the inclusion of the former in the governing body, and in the 17th century in the complete exclusion of the latter. In 1255 Colmar joined the league of Rhenish cities, and in 1476 and 1477 took a vigorous share in the struggle against Charles the Bold. It suffered in the wars of the 17th century, was formally annexed to France in 1681, and to Germany in 1871, and again became a part of France in 1919.

The Roman Catholic parish church (*Münster*) of St. Martin dates from the 13th and 14th centuries. Other notable buildings are the Lutheran parish church (15th century); the former Dominican monastery (1232–1289), known as "Unterlinden" and now used as a museum; the Kaufhaus (trade-hall) of the 15th century. Colmar is the centre of considerable textile industries, comprising wool, cotton and silk-weaving, and has important manufactures of sewing thread, starch, sugar and machinery. Bleaching and brewing are also carried on, and the neighbourhood is rich in vineyards and fruit-gardens.

COLNE, a municipal borough in north-east Lancashire, England, $34\frac{1}{2}$ mi. northeast from Manchester by the L.M.S.R. Pop. (1938) 21,960. Area, 9.3 sq.mi. It stands above a small affluent of the river Calder. Nelson and Colne are towns along a crossway between the Aire valley at Skipton and the Calder valley at Burnley followed by the Leeds and Liverpool canal. Roman coins have been found on the site. As early as the 14th century it was the seat of woollen manufacture. The church of St. Bartholomew retains some Norman work. There is a cloth hall or piece hall, originally used as an exchange when woollens were the staple of the town. The grammar school dates from Reformation times. Textile workers and weavers form a considerable proportion of the population. In the neighbourhood are several limestone and slate quarries. The town was incorporated in 1895 and is in the Nelson and Colne Parliamentary Borough.

COLOCYNTH, COLOQUINTIDA or **BITTER APPLE,** *Citrullus colocynthis,* a plant of the family Cucurbitaceae. The flowers are unisexual; the male blossoms have five stamens with sinuous anthers, the female have reniform stigmas, and an ovary with three large fleshy placentas. The fruit is round, and about the size of an orange; it has a thick yellowish rind, and a light, spongy and very bitter pulp, which yields the colocynth of druggists. The seeds, which number from 200 to 300, and are disposed in vertical rows on the three parietal placentas of the fruit, are flat and ovoid and dark-brown; they are used as food by some of the tribes of the Sahara, and a coarse oil is expressed from them. The foliage resembles that of the cucumber, and the root is perennial. The plant has a wide range, being found in Ceylon, India, Iran, Arabia, Syria, north Africa, the Grecian Archipelago, the Cape Verde islands and the southeast of Spain.

The commercial colocynth consists of the peeled and dried fruits. In the preparation of the drug the seeds are always removed from the pulp. Its active principle is an intensely bitter amorphous or crystalline glucoside, colocynthin, $C_{56}H_{84}O_{23}$, soluble in water, ether and alcohol, and decomposable by acids.

COLOGNE (Ger. *Köln*), a fortified town, archiepiscopal see and third city of the German Reich, in the Prussian Rhine province. Pop. (1939), 768,426. It lies in the form of a vast semicircle on the left bank of the Rhine, 44 m. by rail north-east from Aachen, 24 south-east from Düsseldorf and 57 north-northwest from Coblenz.

Its situation (1) as an important port on the Rhine (2) at the

Rhine crossing of the great natural highway from Paris via the valleys of the Oise, Sambre and Meuse along the north-western margin of the Ardennes and (3) at the emergence of roads along the Rhine from the incised section of that river has made it one of the chief cities in western Europe. The value of the site on the Rhine frontier was realized by the Romans and very little alteration in the town plan had taken place by the days of Archbishop Hildebold in the 9th century. The city was still contained within the rectangle formed by its Roman walls. Trading facilities during the 11th century caused a great increase in the size of the town and early in the 12th century the suburbs of Oversburg, Niederich and St. Aposteln were included. These were later enclosed by a rampart, fortified by walls and gates, some of which survived until the 19th century. Within the crescent formed by these fortifications flourished the mediaeval city—a capital of a third of the Hanseatic league. This mediaeval section of the city still has its tortuous, narrow and dark streets. The long Hohe-Strasse of this section is the city's chief business centre. The mediaeval walls and ditches were dismantled between 1881 and 1885, and the site of the old fortifications, bought from the government by the municipality, were converted into a fine boulevard, the Ring, nearly 4 m. long.

Beyond the Ring, about ½ m. farther out, a new line of fortifications was built and 1,000 acres, now occupied by handsome streets, squares and two public parks, were thus added concentrically to the inner town. Still later extensions have been in the form of "spurs" forming suburbs projecting as it were from the central core. Among the most important suburbs are Bayenthal, Lindenthal, Ehrenfeld, Nippes, Sülz, Bickendorf, Merheim, Niehl, and those on the opposite bank of the Rhine. Cologne is connected with Deutz by bridges. Mulheim, Meiheim and Worringen were incorporated in the city in 1914. Of the former city gates four have been retained, restored and converted into museums: the Severin gate, on the south, contains the geological section of the natural history museum; the Hahnen gate, on the west, is fitted as the historical and antiquarian museum of the city; and the Eigelstein gate, on the north, accommodates the zoological section of the natural history museum.

The most important squares are the Domhof, the Heumarkt, Neumarkt, Alte Markt and Waidmarkt in the old inner, and the Hansa-platz in the new inner town.

The Cathedral and Other Churches.—The cathedral or Dom stands on the site of a church begun in the 9th century by Hildebold, metropolitan of Cologne, and finished under Willibert in 873. This structure was ruined by the Normans, was rebuilt, but destroyed in 1248 by fire. The foundation of the present cathedral was then laid by Conrad of Hochstaden (archbishop from 1238 to 1261). The original plan has been attributed to Gerhard von Rile (d. *c.* 1295). In 1322 the new choir was consecrated. After Conrad's death the work of building advanced but slowly, and in the 19th century the building was finally finished. It contains the shrine of the Magi. The oldest church in the city is St. Maria im Kapitol, situated within the Roman nucleus. It was dedicated in 1049 by Pope Leo IX., though a church built on the old Roman foundation was in existence as early as 696. It is Romanesque in style and is noted for its crypt. A ring of churches surrounded the Roman section of the city, among them are St. Gereon, St. Ursula, St. Severin and St. Kunibert. St. Gereon's was built in the 11th century and shows Romanesque and Gothic features. It was erected on a Roman rotunda and has a square front hall. The crypt has fine mosaics in stone dating from the 11th century. The church has some fine painted glass. St. Kunibert is in the Byzantine-Moorish style, completed in 1248. There are also the church of St. Peter with the famous altar-piece of Rubens; St. Martin's built between the 12th and 13th centuries; the Minorite church built in the same year as the cathedral was begun with the tomb of Duns Scotus; St. Pantaleon, a 13th century structure; St. Cecilia's; the church of the Apostles and that of St. Andrew (1220 and 1414) with the tomb of Albertus Magnus.

Historic Buildings.—The Gürzenich, Rathaus, Tempelhaus and other buildings tell of the rise of the great merchant classes and of their struggle for power against the church and the nobility. The Gürzenich was a former meeting-place of the diets of the Holy Roman empire and built between 1441 and 1447. The ground floor was in 1875 converted into a stock exchange, and the upper hall utilized for public festivities. The Rathaus (13th century) has beautiful Gobelin tapestries. The Tempelhaus, the seat of the patrician family of Overstolzens, is a building of the 13th century, now the chamber of commerce. There is also the Wallraf-Richartz museum, with a collection of paintings by Italian and Dutch masters; the Zeughaus, built on Roman foundations; and the municipal library and archives. The Wolkenburg, a Gothic house of the 15th century, was restored in 1874. Near the cathedral is a museum of church antiquities. Cologne has numerous educational institutions. The municipal theatre (Stadttheater) is famed for its operatic productions. Many of Cologne's famous buildings were destroyed by British bombs in the great raid of May 30, 1942, and subsequent attacks. The British announced in June 1942, however, that the cathedral had escaped serious damage.

Commercially, Cologne is the retail town for the industrial cities of Rhineland and Westphalia, and has a very important trade in corn, wine, mineral ores, coals, drugs, dyes, manufactured wares, groceries, leather and hides, timber, porcelain and many other commodities. The docks are to the south of the city. Cologne manufactures sugar, chocolate, tobacco and cigars; the most famous product is the perfume known as *eau de Cologne* (*q.v.*) (*Kölnisches Wasser, i.e.,* Cologne-water).

HISTORY

Cologne occupies the site of *Oppidum Ubiorum,* the chief town of the Ubii, and here in A.D. 50 a Roman colony, *Colonia,* was planted by the emperor Claudius, at the request of his wife Agrippina, who was born in the place. After her it was named Colonia Agrippina or Agrippinensis. Cologne rose to be the chief town of Germania Secunda and had the privilege of the Jus Italicum. About 330 the city was taken by the Franks but was not permanently occupied by them till the 5th century, becoming in 475 the residence of the Frankish king Childeric. Counts of Cologne are mentioned in the 9th century.

The succession of bishops in Cologne is traceable, except for a gap covering the 5th century, from A.D. 313, when the see was founded. It was made the metropolitan see for the bishoprics of the Lower Rhine and part of Westphalia by Charlemagne, the first archbishop being Hildebold, who occupied the see from 785 to his death in 819. Of his successors one of the most illustrious was Bruno (*q.v.*), archbishop from 953 to 965, who was the first of the archbishops to exercise temporal jurisdiction, and was also "archduke" of Lorraine. The territorial power of the archbishops was already great when, in 1180, on the partition of the Saxon duchy, the duchy of Westphalia was assigned to them. In the 11th century they became *ex-officio* arch-chancellors of Italy (*see* ARCHCHANCELLOR), and by the Golden Bull of 1356 they were finally created electors of the empire. With Cologne itself, a free imperial city, the archbishop-electors were at perpetual feud; in 1262 the archiepiscopal see was transferred to Brühl and in 1273 to Bonn; and the quarrel was not finally adjusted until 1671. The archbishopric was secularized in 1801, all its territories on the left bank of the Rhine being annexed to France; in 1803 those on the right bank were divided up among various German states, and in 1815, by the congress of Vienna, the whole was assigned to Prussia. The last archbishop-elector, Maximilian of Austria, died in 1801.

The municipal history of Cologne follows in general the same lines as that of other cities of Lower Germany and the Netherlands. At first the bishop ruled through his burgrave, advocate, and nominated jurats. Then, as the trading classes grew in wealth, his jurisdiction began to be disputed. Peculiar to Cologne, however, was the *Richerzeche* (*rigirzegheide*), a corporation of all the wealthy patricians, which gradually absorbed in its hands the direction of the city's government. In the 13th century the archbishops made repeated efforts to reassert their authority, and in 1259 Archbishop Conrad of Hochstaden, by appealing to the democratic element of the population, succeeded in overthrowing the Richerzeche and driving its members into exile. His succes-

GENERAL VIEWS OF THE CITY OF COLOGNE

1. Gurzenich street, running along the south side of the Gurzenich (a mediaeval building used for municipal celebrations). This thoroughfare, built in 1914, starts from the suspension bridge and intersects the old town east and west. Much of Cologne was destroyed during World War II by British air raids
2. The cathedral or Dom, considered the finest example of decorated Gothic in Germany, situated 60 ft. above the Rhine, near the Hohenzollern bridge, in the oldest part of the city. Its towers, 515 ft. high, are a distinguishing feature of Cologne and may be seen from a great distance
3. The City Hall, standing on the site of the old Roman walls. The central portion, with the five-storied tower, dates from the 14th century; the ornate portico in the Renaissance style was built in 1569. The carillon was added in 1913
4. General view of centre of old city, showing the station, cathedral towers and, in the distance, the Rhine, with the Hohenzollern and suspension bridges
5. A street in the old town, showing the City Hall in the distance. The old town is situated in a broad semicircle on the Rhine within the new town. Some of its streets date from the 13th and 14th centuries
6. The suspension bridge opposite the Heymarkt, built in 1913–15 from plans of K. Moritz, to replace the old pontoon bridge. Its central opening has a span of 605 feet
7. Barbarossa place, an open square in the new city, showing the Hohenstauffer Ring, one of the broad new boulevards encircling the old city
8. A street along the Rhine, showing the Romanesque church of S. Martin and the suspension bridge, which crosses the river here to Deutz

sor, Engelbert II., however, attempted to overthrow the democratic constitution, with the result that in 1262 the brotherhoods combined with the patricians against the archbishop, and the Richerzeche returned to share its authority with the elected "great council." As yet, however, none of the trade or craft gilds, as such, had a share in the government, which continued in the hands of the patrician families, until long after the battle of

COLOGNE CATHEDRAL

This, the largest Gothic cathedral in northern Europe, begun in the 13th century, was not completed until the 19th century. The towers were completed in 1880, five and one-half centuries after the choir was consecrated

Worringen (1288) had secured for the city full self-government, and the archbishops had ceased to reside within its walls. In the 14th century a narrow patrician council selected from the Richerzeche, with two burgomasters, was supreme; but in 1396, the rule of the patricians having been weakened by internal dissensions, a bloodless revolution established a comparatively democratic constitution, based on the organization of the trade and craft gilds, which lasted until the French Revolution.

The expulsion of the Jews in 1414, and still more the exclusion of Protestants from the citizenship and magistracy, deeply affected the prosperity of Cologne. New trade routes, the decay of the gilds and many prolonged periods of warfare further contributed to its decay; and when, in 1794, Cologne was occupied by the French it was a poor city of some 40,000 inhabitants, of whom only 6,000 possessed civic rights. Incorporated in France in 1801 it was not then important enough to be more than the chief town of an arrondissement. On the death of the last elector in 1801 the archiepiscopal see was left vacant. With the assignment of the city to Prussia by the congress of Vienna in 1815 a new era of prosperity began. Cologne university, indeed, was definitively established at Bonn, but the archbishopric was restored (1821) as part of the new ecclesiastical organization of Prussia, and the city became the seat of the president of a governmental district.

Its prosperity rapidly increased; when railways were introduced it became the meeting-place of several lines, and in 1881 its growth necessitated the pushing outward of the circle of fortifications.

Cologne, together with a bridge head of 18 sq.m., was occupied in Dec. 1918 by the Allies under the terms of the Armistice. It was made the head-quarters of the British army of occupation and was not evacuated until Jan. 30, 1926.

During World War II Cologne was bombed by the British repeatedly and very heavily. One of the most catastrophic raids was on the night of May 30, 1942, when 1,130 planes dropped full loads of explosive and incendiary bombs in 90 minutes. Six great city areas, totalling about 5,000 acres and including the central part of the city and railway station but not the cathedral, were destroyed or severely damaged in this single raid.

COLOMB, PHILIP HOWARD (1831–1899), British vice-admiral, historian, critic and inventor, the son of Gen. G. T. Colomb, was born in Scotland, on May 29, 1831. He entered the navy in 1846, and served first at sea off Portugal in 1847; afterwards, in 1848, in the Mediterranean, and from 1848 to 1851 in operations against piracy in Chinese waters; during the Burmese War of 1852–53; in the Arctic Expedition of 1854; and in the Baltic during the Russian War, taking part in the attack on Sveaborg. From 1859 to 1863 he served as flag-lieutenant to Rear-Admiral Sir Thomas Pasley at Devonport. Between 1858 and 1868 he was employed in home waters on a variety of special services, chiefly connected with gunnery, signalling and the tactical characteristics and capacities of steam warships. From 1868 to 1870 he commanded the "Dryad," and was engaged in the suppression of the slave trade. In 1874, while captain of the "Audacious" he served for three years as flag-captain to Vice-Admiral Ryder in China; and finally he was appointed, in 1880, to command the "Thunderer" in the Mediterranean. Next year he was appointed captain of the steam reserve at Portsmouth; and after serving three years in that capacity, he remained at Portsmouth as flag-captain to the commander-in-chief until 1886, when he was retired by superannuation before he had attained flag rank. Subsequently he became rear-admiral, and finally vice-admiral on the retired list.

Colomb was one of the first sailors to perceive the vast changes which must ensue from the introduction of steam into the navy, which would necessitate a new system of signals and a new method of tactics. He set himself to devise the former as far back as 1858, but his system of signals was not adopted by the navy until 1867.

What he had done for signals Colomb next did for tactics. Having first determined by experiment—for which he was given special facilities by the Admiralty—what are the manoeuvring powers of ships propelled by steam under varying conditions of speed and helm, he proceeded to devise a system of tactics based on these data. In the sequel he prepared a new evolutionary signal-book, which was adopted by the British navy. His conclusions on the chief causes of collisions at sea, though stoutly combated in many quarters at the outset, were ultimately embodied in the international code of regulations adopted by the leading maritime nations on the recommendations of a conference at Washington in 1889.

Colomb helped to initiate an equally momentous change in the popular, and even the professional, way of regarding sea-power and its conditions in his book on *Naval Warfare* (1891). The central idea of his teaching was that naval supremacy is the condition precedent of all vigorous military offensive across the sea, and, conversely, that no vigorous military offensive can be undertaken across the seas until the naval force of the enemy has been accounted for—either destroyed or defeated and compelled to withdraw to the shelter of its own ports, or at least driven from the seas by the menace of a force it dare not encounter in the open. He worked quite independently of Admiral Mahan, and his chief conclusions were published before Admiral Mahan's works appeared.

He died on Oct. 13, 1899, at Steeple Court, Botley, Hants.

His younger brother, SIR JOHN COLOMB (1838–1909), entered the Royal Marines in 1854, and retired in 1869. His books on *Colonial Defence and Colonial Opinions* (1873), *The Defence of*

Great and Greater Britain (1879), *Naval Intelligence and the Protection of Commerce* (1881), *The Use and the Application of Marine Forces* (1883), *Imperial Federation: Naval and Military* (1887), followed later by other similar works, made him well known among the rising school of Imperialists, and he was returned to parliament (1886–92) as Conservative member for Bow, and afterwards (1895–1906) for Great Yarmouth. In 1887 he was created C.M.G., and in 1888 K.C.M.G. He died in London on May 27, 1909. In Kerry, Ireland, he was a large landowner, and became a member of the Irish Privy Council (1903), and in 1906 sat on the royal commission dealing with congested areas.

See H. d'Egville, *Imperial Defence and Closer Union: record of the life-work of Colomb* (1913).

COLOMBES, a town of France, in the department of Seine, arrondissement of St. Denis, 7 mi. N.N.W. of Paris. Pop. (1936) 61,944. It has a 16th-century church with 12th-century tower, a race-course, and numerous villas and boarding-schools. Manufactures include oil, vinegar and measuring-instruments.

COLOMBEY, a village of Lorraine, 4 mi. E. of Metz, famous as the scene of a battle between the Germans and the French, fought on Aug. 14, 1870. It is often called the battle of Borny, from another village 2½ mi. E. of Metz. (*See* METZ and FRANCO-GERMAN WAR.)

COLOMBIA is a republic occupying the north-western angle of South America. It is bounded on the north by the Caribbean sea and Venezuela, on the east by Venezuela and Brazil, on the south by Brazil, Peru and Ecuador, and on the west by Ecuador, the Pacific ocean, Panama and the Caribbean sea. The republic has an extreme length from north to south of 1,050 mi. and an extreme width of 860 miles. The area is 439,714 square miles.

Physical Geography.—The western and north-western portions of Colombia are occupied by the terminal ranges of the great Andean system. The two closely parallel ranges of northern Ecuador unite to form the Macizo de Pasto as they enter southern Colombia. From this great mountain knot, in turn, the Western and Central Cordilleras of the triple-spurred Colombian Andes emerge and stretch away side by side toward the north. The Eastern Cordillera originates in a secondary knot in the central range not far north of the Pasto *macizo,* and crosses the country in a north-easterly direction until it in turn splits asunder, sending one spur north into the Caribbean to form the Goajira Peninsula, and the other to the east to form the Sierra de Mérida south of Lake Maracaibo in western Venezuela.

The Eastern Cordillera sharply divides the mountainous district of northern and western Colombia from the torrid, low-lying plains of the interior which comprise slightly more than half the total area. To the south, a region covered by nearly impenetrable jungle growth is drained by the tributaries of the Amazon. Except along the principal rivers it is largely unexplored and inhabited mostly by uncivilized tribes of Indians. The northern part of these transmontane low-lands, the so-called llanos, is a region of open tropical plains, alternately flooded and parched with the changing seasons, and drained by tributaries of the Orinoco. The approximate length of this region is 640m. and the average width 320 miles.

The Western Cordillera roughly follows the line of the Pacific coast, terminating in three low, wooded spurs which merge into the Caribbean coastal plain in the southern part of Bolívar department. A short transverse range connects it with the Cordillera de Baudó, which extends from the mouth of the San Juan river north to form the highlands of Panama. The Western Cordillera is covered with vegetation, and its Pacific slopes are precipitous and humid. Its highest elevation, the Punta de Mallama, is 13,780 feet.

The Central Cordillera, also called the Quindío, is separated from the eastern and western Andean ranges by the Magdalena river on one side and its principal tributary, the Cauca, on the other. It terminates in low hills near the confluence of the two rivers. The Central Cordillera has a series of lofty volcanoes, some of them perpetually snow-capped. Its highest elevation is the Nevado del Huila (18,701ft.), the highest point in the republic.

The Eastern Cordillera is the region of densest population and is distinguished by its large area of plateau and elevated valley lying within the limits of the vertical temperate zone. The "sabana" of Bogotá (8,661ft.) with an area of 2,000 sq.mi., is a good illustration of the higher of these plateaux. Mild in temperature and fertile, it has the varied production of the temperate zone.

The Pacific coast line, omitting minor convolutions, is about

THATCHED NATIVE HUTS SHADOWED BY DROOPING PALMS, IN THE WESTERN PORTION OF COLOMBIA

500m. in length; that of the Caribbean is about 700 miles. The Caribbean ports are Barranquilla, Cartagena, Santa Marta, and Río Hacha. There are two commercial ports on the west coast, Buenaventura and Tumaco. Because of its unhealthful character and the high mountain barriers, the Pacific coast has played only a slight role in the country's development. The Caribbean plain is hot and low except in the northwestern section of Magdalena department, where the surface is elevated in the Sierra Nevada de Santa Marta, whose lofty, snow-covered peaks reach 17,389ft. in altitude.

Rivers.—For convenience of description the rivers may be divided into three general classes: those which find outlet in the Pacific, those which flow into the Caribbean and those whose waters reach the Atlantic through the Orinoco and the Amazon. The most important rivers in Colombia are the Magdalena and its principal tributary, the Cauca. Both rise in the high plateau of the Andes adjoining Ecuador. The Magdalena empties into the Caribbean sea near Barranquilla. It is about 1,000m. long and traverses 9° of latitude—nearly the entire country. In the lower reaches, throughout perhaps half its course, the waters of the Magdalena are dissipated over a wide area of swamp, lagoons and lakes, and its course is continually changing through the wearing away of its alluvial banks. The Cauca unites with the Magdalena about 200m. from the sea through several channels. The Cauca is navigable in two widely separated stretches of 200m. each. Both the Atrato and Sinú rivers flow to the north coast and are navigable by small steamers.

The rivers of the Pacific coast are numerous. They have short, precipitous courses with comparatively short navigable channels. The waters of the rivers of the great eastern plains pass to the Atlantic through the Orinoco and Amazon rivers. Some of them are navigable, which fact may be of great importance to the future development of this region, which is as yet only partially explored.

Geology.—The Andes reach their northern end in Colombia, where they are divided into three principal ranges, of which the central one is the highest. This range, the Cordillera Central, which is separated from the western one by the valley of the Cauca and from the eastern one by the valley of the Magdalena, includes peaks that rise to heights of more than 18,000 feet. The highest of these, Tolima (18,438 ft.) and Huila (18,701 ft.), are volcanic. The cores of all the ranges consist of old granite, gneiss and schist, which are generally overlain, on the east and west flanks, by folded and contorted beds of sandstone, shale, slate and limestone of Cretaceous age, with which are interbedded sheets and masses of volcanic rock, chiefly porphyry and porphyrite. The western chain, the Cordillera Occidental, extends northward from

Ecuador nearly to the Caribbean sea. In its southern part it is flanked on its west side by steeply tilted Palaeozoic beds; in its northern part on both sides by Mesozoic beds. The eastern Andean range, known as the Cordillera Oriental, or the Cordillera of Sumapaz, is composed mainly of folded Cretaceous beds. The Cordillera Central, which is the continuation of the Cordillera Oriental of Ecuador, consists chiefly of beds of Cretaceous sandstone and porphyritic rocks. The axes of folding in all these ranges conform in direction with the trend of the ranges. Along the Pacific coast of Colombia there is a lower range, composed mainly of Tertiary volcanic rocks, which are covered in places with soft Quaternary sandstones and marls containing the remains of species of marine animals such as inhabit the neighbouring ocean. The Magdalena valley is a structural trough 600 m. long and 9 to 45 m. wide, outlined by faults and filled with Tertiary clay and sandstone, which unconformably overlie Cretaceous beds. The Cúcuta basin, which is a south-westward continuation of the Maracaibo basin of Venezuela, is occupied by Cretaceous and Tertiary formations related to those in the Maracaibo basin. The beds in these basins are wrinkled by small folds that trend north-north-east. The foothills east of the Cordillera Oriental are composed of marine Cretaceous and marine and fresh-water Tertiary beds, which are folded and faulted along lines parallel to the trend of the Andes. In the part of Colombia that lies east and south-east of the Andes the surface deposits are mainly Tertiary and Quaternary sand, loam and gravel.

Colombia produces about half the platinum mined in the world. The emerald mines of Muzo in the eastern Andes are world famous. Gold is found in both lodes and placers. Many of the mines are in the department of Antioquia. Some silver, copper, iron, and coal are mined. Oil, nitre, lead, tin, and mercury are also produced.

Climate.—Colombia lies almost entirely in the north torrid zone. The heat of the tropics is, however, modified throughout a large part of the area by the elevation of the surface and the action of winds. In general torrid heat prevails within the lower areas, including the coastal plains and the valleys of the larger rivers. These regions are characterized by excessive moisture and dense forests, and are in general unhealthy, except in communities where development of modern sanitation and medicine have reduced the dangers attendant upon tropical environment. Above the tropical zone in the mountainous area are found all gradations of cooler climate. The subtropical districts comprise the valleys and slopes lying between 1,500 and 7,500ft. of elevation. Some of them are among the most fertile and productive areas of the country. The temperate zone lies between 7,500 and 10,000ft. of elevation, and the cold, bleak *páramos* at from 10,000 to 15,000. Above these are wastes of ice and snow. Most of the principal cities are situated in the vertical temperate zone.

In general, the year is divided into a wet season (called *invierno,* or winter) and a dry season (called *verano,* or summer). In some sections there are two wet and two dry seasons. The time when these seasons occur and their duration vary greatly, however, in the different regions and even vary from year to year in the same location.

Fauna.—The fauna is essentially tropical, though species characteristic of temperate countries are found in the higher regions, such as the bear, fox, skunk, weasel, squirrel and deer. In the forested lowlands and the lower mountain slopes there are many species of monkeys. The puma, the jaguar and the ocelot are widely distributed and are numerous in the Magdalena valley. The peccary and the tapir are found in many regions of the lowlands and lower forest zones. Among the other commonly known animals are the sloth, armadillo, nutria, porcupine and opossum. There are many varieties of rats, some of them partly amphibious. Lizards are abundant in most parts of the country in many different species, some of them brilliantly coloured. The alligator is common along the banks of the larger rivers, though in some places, especially along the Magdalena, it is becoming scarcer because of the activities of the hide hunters. The large rivers and lakes are plentifully stocked with fish and turtles, of which there are many edible varieties. The shell of one of the varieties of turtle is known as the tortoise-shell of commerce. Snakes abound in many regions.

The condor inhabits the higher Cordilleras. Others of this order are the eagle, osprey, buzzard, kite and hawk. Parrots and parakeets are numerous everywhere in tropical and subtropical regions, also the macaw and toucan. A vast number of waterfowl throng the shallow lagoons and river beaches at certain seasons. These are largely migratory and include the crane, heron, egret, roseate spoonbill, stork, bittern and many species of duck. There is an infinite variety of insect life in Colombia and the country is considered one of the best fields for students and collectors. The varieties include butterflies, spiders, beetles and ants. Practically all the low country swarms with mosquitoes and other insect pests, but there are no mosquitoes on the high plateaux.

Flora.—The Colombian flora is very rich, ranging as it does through all varieties from those of the tropics to the Alpine species of the highest plateaux. A luxuriant forest growth covers a large part of the republic, including the foothills, slopes and valleys of the Cordilleras, a large part of the plains adjacent to the north coast, the entire surface of the Western Cordillera and coast and the southern section of the eastern plains. There are many varieties of forest products, including vanilla and medicinal plants such as quinine, ipecac, sarsaparilla, gums and balsams, also rubber, tanning agents and dyewoods, and the tagua-nut, known as vegetable ivory. These forest products form a potential source of wealth as yet little exploited. Up to an altitude of 10,000ft. the palm is very abundant and varied, with incredibly numerous uses. There are extensive groves of the coco-palm on the Caribbean coast. Orchids are abundant in the forests, and many valuable varieties have been secured in Colombia.

As the surface of the land rises the character of the vegetation changes. From 1,500ft. to 4,500ft. there is a great variety of semi-tropical fruits. The temperate zone commences at 6,000ft. and is the finest agricultural region. Here practically all the cereals, vegetables and fruits commonly found in the United States are produced. Above 10,000ft. are the *páramos* with stunted vegetation. Farther up only Alpine species are found. Colombia is especially rich in fine woods, but very little use has been made of this resource so far. The varieties include mahogany, lignum vitae, Brazil-wood, pine, walnut, cedar, oak and many others. One of the most useful trees of the temperate zone today is the eucalyptus introduced from Australia.

GOVERNMENT AND ADMINISTRATION

Population.—The census of 1938 showed a population of 8,701,816. The population is made up of white, Indian, and Negro, and their mixtures, in the following proportions: pure whites, 35%; pure Negroes, 5%; Indians, 2%; mixed, 58%. The whites are mainly descendants of Spanish settlers; the Negroes were originally imported as slaves. In general the mixture of Indian and white blood predominates in the higher regions, where there is little or no trace of African blood. On the coast and in the river valleys the predominating mixture is the Negro and white, with very few pure whites.

Population of Colombia by Departments. Census of 1938.

Department	*Population*	*Capital City*	*Population*
Antioquia	1,188,587	Medellín	143,952
Atlántico	268,409	Barranquilla	150,395
Bolívar	765,194	Cartagena	72,767
Boyacá	737,368	Tunja	16,597
Caldas	769,968	Manizales	51,025
Cauca	356,040	Popayán	18,292

San Andrés y Providencia	6,528	San Andrés	4,261
Comisarias (territories)	118,028		
	8,701,816		

Of the aboriginal or Indian inhabitants there remain some scattered tribes in a savage state. Their number is estimated at about

160,000, and they are found principally on the eastern plains, also in the Río Hacha, Valle de Upar, and Santa Marta districts, and in the Atrato river basin. There are also civilized Indian communities which to some extent retain their own language and customs. According to one authority nearly 100 native languages are spoken in Colombia, but these belong principally to small and isolated communities, and the traveller in the country hears nothing but Spanish along the ordinary routes of travel.

The principal cities are: Bogotá, the capital; Medellín, the centre of commercial activity; Barranquilla, starting point of steamship service on the Magdalena, which has recently replaced Puerto Colombia as a port of call; Cali, centre of a rich agricultural district; and the Pacific coast port of Buenaventura.

Health.—In general, the coast and lower river valleys are unhealthy but there are regions which form exceptions. Among the latter are the cities of Barranquilla and Santa Marta on the Caribbean coast, where health conditions are reported reasonably good, due largely to improved sanitation. In the low country malaria and dysentery are very prevalent. The Magdalena valley is particularly unhealthy because of the vast swamp areas and the resultant mosquitoes. Hookworm is common in a large part of the country. The Rockefeller Foundation of New York has been carrying on an extensive campaign against disease in cooperation with the Colombian Government, devoting itself especially to the treatment of hookworm and the prevention of yellow fever. Very important results are being obtained.

In general, the higher altitudes are healthy. Many of the Colombian cities were lacking in proper water supply, sewage disposal, street paving, etc., but in most communities this situation is rapidly being corrected. Admirable new water supply systems in Bogotá, Cali, Cartagena, and other cities are indicative of this trend. The ports are generally free from yellow fever and similar diseases.

Immigration.—The law provides some inducements to immigrants such as the grant of agricultural land, but so far there has been little movement of foreign workers into the country. The settlement of Jewish refugees from European anti-Semitic persecution in Colombia has been minimized by the difficulty such persons encounter in complying with the Government's requirement that they settle on the land.

Social Classes.—The settlements of the Spaniards were mainly in the interior elevated sections. Due to the fact that adequate communications with the outside world have only recently been established, communities long remained in great isolation, and the result has been to preserve the language, manners, and physical characteristics of the early colonists with less variation than is found in any other Spanish-American state. The white race, numerically superior, has retained a certain social and economic dominance with respect to the Indians and Negroes, but the process of race mixture has progressed so far that, except for the comparatively few tribal Indians and limited numbers of predominantly pure Negroes, the country is rapidly attaining racial homogeneity. Upper class whites in Colombia, as elsewhere, disdain manual labour. The mestizos of Indian stock are in the main sturdy and patient and furnish the labour of the plateau districts. In the cities they are artisans, domestics and day labourers and in the country farm workers and herders. In the hot low country where the Negro strain is strongest the labour is less efficient than in the elevated sections. Though the men of wealth and position in all sections of the country are generally white, there are numerous exceptions to this rule. There is little colour antagonism, as such, against those of Indian and Negro lineage, and individuals of these races sometimes rise to important positions.

Government.—The Government is that of a centralized republic. The executive branch is formed by the president and nine cabinet ministers and the governors of the departments, who are appointed by the president, as well as other administrative authorities directly or indirectly controlled by him. The president is elected by the people for a term of four years. Attached to the president is a consulting body known as the Council of State, which is composed of seven members. The national loan board has jurisdiction over all borrowing done by the Government.

The legislative power is vested in Congress, consisting of the senate and the house of representatives. The senate is composed of 35 members elected for four years by electoral councils appointed by the departmental assemblies. The house of representatives is elected directly by the people for a period of two years. All male Colombians, 21 years of age or over, who exercise a lawful occupation, are citizens and entitled to vote.

The judicial power is vested in the supreme court of 12 members at Bogotá and a superior court in each judicial district. The supreme court has appellate jurisdiction in judicial matters and original jurisdiction in impeachment trials and in matters involving constitutional interpretation. There are various inferior courts.

Education.—The Constitution provides that public education shall be organized and directed in agreement with the Catholic religion and that primary education, paid for out of the public funds, shall be free but not obligatory. Primary education is under the control of the departments, and the status of education varies in the different departments. At the end of the last century the proportion of illiterates was authoritatively estimated at 90%. On the basis of the 1918 census the proportion of illiterates in the adult civilized population was about 50%. Colombia has, however, made great progress in education, and the percentage has been very considerably reduced, although no statistics have been published on the subject. The education of the majority, however, does not extend beyond the most elementary branches.

The following chart indicates the educational system of Colombia in 1937. Included among the primary schools are 190 Roman Catholic missions in the national territories. The National university at Bogotá, founded in 1572, and the School of Mines at Medellín are under the national Government. Four other universities are departmental; the universities of Antioquia (at Medellín), Cartagena, Popayán, and Pasto. The Government maintains a conservatory of music and a school of fine arts in Bogotá.

Education in Colombia in 1937

Type of School	Total of Official Schools	Total of All Schools	Teaching Staff	Enrolment
Infant	95	326	485	15,112
Primary	8,015	8,714	12,495	573,617
Vocational	127	163	380	7,512
Evening	199	213	340	12,265
Secondary and normal	75	361	3,367	32,585
Commercial	10	100	653	8,337
Superior (preparatory)	19	27	599	3,324
Arts and crafts	19	37	297	3,691
Agricultural	7	9	32	426
Art	3	6	73	684
Military	10	10	—	—
Religious	0	27	211	1,504

Abnormals	4	5	59	243
Unclassified	7	7	40	539
Total	8,491	10,081	19,037	639,854

Religion.—The Roman Catholic faith was introduced into Colombia by the Spanish conquerors and up to 1853 was the only religion permitted to Colombians. Until amended in 1936, the Constitution provided that Roman Catholicism should be the national religion protected by the State, but a complete disestablishment was effected in that year. During the colonial period many churches were built and religious communities established, and the Church was wealthy and powerful. Although under President Mosquera (1861) most of the church property was transferred to the State, the influence of the Church is still quite strong. Its influence in matters of education was materially decreased by the policies followed under President López (1934–1938). Ecclesiastically the republic is divided into four archdioceses and eleven episcopal dioceses. The people of Colombia are overwhelmingly Roman Catholic in religion.

Finances.—Many elements have contributed to the marked improvement which has taken place during the last few years in the economic situation of the country and in the finances of the Government. Of these the most far-reaching has been the great increase in the value of coffee exports, which has materially increased the wealth of the country, and only to a less degree the development of the nation's petroleum resources. The initial impetus to more orderly finances may be said to have been the payment by the United States of $25,000,000 in five yearly instalments, from 1922 to 1926 inclusive, in settlement of claims arising out of the secession of Panama in 1903, and the financial and monetary reforms of the Kemmerer commission in 1923. These reforms included the establishment of a new and sound budget régime, the reorganization of the currency on a gold basis and establishment of a national bank of issue, the reorganization of the administration and collection of the national revenues and the national accounting, and the creation of a department for the general supervision of expenditures.

Revenue and Expenditure.—A sudden freshet of borrowed money from the United States in 1927 and 1928 enabled the budgets for those years to reach record heights, but by 1929 a deficit brought financial difficulties and necessitated short term borrowings in the following year. The indebtednesses thus incurred have loaded the country with a debt from whose effects it is but slowly recovering.

In 1932 the ordinary revenues reached the lowest total for a decade, but since that time they have mounted steadily, as have expenditures.

Ordinary Revenues and Expenditures, 1932–1939
(in thousands of pesos)

	1932	1933	1934	1935	1936	1937	1938	1939
Revenues	35,346	39,787	53,361	57,360	70,063	82,606	83,773	89,200
Expenditures	35,458	31,810	49,365	57,670	65,301	71,892	81,237	89,800

Revenues come principally from import and export duties, which normally account for approximately half the total, especially since adoption of a high tariff policy in 1930. The income tax now supplies around 10,000,000 pesos annually. The largest single item of expenditure in the 1938 budget, which totalled 81,567,979 pesos, was public works (15,216,541 pesos), with national defence (13,050,000 pesos) and public debt (10,825,174 pesos) next in order. Education was allotted 6,840,903 pesos.

Public Debt.—The external debt of Colombia, including that of departments and municipalities, and of institutional indebtedness guaranteed by the Government, aggregated $146,265,930 and £2,666,290 in 1939. Most of this is in complete default, with accrued interest on the dollar loans approximating $53,304,000. In Feb. 1940, however, an agreement was made for temporary resumption of service on the national government's $53,839,530 obligations. Internal indebtedness as of Jan. 1, 1939, was officially reported as 109,418,146.04 pesos.

Money and Banking.—The monetary unit is the peso, which through exchange control has been maintained at approximately 57¢ U.S. This is maintained through the Banco de la República, which is also the sole bank of issue in the country.

Weights and Measures.—The metric system of weights and measures is obligatory for official business and is used in international trade. In the interior, however, the old Spanish weights and measures are still used to a considerable extent in domestic transactions, including the *libra* of 1·102 lb. avoirdupois, the *arroba* of 25 *libras* (12½kg.), the *quintal* of 100 *libras* (50kg.), the *carga* of 250 *libras* (125kg.), the *vara* of 80cm. and the *fanega*. The litre is the standard liquid measure.

National Defence.—Military service is obligatory under the law and all males are eligible. The standing army numbers about 6,000. The naval and aerial equipment for national defence is very limited.

ECONOMICS AND TRADE

Agriculture.—The larger part of the population live by farming and cattle herding. Coffee production is the principal source of wealth, there being no other that approaches it in importance. Agricultural statistics for the most part do not exist. Only a small part of the land is under cultivation, and there are still vast tracts of virgin land in all the departments. The largest proportion of cultivated land is in the temperate zone of the elevated areas. Modern agricultural methods are unknown; there are very few ploughs in use, and other agricultural machinery is practically unknown. There is little or no use of fertilizers. The most common method of preparing land for cultivation is to burn it over, and in the aggregate a large area of good timber land is burned off every year for planting. There are in general use only a few crude implements, of which the most important is the *machete* (heavy knife). Most of the cultivation given the coffee shrubs is done with this.

Coffee is grown principally in the zone between 3,000 and 6,000ft. in elevation. Production has increased greatly in the last quarter century. In 1926 exportation totalled 2,454,288 bags of 132lb. (60 kg.), more than 60% in excess of the average for the preceding 5 years. Except for 1927, when the total was 97% of that figure, exports have been consistently higher ever since, and in 1937 aggregated 165% of the 1926 total, or 4,059,642 bags (4,262,366 bags in 1938). No statistics were published for domestic consumption until 1935, in which year it was estimated at 350,000 bags (400,000 in 1937). The 1937 crop was approximately 10·7% of the world's total, making Colombia second only to Brazil (25,944,000 bags) in world production.

In 1937 16·54% of world consumption (in contrast to production) was of Colombian coffee (Brazil, 52·89%). The United States is the heaviest purchaser of Colombian coffee, which supplied 21·72% of her needs in 1937. Colombian coffee is known in the world's markets as mild, and is blended with stronger grades. It is grown under shade-trees, and a large part of it on mountain slopes. The departments of Caldas (31·56% in 1937), Antioquia (16·45%), Tolima (13·71%), Cundinamarca (11·78%), and Valle del Cauca (10·87%) are the principal producing regions, but coffee is also produced in five other departments. Coffee exports in 1938 represented 55·8% of export values. Although the total volume was 5% greater, value declined 5·1% from 99,172,496 pesos in 1937 to 94,160,136 pesos in 1938.

Bananas grow extensively in nearly all regions of the torrid and temperate zones in a great number of varieties and are one of the principal foods of the people. The production for export is practically all in the region about Santa Marta on the Caribbean coast. Other agricultural products exported are cotton, rubber, tobacco and tagua. Their export value, however, is insignificant. Other agricultural production is mainly food for home consumption. The torrid zone produces rubber, coco-nuts, tobacco, bananas, sugar-cane, corn, cotton, cocoa, beans, rice, etc. The subtropical zone, in addition to coffee, produces a great variety of fruits such as banana, pineapple, mango, papaya, alligator-pear and citrus fruits. The temperate zone is the most favourable for agriculture and produces wheat, barley, potatoes, oats, corn and practically all the fruits and vegetables known in the United States.

Bananas aggregate around 5% of total exports, averaging around 7,500,000 stems annually (6,685,192 in 1937).

Production and extent of cultivation of some of the other leading agricultural products were as follows in 1937:

	Hectares under cultivation	Production in metric tons
Cacao	12,316,451 (trees)	11,359
Corn	556,147	490,505
Sugar	272,818	43,428
Wheat	199,627	90,768
Beans	72,496	36,096
Potatoes	67,546	285,547
Rice	67,170	74,645
Cotton	43,294	18,842
Tobacco	15,087	14,829

Cattle-raising.—Cattle-raising and crop farming sustain the bulk of the population. The largest rural properties are those devoted to cattle, and in both the tropical and the temperate zone there are vast areas suitable for this industry. It is estimated that the country could support 50,000,000 head. The number of head of cattle and other livestock in 1937 was: cattle, 7,592,000; sheep, 830,807; swine, 1,544,617; goats, 517,510; mules, 453,232; asses, 288,455; horses, 925,733.

The only export which has developed is that of hides. In 1938, the exportation of hides was valued at 3,871,000 pesos.

An attempt to establish a meat-packing industry shortly after the close of the War of 1914–1918 failed, and the plant was abandoned.

An important import trade in cattle from Venezuela helps supply domestic demands.

Mineral Wealth.—Gold, formerly the principal source of mineral wealth, has been supplanted by petroleum. Colombia, with a current production of about half that of Mexico, is the third most important petroleum producer among the Hispanic American countries. Concessions are exploited by foreign companies, of whom only one, the Tropical Oil Company, a subsidiary of the Standard Oil Company (N.J.), was actively producing, and the value accruing to the country is in the royalties on production and in special taxes. Under the terms of the Tropical Oil Company grant, 10% of crude production (after deduction of petroleum used in drilling) goes to the State. Between 1921 and June 1937, the nation (and the department of Santander del Sur) received approximately 14,500,000 pesos as its royalty, the amount being paid in money, not oil. Annual production averaged almost 19,000,000bbl. between 1928 and 1939 inclusive. In 1939 it was 22,998,000 barrels.

Production of gold was valued at $15,447,700 (U.S.) in 1937, and $18,225,095 in 1938 with a production of 442,222 fine ounces, the highest on record. Silver production was 167,971 fine ounces, platinum, 29,315 fine ounces. Slightly over half the gold and over 60% of the silver is mined in Antioquia.

There are abundant resources of coal, which have been exploited particularly since 1934. Production over the four-year period 1934–1937 averaged approximately 335,000 metric tons annually. Salt production is a Government monopoly. Total annual output averages three million pesos.

Manufacturing.—Manufacturing was formerly confined to low grade articles of everyday use, but has made great strides under a protective tariff policy since 1930. Textile mills, sugar mills, breweries, and cement plants are the most important industrial enterprises. Practically all the output is for domestic consumption. In 1937, 31,192 persons were employed in factories, 10,009 of them in textile mills. The departments of Cundinamarca, Atlántico, and Antioquia are the principal centres of industrial activity.

Foreign Trade.—Colombia, by reason of her geography and topography, has an almost bewildering range of potential exports, but nevertheless her export trade is confined into such narrow limits as to put her on the edge of the one-crop country group. The following chart shows the percentages of each of the principal commodities exported in 1937, 1938 and 1939 (including gold):

(In thousands of pesos, i.e. add 000)

Commodity	1937	% of total	1938	% of total	1939	% of total
Coffee	99,172	53·8	94,160	55·8	87,125	49·2
Petroleum	35,079	19·0	37,206	22·1	31,903	18·0
Gold (to U. S.)	32,019	17·4	18,780	11·1	40,582	22·9
Bananas	6,983	3·8	8,684	5·2	8,679	4·9
Cattle hides	5,034	2·7	3,876	2·3	3,638	2·0
Platinum	2,666	1·5	1,651	1·0	1,126	0·6
Tobacco	400	0·3	1,027	0·6	....	...
Others	2,834	1·5	3,253	1·9	4,001	2·4
Total exports	184,187	100·0	168,637	100·0	177,054	100·0

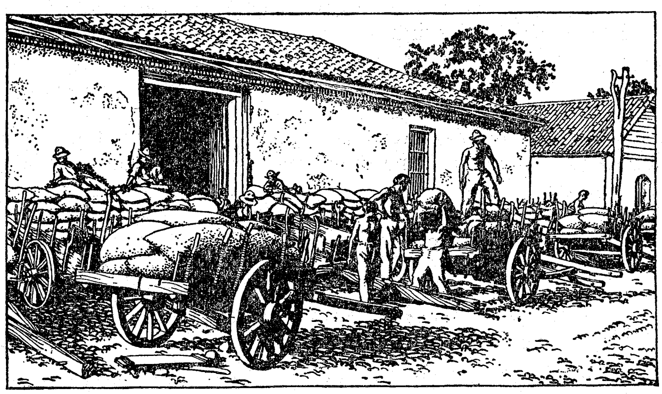
If gold were deducted from the above totals, coffee alone would total 61% of all exports. The United States takes around 60% of the total of Colombia's exports, including, in recent years, all the gold and over 75% of the coffee. Until the outbreak of the European war in 1939, Germany was taking between 10% and 15% annually. Around 12%, representing petroleum for refining, goes to Curaçao.

Imports are textiles, machinery, and miscellaneous manufactured goods. Approximately 50% of imports are supplied by the United States. In recent years Germany, with 13·4% in 1937 and 17·3% in 1938, and Great Britain, with 18·82% in 1937 and 12·3% in 1938, have stood second and third. Imports and exports in recent years have been as follows (not including exports of gold bullion):

Colombian Foreign Trade, 1932–38 (in thousands of pesos)

	1932	1933	1934	1935	1936	1937	1938	1939
Imports	34,327	55,627	98,066	119,677	134,441	169,682	159,259	183,461
Exports	67,109	67,586	123,891	123,602	136,844	152,169	149,857	177,054

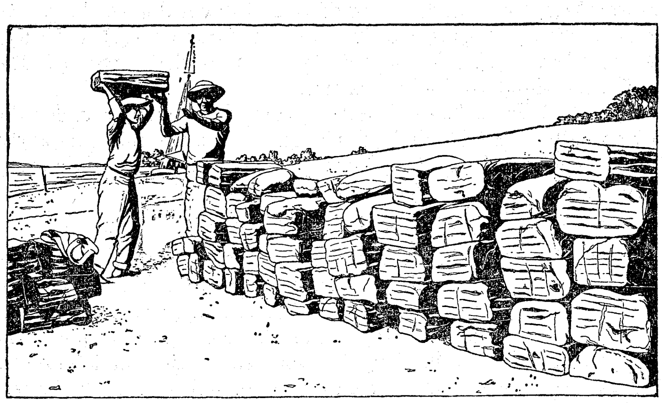
In 1939, exports (not including 40,582,000 pesos value of gold to the United States) were valued at 136,472,000 pesos, going chiefly to the United States (58·9%), Germany (9·5%), France (4·1%), Great Britain (1·8%), Italy (1·7%). During the first 8 months Germany purchased 13·7%, but after Sept. 1, 1939, only 0·3%. Imports of 129,807,000 pesos were chiefly from the United States (55·6%), Germany (12·8%), Great Britain (10·5%). German sales dropped from 16·6% in the first 8 months to 3·5% in the last 4 months.



COFFEE BEING LOADED ONTO CRUDE CARTS

Communications.—The transportation problem in Colombia is one of peculiar difficulty. With few exceptions, the more densely populated districts are in the interior, isolated from the coast by mountain chains, and despite steady and rapid progress in the last few years, communication is still inadequate. This is especially true of Bogotá, although development of aviation has materially alleviated the difficulties. There is no continuous rail or road communication from the interior to the coast. Instead, the Magdalena river is the main artery of traffic. Most of the railroads run from it to interior points. Its navigation is slow and is open only to vessels of small draft, necessitating transhipment at Barranquilla, whose harbour has been recently improved by extensive port works.

In 1921 the country had 1,511km. of railways in operation, but since that time the length has been more than doubled, reaching 3,197km. in 1937. Most of the railways are Government-owned. The National Railway Council administers six lines (1,513km.) of nationally owned railroads and one principally owned by the department of Cundinamarca. Two nationally owned lines (172km.) are operated separately. Five lines (783km.) are owned by departments. The total of railway mileage owned by the nation or by departments is 2,468 kilometres. In addition, 9



NATIVE RUBBER MOULDED INTO BLOCKS, BEING STACKED FOR SHIPPING BY MULE OR CANOE separate privately owned railways (729km.) are in operation.

Highway development has received especial stress in recent years. During the four years ending in 1937, some 3,000km. of highway were added. In that year there were 11,952km. of highways in the country, and an additional 11,614km. in project. National highways aggregated 6,866km. in operation, and 8,172km. in project. Between 1932 and 1936 the number of automobiles in the country increased by 69% (to 19,435), and was estimated at 21,000 in 1937. About half were in the department of Cundinamarca, that is, in and around the national capital.

A peculiar feature of Colombian transportation is the use of aerial cables for handling merchandise and passengers. Three of these, with a total length of 142km., are in operation between Gamarra and Ocaña, Manizales and Mariquita, and in the department of Caldas. The distance between stations on the first named averages 4,700 metres.

Aviation.—Colombia was the first South American country to take up air travel on a commercial scale. In 1920 a concession was granted to the German-Colombian company "Sociedad Colombiana Alemana de Transportes Aéreos," familiarly known as "Scadta" from its initials. This company and some others connect various parts of the country with one another and with the outside. The longest non-stop run, from Barranquilla to Bogotá, some 500 miles, takes $2\frac{1}{2}$ hours by plane, and a minimum of 6 days by rail and river. Between 1934 and 1937 inclusive, passenger and freight traffic quadrupled. Through the internal air transport system, regular and frequent connection with foreign air services is available. Barranquilla, at the mouth of the Magdalena, is the country's largest port. Other ports are Cartagena and Santa Marta on the Caribbean, and Buenaventura on the Pacific. Frequent and regular steamer service by several lines is available to Panama, to New York and New Orleans, and to European ports.

Telephone, Telegraph, Etc.—Both telegraph and radio systems are Government-operated. In 1937 there were 35,990km. of telegraph line and 898 offices. The larger cities have local telephone service owned by private companies or the municipalities. The national Government owns long-distance telephone lines connecting most of the larger cities. External cable communication is through Buenaventura and Cartagena. (L. W. Be.; J. F. Ki.)

ARCHAEOLOGY

From the archaeological point of view the large expanse of territory represented to-day by the Republic of Colombia must be considered separately. But investigation is so incomplete that only the main lines of the prevailing culture can be indicated. The fine technique of the pottery and gold-work of certain regions, and also the traditional history of a few tribes, bring the area into relation with the more organized cultural developments both to the north and south. Large portions of the country were peopled by tribes living under primitive conditions, and the manifestations of higher culture are confined, so far as is known, to the Cauca valley and the plateau of Bogotá.

Historical tradition, as preserved, relates principally to the tribes of the Bogotá plateau, where, at the time of the Spanish invasion, political conditions seem to have been much the same as those of central Peru at the beginning of the rise of the Inca. The expansion of tribes of kindred culture, ruled by paramount chiefs, led inevitably to collision, and the Chibcha people had established a supremacy over their neighbours, which, given time for development, might well have resulted in an "empire" on Inca lines. Far less is known from traditional sources of the people of the Cauca valley, among whom the Quimbaya tribe stand pre-eminent as potters and gold-workers. Existing evidence would place culture of the more advanced peoples of Colombia in exactly that position which their geographical situation suggests. There is undoubtedly a close connection with Panama, and remoter Peruvian and Mexican influence. Influence from the south is a natural assumption, but, owing to the difficulties of travel by land, due to the forested area of eastern Panama, sparsely peopled by tribes of low culture, the very close relationship between the Colombians and the Talamancans appears at first sight surprising. But clearly there was a regular "port-to-port" trade down the western coast, which was so continuous that Vasco Núñez de Balboa received from the Panamanian chief, Tumaco, an itinerary by sea to Peru, as yet undiscovered, together with a description of the llama.

Like the Talamancans, the inhabitants of Colombia did not practise stone-building, with one notable exception. This is the prehistoric site of San Agustín, on the upper Magdalena, where sculptures have been found in a style obviously connected with the art of the Peruvian Chimú. The pottery, especially in ornamentation by means of the "lost-colour" process (the reservation of designs in the ground-colour by means of wax or resin painting before the second slip was applied) shows a close relationship with Talamancan technique, while the forms and paste display near relationship to the ware of the Ecuadorian highlands. The gold-work, produced by the *cire-perdue* process of casting, with soldered details, or by hammering is, as far as the province of Antioquia (the Quimbaya area) is concerned, almost indistinguishable from the Talamancan. But the Chibcha produced castings, of very inferior quality, in a peculiar style of their own, which is easily recognizable. Gold was common in the Colombian region, and was employed for divine offerings, either in the form of dust or of manufactured articles. At certain ceremonies, practised in common by the tribes of the Bogotá plateau, rich offerings of this metal were thrown into certain sacred lakes (especially Lake Guatavitá) or deposited on the banks. The particular rite of investiture of the ruler of Guatavitá, in accordance with which, plastered with gold-dust, he plunged into the lake, gave rise to the many stories of "El Dorado" found in the pages of the early chroniclers. Religion, so far as can be ascertained, was expressed in the worship of various powers of nature, the sun, moon, rain and lakes. Creator-gods and culture-heroes were also included in the pantheon. In outline, religion seems to have corresponded to that of the early Peruvian tribes, but much of the ritual shows a very close correspondence with that of the later Mexicans, especially in the extent, and methods, of human sacrifice. Nahuatl influence extended into the Talamancan area, and certain features of Nahuatl ritual may have been introduced into Colombia together with Talamancan methods of pottery decoration and gold-technique. Human sacrifice, if it existed under the Inca régime in Peru, was rare, and was only practised on special occasions. In this respect Colombian religion approximates very closely to the Mexican. For chronology *see* chronological table, Central America: *Archaeology*. (T. A. J.)

HISTORY

The coast of Colombia was one of the first parts of the American continent visited by the Spanish navigators. There, too, at Darien, was located the first permanent European settlement on the American mainland (1510). In 1525 Rodrigo de Bástidas founded Santa Marta, from which stemmed colonial New Granada (as Colombia was known until 1861). From Santa Marta, in April 1536, Gonzalo Jiménez de Quesada pushed inland and founded Bogotá (Aug. 6, 1538). Soon there were several well established, growing communities on the coast and in the interior highlands, among the former the great fortress city of Cartagena, focal point of foreign attacks throughout the Spanish era. Until the early 18th century, New Granada was governed by the Viceroy of Peru. In 1718 (temporarily) and definitely in 1740, however, New Granada was erected into a viceroyalty which included under its jurisdiction not only the present Colombia, but what is now Panama, Ecuador, and Venezuela as well. Throughout the colonial era geographically isolated New Granada was neglected by Spain, and toward the close of the 18th century, rumblings of discontent were manifest.

In 1811 insurrection against Spanish domination was formally commenced, and almost incessant warfare was carried on with the mother country until 1824. Simón Bolívar, the great national hero, headed the struggle. In 1831 the republic of New Granada was founded, which included the territory at present known as Colombia and Panama, and a Constitution was promulgated. From then up to 1903 the country was carrying on intermittent civil war. Under President Tomás de Mosquera in 1861 the power of the

Church was reduced and its property appropriated by the nation. In 1861 the name The United States of Colombia was adopted.

Through the many years of strife the conciliation of warring factors was effected, the unity of the country consolidated, and the way laid for permanent peace. There was, however, a constant drain on the manhood and resources of the country, and the intervals of peace were too short to permit of the development of the natural resources or progress in transportation. Colombia entered the 20th century as a country in which the principal centres of population were scattered over a vast territory more or less isolated from each other. A life of considerable comfort and culture developed in the various cities, but the country as a whole remained in a backward state. In 1903 peace was attained, which has proved to be lasting.

Perhaps the most important event of the 20th century has been the loss of Panama, which seceded in 1903 (*see* PANAMA). The differences between Colombia and the United States over the secession of Panama were adjusted by the Thompson-Urrutia Treaty, which was finally ratified by the Colombian senate in Dec. 1921. Among other conditions this provided for the payment of $25,000,000 indemnity to Colombia for the loss of Panama in five yearly payments, Colombia engaging to recognize the independence of Panama.

Under Gen. Pedro Nel Ospina, who became president in Aug. 1922, an impetus was given to the construction of public works, especially roads and railroads. For this purpose loans to the amount of $25,000,000 in July, 1927, and $34,000,000 in March, 1928, were concluded in New York; particular projects involved included a railway giving Bogotá direct connection with the Pacific and another extending from Bogotá northward to connect with the existing line in the lower Magdalena valley. In 1926 Dr. Miguel Abadia Méndez was elected to the presidency for a four-year term. A treaty with Nicaragua, signed March 24, 1928, settled several century-old territorial disputes between the two countries by awarding the Mosquito Coast and the Great and Little Corn Islands to Nicaragua and islands of the Andrés Archipelago to Colombia. In Feb. 1930, Dr. Enrique Olaya Herrera was elected president, the first Liberal in several decades. The financial crisis forced the Conservative majority in Congress to provide checks on the export of gold, regulation of exports and imports, a virtual suspension of debt payments, a system of agricultural credits, and appropriations for public works. The Conservatives sought by voting war preparations to magnify a minor Peruvian invasion of Leticia, Sept. 1931, into a major issue; only the friendly agency of Brazil, the U.S.A., and the League of Nations secured the interposition of a League Commission to administer the province while a Protocol favorable to Colombia was negotiated; Conservative opposition delayed ratification until 1935. Meanwhile the Liberals captured control over Congress and reopened their attack on the favoured position of the Catholic Church. In the presidential election of 1934, boycotted by the Conservatives, Dr. Alfonso López, advocate of a "New Deal," easily won over his Communist rival. A series of constitutional and other reforms featured his administration, an eight-hour day law, the guarantee of labour's right to strike, and the disestablishment of the Roman Catholic Church being the most outstanding. A reaction set in by 1937, however, and the more moderate Liberals were able to nominate the relatively conservative Eduardo Santos, a prominent newspaper publisher, as the party candidate, and to elect him in Feb. 1938. The new president's policy was, in general, one of progressive but not radical action. Meanwhile, in international affairs, Colombia continued to work in close harmony with the United States.

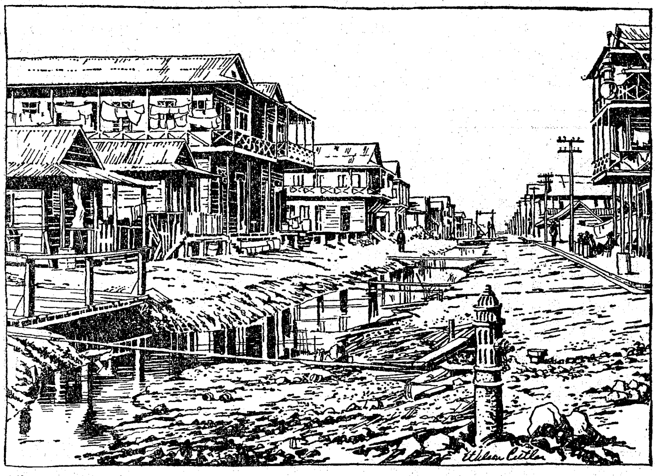
COLOMBO, the capital and principal seaport of Ceylon, situated on the west coast. Pop. (1931), 284,155; est. 1943, 345,000. Near the mouth of the Kelani river, the environs of the town are low-lying and wide areas are liable to inundations against which considerable protective works have been constructed. Galle, 70 mi. S. by rail, was Ceylon's principal port of call until harbour works were undertaken at Colombo between 1874 and 1886. The large artificial harbour has an area of 643 ac. at low water. An area of 246 ac. has been dredged to a low-water depth of 36 ft. and over, 140 ac. to a depth varying between 36 ft. and 34 ft. and 106 ac. to between 33 ft. and 30 ft.; the remaining 151 ac. have a depth of less than 30 ft. Vessels drawing 34 ft. can enter by the western channel (630 ft. wide), and vessels drawing 29 ft. by the northern channel (550 ft. wide). Berthing accommodation, exclusive of the graving docks, guide pier and oil jetties, is available for 35 vessels in the N.E. monsoon and 38 vessels in the S.W. monsoon. The outer graving dock has a length of 695 ft., and the inner, completed in 1938, 350 ft. The Beira lake, and the canal connecting to the harbour, is an integral part of the port of Colombo. The canal is navigable by 40-ton barges, and the lakeside barge yards relieve congestion in the harbour where hitherto they had been moored.

The business part of Colombo is known as the Fort; it occupies the site of the old fortified area, the defenses of which were demolished by Lord Rosmead (then Sir Hercules Robinson) in 1869. Here are also Queen's House, the official residence of the governor, and the main block of government offices. The law courts are built on a site in the suburb known as Hultsdorf, which, during the Dutch period, formed with Wolfendahl the principal European quarter. Colombo has few buildings of any architectural interest or value, but mention may be made of the Dutch church at Wolfendahl and the Buddhist temple at Kotāhena. Ceylon University college, established 1921, prepared students for the examinations of the University of London, and Ceylon Medical college, founded 1870, provides instruction of such standard that it has been recognized by the General Medical Council of the United Kingdom since 1887. These two institutions, by legislation enacted in 1942, were merged to constitute the University of Ceylon. Colombo has a general hospital with 935 beds and an ophthalmic hospital, hospitals for women and for children, a Pasteur institute and bacteriological, dental and anti-tuberculosis institutes.

Colombo is a municipal town. It is administered by a municipal council, the members (of either sex) being elected by the ratepayers; the mayor is elected annually from among the councillors. The town is not only the administrative capital of the colony but is by far the greatest business centre. All the principal firms doing business in Ceylon have their offices in Colombo, and by means of visiting agents attached to some of these firms the management of most of the tea and rubber plantations in the island is controlled. The principal open spaces are the Victoria park, in the suburb that still bears the name of the Cinnamon Gardens, the Galle Face esplanade, the Havelock racecourse, Havelock park and the Ridgeway golf links. There are numerous cricket fields, several of which are of exceptional quality. The climate is warm and humid, but the town is healthy and has always been singularly free from malaria, in spite of its somewhat low-lying and waterlogged situation. The mean temperature is 80.8° F., and the mean annual rainfall 91 in. The hotel at Mount Lavinia, a few miles to the south of Colombo, originally built as a residence for the governor without colonial office authorization and promptly sold, is a favourite sea-bathing and pleasure resort. Cotta, a suburb distant some 5 mi. from the port, was the original capital of the Sinhalese kings in the neighbourhood. The Kelani river is spanned by the Victoria bridge, from the head of which roads lead northward to Negombo and Chilaw, and east by north to Kandy. South of the Kelani river, main roads lead southward along the coast to Hambantota and up the Kelani valley to Avisawella. From these points main roads branch off to every part of the island.

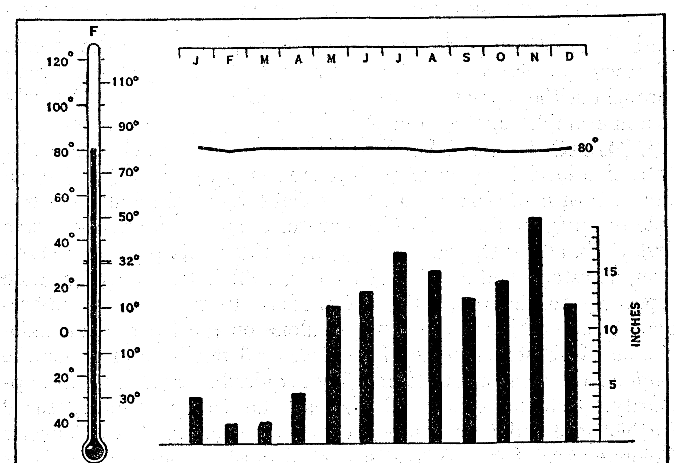
COLÓN, a town of Matanzas province, Cuba, on the railway between Matanzas and Santa Clara, and the centre of a productive cattle, sugar and tobacco region. Population (1943 census) 11,534 (city); 25,052 (*municipio*).

COLÓN, the second city of the Republic of Panamá, and the northern gateway to the Panama canal. The American town of Cristóbal, which is within the Canal Zone, adjoins Colón and is virtually a part of it. The great port works and docks built by the American government at Cristóbal make Colón one of the most important ports of the Caribbean sea, a considerable portion of the freight for neighbouring coastal points in Central America and northern South America being transshipped there and other goods being unloaded for storage in the large bonded warehouses within the Canal Zone. Colón has a population (1940) of 44,393, not including the residents of the Canal Zone. It is the northern terminus of the Panama railroad, 48 mi. from the city of Panamá. It is the capital of the province of Colón, the seat of a Panaman custom-house and of consuls of various countries.



BY COURTESY OF U.S. WAR DEPARTMENT
"D" STREET IN COLÓN, BEFORE CONSTRUCTION OF PANAMA CANAL

Colón is now one of the busiest tourist centres in the world, its streets lined with shops owned by natives of every land under the sun, and selling the varied products of the world. The native population is largely Negro, chiefly descendants of labourers, imported from the British West Indies during the various periods of construction on the Panama canal, and the rule of the road is to keep to the left, one of the few cities of importance in Latin America following the British custom. The town was founded in 1850, at the Atlantic terminus of the original Panama railway, and was first called Aspinwall, after William H. Aspinwall (1807–75), one of the builders of the railway. The present name, Colón, is the Spanish form of Columbus, as the twin city of Cristóbal is the Spanish of his Christian name. On the completion of the railway in 1855, Colón attained outstanding importance as compared with the older Caribbean ports of Panamá, and with the first plans for the isthmian canal, took on additional prestige. Prior to the beginning of work on the American canal, in 1903, Colón was notoriously unhealthy, and one of the provisions of the Canal treaty of 1903, giving the United States full sanitary control over the cities of Panamá, was to enable it to clean up Colón before the work of construction was begun. Much of the work of Gen. Gorgas (*q.v.*), the sanitary genius of the canal construction, was done in and about Colón, which was given a new system of waterworks and sewerage as well as a complete drainage of the surrounding swamps in the triumphant fight against yellow fever and malaria. Colón is one of the most healthful tropical cities in the world. The Hotel Washington, operated by the U.S. government, is the popular resort of the Canal Zone. (W. THO.; X.)



WEATHER GRAPH OF COLÓN. THE THERMOMETER REGISTERS THE ANNUAL MEAN TEMPERATURE. THE CURVE SHOWS THE MONTHLY MEAN TEMPERATURE. COLUMNS INDICATE NORMAL PRECIPITATION FOR EACH MONTH

COLON. (1) In anatomy, part of the greater intestine (Gr. κόλον, from κόλος, curtailed) (*see* ALIMENTARY CANAL). (2) Originally in Greek rhetoric a short clause, hence a mark (:) in punctuation, used to show a break greater than that marked by the semicolon (;), and less than that marked by the full stop (Gr. κῶλον, a member, or part). Applied in palaeography to a unit of measure in mss., amounting in length to a hexameter line.

COLONEL, the superior officer of a regiment of infantry or cavalry (derived either from Lat. *columna*, Fr. *colonne*, column, or Lat. *corona*, a crown); also an officer of corresponding rank in the general army list. The colonelcy of a regiment formerly implied a proprietary right in it. Whether the colonel commanded it directly in the field or not, he always superintended its finance and interior economy, and the emoluments of the office, in the 18th century, were often the only form of pay drawn by general officers. The general officers of the 17th and 18th centuries were invariably colonels of regiments, and in this case the active command was exercised by the lieutenant-colonels. At the present day, British general officers are often, though not always, given the colonelcy of a regiment, which has become almost purely an honorary office. The sovereign, foreign sovereigns, royal princes and others, hold honorary colonelcies, as colonels-in-chief or honorary colonels of many regiments. In other armies, the regiment being a fighting unit—usually of three battalions, the colonel is its active commander; in the British army the battalions of a regiment serve separately—normally one abroad and one at home in peace—and are organized in brigades composed of battalions of different regiments. Thus 18th century practice has become the modern regulation, and a lieutenant-colonel is the commanding officer of the battalion of infantry and regiment of cavalry. Colonels are actively employed in the army at large in staff appointments, brigade commands, etc., extra-regimentally. Colonel-general, a rank formerly used in many armies, still survives in the German service, a colonel-general (*General-Oberst*) ranking between a general of infantry, cavalry or artillery, and a general field marshal (*General-Feld-marschall*). Colonels-general are usually given the honorary rank of general field marshal.

The United States.—The colonel in the U.S. army is the highest rank to which officers are promoted by seniority. His appropriate command is the regiment. Colonels are assigned to duty as chief of staff of divisions, assistant chiefs of staff in the larger units, and as assistants in the administrative and supply services. The insignia of rank of the colonel is the silver eagle worn on the shoulder strap of the uniform.

COLONIAL OFFICE: *see* GOVERNMENT DEPARTMENTS.

COLONIAL PREFERENCE: *see* IMPERIAL PREFERENCE.

COLONIAL STYLE, in architecture, a term loosely applied to any style developed by colonizers; *e.g.*, the French colonial architecture of Morocco, the colonial architecture of Bermuda, etc. When used without a qualifying adjective, the term denotes specifically the architecture of the English colonies of the North American continent during the 17th and 18th centuries; and also, by extension, the continuation and development of that style after the Revolution, down to the coming of the classic revivals, 1800–30 (*see* MODERN ARCHITECTURE, 18TH AND 19TH CENTURIES). The peculiar characteristics of any colonial architecture result from the attempt to reproduce as closely as possible the architecture of the mother country in places where labour may be limited or untrained or influenced by native tradition, materials may be different and climate and environment may be unfamiliar.

COLONNA, a noble Roman family, second only to the Gaetani di Sermoneta in antiquity, and first of all the Roman houses in importance. The popes Marcellinus, Sixtus III., Stephen IV. and Adrian III. are said to have been members of it, but the authentic pedigree of the family begins with Pietro, lord of Columna, Palestrina and Paliano (about 1100), probably a brother of Pope Benedict IX. His great grandson Giovanni had two sons, respectively the founders of the Colonna di Paliano and Colonna di Sciarra lines. The third, or Colonna-Romano line, is descended from Federigo Colonna (1223). In the 12th century we find the Colonna as counts of Tusculum, and the family was then famous as one of the most powerful and turbulent of the great Roman clans; its feuds with the Orsini and the Gaetani are a characteristic feature of mediaeval Rome and the Campagna; like the other great nobles of the Campagna, the Colonna plundered travellers and cities and did not even spare the pope himself if they felt themselves injured by him. Boniface VIII. attempted to break their power, excommunicated them in 1297, and confiscated their estates. He proclaimed a crusade against them and captured Palestrina, but they afterwards revenged themselves by besieging him at Anagni, and Sciarra Colonna laid violent hands on His Holiness, being with difficulty restrained from actually murdering him (1303). In 1347 the Colonna, at that time almost an independent power, were defeated by Cola di Rienzi, but soon recovered. Pope Martin V. (1417–1431) was a Colonna, and conferred immense estates on his family, including Marino, Frascati, Rocca di Papa, Nettuno, Palinao, etc., in the Campagna, and other fiefs in Romagna and Umbria. Their goods were frequently confiscated and frequently given back, and the house was subject to many changes of fortune; during the reign of Pope Alexander VI. they were again humbled; but they always remained powerful and important, and members of the family rose to eminence as generals, prelates and statesmen in the service of the Church or other powers. In the war of 1522 between France and Spain there were Colonna on both sides, and at the battle of Lepanto (1571) Marc Antonio Colonna, who commanded the papal contingent, greatly distinguished himself. A detailed record of the Colonna family would be a history of Rome. To-day there are three lines of Colonna: (1) Colonna di Paliano, with two branches, the princes and dukes of Paliano, and the princes of Stigliano; (2) Colonna di Sciarra, with two branches, Colonna di Sciarra, princes of Carbagnano, and Barberini-Colonna, princes of Palestrina; and (3) Colonna-Romano. The Colonna palace, one of the finest in Rome, was begun by Martin V. and contains a valuable gallery.

BIBLIOGRAPHY.—*Almanach de Gotha* (1775, etc.); A. von Reumont, *Geschichte der Stadt Rom* (1868), containing an elaborate account of the family; F. Gregorovius, *Geschichte der Stadt Rom in Mittelalter*, 8 vols. (Stuttgart, 1859–72 trans. from the 4th Ger. ed. by G. W. Hamilton, 8 vols. 2nd ed. rev. 1900–09); A. Norvack, *Die Reichsgrafen Colonna Freiherrn von Fels* (Gross-Strehlitz, 1902); L. Ross, *Die Colonna*, 2 vols. (Leipzig, 1912).

COLONNA, VITTORIA (1490–1547), marchioness of Pescara, Italian poetess, daughter of Fabrizio Colonna, grand constable of the kingdom of Naples and of Anna da Montefeltro, was born at Marino, a fief of the Colonna family. She married at 19 Ferrante de Avalos, marquis of Pescara, who was subsequently a noted captain of Charles V., and who died of wounds at Milan in 1525. During their long separation they corresponded with each other in passionate terms in prose and verse. After her husband's death, Vittoria lived at Ischia where she composed the first of the *Rime spirituali* that are a characteristic feature of her poetic genius. In 1539 she was living in Rome, and was the object of a romantic friendship on the part of the ageing Michelangelo. Among her other friends were Cardinal Reginald Pole, Contarini, Cardinal Bembo and Baldassare Castiglione. Her amatory and elegiac poems were printed at Parma in 1538; a third edition, containing 16 of her *Rime spirituali*, was published at Florence soon afterwards; and a fourth was printed at Venice in 1544.

BIBLIOGRAPHY.—A great deal has been written about Vittoria Colonna, but perhaps the best account of her life is A. Luzio, "Vittoria Colonna" in the *Rivista Storica Mantovana*, vol. i. (Mantua, 1885); A. von Reumont, *Vittoria Colonna Vita, fede e poesia*, (Italian revised ed., Turin, 1883), and Amy A. Bernardy, *La vita e l'opere di Vittoria Colonna* (Florence, 1927) are also excellent. For English readers M. Roscoe, *Vittoria Colonna* (1868) and the biography by M. F. Jerrold (London, 1906) may be recommended. The best edition of her *Rime e lettere* is by G. E. Saltini (Florence, 1860). *See* also D. Tordi and G. Sassi, "Michelangelo e Vittoria Colonna," *Nuova Rivista Storica*, X, 478 ff. (1926).

COLONNADE, in architecture, a row of columns. When a colonnade completely surrounds a building or a court-yard, it is known as a peristyle (*q.v.*). When it projects as a separate motif or as an entrance porch, it is called a portico (*q.v.*). Colonnades

were frequently used in the Hellenistic period to line the streets of towns in Syria and Asia Minor, and this custom spread throughout the Roman empire; the city of Rome was particularly rich in examples of this usage.

COLONNE, EDOUARD (1838–1910), French conductor of Italian origin, was born at Bordeaux on July 23, 1838. He began to earn his living when he was eight years old, but later was able to study at the Paris Conservatoire, and from 1858–67 was first violin at the Opéra. In 1873, with the music publisher Hartman, he established a series of concerts which were devoted more especially to the production of modern French works. Subsequently he continued the concerts alone on the basis of an association of artists supported by the general public, and under the name of the Concerts Colonne they acquired great fame and popularity. Colonne conducted also at the Opéra, and appeared further in London and other European centres. The Concerts Colonne were of great value to French music because of the large number of new works by Lalo, Dubois, Franck, Reyer, and other modern French composers which were given at them for the first time. Much attention was given also in their programmes to Berlioz, whose works were frequently performed, in many cases after long-continued neglect. Colonne died in Paris on March 28, 1910.

COLONSAY: *see* HEBRIDES.

COLONY, a term denoting the settlement of the subjects of a State beyond its territorial limits. It is applied by usage to a group of the subjects of one sovereign State living within the bounds of another, and, in this sense, most of the European countries have "colonies" in London. By a variant of this usage the term is applied also to groups of persons of one original nationality admitted as denizens to another State. Thus in the United States there are many "colonies" or emigrants from European powers. More strictly the term refers to (a) the settlement of the subjects of a State in an area outside its geographical boundaries, but within its administrative sphere; or (b) a territorial unit outside the limits of a State but closely associated with it by ties of nationality, administration, economic interest or sentiment. The first finds examples in the Teutonic colonies settled in the Baltic provinces and in colonies of similar type but different nationalities in the Balkan peninsula. The second and more general definition covers all the variations of colony connected with those States which are commonly described as "colonial powers."

Early Period.—The history of colonization in the European sphere is generally opened with the activities of the Phoenicians on the Mediterranean sea-board. At first from Tyre, and later also from Carthage, the Phoenicians founded a series of settlements among the islands and along the North African coast. Their establishment was due to the necessities of trade expansion, and they remained trading-posts of the type which became general in a later age in the history of European contact with the East.

The next colonizing power in this region was Greece. In this case the character of the colonies and the motives of their establishment were more diverse, and present many points of comparison with modern colonization. Some were, like the Phoenician colonies, outposts for trade; but desire for adventure, political discontent and the pressure of population all contributed to the exodus from the city-states, as they did later to emigration from Britain. The system of government in these colonies was of a kind less familiar in modern times. All the Greek colonies, except those founded by Athens, were independent of the parent State, bound to it only by economic or military advantage or by sentiment; and this independence was, moreover, assumed from the beginning, in contrast to the slow growth of autonomy in the British dominions.

The Roman colony was again of a different type. The expansion of Rome was by land, and its method was by conquest, and its modern parallel is to be found in the Balkans or the Baltic rather than among the colonies of "colonizing powers." The Roman colonies of Imperial Rome were settlements within a province, with certain characteristics and privileges, and were primarily centres for the spread of Roman influences in civilization and culture.

Between the downfall of Rome and the great expansion of Europe in the 15th and 16th centuries, the chief exponents of colonization were the city-states of the Italian sea-board. Both Genoa and Venice planted colonies in the 12th and 13th centuries along the Spanish and Barbary coasts, in Dalmatia and among the Greek islands. Like the Phoenician settlements these were mainly out-posts for trade, though the grant of land to the great Venetian families in Dalmatia and the islands offers a closer approximation to modern colonizing methods.

The Period of World Colonization.—These Italian settlements ended the period of colonization in which the Mediterranean was the centre. Henceforth the history of colonization pivoting about the Atlantic, Indian and (later) Pacific Oceans, came to imply the spread of European influence in the non-European world. Before the end of the first half of the 16th century, the Spanish empire had grown up in Central and South America, at Cuba and Hispaniola among the islands and in New Spain and Peru on the mainland. By that time too Portugal had established her claim to Brazil, and had set her mark on the west coast of India and in the Spice islands. France, England and the Dutch followed close upon them, wresting from Spain and Portugal their early monopoly and founding new colonies in North America and the West Indies and trading settlements on the African coast and in the East. The Danes and the Swedes took part also in this wave of expansion, but the west European powers kept their leadership throughout the 17th and 18th centuries.

The motives of colonization in this period included most of those which had led to earlier activities. The increase of trade was perhaps the most important factor, but desire for adventure and the force of religious or political discontent explained much of the emigration. The proselytizing zeal of Portugal and Spain was also of some importance, while the whole movement gained strength and persistence from international rivalries. Colonies changed hands as the result of European wars; the Dutch succeeded Portugal in the Spice islands, and England struggled with France for trading predominance on the African coast and in India, while the French colonies of Canada and certain West Indian islands passed to English control. Trade was the most important consideration for all these colonizing powers, and all followed the lead of Spain and Portugal in seeking a monopoly of their colonial products. They met with varying success. Both the competition and the colonies grew rapidly in the 17th century, and two factors came to determine the measure of the success of the parent State: sea-power was needed to ward off interloping rivals, and cargoes of manufactured goods to supply the colonists' demands. Spain lacked both in the 17th century; Holland could not compete with France or England, and these two were left as the chief protagonists in the colonial struggle.

The government of the colonies had another feature in common besides the principle of trade monopoly, for the tendency in all States was to reproduce in their outlying parts their own constitutional system. This was less marked in the case of Spain than in that of France or England; but while the Spanish king ruled the Indies, as he did Spain, as part of a medley of dominions which had little uniformity of government, yet in many details he followed Spanish procedure. France introduced into Canada the system of legislation by royal edict registered in local *parlements* and the reliance on *intendants* for maintaining local government; while the English colonies possessed legislative assemblies which reproduced the spirit and the forms of Stuart parliaments.

The 19th and 20th Centuries.—This period of colonization ends with the close of the 18th century. The economic changes which formed the Industrial Revolution (*q.v.*) destroyed the economic basis of the colonial system, and the revolutionary era in Europe was accompanied by a movement for colonial freedom. The United States started the change, and were followed by the revolt of Central and South America and the ruin of the empires of Spain and Portugal.

Alone among the colonizing powers Britain carried forward some of her colonial traditions to the new age. The early years of the 19th century saw the expansion of Canada and the growth of new colonies in Australia, South Africa and New Zealand. The great emigration of the middle years of the century, and the increasing demand of industrial England for food-stuffs and raw materials transformed these colonies into great dominions who could support a quasi-national status. At the same time trading interests led to the expansion of control in tropical and semi-tropical regions and the establishment of new "crown colonies" under the administration of the Colonial Office. International rivalry re-appeared in the last quarter of the 19th century. French colonization on the south side of the Mediterranean and inland penetration from the west coast led to the growth of French control over a large part of North Africa, while Spain and Italy later extended their interests in the same region. At the end of the century Germany started her colonial period. The partition of Africa followed, with its welter of delimiting treaties and its multiplication of the types of colony, protected areas, and spheres of influence. The struggle for Pacific islands and trading posts in China accompanied this process, and the United States appeared as a colonizing power. The World War brought some readjustment in the distribution of colonies, and added the new class of "mandated territories" to the existing types.

The developments of the last 50 years seem to be leading to a new limitation of the word "colony," at least in Britain. The great dominions have acquired most of the characteristics of independent States and have to a great extent abandoned the use of the term "colony" as applicable to themselves. It is being restricted, therefore, in general use to those regions to which rights of self-government have not yet been granted. (*See* also BRITISH EMPIRE; AFRICA; MANDATE.) (L. M. P.)

COLOPHON, an ancient city of Ionia, situated inland about 15 m. N. of Ephesus. Its port was at Notium or New Colophon. The site, now called *Tracha,* lies near Diermendere, 5 m. S. of Develikeui. Excavations, commenced during 1922, were interrupted by the Turkish reconquest of Asia Minor. Colophon was a very flourishing city in the great period of Ionia. It was the mother-city of Smyrna; it was ruled by a timocracy (oligarchy of wealth) which provided a famous troop of cavalry. It was famous for its luxury, imitated from the Lydians. It claimed to have produced Homer, but its greatest genuine literary names were Xenophanes and Mimnermus. The first shock to its prosperity was the sack by Gyges of Lydia in 665 B.C. It declined in favour of Notium until in 287 Lysimachus transferred a part of the population to his new city at Ephesus.

Notium contained the important shrine of the Clarian Apollo.

COLOPHON, a final paragraph in some manuscripts and many early printed books (*see* BOOKS), giving particulars as to authorship, date and place of production, and sometimes expressing the thankfulness of the author, scribe or printer on the completion of his task. Thus the Guillermus, who made a famous collection of sermons on the gospels for Sundays and saints' days, records its completion in 1437 and submits it to the correction of charitable readers, and Sir Thomas Malory notes that his *Morte d'Arthur* "was ended in the ix yere of the reygne of Kyng Edward the fourth," and bids his readers "praye for me whyle I am on lyue that God sende me good delyuerance, and whan I am deed I praye you all praye for my soule." The earliest printed paragraph of this kind is that which Fust and Schoeffer printed at the end of their famous psalter of 1457 in red ink: *Presens spalmorum* (*sic* for *psalmorum*) *codex venustate capitalium decoratus Rubricationibusque sufficienter distinctus, Adinuentione artificiosa imprimendi ac caracterizandi absque calami vlla exaracione sic effigiatus, Et ad eusebiam dei industrie est consummatus, Per Iohannem fust ciuem maguntinum, Et Petrum Schoffer de Gernszheim Anno domini Millesimo. cccc. lvii. in vigilia Assumpcionis.* In the Vienna copy of this and in their Latin Bible of 1462 they added a device of two shields at the end of the paragraph, and this addition was widely copied. When a leaf or page was added to the title of a book at its beginning the importance of these final paragraphs slowly diminished, and the information they gave was gradually transferred to the title-page. Complete title-pages bearing the date and name of the publishers are found in most books printed after 1520, and the final paragraph, if retained at all, was gradually reduced to information as to the printer and date. From the use of the word in the sense of a "finishing stroke" (from the story that the final charge of the cavalry of Colophon was always decisive) such a final paragraph as has been described is called by bibliographers a "colophon," but this name for it is quite possibly not earlier than the 18th century. (A. W. P.)

COLORADO, known as the "Centennial State" because of its entrance into the Union in 1876, 100 years after the Declaration of Independence, is a State of the United States of America, situated between 37° and 41° N. lat. and 102° and 109° W. longitude. The State is bounded on the north by Wyoming and Nebraska, on the east by Nebraska and Kansas, on the south by Oklahoma and New Mexico and on the west by Utah. It is the seventh largest State in the Union, having an area of 104,247 sq.mi., of which 280 are water surface and 103,967 land.

Physiography.—Colorado embraces in its area a great variety of plains, mountains and plateaux. It lies at the junction of the Great Plains—which in their upward slant to the westward attain an average elevation of about 4,000 ft. along the eastern boundary —with the Rocky mountains, to the west of which is a portion of the Colorado plateau. These are the three physiographic provinces of the State. The Colorado plateau includes a number of lofty plateaux—the Roan or Book, Uncompahgre, etc., which form the eastern continuation of the high plateaux of Utah and cover the western quarter of the State. Its eastern third consists of rich, unbroken plains.

On the western edge of these plains lies an abrupt, massive and strangely uniform chain of mountains, known in the neighbourhood of Colorado Springs as the Rampart range, and in the extreme north as the Front range, and often denominated as a whole by the latter name. The upturning of the rocks of the Great Plains at the foot of the Front range develops an interesting topography, the harder layers weathering into grotesquely curious forms, as seen in the famous Garden of the Gods at the foot of Pikes peak. Behind this barrier the whole country is elevated about 2,000 ft. above the level of the plains region. In its lowest portions just behind the front ranges are the natural "parks"—great plateaux enclosed by superb ranges. To the west of these and between them, and covering the remainder of the State east of the plateau region, is an entanglement of mountains, tier above tier, running from north to south, buttressed laterally with splendid spurs, cut by river valleys and divided by mesas and plateaux. These various chains are known by a multitude of local names. Among the finest of the chains are the Rampart, Sangre de Cristo, San Juan, Sawatch (Saguache) and Elk ranges. The first, like the other ranges abutting from north to south upon the region of the prairie, rises abruptly from the plain and has a fine, bold outline. It contains a number of fine summits dominated by Pikes peak (14,110 ft.). Much more beautiful as a whole is the Sangre de Cristo range. At its southern end are Blanca peak (14,363 ft.) and Old Baldy (14,125 ft.), both in Costilla county. The mountains of the San Juan ranges of the south-west are particularly abrupt and jagged. Most magnificent of all the mountains of Colorado, however, are the Sawatch and adjoining ranges in the centre of the State. The former (the name is used a little loosely) consists of almost a solid mass of granite, has an average elevation of probably 13,000 ft., presents a broad and massive outline and has a mean breadth of 15 to 20 miles. Mt. Ouray (13,955 ft.), in Chaffee county, may be taken as the southern end, and the splendid Mount of the Holy Cross (13,978 ft.), in Eagle county—so named from the figure of its snow-filled ravines—as the northern. Between the two lie numerous high peaks including Mt. Elbert (14,431 ft.), the highest peak in the State. The Elk range is geologically interesting for the almost unexampled displacement of the strata of which it is composed and the apparent confusion which has thence arisen. The most remarkable of its separate summits, which rise superbly in a crescent about Aspen, is North Italian peak (13,225 ft.), displaying the red, white and green of Italy's national colours. A few miles to the north and north-east of the Mount of the Holy Cross are Torrey peak (14,264 ft.) and Grays peak (14,274 ft.), in Summit county; Mt. Evans (14,259 ft.), in Clear Creek county; and Rosalie peak (13,574 ft.), in Park county; a little farther north, in Gilpin, Grand and Clear Creek counties, James peak (13,259 ft.), and, in Boulder county, Longs peak (14,255 feet). Altogether there are at least 600 summits exceeding 12,000

BY COURTESY OF THE CHAMBER OF COMMERCE, COLORADO SPRINGS

THE SWITCHBACKS, PIKES PEAK, SHOWING THE MODERN MOTOR HIGHWAY TO THE SUMMIT OF THE MOUNTAIN, 14,110 FT. ABOVE SEA LEVEL ft. in altitude, 300 above 13,000 and 50 above 14,000.

Cirques, valley troughs, numberless beautiful cascades, sharpened alpine peaks and ridges, glacial lakes and valley moraines offer everywhere abundant evidence of glacial action, which has modified profoundly practically all the ranges. The Park range, east of Leadville, and the Sawatch range are particularly fine examples. Much of the grandest scenery is due to glaciation.

Among the most remarkable orographical features of the State are the great mountain "parks"—North, Estes, Middle, South and San Luis—extending from the northern to the southern border of the State, and lying (with the exception of Middle park) just east of the continental divide. These "parks" are great plateaux, not all of them level, lying below the barriers of surrounding mountain chains. North park, the highest of all, is a lovely country of meadow and forest. Middle park is not level, but is traversed thickly by low ranges like the Alleghenies; in the bordering mountain rim are several of the grandest mountain peaks and some of the most magnificent scenery of the State. Estes park is small, only 20 m. long and never more than 2 m. broad; it is in fact the valley of Thompson creek. By many it is accounted among the loveliest of Colorado valleys. Seven ranges lie between it and the plains. South park is similarly quiet and charming in character. Much greater than these is San Luis park. The surface is nearly as flat as a lake, and it was probably at one time the bed of an inland sea. In the centre there is a long narrow lake fed by many streams. It has no visible outlet, but is fresh. The San Luis park, which runs into New Mexico, is traversed by the Rio Grande del Norte and more than a dozen of its mountain tributaries. These parks are frequented by great quantities of large game, and—especially the North and Middle—are famous hunting-grounds. They are fertile, too, and their combined area is something like 13,000 sq. miles.

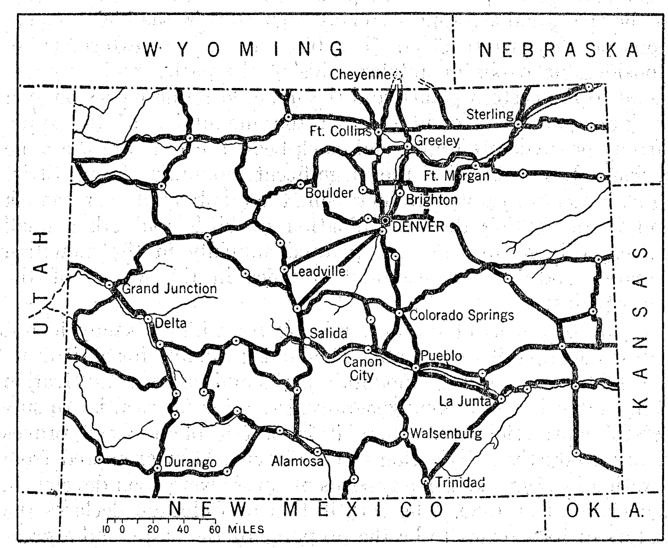
CATHEDRAL SPIRES OF ROCK IN THE GARDEN OF THE GODS, PART OF THE MUNICIPAL PARK SYSTEM IN COLORADO SPRINGS

The drainage system of the State is complicated. Eleven topographical and climatic divisions are recognized by the United States Weather Bureau within its borders, including the several parks, the continental divide and various river valleys. Of the rivers, the North Platte has its sources in North park; the Colorado (the Grand branch), in Middle park; the South Platte, in South park; the Arkansas, in Lake county; and the Rio Grande in San Luis park. Four of these flow east and south-east to the Missouri, the Mississippi and the gulf; but the waters of the Colorado system flow to the south-west into the Gulf of California. Among the other streams, almost countless in number among the mountains, the San Juan, Dolores, White and Yampa, all in the west, are of primary importance. The scenery on the head-waters of the White and Bear, the upper tributaries of the Gunnison and on many of the minor rivers of the south-west, is wonderfully beautiful. The South Platte falls 4,830 ft. in the 139 m. above Denver; the Grand, 3,600 ft. in the 224 m. between the mouth of the Gunnison and the Forks; the Gunnison, 6,477 ft. in the 200 m. to its mouth (except for 16 m., never with a gradient of less than 10 ft.); the Arkansas, 7,000 ft. in its 338 m. west of the Kansas line. Of the smaller streams the Uncompahgre falls 2,700 ft. in 134 m., the Las Animas 7,100 ft. in 113 m., the Los Pinos 4,920 ft. in 75 m., the Roaring Fork 5,923 ft. in 64 m., the Mancos 5,000 ft. in 62 m., the La Plata 3,103 ft. in 43 m., the Eagle 4,293 ft. in 62 m., the San Juan 3,785 ft. in 303 m., the Lake Fork of the Gunnison 6,047 ft. in 59 miles. The canyons formed in the mountains by these streams are among the glories of Colorado and of America. The grandest are the Toltec gorge near the southern boundary line, traversed by the railway 1,500 ft. above the bottom; the Red gorge and Rouge canyon of the Upper Grand, and a splendid gorge 16 m. long below the mouth of the Eagle, with walls 2,000–2,500 ft. in height; the Grand canyon of the Arkansas (8 mi.) above Canon City, with granite walls towering 2,600 ft. above the boiling river at the Royal gorge; and the superb Black canyon (15 m.) of the Gunnison and the Cimarron. But there are scores of others which, though less grand, are hardly less beautiful. The exquisite colour contrasts of the Cheyenne canyons near Colorado Springs, Boulder canyon near the city of the same name, Red Cliff and Eagle River canyons near Red Cliff, Clear Creek canyon near Denver—with walls at places 1,000 ft. in height—the Granite canyon (11 m.) of the South Platte west of Florissant, and the fine gorge of the Rio de las Animas (1,500 ft.), would be considered wonderful in any State less rich in still more marvellous scenery. Among the peculiar features of the mountain landscapes are the mines. In districts like that of Cripple Creek their enormous ore "dumps" dot the mountain flanks like scores of vast ant-hills; and in Eagle River canyon their mouths, like dormer windows into the granite mountain roof, may be seen 2,000 ft. above the railway. More than a dozen mountain passes lie above 10,000 feet. Argentine pass (13,132 ft.), near Grays peak, is one of the highest wagon roads of the world; just east of Silverton is Rio Grande pass, about 12,400 ft. above sea level, and in the Elk mountains between Gunnison and Pitkin counties is Pearl pass (12,715 feet). Many passes are traversed by the railways, especially the splendid scenic route of the Denver and Rio Grande Western, with a water-level route through the Royal gorge of the Arkansas river. Among the higher passes are Hoosier pass (10,780 ft.) in the Park range; Hayden Divide (10,780) and La Veta pass (9,378), both of these across the Sangre de Cristo range; the crossing of the San Miguel chain at Lizard Head pass (10,250) near Rico; of the Uncompahgre at Dallas Divide (8,977) near Ouray; of the Elk and Sawatch ranges at Fremont (11,320), Tennessee (10,424) and Breckenridge (11,503) passes, and the Busk tunnel, all near Leadville; and Monarch pass (11,302) above Salida.

The climate of Colorado is exceptional for regularity and salubrity. The mean annual temperature for the State is about 45° F. Owing to the complex orography of the State, few climatic generalizations can be made. It may be said, however, that the south-east is the warmest portion, lying as it does outside the mountains; that the north-central region is usually coldest; that the normal yearly rainfall for the entire State is about 16·38 in., with great local variations (rarely above 27 in.). Winds are constant and rather high (5 to 10 m.), and for many persons are the most trying feature of the climate. Very intense cold prevails in winter in the mountains, and intense heat (110° F or more in the shade) is often experienced in summer, temperatures above 90° being very common. Nevertheless, the climate of Colorado is not to be judged severe, and that of the plains region is in



MAP OF THE MAIN ROADS OF COLORADO

many ways ideal. In the lowlands the snow is always slight and it disappears almost immediately, even in the very foothills of the mountains, as at Denver or Colorado Springs. However hot the summer day, its night is always cool and dewless. Between July and October there is little rain, day after day bringing a bright and cloudless sky. Humidity is moderate (annual averages for Grand Junction, Pueblo, Denver and Cheyenne, Wyo., for 6 A.M., about 50 to 66; for 6 P.M., 33 to 50). Sunshine is almost continuous; for the whole state the average of perfectly "clear" days is normally above 50%. Colorado, because of its lowness of humidity and clarity of atmosphere, has many famous arid health resorts.

The wide variation in climatic conditions is explained by the fact that the altitude of the state varies from 3,385 ft. in the bed of the Arkansas river at the Kansas line to 14,431 ft. at the summit of Mt. Elbert.

Flora and Fauna.—The life zones of Colorado are simple in arrangement. The boreal embraces the highest mountain altitudes; the transition belts it on both sides of the continental divide; the upper Sonoran takes in about the eastern half of the plains region east of the mountains, and is represented further by two small valley penetrations from Utah. Timber is confined almost wholly to the high mountain sides, the mountain valleys and the parks being for the most part bare. Nowhere is the timber large or dense. The timber-line on the mountains is at about 10,000 ft., and the snow line at about 11,000 feet. It is supposed that the forests were much richer before the settlement of the state, which was followed by reckless consumption and waste and the more terrible ravages of fire. In 1872–76 the wooded area was estimated at 32% of the state's area. It is certainly much less now. The principal trees, after the yellow and lodgepole pines, are the red fir, so-called hemlock and cedar, the Engelmann spruce, the cottonwood and the aspen (*Populus tremuloides*). In 1899 Federal forest reserves had been created aggregating 4,849 sq.mi. in extent, and by 1940 this had been increased to 21,300 sq. miles. These national forests cover altitudes of 7,000 to 14,000 feet.

Large game is still found in limited numbers west of the continental divide. The great parks are a favourite range and shelter. Deer and elk frequent the mountains of the entire western part of the state, and are almost equally numerous in the higher elevations on the eastern slope. The bison have been exterminated. Considerable bands of antelope live in the parks, and even descend to the eastern plains, and the mule deer, the most common of large game, is found through the mountains of the state. Grizzly or silver-tip, brown and black bears are found in the same regions. Rarest of all is the magnificent mountain sheep. Strict game laws have resulted in increasing the numbers of deer and elk and in preventing the extermination of birds and other small game. Millions of trout are planted annually in the mountain streams, and bass, catfish and crappies in the waters of the lower plains.

Soil.—The soils of the lowlands are prevailingly sandy loams, with a covering of rich mould. The lands available for agriculture are the lowlands and the mountain parks and valleys. Cultivation is not intensive. Speaking generally, irrigation is essential to successful cultivation, and where it is practicable the soil proves richly productive. Irrigation ditches having been exempted from taxation in 1872, extensive systems of canals were soon developed, especially after 1880. The constitution of Colorado declares the waters of its streams to be the property of the state, and a great body of irrigation law and practice has grown up about this provision. The riparian doctrine does not obtain in Colorado. In no other part of the semi-arid region of the country are the irrigation problems so diverse and difficult. In 1940 investments in irrigation works for 3,400,000 ac. totalled $100,000,000. There are irrigated lands in most of the counties. Except for the fact that quantities of water diverted for irrigation return to the streams through underground channels, both the Arkansas and the South Platte would be dry at the state line. To end litigation and secure the best possible use of available waters, Colorado has compacts with some of the neighbouring states for a division of river waters, similar to the compact between the United States and Mexico covering the Rio Grande river. Most important among recent irrigation developments is the construction of a 13-mi. tunnel under the continental divide, which will bring annually to the valley of the South Platte, most intensively farmed area in the state, 320,000 ac.ft. from the headwaters of the Colorado river at Grand lake. This tunnel, with accompanying compensatory storage and power plants, totals $50,000,000 in cost. Its effect will be to bring security to a rich, irrigated area without injuring the region from which the water is taken, and to provide firm and cheap electric power. Colorado has two large federal reclamation projects—the Grand valley and the Uncompahgre, both on the western slope. The parks and mountain valleys are largely given over to ranges. The native grasses are especially adapted for fodder. The grama, buffalo, and bunch varieties cure on the stem and furnish throughout the winter an excellent range food. These native grasses, even the thin bunch varieties of dry hills, are surprisingly nutritious, comparing very favourably with cultivated grasses. Large areas temporarily devoted to cultivation with poor success, and later allowed to revert to ranges, have become prosperous and even noted as stock country. This is true of the sand-hill region of eastern Colorado. The grass flora of the lowlands is not so rich in variety nor so abundant in quality as that of high altitudes.

SUNNYSIDE GOLD MINING PLANT NEAR SILVERTON, COLORADO

Minerals.—Colorado was primarily a mineral region, and to this fact it owes its colonization. It possesses unlimited supplies, as yet not greatly exploited, of fine building stones, some oil and asphalt and related bituminous products, a few precious and semi-precious stones (especially tourmalines, beryls and aquamarines found near Canon City and the Royal gorge of the Arkansas river), rare opalized and jasperized wood (in the eastern part of El Paso county), considerable wealth of lead and copper, enormous fields of bituminous coal and great wealth of the precious metals. In the exploitation of the last there have been three periods: That before the discovery of the lead-carbonate silver ores of Leadville in 1879, in which period gold-mining was predominant; the succeeding years until 1894, in which silver-

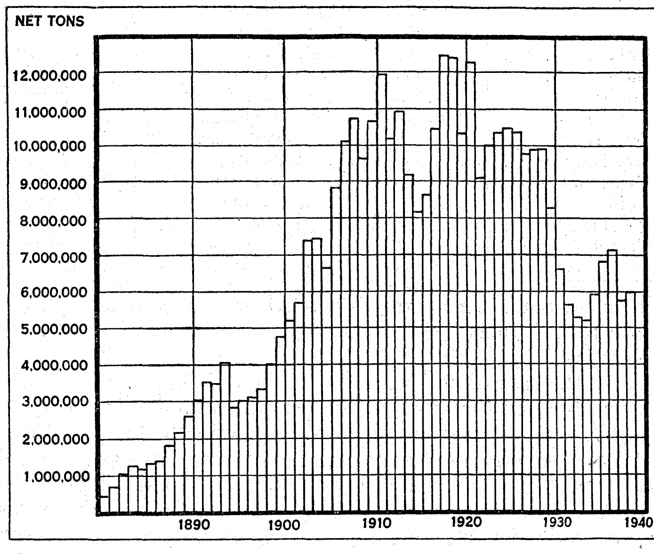
6. View of Telluride. Since the comparative exhaustion of Alaskan sources of gold supply, the mines of Colorado have become especially valuable

mining was predominant; and the period since 1894, in which gold has attained the primacy. The two metals are found in more than 50 counties, San Miguel, Boulder, Eagle, Clear Creek, Park, San Juan and Teller being the leading producers. The Cripple Creek field in the last-named county was one of the most wonderful mining districts of America. Leadville, in Lake county, was another. The district about Silverton (product 1870–1939 about $108,250,000, principally silver and lead, and mostly after 1881) also had a remarkable development; and Creede, in the years of its brief prosperity, was a phenomenal silver-field.



GRAPH OF COAL MINED IN COLORADO FROM 1880 TO 1939. THE RECORDED PRODUCTION BEGINS IN 1864 WITH 500 TONS FROM THE MAIN COAL AREAS

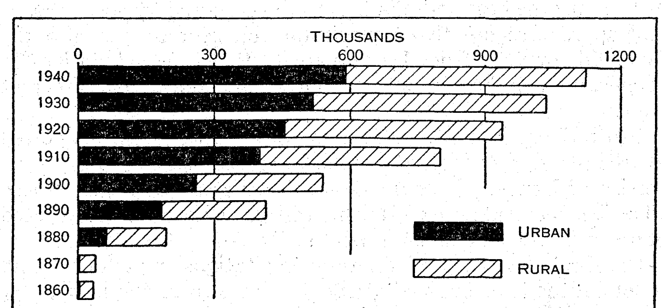
The stratified rocks of the Great Plains, the parks and the plateaus contain enormous quantities of coal. The coal-bearing rocks are confined to the Upper Cretaceous, and almost wholly to the Laramie formation. The main areas are on the two flanks of the Rockies, with two smaller fields in the parks. The east group includes the fields of Canon City (whose product is the ideal domestic coal of the western states), Raton and the South Platte; the park group includes the Cones field and the Middle park; the west group includes the Yampa, La Plata and Grand river fields. The total includes every variety from typical lignite to typical anthracite. The aggregate area of beds is estimated by the United States Geological Survey at 19,750 sq.mi. (seventh in rank of the states of the union). The industry began in 1864. Production reached its peak in 1918, when 12,658,000 tons were produced, but natural gas and other factors brought about a gradual reduction to about 6,000,000 tons in 1939.

Mineral springs are numerous and occur in various parts of the state. The most important are at Buena Vista, Ouray, Wagon Wheel Gap, Poncha or Poncha Springs (80°–168° F.), Canon City, Manitou, Idaho Springs and Glenwood Springs (106°–125° F., highly mineralized). The last three places, all beautifully situated—the first at the base of Pikes peak, the second in the Clear creek canyon, and the third at the junction of the Roaring Fork with the Grand river—have an especially high repute.

Government.—The first and only state constitution of Colorado was adopted in the year 1876. It requires a separate popular vote on any amendment—though as many as six may be (since 1900) voted on at one election. Amendments have been rather freely adopted. The general assemblies are biennial, sessions not limited, average about 110 days; state and county elections are held at the same time (since 1902). A declared intention to become a United States citizen ceased in 1902 to be sufficient qualification for voters, full citizenship (with residence qualifications) being made requisite. An act of 1909 provides that election campaign expenses shall be borne "only by the state and by the candidates" and authorizes appropriations for this purpose. Full woman suffrage was adopted in 1893 (by a majority of about 6,000 votes). Women have served in the legislature and in many minor offices. The governor may veto any separate item in an appropriation bill. The state treasurer and auditor may not hold office for two consecutive terms. Popular initiative and referendum were introduced in 1910, recall of officials in 1912. County government is of the commissioner type.

By constitutional amendment in 1902 the city and county of Denver were established, with authority in the electorate to establish by charter such form of government as they desired. Following many experiments, the present government provides for a mayor with broad powers, four appointed departmental managers and a council with legislative authority, only the auditor and the school authorities being elected independently.

Population.—The population of Colorado in 1860 was 34,277; in 1880, 194,327; in 1910, 799,024; and in 1940, 1,123,296. This last figure represents an increase of 8·4% over the population in 1930. The population per square mile was 10·8, as compared with 44·2 for the United States as a whole. Of the 1940 population, 590,756, or 52·6%, lived in urban places; that is, in cities of 2,500 or more. The number of occupied dwelling units returned in the housing census of 1940 was 316,112, which is approximately the same as the number of families. The average population per family (occupied dwelling unit) declined from 3·9 in 1930 to 3·6 in 1940. The white population of Colorado (including Mexicans) formed 98·5% of the total in 1940. The population of the state and of its principal cities is summarized for recent censuses in the following table:



BY COURTESY OF THE U.S. BUREAU OF THE CENSUS

URBAN AND RURAL POPULATION OF COLORADO, 1860–1940

Area	Population			Percent of increase

Finance and Education.—The general assessment valuation of taxable property in 1939 was $1,114,278,000, on which there was a state levy of 4·4 mills, including 1·18 mills levied in 1937 for a 10-year period for new buildings at state institutions. Principal sources of revenue in addition to property taxes include taxes on sales, services, incomes, liquors, inheritances, corporations and motor fuel, and federal aid. State disbursements for public welfare, including old-age pensions and direct relief, were $20,000,000 in 1940. Colorado has the highest old-age pension program in the United States. Disbursements for highway construction in 1939, including federal aid, were $12,200,000. Total bonded indebtedness of the state and its subdivisions at the beginning of 1940 was as follows: state, $3,257,700; Moffat tunnel district, $15,470,000; counties, $1,758,000; cities and towns—general, $49,124,000; special, $9,572,000; school districts, $21,528,000.

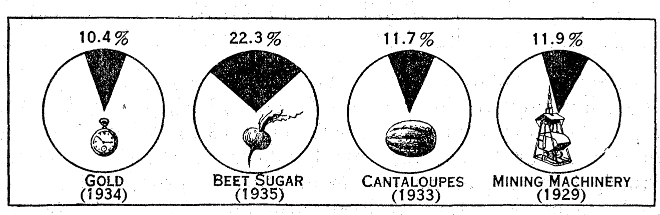
The public-school system of Colorado dates from 1861, when a school law was passed by the territorial legislature; this law was superseded by that of 1876, which with subsequent amendments is still in force. In expenditure for the public schools per head of total population, Colorado is sixth in rank of the 48 States. The school population in 1938 was 312,845, of whom 233,141 attended school. The total number of teachers was 9,590, and of school buildings 2,905. The average number of days attended per year per pupil enrolled was, in 1938, 138·3, an increase from 93·4 in 1900. The total expenditure for public schools in 1938 was $23,017,216, $98.72 per head. The income of the permanent school fund, derived from federal land grants, is annually apportioned among the districts. The remainder of the school funds, and by far the greater amount, is raised by local taxation. Only 2·8% of the population ten years of age and over were listed as illiterate in the census of 1930. The percentage of illiterates among the native whites was 0·8; among the foreign-born white, 8·6; and among the Negroes 3·9. The state institutions are: The University of Colorado, at Boulder (opened 1877); the School of Mines, at Golden (1874); State College of Agriculture and Mechanic Arts, at Fort Collins (1879); State College of Education, at Greeley (1889); Western State college, at Gunnison (1909); Adams State Teachers college, at Alamosa (1925); and a school at Colorado Springs for the deaf and blind. All are supported by special taxes and appropriations—the Agricultural college receiving also the usual aid from the federal government. Experimental stations in connection with the Agricultural college are maintained at different points.

Institutions of higher education, other than those supported by the state, are: Colorado college at Colorado Springs; University of Denver, Colorado Woman's college, and Regis college, all at Denver; and Loretto Heights college at Loretto. The United States maintains an Indian school at Towaoc.

Of charitable and reformatory institutions, a soldiers' and sailors' home is maintained at Monte Vista, an insane hospital at Pueblo, a home for dependent and neglected children at Denver, homes for mental defectives at Ridge and Grand Junction, an industrial school for girls near Morrison, and for boys at Golden, a reformatory at Buena Vista and a penitentiary at Canon City. Denver was one of the earlier cities in the country to institute special courts for juvenile offenders, a reform that is widening in influence and promise.

The parole system is in force in the state reformatory, and in the industrial school at Golden (for youthful offenders) no locks, bars or cells are used, the theory being to treat the inmates as "students." The state has a parole law and an indeterminate-sentence law for convicts.

Industry, Trade and Transport.—In the decade 1910–20 agriculture displaced mining as Colorado's most important industry. The number of farms in 1935 amounted to 63,644; their total area amounted to 29,978,472 acres, and their average size increased by 1935 to 471·2 acres. The value of all farm lands and buildings amounted to $418,757,555. Reports for 1935 indi-



GRAPH SHOWING PERCENTAGE PRODUCED IN COLORADO OF THE TOTAL OUTPUT OF CERTAIN COMMODITIES IN THE UNITED STATES

cated increased numbers of farms but decreased acreage in farms, capital valuations and values of products, as compared with the 1930 figures. The farm population decreased between the years 1930 and 1935 from 282,827 to 276,198. Less than one-half of the farms are operated by managers or tenants. Irrigation is extensively used throughout the main agricultural areas. The acres actually irrigated increased from 2,792,032 in 1910 to 3,393,619 in 1930. Organized drainage enterprises, most of them having been rendered necessary by faulty irrigation, had affected, in 1930 366,719 ac., at a cost of $4,358,866. According to the 1935 census of agriculture, 4,961,000 ac. of the farms were in crops; the remaining acreage was in pasture or idle under provisions of the Agricultural Adjustment administration. The severe drought in 1934 caused production of crops to fall to the lowest point in 25 years; only 3,947,390 acres were harvested. The principal 1935 farm crops were:

Crops	Acreage	Production	Farm Value
			$
All Crops	4,961,000	. .	62,693,000
Corn	1,266,000	10,761,000 bu.	7,102,000
Wheat	553,000	6,532,000 bu.	5,885,000
Oats	160,000	4,480,000 bu.	1,532,000
Barley	321,000	6,420,000 bu.	2,825,000
Potatoes	100,000	18,000,000 bu.	9,540,000
Tame Hay	1,069,000	1,712,000 tons	11,128,000
Wild Hay	354,000	354,000 tons	2,124,000
Dry Beans	435,000	117,400,000 lbs.	3,003,000
Cantaloupes	6,240	1,030,000 crates	772,000
Apples	. .	1,590,000 bu.	1,097,000
Peaches	. .	1,276,000 bu.	1,021,000
Cherries	. .	4,662 tons	233,000
Sugar Beets	140,000	1,826,000 short tons	10,609,000

On Jan. 1, 1935, there were 312,000 horses; 22,000 mules; 1,439,000 cattle; 2,736,000 sheep and 273,000 swine on the farms of Colorado.

As in the case of agriculture, the mining industry in Colorado was hard hit by the economic depression beginning in 1929; by 1934, however, a marked revival of production had set in. Colorado, with mineral products valued at $60,403,000 in 1938 ranked 15th among the states, producing 1·52% of the total value for the United States. Colorado, which ranks seventh among the states in coal production, had an output in 1939 of 5,991,022 tons, worth approximately $15,816,000. Coal has long been the state's most valuable mineral product. In 1938 with an output valued at $13,136,100, Colorado ranked fifth among the states in gold production. It was third for silver, with output worth $5,046,000, and seventh for lead and for zinc. The production of lead and of zinc in 1938 had dropped to $869,800 and $437,100, respectively. Petroleum production dropped from 2,750,060 bbl. in 1928 to 908,504 in 1933; by 1938 it had picked up to 1,448,600 bbl. valued at $1,594,700. Brick and other clay products in 1935 had a value of $1,393,000.

A marked influence on Colorado's economic life is found in the existence of large forested and mountain areas and the consequent establishment of forest reserves and national parks. There were in 1940, 13,638,381 ac. in national forests, and there were two national parks and six national monuments. Timber supplies, grazing for stock, irrigation and hydro-electric power are important. The tourist business is a leading industry of the state.

From 1900 to 1920 the number of manufacturing establishments in Colorado nearly doubled, the number of persons engaged more than doubled, and the capital invested increased 225%. In 1937 there were, according to the U.S. census of manufactures, 1,233 industrial establishments, employing 25,932 wage earners, with products valued at $237,838,370. Beet-sugar manufacturing has been the chief industry since 1914. There were 16 operating plants in 1937, which manufactured sugar amounting to 303,000 short tons. Other important industries were: Slaughtering and meat packing $39,806,000; flour and other grain-mill products $10,299,600; construction and repairs in steam railway shops $5,890,209; butter, cheese and condensed milk products $8,890,100; bakery products $11,844,000; and printing and publishing newspapers and periodicals $9,471,500. Denver, the chief industrial centre, had 610 manufacturing establishments and products valued at $115,847,600.

The state is well supplied with railway mileage in spite of its rugged topography. In the year 1939 there were 4,868 mi. of main line railways in operation—a decline from the 5,724 mi. in operation in 1915. The Denver Pacific, built from Cheyenne, Wyo., reached Denver in June 1870, and the Kansas Pacific, from Kansas City, in August of the same year. Then followed the building of the Denver and Rio Grande (1871), to which the earlier development of the state is largely due. The Santa Fe (1873), Burlington (1882), Missouri Pacific (1887) and Rock

Island (1888) systems reached Pueblo, Denver and Colorado Springs successively from the east. The Colorado and Southern, a consolidation of roads connecting Colorado with the south, and the Denver and Salt Lake have also become important. The electric railway systems, operated by eight companies, had in 1937 a total of 267 mi. of track.

There were 12,202 mi. of highway in the State system at the end of 1939. Of this amount 8,272 mi. were surfaced; there were also 8,466 mi. of surfaced county roads. The total number of motor vehicles registered in the year 1939 was 344,838, of which 312,847 were passenger cars, buses and taxis. Motor licence fees and a gasoline tax of five cents per gallon are the chief sources of highway revenue.

HISTORY

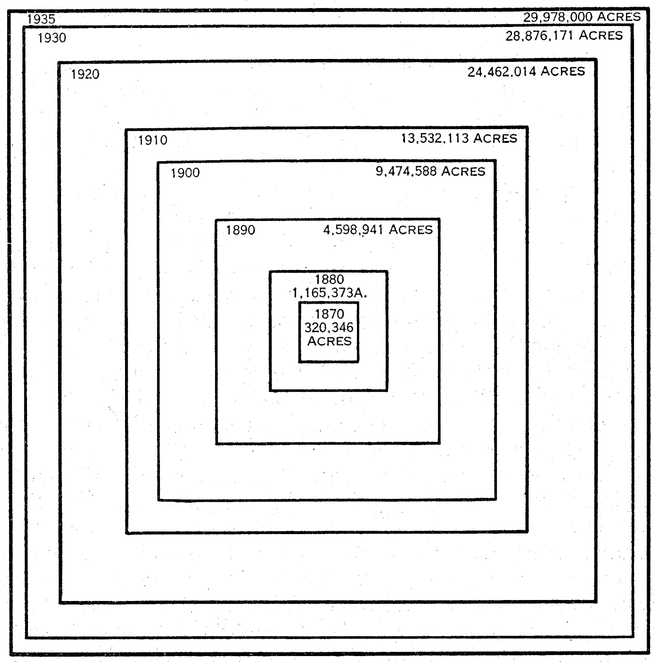
Colorado was acquired by the United States in three successive waves of westward expansion. The portion north of the Arkansas river and east of the meridian of its head was acquired by the Louisiana Purchase (*q.v.*) in 1803, but its exact boundary was not established until 1819, when the western boundary of the United States was incorporated in the treaty with Spain. The boundary of the United States was extended farther westward in 1845, with the admission of Texas. By a boundary adjustment between that State and the Federal Government in 1850, a strip of territory between the Rio Grande river and the present boundaries of Texas became a part of the public domain. The territory west of the Rio Grande was included in the Mexican cession of 1848.

Before the coming of the white men two types of Indians inhabited the country. The southern and south-western parts of the State were occupied by the cliff-dwellers, a sedentary, agricultural people. On the plains and to the northward dwelt the Utes and other nomadic, hunting tribes. Only a few of the pueblos and cave dwellings remain to commemorate the Indian culture of the south-west.

Early Explorers and Fur-traders.—The first Europeans to enter the bounds of the State were Spaniards who came in from Mexico to seek their fortune or to christianize the savages. It is tolerably certain that Coronado entered Colorado territory in 1540 in search of the fabled "Seven Cities of Cibola." Almost a decade before the founding of the first English settlement in America, a Spanish adventurer, Juan de Oñate, planted a colony on the Rio Grande, and seven years later founded Santa Fe (*q.v.*), the second oldest city in the United States. Through the 17th century expeditions were made by small bands of Spaniards in almost every direction from the settlements on the Rio Grande, and the mountains of Colorado must have become a familiar sight to them. The next explorer supposed to have entered the country was Juan Maria Rivera, who, with several companions, prospected on the Rio San Juan and is thought to have gone as far west and north as the valley of the Gunnison. There are meagre records of indisputable Spanish exploration in 1776, in what is now the southern part of the State, by the friars Escalante and Dominguez who were in search of a route to northern California. Fur traders were the next to enter the country. In 1799 Jean de la Maisonneuve and a Swiss named Preneloupe, while trading on the Upper Missouri, decided to visit the mountain country to the west and on July 20, 1799, arrived at the present site of Denver. It was also the fur trade that took the first American, James Purcell, into the Colorado region in 1803. In 1806 Zebulon M. Pike, mapping the Arkansas and Red rivers of the Louisiana territory for the U.S. Government, followed the Arkansas into Colorado, incidentally discovering the famous peak that bears his name. In 1819–20 Maj. S. H. Long explored the valleys of the South Platte and Arkansas, pronouncing them uninhabited and uncultivable (as he also did the valley of the Missouri, whence the idea of the "Great American Desert"). His name is also commemorated by a famous summit of the Rockies. There is nothing more of importance in Colorado annals until 1858. From 1804 to 1854 the whole or parts of Colorado were included, nominally, in some half-dozen territories carved successively out of the trans-Mississippi country; but not one of these had any practical significance for an uninhabited land. From 1828 to 1832 a fortified trading post was maintained near La Junta in the Arkansas valley on the Santa Fe trail; in 1834–36 several private forts were erected on the Platte; in 1841 the first overland emigrants to the Pacific coast crossed the State, and in 1846–47 the Mormons settled temporarily at the old Mexican town of Pueblo. John C. Frémont had explored the region in 1842–43 and 1845 (and unofficially in later years for railway routes), and gave more trustworthy reports of the country to the world than had his predecessors. Commerce in these years centred in the (New) Mexican town of Taos.

Colorado Becomes a State.—Colorado was practically an unknown country when in 1858 gold was discovered in the plains, on the tributaries of the South Platte, near Denver. In 1859 various discoveries were made in the mountains. The history of Denver dates from the gold rush in 1858. Julesburg, in the extreme north-east corner, at the intersection of the Platte valley and the overland wagon route, became transiently important during the rush of settlers that followed. Emigration from the east was stimulated by the panic, and hard times following 1857. During 1860–62 there was a continuous stream of immigration. Denver (under its present name), Black Hawk, Golden, Central City, Mount Vernon and Nevada City were all founded in 1859; Breckenridge, Empire, Gold Hill, Georgetown and Mill City in 1860 and 1861. The political development of the next few years was complicated. "Arapahoe county," including all Colorado, was organized as a part of Kansas territory in 1858; but a delegate was also sent to Congress to work for the admission of an independent territory (called "Jefferson"). At about the same time, early in 1860, a movement for Statehood was inaugurated, a Constitution being framed and submitted to the people, who rejected it, adopting later in the year a Constitution of territorial government. Accordingly the territory of Jefferson arose, claiming to extend over 6° of latitude (37°–43°) and 8° of longitude (102°–110°). Then there was the Kansas territorial Government also, under which a full county organization was maintained. Finally peoples' courts, acting wholly without reference to Kansas, and with little reference to the local "provisional" legislature, secured justice in the mining country. The provisional legislature of the territory of Jefferson maintained an illegal but rather creditable existence somewhat precariously and ineffectively until 1861. Its acts had slight importance. Some, such as the first charter of Denver, were later re-enacted under the legal territorial Government, organized by the United States in Feb. 1861. Colorado City, the first capital, was replaced by Golden in 1862. In 1868 Denver was made the seat of government (in 1881 permanently, by vote of the people). In 1862 some Texas forces were defeated by Colorado forces in an attempt to occupy the territory for the Confederacy. From 1864 to 1870 there was trouble with the Cheyenne and Arapahoe Indians. A sanguinary attack on an Indian camp in Kiowa county in 1864 is known as the Sand Creek Massacre. In 1867 the Republican Party had prepared for the admission of Colorado as a State, but the enabling act was vetoed by President Johnson, and Statehood was not gained until 1876. Finally, under a Congressional enabling act of March 3, 1875, a Constitution was framed by a convention at Denver (Dec. 20, 1875 to March 14, 1876) and adopted by the people July 1, 1876. The admission of Colorado to the Union was thereupon proclaimed on Aug. 1, 1876.

Labour Troubles.—For a considerable time after this the history of the State was identified with that of her great mining camps. After 1890 industrial conditions were confused and development retarded by strikes and lock-outs in the mines, particularly in 1894, 1896–97 and 1903–04, when martial law was several times necessary. Questions of railways, franchises, union wage scales, and sheep and cattle interests entered into the political and economic troubles of these years. The Colorado "labour wars" were among the most important struggles between labour and capital, and afforded one of the most sensational episodes in the story of all labour troubles in the United States in these years. A State board of arbitration was created in 1896, but its usefulness was impaired by an opinion of the State attorney-general (in 1901) that it could not enforce subpoenas, compel testimony or enforce decisions. A law establishing an eight-hour day for underground miners and smelter employees (1899) was unanimously voided by the state supreme court, but in 1902 the people amended the constitution and ordered the general assembly to re-enact the law for labourers in mines, smelters and dangerous employments. Following the repeal of the Sherman law in 1893, the silver question became the dominant issue in politics, resulting in the success of the Populist-Democratic fusion party in three



GRAPH SHOWING THE INCREASE IN THE AMOUNT OF LAND IN FARMS AND RANCHES IN COLORADO, 1870 TO 1935

successive elections, and permanently and greatly altering prior party organizations. In recent years the two major parties have been so equally balanced in strength that the state administration has been at times Republican and at times Democratic.

Colorado was a great cattle country until about 1890, when the free range began to pass away because of fencing for agricultural enterprises. The cattlemen had to adjust themselves to the new situation by providing winter forage, and this led to the cultivation of alfalfa and other hays. Later, with the introduction of the sugar-beet industry, Colorado regained some of its former importance as a meat-producing state. Lambs and cattle are fattened on the hay crops, and sheep and cattle consume the by-products of the sugar-beet industry.

Constitutional Reforms.—A constitutional amendment adopting initiative and referendum was ratified in Nov. 1910. In the same year a primary election law provided for direct nominations by the people of candidates for the U.S. senate, representatives in congress, and all elective state, district, county, ward and precinct officers, as well as members of the state legislature. The expense of candidates in such primary elections was limited by the act, and severe penalties were provided for violations. In 1911 an act was passed providing for registration of voters for all elections to be held in the state except school elections, and providing severe penalties for false registration and other violations of the act. In Nov. 1912 the people approved amendments to the state constitution providing for the recall of elective officials and, in certain cases, for the recall of judicial decisions. An act, proposed by initiative, was passed at the same time, providing for a ballot without party headings. The voters adopted in Nov. 1914 an amendment to the state constitution, prohibiting the sale and manufacture of intoxicating liquor, which became effective on Jan. 1, 1916; and the prohibition amendment to the federal constitution was ratified by the Colorado legislature in regular session on Jan. 15, 1919. Following the repeal of national prohibition, Colorado, in 1934, gave up state prohibition. The law of 1935 allowed the sale of liquor by the glass and in bulk.

The legislature in 1919 passed an act providing for a budget system in making appropriations and creating a state budget and efficiency commissioner. The first budget prepared under this act was presented to the legislature in 1921. In 1920 the voters adopted an initiated constitutional amendment raising the limit on state tax levy from four mills to five, the additional revenue being limited to the use of state educational institutions. In 1921 a proposed amendment to extend the tenure of office of state and county officers was defeated. Proposals for a convention to revise the state constitution were rejected in 1921 and 1930. In 1921 inheritance tax laws were strengthened by raising the rates thereof. Persistent advocacy by the governor secured the passage of laws for the re-establishment of a national guard and for a Department of Safety, with a body of rangers as a state police force; the latter was disbanded in 1923. The legislature in 1922 voted a $6,700,000 bond issue to finance the Moffat tunnel, and before it was completed in 1934 a total issue of $18,000,000 had been authorized. A loan of $3,850,000 from the Reconstruction Finance corporation enabled the Denver and Rio Grande railroad to build its strategic Dotsero cut-off connecting Denver with Salt Lake City. Serious labour disturbances occurred beginning with the depression in 1930 as coal production fell off 45%, petroleum 50%, and the major crops even more precipitously. Democrats strengthened by the party's national ascendancy swept state and national elections in 1932, 1934 and 1936. In 1931 Colorado ratified the national child labour amendment. Under pressure of necessity laws for prohibition repeal, closer supervision of insurance and banking companies, and grants to aid the destitute were passed in 1934. A 2% emergency retail sales tax was passed in 1935 supplemented by the 2% professional service tax in 1937. In 1936 a $45 per month old age pension was ratified by popular vote.

BIBLIOGRAPHY.—The history of the state is treated in the following works: W. F. Stow, *History of Colorado* (3 vols., 1918); J. C. Smiley, *Semi-centennial History of Colorado* (1913); F. L. Paxson, "A Preliminary Bibliography of Colorado History," vol. iii., No. 3 of *University of Colorado Studies* (June 1906); H. H. Bancroft, *History of . . . Nevada, Colorado and Wyoming, 1540–1888* (1890); J. F. Willard, *Union Colony of Greeley* (1918); and *University of Colorado Semi-centennial Series* (1927). Works chiefly descriptive are: Irving Howbert, *Indians of the Pike's Peak Region* (1914) and *Memories of a Lifetime in the Pike's Peak Region* (1925); A. P. Hill, *Colorado Pioneers in Picture and Story* (1915); M. L. Baggs, *Colorado, the Queen Jewel of the Rockies* (1918); A. C. Carson, *Colorado, the Top of the World* (1912); E. A. Mills, *Spell of the Rockies* (1911), *In Beaver World* (1913), *Rocky Mountain Wonderland* (1915), *Your National Parks* (1917); and E. Parsons, *Guide Book to Colorado* (1911).

Governmental administration is dealt with in *Colorado Statutes Annotated*, 1935; governmental reorganization in 1941 *Session Laws*. On soil and agriculture consult: *Annual Reports* of Colorado Co-operative Crop Reporting Service (state-federal); *Colorado Year Book*, published biennially by the State Planning commission; *Annual Reports* of Colorado State Director of Markets; U.S. Forest Service *Reports;* publications of the U.S. Department of Agriculture (*see* department bibliographies); *Sixteenth United States Census* (1940). Frémont, *Report of the Exploring Expedition to the Rocky Mountains in 1842*, published 1845 as Congressional document No. 166, and in various other editions. Other reports of early explorations are: *The Expedition of Zebulon Montgomery Pike . . . through Louisiana Territory and in New Spain in the Years 1805–06–07*, edit. E. Coues (3 vols., 1895); *Account of an Expedition from Pittsburgh to the Rocky Mountains, 1819–20, under the Command of Major S. H. Long, compiled . . . by Edwin James* (1823); Capt. H. Stansbury, *Exploration of the Valley of the Great Salt Lake* (1852; also published as Senate Executive document No. 3, 32nd Congress, Special Session); *Colorado*, American Guide Series. (C. A. D.; E. D. F.)

COLORADO DESERT, a name applied to that arid region of southeastern California which extends from San Gorgonio pass south-eastward to the Gulf of California, and includes the depression (248·7 ft. below sea level) known as "Salton sink." It is separated from the Mohave desert (*q.v.*) by the San Bernardino, Cottonwood, Chuckwalla and Chocolate mountains. The Colorado desert is about 200 m. in length and attains a maximum width of 50 miles. The northwestern portion consists chiefly of shifting sand dunes but farther southeast, below the sea level, the valley floor is silt-covered and fertile; the soil of the Imperial valley (*q.v.*) is highly productive when irrigated. The rainfall varies considerably from year to year, but the average is between 3 and 4 in. yearly. During the five summer months the mean daily temperature is high, about 90° F, and occasionally an extreme of 125° or more in the shade is reached.

See W. C. Mendenhall, *Ground Waters of the Indio Region, California with a sketch of the Colorado Desert,* and *Some Desert Watering Places in South-eastern California and South-western Nevada.* These are U.S. Geological Survey *Water Supply Papers,* nos. 225 and 224, respectively. *See* also J. Smeaton Chase, *California Desert Trails* (1919).

COLORADO NATIONAL MONUMENT, a tract of 13,883 ac. in central Colorado, U.S.A., near the west boundary, set apart by the Government as a reservation in 1911. It is notable for its enormous sandstone monoliths which have been grotesquely formed by erosion. One of the largest of these is Independence rock; its base is 250 ft. by 100 ft. and it rises to a height of 500 feet. Another, Fisherman's Head, is over 400 ft. high and is topped by the semblance of a human face.

COLORADO POTATO BEETLE, a chrysomelid beetle (*Leptinotarsa decemlineata,* Say), native to the western United States. This leaf-beetle, first named and described by Say in 1824, fed originally on a wild solanaceous plant, *Solanum rostratum,* abounding in the Rocky Mountain region. With the westward advance of civilization, the cultivation of potatoes was brought to its neighbourhood, and the insect at once took to the cultivated plant and began an eastward spread. By 1864 or 1865 it had crossed the Mississippi river in Illinois. By 1869 it reached Ohio. In 1874 it reached the Atlantic seaboard. In its spread across the country, it flourished best in what is known as the Upper Austral life zone. It did not readily accommodate itself to the severe winters of the far north nor to the hot summers of the far south. As it progressed, certain predatory insects and certain birds became accustomed to it, and as early as 1869 Paris green began to be used against it; so that by the time the beetle reached the Atlantic, potato growers in the mid-west were able to control it in their fields.

Great alarm was expressed in Europe. The German Government, early in 1875, issued a decree against the importation of American potatoes, and was followed the same year by Belgium, Spain, France, Russia, Italy, Hungary and Austria, and by Portugal and Sweden the following year. In spite of the German decree, the beetle was discovered in a potato field near Hamburg, but was exterminated by radical measures. It is quite likely that the insect has been imported by accident into European countries since that date, but in no case has it been established except that shortly after the War of 1914–18 it was found to have been introduced near Bordeaux in France in a region where there had been large bodies of American troops. From that region it has since spread, rather slowly, into surrounding departments, but the French Government, having adopted American methods, feels that it can well be kept in check. It is now known to be established in France, Belgium, Holland, Luxembourg, Germany, and Switzerland. It has been found sporadically in England but repressive measures are believed to have exterminated the species.

Both the adult beetles and the larvae feed upon the foliage of the potato plant. In the early days it not only caused the loss of entire crops but sometimes destroyed the potato yield of whole counties and of large portions of some States. It materially affected the market price of potatoes. The extensive work of the insect on the foliage affected the quality of the tuber, and at one time it was difficult to obtain potatoes that were not watery when cooked. The adult beetles pass the winter underground, and in the spring lay their eggs upon the plants. There are two generations each year, the leaf-feeding larva descending to the ground to turn to pupa. The insect feeds on nearly all solanaceous plants, including eggplant, tomato and tobacco among the cultivated species. The tender-leaved varieties of potato are most affected. The insect is held in check by the application of arsenicals. In the U.S. one formula is, one part Paris green to 10 to 20 parts of flour, sifted land plaster or fresh air-slaked lime. Another is, 1 lb. Paris green to 75 to 125 gal. of water, 1 lb. of quicklime being added to prevent scorching of the foliage by the arsenical.

(L. O. H.)

COLORADO RIVER, a stream in the south of the Argentine Republic. It has its sources on the eastern slopes of the Andes in the latitude of the Chilean volcano Tinguiririca (about 34° 48′ S.), and pursues a general east-south-east course to the Atlantic, where it discharges through several channels of a delta extending from lat. 39° 30′ to 39° 50′ S. Its total length is about 620 m., of which about 200 m. from the coast up to Pichemahuida is navigable for vessels of 7 ft. draught. It has been usually described as being formed by the confluence of the Grande and Barrancas, but as the latter is only a small stream compared with the Grande it is better described as a tributary, and the Grande as a part of the main river under another name. After leaving the vicinity of the Andes the Colorado flows through a barren, arid territory and receives no tributary of note except the Curaco, which has its sources in the Pampa territory and is considered to be part of the ancient outlet of the now closed lacustrine basin of southern Mendoza. The bottom lands of the Colorado in its course across Patagonia are fertile and wooded, but their area is too limited to support more than a small, scattered population.

COLORADO RIVER. The Colorado river and its upper tributaries rise in the mountains of Wyoming, Colorado and Utah, where precipitation, especially in the form of snow, is heavy. Including the Green river, the Colorado river is about 1,700m. long. Its drainage basin covers 244,000sq.m. or $\frac{1}{13}$ of the area of the United States, and includes parts of seven States—Wyoming, Colorado, Utah, New Mexico, Nevada, Arizona and California. The river forms for 17m. the boundary between Arizona and Mexico and then flows 80m. through the Republic of Mexico to the Gulf of California. Its discharge varies from about 3,000 second-feet at low water to a flood discharge of more than 200,000cu.ft. per second. Its water supply, with storage, is estimated to be equivalent to a uniform flow of 19,300 second-feet at Lees Ferry, 22,600 second-feet at the lower end of Black Canyon, and 21,100 second-feet at Parker. When development in the upper basin is completed and the canyon section and the lower river are developed these quantities will be reduced. With an average annual flow at Yuma of 17,000,000 acre-feet at the present time and an average silt content of 0·62% by volume, the annual load of silt brought to the delta region by the Colorado and Gila averages 105,000 acre-feet, or 170,000,000 cubic yards.

The region traversed by the Colorado and its tributaries is for many reasons of intense interest to the people of the United States. Here was the home of that forgotten people of which there is almost no record except the hieroglyphics on the rocks, the ruins of their irrigation systems, and the cliff dwellings by which they are most widely known; in this region were Spanish missions whose history extends back nearly to the days of Balboa and Cortez; here is the Grand Canyon, whose grandeur cannot be described; and here are the greatest known natural bridges, so remote and inaccessible that they have only recently been discovered.

For more than 1,000m. along its course the Colorado has cut for itself a deep, narrow gorge or canyon, but at some points where lateral streams join it the canyon is broken and these narrow transverse valleys divide it into a series of canyons. Virgin, Kanab, Paria, Escalante, Fremont, San Rafael, Price and Duchesne rivers on the west, and the Little Colorado, San Juan, Grand, White and Yampa on the east have also cut out for themselves narrow, winding gorges or deep canyons. Each river entering these has cut another canyon; each lateral creek has cut a canyon; and each brook runs in a canyon; so that much of the upper part of the basin of the Colorado is traversed by a labyrinth of these deep gorges. The longest unbroken canyon through which the Colorado runs is that known as the Grand Canyon between the mouth of the Paria and the Grand Wash.

The Grand Canyon is 278m. long and at one place is 13m.

wide and nearly 6,000ft. deep. All the scenic features of this canyon are on a grand scale. Low plateaux, dry and treeless, stretch back from the brink of the canyon. In some places rock is composed of richly coloured and variegated marls, and here the surface is a bed of loose, disintegrated material through which one walks as though in a bed of ashes. In other places the rock is a soft sandstone, the disintegration of which has left broad stretches of drifting sand, white, golden and vermilion. Where this sandstone is a conglomerate, a paving of pebbles has been left—a mosaic of many colours, polished by the drifting sands, glistening in the sunlight.

On the California side of the lower portion of the river in the United States a vast desert, which has been known as the Colorado desert and more recently as the Salton basin, stretches north-westward from the head of the Gulf of California, a distance of 150 miles. At one time in the geological history of this country, the Gulf of California extended a long distance farther to the north-west, above the point where the Colorado now enters it, but this stream brought its mud from the mountains and hills above and bore it into the gulf, across which it gradually erected a vast dam until the waters on the north were separated from those on the south. Then the Colorado cut a channel into the lower gulf. The upper waters, being cut off from the sea, gradually evaporated. The bottom of this ancient upper gulf has come to be known as the Salton sink. It is now land about 278ft. below the level of the sea. On the Arizona side of the river there are similar desert plains, but these are interrupted by mountains.

In the year 1905 there occurred, about 3m. below the California-Mexico line, a break which diverted all the waters of the Colorado into the Salton sink and created the Salton sea, with a maximum depth of 76ft., a length of 50m. and a width of 10m. to 15m., a total water area of 445 square miles. The break threatened inundation of the entire Imperial valley and permanent blocking of the Southern Pacific route. Because of this latter danger the Southern Pacific company stopped the crevasse and completed, in 1907, a line of protective levees, the whole involving a deal of engineering skill and an outlay of $2,000,000.

The Colorado problem is international. Under existing treaties neither the United States nor Mexico can take action along the common boundary line which might impede navigation in the Colorado river. The language of the treaties does not, however, appear to prevent the taking of water for navigation purposes from the Rio Grande in the United States above the point where it forms the boundary line between the two countries.

Colorado river is one of the remarkable rivers of the world in its value for irrigation and water-power. It combines, in proper sequence for complete use, a large quantity of water, great concentrations of fall, reservoir sites for the control of flow, sites for power plants, and several million acres of irrigable land below the stretch where power may be developed. Over 5,000,000 prime h.p. can be developed. The flood menace is a serious one; the silt brought down annually to Yuma produces dangerous meandering in the leveed sections in the delta and causes the river to seek new outlets. These threats necessitate large expenditures for revetment and the steady raising of levees to prevent further disasters such as occurred in 1905.

For the purposes of controlling floods and regulating the flow of the lower Colorado river and for interception of silt, providing for storage and delivery of water for irrigation purposes and for the generation of power, Congress has provided for the construction of a dam in the Colorado river at Black canyon or Boulder canyon. As the project entailed an adjustment of the water rights claimed by Arizona, California, Colorado, Nevada, New Mexico, Utah and Wyoming, a commission comprised of representatives of each of these States and of the United States prepared, in 1922, a plan for the distribution of the waters, giving 7,500,000ac.ft. annually to the upper States (Colorado, New Mexico, Utah and Wyoming), and 8,500,000 to the lower States. A disagreement between Arizona and California delayed ratification of this compact until 1928 when all but Arizona ratified by agreeing to an amendment that the ratification of any six of the States would make it effective. Congress followed by passing the Boulder Canyon Project Act on Dec. 21, 1928 and President Hoover issued a proclamation the following June authorizing construction. Construction was not formally begun until Sept. 17, 1930, but the rapid completion of four huge diversion tunnels, each 56ft. in diameter, during the next three years, providing a dry bed on which to construct the dam at the boulder, and the erection of a modern city to house 600 workers high above the waters of the projected dam, and the construction of 53 miles of railway and 40 miles of improved highway completed the early stages of the project and attracted national attention to that great engineering feat. The acceleration of public works projects under the Roosevelt administration speeded construction and by 1935 such progress was made that the water was already backed up sixty-five miles behind the world's greatest dam, starting the man-made lake that will eventually extend 115 miles and have an average width of two miles. The hydro-electric plant will distribute 1,835,000 horse power and an area of 2,100,000 acres will be irrigated. The income will gradually cancel the entire cost of construction, towards which Congress had appropriated $165,000,000 in 1928 and in the course of fifty years accumulate a surplus calculated at an additional $165,000,000. The dam itself, 730ft. in height and 1,000ft. along the crest of its brim, is the largest in the world although several others boast a greater length.

Its services to the Rocky Mountain States will open a new field for colonization provided with an adequate supply of hydro-electric power and irrigation.

See U.S. Geological papers Nos. 395 and 556; Senate document No. 142 of the 67th Congress, 2nd session; *Annual Report of U.S. Federal Power Commission* (1922). (E. JA.)

COLORADOS, a tribe of South American Indians belonging to the Barbacoan (*q.v.*) linguistic stock, living in north-western Ecuador. At the present time the Colorados occupy the region west and south-west of Quito, on the upper waters of the Esmeraldas, Daule and Quevedo rivers. Their culture is simple. Clothing for the men consists of a cotton kilt and small poncho-like cape covering only the shoulders, for the women of a longer skirt. The teeth are stained black, and there is much use of body painting. Their dwellings consist merely of a thatched roof, without side walls. They are agricultural and make serviceable pottery and textiles. Weapons comprise the bow and the pellet blow-gun. The dead are buried under the floor of the house.

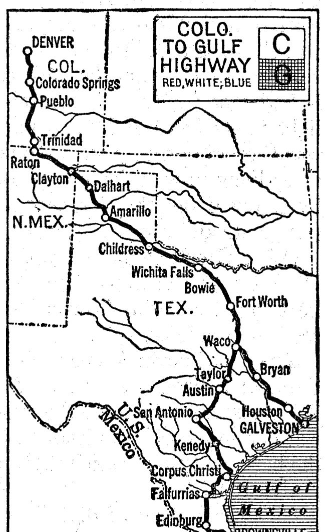
See P. Rivet, "Les Indiens Colorados," *Journ. Soc. Americanistes de Paris* (N.S.), vol. ii., pp. 177–208.

COLORADO SPRINGS, a city of Colorado, U.S.A., 75m. S. of Denver, on a mesa 6,036ft. above the sea, open to the great plains on the south-east and backed by mountains, including Pike's Peak (14,110 ft.); the county seat of El Paso county. It lies at the point where Monument creek joins Fountain creek; is on federal highways 24 and 85; and is served by the Santa Fe, the Rock Island, the Denver and Rio Grande Western, the Colorado and Southern, and the Missouri Pacific railways. The population was 33,237 in 1930 and 36,789 in 1940 by the federal census. Colorado Springs is the most popular tourist centre of the Rocky mountains, a noted health resort, an important railway point, the headquarters of the Cripple Creek mining companies, and a delightful residence city. It has ore-reduction plants, iron foundries and railroad shops. The assessed valuation of property in 1940 was $28,402,180.

Colorado college, the oldest college in the State, was established here in 1874. It has an enrolment of about 800, and an endowment of over $2,000,500. For a field laboratory in forestry it uses a tract of 6,000ac. (Manitou forest) 25 mi. N.W. of the city. Other institutions are the International union printers' home, the national home of the Modern Woodmen of America, the State institution for the deaf and blind and several sanatoria for the treatment of tuberculosis. In Manitou Springs, 5 mi. W. (pop. 1940, 1,462) a summer resort and the starting-point of the Cogwheel road to the top of Pike's Peak, are the 16 varied mineral springs which gave Colorado Springs its name. The Garden of the Gods, between the two cities (500ac. strewn with grotesque formations of bright-coloured sandstone) has been since

1909 a part of the park system of the city. Among other points of interest are the two Cheyenne canyons, the Cave of the Winds, the Grand Caverns and (at Florissant) a petrified forest. Many descriptions of this country may be found in the stories of Helen Hunt Jackson ("H.H."). Colorado Springs was laid out as a model city in 1871 by Gen. W. J. Palmer, president of the Denver and Rio Grande railway, which reached the valley that year. It was incorporated in 1872, chartered as a city in 1878, and in 1921 adopted a city manager form of government. The historic town of Colorado City, which sprang up during the gold rush of 1859 and was for four days in 1862 the seat of the territorial legislature, was consolidated with Colorado Springs in 1916.

COLORADO TO GULF HIGHWAY extends from Denver, Colo., to Galveston, Tex., about 1,200 m., and also to Brownsville, Tex., about 1,450 miles. For nearly 200 m. of the way, and at an elevation of 5,000 ft., its route is within view of the Rocky mountains. It skirts the eastern base of Pikes Peak, and traverses Raton pass between New Mexico and Colorado, affording from points in the latter views that extend southward for more than 100 miles. This highway crosses immense agricultural and live stock districts in Texas, and forms the main artery of travel from the Colorado Rocky mountains to the gulf of Mexico. Colorado Springs, Pueblo, Wichita Falls, Fort Worth, Houston, San Antonio and Corpus Christi are among the cities situated along its course.



COLORADO TO GULF HIGHWAY

COLORATURA (It.), a term in music applied to vocal passages of a florid and brilliant character, whereby the underlying melody is ornamented and, as it were, "coloured"; *aria di coloratura,* coloratura singing, and so on, being common uses of the term.

COLORIMETER, an instrument for determining the *intensity* of a colour (*q.v.*) relative to a standard colour intensity. The two are viewed simultaneously and the standard is modified by definite degrees until the intensities appear equal. This modification may be effected (*a*) for liquids, by altering the length of the column or the concentration of the standard liquid, (*b*) for solids or liquids, by interposing in front of or behind the standard a movable transparent, coloured wedge or some such device. *Colorimetric* methods may be used to determine hydrogen ion concentration. (*See* HYDROGEN ION CONCENTRATION; *Determination of Hydrogen,* etc.) (*See* CHEMISTRY: *Analytical.*) (*See* also CHROMATOMETER.)

COLOSSAE, once the great city of south-west Phrygia, was situated on rising ground (1,150 ft.) on the left bank of the Lycus (*Churuk Su*), a tributary of the Maeander, at the upper end of a narrow gorge 2½ m. long. It was a large, prosperous city (Herod. vii. 30; Xenophon, *Anab.* i. 2, § 6), until it was ruined by the foundation of Laodicea in a more advantageous position. Colossae was the seat of an early Christian church, the result of St. Paul's activity at Ephesus, though perhaps actually founded by Epaphras. The church, to which St. Paul wrote a letter, was mainly composed of mingled Greek and Phrygian elements deeply imbued with fantastic and fanatical mysticism. Colossae lasted until the 7th and 8th centuries, when it was gradually deserted under pressure of the Arab invasions.

COLOSSAL CAVERN, a limestone solution cave in Edmonson county, central Kentucky, U.S.A., 1½ m. from the famous Mammoth cave with which it is probably connected. Eden valley, which lies between these caves, is indisputably a "sink" formed by the collapse of a great chamber or series of chambers that formerly united them. Bed Quilt cave as well as many smaller caverns and grottoes in the vicinity are doubtless part of the same system of caverns, all hollowed out by solution in the St. Louis limestone beneath the overlying Chester sandstone. From the main entrance at the foot of a steep hill across Eden valley from Mammoth cave, the cavern extends southward by the "Chinese Wall," "Uncle Tom's Pool" and "Lizard Spring" to Vaughan's Dome, a great chamber 40 ft. wide, 300 ft. long and 79 ft. high, thence southward by Florence Avenue and the "Ruins of Carthage," a spacious hall 400 ft. long, 100 ft. wide and 30 ft. high of which the flat roof is one continuous limestone block to the so-called "Ruins of Martinique," where the general course changes south-eastward, and passing by a number of spectacular features, leads to Colossal Dome, the most impressive of all the chambers, fringed by innumerable tinted stalactites and stalagmites, richly resonant when struck. Continuing south-eastward past the "Pearly Pool" of limpid water, and by a passageway between stately columns and grotesque figures, the cavern ends in a copious chalybeate spring. The fauna of the cavern is characterized by paucity of species, though of these the number of individuals is relatively large. The temperature is uniformly 54° F., the atmosphere fresh and pure. (W. E. E.)

COLOSSEUM, the Flavian amphitheatre in Rome, begun by Vespasian, on the site of part of Nero's famous Golden House, and inaugurated by Titus in A.D. 80. It consisted originally of three arcaded storeys of stone and an upper gallery, originally of wood, which was rebuilt of stone in the present form sometime in the third century. The colosseum probably seated between 40,000 and 50,000 people. It is elliptical in plan with its long axis 620ft. and its short axis 513ft.; its arena, 281ft. long and 177ft. wide. Its total height to the top of the third century stone screen wall is about 160 feet. For a further description *see* AMPHITHEATRE.

COLOSSIANS, EPISTLE TO THE, the 12th book of the New Testament, one of the later letters of the Apostle Paul. Colossae, like the other Phrygian cities of Laodicea and Hierapolis, had not been visited by Paul, but owed its belief in Jesus Christ to Epaphras, a Colossian who had laboured not only in his native city, but also in the adjacent portions of the Lycus valley—a Christian in whom Paul reposed the greatest confidence (i. 7; iv. 12, 13). This Epaphras, like the majority of the Colossians, was a Gentile. It is probable, however, that Jews were there with their synagogues (*cf.* Josephus *Ant.* xii. 149) and that some of the Gentiles, who afterwards became Christians, were either Jewish proselytes or adherents, who paid reverence to the God of the Jews. At all events, the letter indicates a sensitiveness on the part of the Christians not only to oriental mysticism and theosophy (*cf.* Sir W. M. Ramsay, *Cities and Bishoprics of Phrygia* and the *Church in the Roman Empire*), but also to the Judaism of the Diaspora.

Our first definite knowledge of the Colossian Church dates from the presence of Epaphras in Rome, *c.* A.D. 60, when Paul was a prisoner. Paul has received news, perhaps by letter (J. R. Harris, *Expositor,* Dec. 1898, pp. 404 *et seq.*) touching the state of religion in Colossae. He learns, to his joy, of their faith, hope and love, but detects a lack of that strength and joy and perfection, that richness of the fullness of knowledge expected of those who had been made full in Christ (i. 6, 9–11, 28; ii. 2, 7, 10). The reason for this, Paul sees, is the influence of the claim made by certain teachers in Colossae that the Christians, in order to attain unto and be assured of *full* salvation, must supplement Paul's message with their own fuller and more perfect wisdom, and must observe certain rites and practices (ii. 16, 21, 23) connected with the worship of angels (ii. 18, 23) and elementary spirits (ii. 8, 20).

The origin and the exact nature of this religious movement are alike uncertain. (1) If it represents a type of syncretism as definite as that known to have existed in the developed gnostic systems of the 2nd century, it is inconceivable that Paul should have passed it by as easily as he did. (2) As there is no reference to celibacy, communism and the worship of the sun, it is improbable that the movement is identical with that of the Essenes. (3) The phenomena might be explained solely on the basis of Judaism (von Soden, Peake). Certainly the asceticism and ritualism might be so interpreted, for there was among the Jews of the Dispersion an increasing tendency to asceticism, by way of protest against the excesses of the Gentiles. The reference in ii. 23 to severity of the body may have to do with fasting preparatory to seeing visions (*cf. Apoc. Baruch,* xxi. 1, ix. 2, v. 7). Even the worship of angels, not only as mediators of revelation and visions, but also as cosmical beings, is a well-known fact in late Judaism (*Apoc. Bar.*, lv. 3; *Ethiopic Enoch,* lx. 11, lxi. 10; Col. ii. 8, 20; Gal. iv. 3). As for the word "philosophy" (ii. 8), it is not necessary to take it in the technical Greek sense when the usage of Philo and Josephus permits a looser meaning. Finally the references to circumcision, *paradosis* (ii. 8) and *dogmata* (ii. 20), directly suggest a Jewish origin. If we resort solely to Judaism for explanation, it must be a Judaism of the Diaspora type. (4) The difficulty with the last-mentioned position is that it under-estimates the speculative tendencies of the errorists and ignores the direct influence of oriental theosophy. It is quite true that Paul does not directly attack the speculative position, but rather indicates the practical dangers inherent therein (the denial of the supremacy of Christ and of full salvation through Him); he does not say that the errorists hold Christ to be a mere angel or an aeon, or that words like *pleroma* (borrowed perhaps from their own vocabulary) involve a rigorous dualism. Yet his characterization of the movement as an arbitrary religion (ii. 23), a philosophy which is empty deceit (ii. 8), according to elemental spirits and not according to Christ, and a higher knowledge due to a mind controlled by the flesh (ii. 18); his repeated emphasis on Christ, as supreme over all things, over men and angels, agent in creation as well as in redemption, in whom dwelt bodily the fullness of the Godhead; and his constant stress upon knowledge—all these combine to reveal a speculation real and dangerous, even if naïve and regardless of consequences, and to suggest (with Jülicher and McGiffert) that in addition to Jewish influence there is also the direct influence of Oriental mysticism.

To meet the pressing need in Colossae, Paul writes a letter and entrusts it to Tychicus, who is on his way to Colossae with Onesimus, Philemon's slave (iv. 7, 9). (On the relation of this letter to Ephesians and to the letter to be sent from Laodicea to Colossae, *see* EPHESIANS, EPISTLE TO THE.)

A letter like this, clear cut in its thought, teeming with ideas emanating from a unique religious experience, and admirably adjusted to known situations, bears on its face the marks of genuineness even without recourse to the excellent external attestation. It is not strange that there is a growing consensus of opinion that Paul is the author. With the critical renaissance of the early part of the 19th century doubts were raised as to its genuineness (*e.g.,* by E. T. Mayerhoff, 1838). Quite apart from the difficulties created by the Tübingen theory, legitimate difficulties were found in the style, in the speculation of the errorists and in the theology of the author. (1) As to style, it is replied that if there are peculiarities in *Colossians,* so also in the admittedly genuine letters, *Romans, Corinthians, Galatians.* Moreover, if *Philippians* is Pauline, so also the stylistically similar *Colossians* (*cf.* von Soden). (2) As to the speculation of the errorists it is explicable in the lifetime of Paul, recourse to the developed gnosticism of the 2nd century being unnecessary. (3) As to the Christology of the author, it does not go beyond what we have already in Paul except in emphasis, which itself is occasioned by the circumstances. What is implicit in *Corinthians* is explicit in *Colossians.* H. J. Holtzmann (1872) subjected both *Colossians* and *Ephesians* to a rigorous examination, and found in *Colossians* at least a nucleus of Pauline material. H. von Soden (1885), with well-considered principles of criticism, made a similar examination and found a much larger nucleus, and later still (1893), in his commentary, reduced the non-Pauline material to a negligible minimum. Harnack, Jülicher, McGiffert, Moffatt and Dibelius agree with Lightfoot, Weiss, Zahn (and early tradition) in holding that the letter is wholly Pauline—a position which is proving more and more acceptable to contemporary scholarship.

COLOSSUS, in antiquity, a term applied generally to statues of great size (hence the adjective "colossal"), and in particular to the bronze statue of the sun-god Helios in Rhodes, one of the wonders of the world, made from the spoils left by Demetrius Poliorcetes when he raised the siege of the city. The sculptor was Chares, a native of Lindus, and of the school of Lysippus. The work occupied him 12 years, it is said, and the finished statue stood 70 cubits high. It stood near the harbour, but at what point is not certain. As early as the 16th century the belief was current that it had stood across the entrance to the harbour, with a beacon light in its hand and ships passing between its legs. The statue was thrown down by an earthquake about the year 224 B.C.; then, after lying broken for nearly 1,000 years, the pieces were bought by a Jew from the Saracens, and probably reconverted into instruments of war.

Other Greek colossi were the Apollo of Calamis; the Zeus and Herakles of Lysippus; the Zeus at Olympia, the Athena in the Parthenon, and the Athena Promachos on the Acropolis—all the work of Pheidias.

The best-known Roman colossi are: a statue of Jupiter on the Capitol; a bronze statue of Apollo in the Palatine library; and the colossus of Nero in the vestibule of his Golden House, afterwards removed by Hadrian to the north of the Colosseum, where the basement upon which it stood is still visible (Pliny, *Nat. Hist.,* xxxiv. 18).

Gigantic statues of divinities and royalties are characteristic of Egyptian, Assyrian and Indian archaeology, size being an indication and measure of social and religious importance.

COLOUR. In this article colour is discussed mainly from the physical point of view. Under VISION it is discussed from the physiological point of view. It is not possible to make a clear-cut separation of the two aspects, and therefore the two articles supplement and overlap one another at certain points.

The Nature of Colour.—In looking round at the different objects surrounding him the person of normal vision recognises not only that they differ in form, but also that some are brighter than others and further that they differ in a respect which we name colour. As bodies are seen by the light proceeding from them this means that light as modified by various physical causes can produce different colour sensations. The nature of the sensation of colour is not a thing that can be explained to anybody who has never experienced it, although there have often been attempts to find analogies between sound and colours.

The sensation of colour can be produced by stimuli other than light, for instance by pressure on the eyeball in complete darkness. It can also be produced in darkness if the eye has previously been exposed to bright light of any colour: the so-called after-images are then formed. The particular colour sensation produced by a light of a particular kind and strength from a coloured object also depends upon the light to which the eye has been previously exposed, and upon the colour of the objects immediately surrounding it, phenomena which are referred to as successive and simultaneous contrast. These physiological effects are dealt with under VISION as are also the various types of deficiency of colour perception. We are here dealing with the colour effects produced in a normal eye in a normal state.

The physical side of the subject is approached most simply by considering pure spectral colours. When white light from a slit is passed through a prism and projected on a screen by a suitable arrangement of lenses, there is produced a band of light which is called a spectrum. The normal eye at once recognizes that the light at different parts of this band varies not only in brightness, but also in colour. The band is red at one end, violet at the other, and between lie a range of colours, in the order orange, yellow, green, blue and indigo, making in all the so-called seven primary colours. Physically the spectrum represents a continuous range of wave-lengths of light, which extends beyond the limits of vision at both ends, beyond the red into the infra-red, and beyond the violet into the ultra-violet. The wave-length of the extreme visible red is something less than twice the wave-length of the extreme visible violet. (*See* RADIATION.) The colour sensations excited by the light blend into one another, and it is impossible to say exactly where one of the primary colours stops, and the next begins. The distinction of these colours is entirely subjective, that is, a matter of the organs of sense-perception, for physically there are no steps in the spectrum corresponding to the different colours. While by using sufficiently refined instruments the number of wave-lengths distinguishable by physical means can be made practically as great as we like, yet the most trained eye never sees more than seven primary colours, within which are distinguishable shades of colour. The number of shades of colour, or hues, which the eye can pick out as distinguishable within the seven primary colours is also very limited. There is some dispute as to the number, which depends to a great extent upon the method employed to isolate patches which appear monochromatic to the eye; different experts vary in their estimate between 130 and 30. In any case the sensations of colour divide up the spectrum in a way manufactured by the observer, and not represented by any physical divisions. Roughly speaking, the wave-lengths corresponding to the boundaries between the primary colours found by a normal observer are given in the following table, but some people of good colour vision do not make any distinction between blue and indigo, and so naturally make a different division, while people of inferior colour vision distinguish still fewer primary colours (*see* VISION). The arbitrary element is still further emphasized by comparing the results of the two experienced investigators cited. The wave-lengths are given in thousandths of a millimetre, denoted by μ.

	Observations by Abney	By Listing
Red	End to ·62 μ	·723 to ·647μ
Orange	·62 ,, ·592μ	·647 ,, ·585μ
Yellow	·592 ,, ·578μ	·585 ,, ·575μ
Green	·578 ,, ·500μ	·575 ,, ·492μ
Blue	·500 ,, ·464μ	·492 ,, ·455μ
Ultramarine indigo	·464 ,, ·446μ	·455 ,, ·424μ
Violet	·446 ,, end	·424 ,, ·397μ

A coloured light that reaches the eye from, say, a lantern provided with coloured glasses, or from a coloured body, such as a piece of cloth, will not, in general, be a pure spectral colour, *i.e.,* light of a given single wave-length, or of a narrow range of wave-lengths. Rather, it will consist of one or more wide continuous ranges of wave-lengths. If we want to specify the light physically we must not only be able to measure what wave-lengths are present in the mixture, but also the intensity of each. When we have done this we shall have sufficient information to enable us to reproduce a coloured light which will have the same effect on any normal eye in a normal state. It must be emphasized, however, that the reverse does not hold, namely if we have a second coloured light which produces exactly the same effect as the first on a normal eye, it does not follow that it consists physically of the same wave-lengths in the same strength. For instance light of a pure spectral yellow, consisting of a narrow range of wave-lengths in the neighbourhood of ·590μ, can be matched exactly by a mixture of spectral green light and of spectral red light in suitable intensities. The eye is quite unable to decide if a colour is simple or compound. It is a fact of the greatest practical importance that any colour sensation, whatever the physical characteristics of the light that produce it, can be matched by light of three selected wave-lengths, by varying the relative intensities of these three components. This is an experimental fact which is quite independent of the validity of any three colour theory of vision. The question of the connection between the physical stimulus and the colour perceived is further considered in the last section of this article.

Coloured Bodies.—For the discussion of colour, white light, such as daylight, can be considered as consisting of a mixture of all wave-lengths of the visible spectrum. (The physical nature of white light is discussed in detail in LIGHT.) A body, such as a piece of cloth, illuminated by such light, appears coloured because it absorbs light of certain wave-lengths partially or completely, and throws back the remainder. Thus an ordinary blue object absorbs red, orange and yellow rays, and scatters blue together with some green, indigo and violet; the purer the colour the smaller is the spectral region of the unabsorbed light. A yellow object absorbs the blue, indigo and violet, and generally throws back with the yellow a certain amount of green, orange and red. The colour is thus produced by absorption. When white light, say, falls on a pigment a small part is reflected unchanged at the surface as white light, but the greater part penetrates a short distance into the body and then, as a result of internal reflections and refractions due to irregularities, emerges again, modified by the loss of the rays which are most strongly absorbed. This fact can be strikingly illustrated by taking a piece of brilliantly coloured glass, and crushing it to a fine powder; the powder will appear white. The crushing leads to the creation of a very large amount of new surface, at each of which a certain amount of surface reflection takes place, so that the light is no longer able to penetrate sufficient thickness of the substance for marked absorption to manifest itself. If the powder is now wetted with water or still better with an oil of about the same refractive index as the glass, which markedly diminishes the surface reflection, the colour is largely restored. Another illustration of the same phenomenon, given by R. W. Wood, is provided by a bead of fused borax, coloured with cobalt so deeply as to appear black. If such a bead is crushed the powder appears blue, for the diminished penetration leads to a less complete absorption. The white froth on a coloured liquid such as beer, is another aspect of the same phenomenon: the liquid of which the froth is composed appears brown when the light can penetrate a sufficient depth before being turned back, but the bubbles present so great a number of reflecting surfaces, that the light is unable to penetrate any depth, and the bubbles appear white.

Similarly, a transparent substance, such as a piece of coloured gelatine, held between a white light and the eye, owes its colour to the fact that it absorbs the remainder of the spectrum. Neglect of the fact that the colours of glasses and pigments are due to absorption often leads to great confusion as to the result of mixing colours. If we mix a blue and a yellow pigment the green sensation produced is not the result of mixing blue and yellow light. The blue pigment absorbs, roughly speaking, the red, orange and yellow: the yellow pigment absorbs the blue, indigo and violet. It follows that the only colour which escapes the double absorption is green, which accordingly is thrown back from the mixture. If we mix blue and yellow light, by letting a beam which has passed through a piece of ordinary yellow glass fall on a white screen which is also illuminated by the appropriate amount of light which has passed through an ordinary blue glass, the result is a white light, for yellow and blue are complementary colours. Of course if we let the light pass first through one glass and then through the other the result will be green light as with the pigments, for the light transmitted is the spectral region which escapes the double absorption. In the same way a red and blue glass, put together may stop all light and appear black, but red and blue light mixed produce a purple.

An interesting phenomenon due to absorption colour is the so-called dichromatism exhibited by certain bodies, which, viewed by transmitted light, appear one colour in thin layers, and another colour in thick layers. For instance, a thin plate of cobalt glass appears blue, a thick plate red. In such substances the fraction of the incident light absorbed in a layer of given thickness varies markedly with the wave-length. Thus if in the incident white light the green is visually more intense than the red, but the absorption coefficient for green in the substance is greater than that for red, a thin layer will appear green, a thicker layer, in which the green has been relatively reduced, yellow, and a thicker layer still, red. R. W. Wood has shown this well by dissolving the dyes "brilliant green" and "naphthalene yellow" in hot Canada balsam, and preparing a thin wedge of the substance between two glass plates; the thin edge of the wedge appears green, the thick edge red, the intermediate portion yellow. The fact that most bodies do not exhibit dichromatism means that their absorption coefficient is much the same for all wave-lengths.

The colour which a body exhibits must clearly depend upon the illuminating light. While there are certain exceptional substances which actually transform the light which falls on them to a different colour (*see* FLUORESCENCE AND PHOSPHORESCENCE) the ordinary pigment, whether natural, as in a flower, or artificial as in a dyed cloth, merely scatters back one colour of the mixed light falling upon it, and absorbs the rest; if the colour which we normally attribute to the body is not present, or is present only in reduced quantity, in the illuminating light, then the appearance of the body will be much modified. If a piece of white paper is placed in various coloured lights it will in each case take on the colour of the light, appearing blue in blue light, green in green light. If, on the other hand, a red poppy is placed in blue light it will appear black, for it completely absorbs blue light: in red light it will appear brilliant red, in yellow light a less brilliant yellow and in the green very dark indeed. The average blue pigment appears black in red, orange or yellow light, greenish in green light, for most blues do not completely absorb the green, and, of course, blue in blue light. The modifications in appearance which coloured bodies undergo with change of illumination is familiar to most people from the change in appearance of fabrics in natural and artificial light. This is particularly marked with blue, in consequence of the fact that artificial light differs from daylight chiefly by relative deficiency of blue. Thus a cloth that appears blue by day will appear nearly black by artificial light, for it absorbs all colours but blue, and there is little blue present in the illuminating light. Petruschewski showed that a white surface illuminated by light from a petroleum lamp presented exactly the same appearance as a dark orange surface illuminated by daylight, and a bright blue surface seen by the petroleum light matched a bright brown surface seen by daylight.

FIG. 1.—CURVES SHOWING THE RELATIVE ENERGY OF THE DIFFERENT SPECTRAL REGIONS FOR VARIOUS SOURCES OF LIGHT, ALL COMMONLY TERMED WHITE

While most ordinary bodies, such as pigments, exhibit the absorption, or *body colour* which has just been discussed, with certain bodies the light that is reflected at the surface, without penetration, shows a marked colour. Such bodies are said to reflect selectively, and to show *surface colour;* they show a different colour when viewed by reflected light from that which they exhibit when viewed by transmitted light. Many of the aniline dyes show strong surface colour when prepared in thin films. The colours of the metals are of this nature; gold, for instance, which shows the well known yellow colour by reflected light, appears green by transmitted light, as can be easily shown by placing a goldleaf between two plates of glass, and looking at a white light through it. The leaf is thin enough to transmit an appreciable quantity of light.

Colours due to other physical causes also occur. Thin films, such as soap-bubbles, oil on water, and slivers of mica exhibit colours due to interference (*see* LIGHT). Films of uniform thickness exhibit a uniform colour, but wedge-shaped films, such as, using the term in a general sense, the air film between a slightly convex surface and a plane surface which gives rise to Newton's rings, show complicated sequences of colours due to the removal of different spectral regions by interference at the different thicknesses. The colours of certain iridescent crystals such as are found in potassium chlorate, and opals, are due to interference from a number of approximately equidistant thin laminae. The colour of the blue sky is due to the diffraction of light by small suspended particles and the air molecules themselves; the shorter wave-lengths, *i.e.,* those at the blue end of the spectrum, are more scattered by small particles than the larger wave lengths, so that, if light is passing through a medium containing such particles, an observer standing to one side sees the path of the light as blue (*see* LIGHT). As the blue light is not created, but merely scattered out of the white light, the beam itself will become redder. This accounts for the red appearance of the sun at sunset, when the rays pass through a great thickness of scattered particles, and on foggy days, when the number of particles in the atmosphere is large. The colours of the rainbow are due to interference, the refraction and general theory being more complicated than the refraction explanation given in elementary text books.

White, Black and Grey.—When we turn to the question of what precisely is meant by white light, which has been so frequently mentioned, we are confronted by the fact that there is no precise standard. It can be roughly defined as sunlight at noon on a clear day. It is necessary to mention the time of day and the atmosphere since the relative intensities of the different colours into which sunlight can be resolved are affected by the absorption of the atmosphere, so that sunlight in the early morning, at noon and at late afternoon is not of precisely the same colour. The colour of sunlight will similarly be slightly different at noon on a clear day in different latitudes. Artificial lights which are usually called white differ still more among themselves and are all much yellower than sunlight, that is, the blue end of the spectrum is relatively faint in the artificial light (*see* fig. 1).

White light serves to emphasize the fact that identical colour sensations can be produced by different physical stimuli. Not only can any white light containing all wave lengths be imitated by the mixture of light of three different narrow spectral regions, but there are various pairs of colours which, when taken together in correct proportions, produce the sensation of white. Any two colours constituting such a pair are called complementary colours. Such pairs are red light of wave length $\cdot 656\mu$ and bluish green light of wave length $\cdot 492\mu$; yellow light of wave length $\cdot 585\mu$ and blue light of wave length $\cdot 485\mu$. The most skilled eye is quite unable to analyse a white light or a coloured light into its spectral components.

The fact that "white" artificial light differs so markedly from white daylight, by reason of its deficiency of the blue end of the spectrum, leads to coloured fabrics appearing quite a different colour in daylight and in artificial light, as has already been mentioned. To obtain an artificial illumination which shall make coloured objects appear as they do in daylight, various types of so-called "daylight lamps" are made, which are extensively used by those who deal in fabrics. One such lamp is the Sheringham daylight lamp, illustrated diagrammatically in fig. 2, on which an ordinary electric hot wire lamp is used. The light from this lamp is thrown by a silvered reflector, which cuts off all direct light, on to a shade, the inside of which is covered with patches of colours in which green and blue predominate. These green and blue patches absorb most of the red end of the spectrum, while throwing back the green and blue practically unabsorbed, and so increase the relative proportion of the blue end in the way required to give a rough imitation of daylight. A body which absorbs a large fraction of the incident light, without absorbing any one colour markedly better than another, throws back a feeble white light, and appears grey. A body which absorbs completely inci-

FIG. 2.—THE SHERINGHAM LAMP FOR PRODUCING A LIGHT EQUIVALENT TO DAYLIGHT BY MEANS OF A COLOURED REFLECTOR

dent light of all wave-lengths throws back no light, and appears black. Black is an absence of all colour. Helmholtz says that black is a true sensation, even although it is produced by the absence of all light, and seeks to justify this somewhat paradoxical statement by pointing out that an object in our field of view which throws back no light appears black, but an object behind our back, which also throws no light into the eye, produces no sensation.

Classification and Measurement of Colour.—If we wish to classify the colour sensations produced by the light from coloured bodies the immediate problem is not to analyse the light physically into its different wave-lengths, each of a given intensity, but rather to find the simplest way in which the same colour sensation can be produced. It is a fact of experience that, apart from intensity, *i.e.,* the brightness of the colour, any colour can be matched by a spectral colour to which a proportion of white light has been added. Pure spectral colours, without admixture of white light, are said to be *saturated,* and, in proportion as white light is added, become less and less saturated. The spectral colour is usually referred to as a *hue,* the term colour being reserved for the general sensation. The statement that any colour can be matched by a spectral hue to which white has been added requires qualification, for the purple sensation cannot be so matched. A saturated purple is itself produced by mixing light from the violet and red ends of the spectrum, and such a purple must be added to the spectral hues to complete the description. The purple hue, which is compounded of the ends of the spectrum, can be regarded as affording a transition from one end to the other, so that the hues can be arranged in a circle, with purple between the red and violet, forming a bridge from one to the other. We may, then, taking the spectral colours and purple as saturated hues, say that colour sensations can differ in three respects only: hue, saturation and intensity. This classification was introduced by Helmholtz. Expressed somewhat differently, the sensation produced by any given coloured light, however mixed it may be physically, can be matched by a certain quantity of white light and a certain quantity of a saturated hue. To specify the sensation we must give the wave-length of the hue and the quantities of white light and of this coloured light. If we are dealing with a coloured surface we must clearly illuminate it with some kind of standard white light in order to make a measurement of the hue and saturation. The intensity of the light from the coloured surface will be proportional to the intensity of the illuminating light. It is therefore reasonable to take, as a measure of the intensity of the colour of the body, the ratio of the brightness of the light proceeding from the body to the brightness of the light from a perfectly white surface similarly illuminated. The term *brilliance* is often used, especially in America, to denote this ratio.

Newton arranged the saturated hues round the circumference of a circle as shown in fig. 3, and placed at the middle of the circle white. Any line joining the centre W to a point P of the circumference then represents the transition from the saturated hue represented by P to white light, the degree of saturation lessening to zero as we approach the centre. Newton also gave a rule by which the result of mixing colours could be obtained from his figure, certain weights being attributed to each spectral hue, and the centre of gravity found. This two-dimensional figure has been variously modified, a colour triangle being a more usual method of representation (*see* VISION). If, as Lambert did, we use three dimensions and let lines normal to the surface represent intensities, diminishing as we go upwards, we can represent any colour sensation. We have a pyramid of colour, the point of which will represent black. There have been many modifications of this three dimensional representation of colour sensation, designed to get over certain difficulties which arise in respect of the

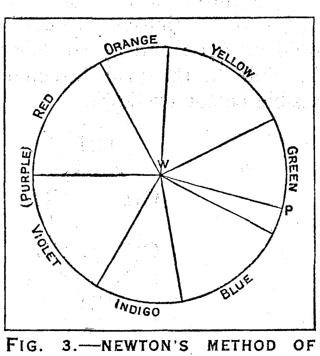

FIG. 3.—NEWTON'S METHOD OF COLOUR CLASSIFICATION

luminating values of the colour sensations. One of the most recent is that of Munsell, in which the three co-ordinates are:—the height of the point from the horizontal plane, representing the intensity, or brilliance; the distance from a vertical axis, representing the saturation; and the angle from a vertical plane, representing the hue.

A method of colour classification much adopted, on account of its simplicity of use, among those practically concerned with colour, such as manufacturers of paints and printing inks, is some form of colour atlas or colour chart, in which patches of various colours are arranged on some system. The Munsell colour tree to which reference has just been made is used to effect the classification in such a chart, known as the Munsell colour atlas, issued by the Munsell Colour Company, in America. Ostwald in 1917 brought out a very elaborate colour atlas, with about 3,000 colour specimens. He used a special classification—hue, white-content, black-content—in place of Helmholtz's hue, saturation and intensity. The Société des Chrysanthémistes issues a colour chart with colour names in four languages. A necessity of any such colour chart, is of course that all copies shall conform accurately and that the colours shall not fade.

A large number of instruments have been devised for colour measurement. For scientific investigations of colour perceptions much use has been made of the colour-patch type of apparatus, in which lights of two or more different wave lengths, isolated from a spectrum by slits, are brought into coincidence as superimposed patches on a white diffusing screen. The intensities of the separate colours can be varied so as to produce all possible shades. This apparatus exists in various forms. For technical work instruments are now being constructed in which, instead of a spectral hue, light which has passed through an arbitrary colour filter is being used. The three beams of light, one of which has passed through a red filter, the second through a green filter and the third through a blue filter, are brought into superposition on a screen. Each beam can be varied in intensity. One of the best forms of such apparatus is due to Guild. In Guild's trichromatic colorimeter the light enters by three sector-shaped windows, provided respectively with red, blue and green filters. By the mechanism of a revolving prism the field is illuminated by light from the three windows in rapid succession. When the speed of alternation is high enough the sensations blend and the mixed colour is perceived. Still another type of instrument, called the tintometer, depends upon passing the light *successively* through three filters of different colour, each of which subtracts something from the original white light. Although only three colours are chosen each must be represented by a series of various depths of colour, so that some 470 glasses are necessary in a complete matching set. The match is then given in terms of the depth of colour of each of the three filters which, placed one behind the other, transmit the given light.

A different type of apparatus is the spectrophotometer, by means of which the physical constitution of a coloured light may be actually measured. The light is resolved into a spectrum, and the intensity of each wave-length present is measured separately. This measurement is usually effected by the help of a standard source of white light, the intensity of the transmitted hue being controlled by polarizing prisms of one type or another. If two such prisms are used, one as polarizer and the other as analyser, the intensity of the light transmitted can be controlled by rotating the analyser, the angular position of which gives an exact measure of the percentage of light cut off (*see* LIGHT). The Nutting spectrophotometer and the König-Martins spectrophotometer are two well-known instruments which make use of this principle (*see* PHOTOMETRY). Such instruments are largely used for measuring the light transmitted by colour filters, coloured glasses, dyes and so on.

A third type of instrument is the colorimeter of the Nutting pattern, which matches any given coloured light by manufacturing a light of given hue, saturation and intensity. A spectral hue is separated out from a spectrum by means of an adjustable slit, and a given quantity of white light is added from a separate source. This gives adjustable hue and saturation. The intensity is varied by altering the width of the slits, or else by other means commonly used in physical instruments, such as rotating sectors with controllable gaps or polarizing prisms.

BIBLIOGRAPHY.—H. von Helmholtz, *Handbuch der physiologischen Optik* (1911) (English translation published by the Optical Society of America in 1924–25), this is the classical book on the subject; L. C. Martin, *Colour and Methods of Colour Reproduction* (1923), this book contains a good description of colour-measuring instruments; Luckiesh, *Color and its Application* (1915); Ostwald, *Die Farbenlehre* (1918–19), this book contains a full account of Ostwald's own system; "Report of the Committee on Colorimetry" *Journal Optical Society of America* (bibl., 1922); J. Guild, "Survey of Modern Developments in Colorimetry," *Proceedings of the Optical Convention,* Part I. (bibl. 1926). (E. N. DA C. A.)

INFLUENCE OF CHEMICAL CONSTITUTION

The sensation of white light is caused by electromagnetic vibrations of a certain wave length impinging on the retina of the eye. The sensation of colour is produced by the absorption of one or other of the coloured components of white light when the light strikes some suitable surface or passes through a suitable medium —the light reflected from the surface or transmitted through the medium consequently conveying to the retina a sensation of colour complementary to that absorbed. There is an analogy between variations of colour in light and pitch in sound.

Many substances do not absorb any definite portion of the visible spectrum—the name applied to the range of colours into which white light can be resolved—but give *general* absorption throughout the range.

Such substances appear, therefore, colourless both by transmitted and reflected light and it is only those materials which cause selective absorption, that is which absorb some definite portion of the visible spectrum, that appear coloured. It follows, therefore, that there must be some special property possessed by substances which produce the sensation of colour which distinguishes them from other substances that appear colourless.

As a matter of fact it is quite easy to detect the causes leading to the main underlying difference between the two types, for they may be divided into two classes which, for the sake of convenience, may be named the physical cause and the chemical cause; and, in the first instance at any rate, the reason for production of colour is quite clear and it is a comparatively simple matter to reproduce the effect mechanically. For example, white light is resolved into its component colours when it is allowed to impinge on a glass surface which has been ruled with a number of fine lines, and there are a number of other ways by which the sensation of colour can be imparted by purely mechanical means.

As a matter of fact many natural objects, especially in the animal kingdom, owe their colour to the physical cause. The vivid green of certain beetles, the colours of the peacock's feathers, the colours of butterflies' wings and the colour of blue eyes are all produced in this way, the colour effect being caused by the interference of white light through the agency of minute excrescences or fine filaments on the surface of the objects that appear coloured. The colour effects in such cases are, therefore, subjective and it would be just as reasonable to attempt to extract a coloured substance from the peacock's feather as it would be to do so from the rainbow.

On the other hand there are a great number of substances the colours of which must be ascribed to the second or chemical cause. These occur both naturally and artificially and are distinguished from those of the first or physical section by reason of the fact that the coloured substances in them can be extracted from the coloured materials and, when extracted, are found to be definite chemical compounds which owe their colour to their chemical constitution. In nature such coloured substances are to be found mainly in the vegetable kingdom, in the colouring matters, for example, of the flowers and of green grass or leaves. Moreover, it is easy to distinguish by a practical test between the two types because if a peacock's feather is viewed by transmitted light the brilliant colours will disappear, whereas, if a red rose leaf is treated in the same manner no change in colour will be noticed.

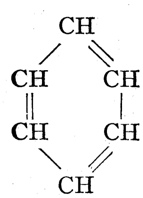
Nevertheless, it is only reasonable to suppose that the two types of phenomena are of the same order and that whilst the physical or subjective colour is due to the *intermolecular* interference of white light, the chemical colour is due to *intramolecular* interference, or, in other words, white light is "filtered" through the molecular structure of the chemical substance, leaving a "portion" behind in its passage. The colour is therefore dependent on the chemical composition of the particular compound. It remains then to compare those chemical compounds which produce colour with those that are colourless so as to reach some conclusion as to the influence of molecular structure on colour production. In the first place, however, it is necessary to attempt to arrive at some definition of what is meant by colour in a strictly scientific sense.

The Spectrum.—The range of the visible spectrum which is produced, for example, when a beam of white light passes through a quartz prism, represents a range of electromagnetic vibrations of wave lengths between 4,000 and 8,000 Ångström units. This is, however, only one octave in the range of 62 octaves of wave lengths from 0·01 to $3{\cdot}5\times10^{16}$ Ångström units which has been investigated. It is clearly, therefore, scientifically illogical to restrict the term "coloured" to those substances which cause absorption only in the short region capable of detection by the eye, because a substance which produces selective absorption in any other region of the electromagnetic range is also "coloured" although such colour requires the aid of some external influence in order that it may be detected.

It is necessary, therefore, to distinguish between *visible* colour and *invisible* colour and to describe those substances which give selective absorption in the visible region as visibly coloured and those which give selective absorption in other regions as invisibly coloured.

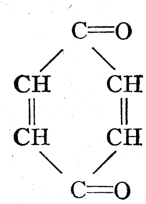
Infra-red and Ultra-violet Regions.—It is fortunate that the photographic plate is more sensitive to waves immediately outside the visible region of the spectrum than is the eye, for by its aid it is possible to detect selective absorption in those regions immediately outside the visible spectrum, which are known as the infra-red and the ultra-violet, and thus to show that many substances which appear colourless to the eye possess nevertheless intense invisible colour. Moreover, it is possible by simple chemical reactions to transform compounds having this invisible colour into those having visible colour or, in other words, by a change of structure, to throw the absorption from the invisible region into the visible region. In this way it is possible to correlate structure with visible colour.

For example, the hydrocarbon benzene (C_6H_6) appears colourless to the eye both by reflected and transmitted light, nevertheless when its spectrum is photographed marked selective absorption in the ultra-violet region is manifested. Benzene is, therefore, a substance having a strong invisible colour. By a simple series of reactions it is possible to transform benzene (I.) into quinone (II.) and by so doing to shift the absorption from the invisible to the visible region of the spectrum, thus obtaining visible colour (yellow).



I.

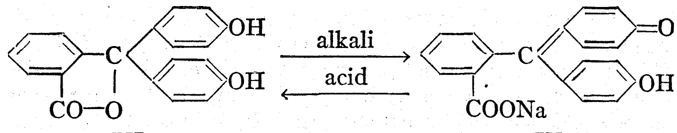
Benzene (invisibly coloured)



II.

Quinone (yellow)

Absorption.—This change, in the case of many derivatives of benzene, takes place with remarkable ease and with astonishing rapidity, thus the change from phenol-phthalein (III.), the benzenoid or invisibly coloured form, to the sodium salt (IV.), the quinonoid or visibly coloured form, by the action of alkali, and the reverse change which is effected by the action of acid, is so rapid and sensitive that the substance is used as an effective indicator in alkalimetry.

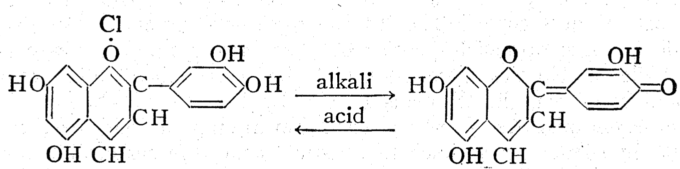


III. Benzenoid form (invisibly coloured)

IV. Quinonoid form (red)

The hydrocarbons naphthalene ($C_{10}H_8$) and anthracene ($C_{14}H_{10}$) provide further examples of the same kind and, in fact, the occurrence of colour among organic compounds which has led to the foundation of the coal-tar colour industry is based mainly on this change. It is also possible to start with a benzenoid derivative which by reason of its structure is visibly coloured and by a simple chemical change, such as that illustrated above, to throw absorption from one end of the visible spectrum to the other and thus to transform a red substance into a blue one. As a matter of fact Nature has utilized this method to produce her red and blue flowers. The red flowers are those in which the cell sap is acid, the blue those in which it is alkaline. If the cell sap is neutral the flowers are purple.

(*See* also ANTHOCYANINS AND ANTHOXANTHINS.)

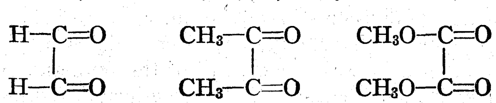


Red (rose)

Blue (cornflower)

It would appear, therefore, that the occurrence of visible colour is mainly adventitious and depends on molecular conditions which are subject to control. It happens to be a property of the quinone ring because the parent substance benzene possesses the power of causing absorption just outside the visible region. Even so, the formation of the quinone ring may not shift the absorption of benzene far enough to bring it within the visible region, and there are thus derivatives of quinone which have no visible colour. On the other hand the shift of the bands may be caused by other structures and there are, in consequence, derivatives of benzene such as azobenzene, $C_6H_5{-}N{=}N{-}C_6H_5$, to which no quinone structure can be assigned, yet which possess strong visible colour.

If the wider definition of colour be accepted it is probable that there is no such thing as a colourless material, because it is likely that every substance gives selective absorption somewhere within the range of electromagnetic vibrations. It appears to be in the power of many substances belonging to the aliphatic series of organic chemistry to give selective absorption in the infra-red region of the spectrum. Visibly coloured substances in this portion of organic chemistry are not of frequent occurrence, but when such colour occurs it is always associated with the presence of what is known as the conjugated system of double linkages; thus glyoxal (V.) and diacetyl (VI.) are yellow:—



(V.) (VI.) (VII.)

Methyl oxalate (VII.) is, however, visibly colourless and it must be assumed that in this case the infra-red absorption has not been thrown into the visible region. It is of interest to note that the same system of conjugated linkages is present in the conventional formula for benzene (I.).

Colour in Chemistry.—It is also significant that visible colour is shown only by unsaturated carbon compounds and that in no case has a visibly coloured saturated compound been prepared. It follows therefore:—That both visible and invisible colour are associated with unsaturation. That they are associated with the occurrence of selective absorption either outside or within the visible region of the spectrum, the former causing invisible, and the latter visible colour. That occurrence of this absorption is bound up with the presence of a system of conjugated double linkages within the molecule. (*See* also DYES, SYNTHETIC.)

The causes leading to the production of visible colour in inorganic compounds will not be clearly understood until more is known about the molecular structures of such substances. It is obviously due, initially, to the presence of a colour-producing element such as copper, chromium, cobalt, etc. The cause of colour in these elements is probably molecular, as instance the change in colour iodine undergoes when heated. Nevertheless the structure of the salt must also play a part as is shown, for example, in the disappearance of the blue colour of hydrated copper sulphate when it loses part of its water of hydration. In any case the causes of visible colour in this section of chemistry are not so clearly defined as they are in the organic section, and no useful purpose would be served by dealing with them in the present state of our knowledge. (*See* also RADIATION, RAYS; VISION OR SIGHT; LIGHT; OPTICS; SPECTROSCOPY.)

COLOUR AND RACE. The political and social questions involved in the differences of colour and race have gained in intensity and importance in the 19th and 20th centuries. Closer geographical contact, the spread of more uniform patterns of civilization and aspirations all over the earth, and especially the proclamation and propagation of the "racial" interpretation of history have emphasized a growing trend. In the political and social controversies much confusion is due to the indiscriminate interchange of three different meanings in which the word "race" is used today. The tension produced by colour and race theories is responsible for some of the most fateful misinterpretations and maladjustments which threaten to engulf many countries, and perhaps mankind itself, in bitter racial conflicts and to demoralize human relations by racial arrogance and colour prejudice.

The word race is primarily a biological term (*see* RACES OF MANKIND) and denotes groups of men differentiated by anatomical characteristics. None of them shows any fundamental or far reaching differences among the races: in all essential features mankind is one and clearly differentiated from all other species of the animal world. It is only in minor secondary attributes, like shape of skull, form of nose, texture of head hair, quantity of body hair and colour of skin that there is any measurable or appreciable difference among the various racial groups. The Biblical story of the common origins of the human race has not been contradicted by any modern scientific discovery.

Old and primitive superstitions have linked race and class with blood. In reality no such link exists. Medical science, in its early attempts at blood transfusion, has discovered four different types of blood; but these types, called O, A, B and AB, are found among all races. Certain of these blood types do not mix without agglutination of the red cells. Modern medical practice has eliminated this danger by the removal of the red and white blood cells; the remaining plasma in its dried form is entirely independent from all types of blood and equally usable for all men.

Of the non-essential differences among human groups those of the texture of the head hair and of the colour of the skin are most frequently used to establish a division of mankind into primary races. The various shapes of the skull (dolichocephalic or long-skulled, mesocephalic or medium-skulled, brachycephalic or short-skulled) are found among all the primary races. A clearer line of division is offered by the texture of the head hair, distinguishing the Caucasians with wavy hair (Cymotrichi), the Mongolians with smooth or lank hair (Leiotrichi) and the Negroes with frizzy or woolly hair (Ulotrichi). These differences of the texture of the head hair overlap, however, with the differences of colour, as there are black African tribes with wavy hair. Differences of the colour of the skin lead to the establishment of three similar primary races. Chemical research has established that the different shades of the skin are due to the quantity of two chemicals in the skin, melanin which darkens it, and carotene which gives it a yellowish colour. People with the whitest skin are found in northern Europe and are called Nordics, people with the blackest skin live in West Africa, while people in southeast Asia are distinguished by yellowish tan. The majority of men, however, are neither white, black nor yellow, but represent innumerable shades of swarthy and brown men.

Whatever the anatomical differences of various races, there is no scientific proof for any correspondence between colour or texture of hair and mental ability. The idea that differences of colour imply differences of mental ability is comparatively recent. All civilization originated with "coloured" races, the yellow men in the Chinese river valleys, the brown men of India, Mesopotamia and Egypt, and the swarthy men of the Mediterranean basin. Among them all the great religions of mankind were founded; their depth of religious feeling and of metaphysical thought was never surpassed in Nordic lands. Throughout the middle ages Europeans and orientals met as equals; Greek civilization was transmitted to the rising universities of the west by Arabic scholars.

Marco Polo travelling to the far east was awed by the splendour of the oriental realms. Islamic civilization, including Caucasians, Negroes in Africa, and brown men in the East Indies, has always been entirely free from any colour feeling. It began to show itself only after the centre of western civilization shifted from the Mediterranean to the North Atlantic.

With the 16th century began a rapid progress of western European civilization in the conquest of nature, in scientific research and in the application of rational and very soon also humanitarian principles to the art of government. In the 18th and 19th centuries far greater progress was achieved in the North Atlantic region in these fields than in all preceding ages and civilizations. Equipped with the new methods of science and government, the European communities, especially those bordering the north Atlantic and the North sea, soon faced the other lands and peoples with such a superiority that by the middle of the 19th century the whole globe was controlled by western men. Ancient and powerful empires like the Chinese, the Moghul, the Persian and the Ottoman empires, had to bow before the superiority of the rising influence of the white men, a superiority based not only on scientific rationalism and technical inventiveness but above all on a new spirit of civic responsibility, of individual initiative and of enlightened humanism.

In the middle of the 19th century Count Joseph Arthur Gobineau in his book *Essay on the Inequality of the Human Races* proclaimed the true Nordic Germans, whom he identified with the French aristocracy, the supremely creative race. According to him the human races were most unequal in creative ability; it was impossible for them to reach the same level of cultural life; he ascribed the decay of the Nordic race, which he as a violent opponent of all democratic trends believed to be taking place in the 19th century, to race mixture. This theory found only very few followers in France or England, but it was taken up and popularized by German scholars, propagandists, and artists like Richard Wagner, who developed a race theory based upon two premises: that there is a definite hierarchy of races and that the German race (sometimes identified with the Nordic and sometimes with an "Aryan" race) is the highest and most creative race; and that the ability of a race depended upon the "purity of its blood" and that therefore intermarriage was detrimental to civilization. This theory, widely held in Germany even before the rise to power of national socialism, became in 1933 the official fundamental doctrine of German science and of the German state. Its propaganda outside Germany served as an instrument of German aspirations. This accentuation of racial prejudice was one of the most aggravating factors in the era of violent political and intellectual clashes following the rise of national socialism. It was German influence which made the racial myth an integral part of all fascist movements to which it had originally been alien.

In reality it is impossible to define any modern nation by somatic characteristics. The whole "mythical" and unscientific character of the racial theory was recognized by the leading German authorities themselves. For how many people in Germany corresponded to the "Nordic" character of blond, tall, blue-eyed and straight-nosed humanity? Among all nations racial intermixture has gone on everywhere over a long period. Sexual attraction is common between men of different races, and even taboos and legislation have been unable to check it. Negroes and whites in the Caribbean and in the United States, Spaniards and Indians in Central and South America, Boers and Hottentots in South Africa have successfully intermingled. There exists no objective proof to show that offspring of even widely different races decrease in efficiency, intelligence or vitality.

This insufficiency of somatic characteristics led the "racialists" to use the word "race" increasingly in the ethnical sense meaning "nation" or "people." Thereby the confusion and the propagandistic value of racial theories has been many times increased. While the Nordics represent a biological race, tall, blond-haired and blue-eyed, the Germans or the English are not biological races but mixtures of several races; they are nations held together not by common somatic characteristics or uniform descent but by a common civilization and loyalty. Nor are there any Polish and Russian "races"; both are sometimes regarded as members of the same Slavonic "race," but in reality they represent nations with different civilizations and loyalties. Even Slavs are not a "race," but a linguistic group, peoples of Caucasian, Tartar, Finnish and many other racial strains, yet speaking closely related languages.

Race can be as little identified with modern nations, as with linguistic groups. The term "Aryan" does not denote any racial community, but a linguistic group, people speaking Aryan or Indo-European languages, a group including Nordics and coloured people, white men and brown men. Languages and civilizations have migrated and have been imposed or accepted irrespective of any boundaries of race or colour; in the 7th century Arabic became the language of all the various peoples in Syria and North Africa, while Latin was accepted by the Iberians in Spain, the Celts in Gaul, and the complex racial mixture living in Rumania.

With the failure of somatic or any other objective characteristics the racialists fall back upon the "racial spirit" or *Volksgeist*. Unfortunately the Nordic racial spirit is not "instinctively" shown by all men of Nordic "blood"; it has even to be forced upon Germans, and the truly Nordic Norwegians show very little of it and are predominantly dominated by the "un-Nordic," "unheroic" spirit of Western or "Jewish" liberalism. The German racialists regard what corresponds in their opinion to the presupposed mythical racial soul as *arteigen,* what is alien to the racial character as *artfremd.*

Yet the general division of mankind into several primary races, largely distinguished by colour, is a fact which gained political and social importance with the growth of the "superiority" of the white race in the 19th century. This "superiority" did not remain unchallenged. Western civilization, fundamentally rational and liberal, regarded itself from the beginning as universal in scope and its message of liberty destined for all. With the spread of European control throughout Asia, Africa, America and the Pacific, the European methods of political and economic organization and the underlying civilization of rational humanism and belief in progress began to influence the non-European populations and to arouse them from the tradition-bound ways of life. The European skill in administration, the integrity of the judicial system and the blessings of ordered liberty were understood and partly assimilated by tiny but growing numbers of non-European intellectuals. With the spread of European education the populations of India, China and other countries began to accept the western methods and standards as their own and to resent the superiority of the white man, especially its often tactless and arrogant assertion.

It was above all the contact with the liberal civilization of England, the mother country of modern liberty and of the spirit of tolerance, as it began to develop in the 17th century, which infused a new spirit into the coloured races, as it had influenced the growth of liberty in France and in the European countries. England offered the best example of a political organization which succeeded in adapting itself to a changing public sentiment with unparalleled flexibility and without doctrinaire theorizing; at the same time it derived its vigour from ideas which seemed to promote the evolution and the liberties of all mankind. English rule brought the most powerful ferment to the coloured races, especially to India, from where it began to radiate to the far east on the one hand and to Mohammedan Asia on the other. English policy and methods stirred the desire for extended liberty and self-government, unknown formerly in the orient. In bringing to the orientals English civilization and ideas, England roused in them the desire for their political freedom which is the inherent right of civilized man in the western concept.

As chairman of the Committee of Public Instruction in India, Thomas Macaulay presented in 1835 a memorandum pleading for the introduction of a system of education based upon the knowledge of natural science and of the growth of the tradition of liberty from ancient Greece to 19th century England. He wrote:

"It may be that the public mind of India may so expand under our system that it may outgrow that system, and our subjects having been brought up under good government may develop a capacity for better government, that having been instructed in European learning, they may crave for European institutions. I know not whether such a day will ever come, but if it does come it will be the proudest day in the annals of England."

This belief in the idea of liberty and in progress through education was later also applied in the United States to its coloured peoples, whether Negroes within the continental limits or dependent peoples in the Pacific and Caribbean areas. Under the influence of western ideas the educated classes among coloured peoples began, at the end of the 19th century, to demand complete equality; they became the leaders in the "revolt of the east," the rising tide of the coloured peoples which in the 20th century made itself felt in varying degrees yet without exception, among Indians and Negroes in the Americas, in Africa and above all in Asia.

With great justice the Montagu-Chelmsford Report on Constitutional Reforms in India (1918) characterized India's intelligentsia in a way applicable to the modern intelligentsia of all coloured peoples:

"Our obligations to them are plain, for they are intellectually our children. They have imbibed the ideas which we ourselves have set before them, and we ought to reckon it to their credit. The present intellectual and moral stirring in India is no reproach but rather a tribute to our work . . . we owe him (the educated Indian) sympathy because he has conceived and pursued the idea of managing his own affairs, an aim which no Englishman can fail to respect."

The multi-racial character of the empire was at the same time stressed:

It "can not be based on ties of race. It must depend on a common realization of the ends for which the empire exists, the maintenance of peace and order over wide spaces of territory, the maintenance of freedom and the development of the culture of each national unity of which the empire is composed."

The intellectual and moral stir among the coloured peoples and their desire for managing their own affairs and for complete equality was greatly accelerated by the victory of Ethiopia over Italy in 1896 and above all of Japan over Russia eight years later, the first two defeats of white powers by coloured peoples in modern times. Japan, which succeeded within a few decades, by unsurpassed national energy and discipline, in modernizing its governmental and economic structure and being recognized as an equal by the white powers, set an example for the coloured races everywhere. Unprecedented revolutionary movements shook the ancient theocratic empires of Persia (1906), Turkey (1908) and China (1912) and converted them into constitutional monarchies or republics after the 19th century western model. These revolutions aimed not only at internal reform but also at securing complete independence from foreign interference. Equality and self-government became the goals of all peoples under white control. In the Americas the Indians began to stir after four centuries of lethargy and oppression, and the revolution in Mexico in 1917 succeeded in their interests. The coloured and oppressed peoples of the Russian empire saw in the revolution of 1917 an opportunity for equality and self-government and their aspirations were, at least partly, fulfilled by the soviet government which granted complete equality to all the races of the multi-racial empire. This new status of the coloured peoples in the Russian empire acted as a powerful stimulant also outside its borders and contributed largely to the growing demand for equality among the coloured races. Nor did the Allied slogans of self-determination during World War I prove less effective. Constitutional reforms were everywhere introduced, the facilities for education and economic development increased, and a new feeling of confidence and rights began to animate the masses of the coloured peoples. The example of complete emancipation of dependent peoples was first set by Britain, which gave independence to Egypt (1922, completed 1936) and to the Arabs of Iraq (1932), and followed by the United States in 1934 when congress promised to grant independence to the Philippine Islands after a transitional period of 12 years.

A widespread popular error assumes that racial conflicts and colour prejudice are confined to the relations between white and coloured populations. But racial arrogance and conquest and exploitation of weaker races have been practised by all races, white and coloured alike. Coloured races, whether Asiatic Mongols or African Bantus or American Aztecs, have been great conquerors throughout the ages, many of them down to present times, and they have on the whole treated their subject races with greater cruelty than the white man has in modern times. In fact in many coloured areas like India and Africa the white man's administration has brought peace and has, by establishing the principle of equality before the law, considerably lessened existing racial conflicts and exploitations.

The most extreme system of colour bar and racial prejudice prevails in the caste system of Hindu India which has been sanctified by religious tradition. As the name for caste, *varna* or colour, reveals, the hereditary and strictly separated castes were originally determined by colour. The lowest of these castes, the so-called untouchables, *pariahs* or *panchamas*, represent in all probability the aboriginal deeply dark-skinned races who have retreated before the more light-skinned "Aryan" invaders from the northwest to the south. According to the Indian census of 1941 their number amounted to 48,813,180 among a total population of 254,931,000 Hindus. Their position among the Hindus has been infinitely worse than that of the Negroes in the Union of South Africa or in the southern United States. It amounts to a Jim Crowism of fantastic proportions. Only lately the position of the untouchables has improved; one of them, Bhimrao Ramji Ambedkar, became through the help of a native prince a doctor of science of Columbia university and was appointed a member of the Viceroy's Executive council in charge of the All-India department of labour.

Nor are the coloured races free of a highly elated racial superiority complex equalling, by the open assumption of divine sanction, even the most extreme cases of white racial superiority feeling. Japanese imperialism has been based on a racial theory similar to that of Germany. As the Germans regarded themselves as a race set apart from other white-skinned people (Poles or Czechs), and destined to govern them irrespective of colour, so the Japanese established an official religion of state, Shintoism, which proclaims Japanese racial superiority over all others, whatever their race or colour. The Japanese regard their country as "the Land of the Gods, whence we perceive the reason why our national structure is supreme among all the nations of the world." Japan was founded, according to the official Japanese doctrine, by the sun goddess, Amaterasu Omikami, from whom the imperial house is descended. Japan and the Japanese emperor are therefore singled out above all other nations for world domination, the divine Japanese imperial throne, "coeval with heaven and earth," is destined in the official word to "bring the whole world under one roof," the sacred policy of Hakko Ichi-u.

Racial conflicts and prejudices in the coloured world are in no way confined to the Japanese empire. Even light-skinned Negroes feel a "colour prejudice" against the black Negroes with pronounced Negro features. The Chinese empire has extended its dominion over numerous non-Chinese tribes in southwestern China, over Mongolia, Tibet and Sinkiang, and in the recent past over countries like Annam, Siam and Burma, which all wish to maintain or to regain their independence. Racial conflicts among colonial races are not only provoked by attempts at domination or by conflicting expansionist ambitions, or by the subordination of (often very large) minorities to majorities but also by immigration and economic competition. The immigration of British Indians to Burma has been as much resented as Chinese immigration to the Dutch East Indies, to Burma, Thailand and other oriental countries. The British colony of the Straits Settlements in Malaya had on June 30, 1940 a population of 17,322 Europeans, 149,074 Indians, 904,512 Chinese, and only 309,226 Malays. Even in the native Malay states the Chinese immigrants have outnumbered the Malays; there, as in many other oriental countries, the Chinese immigrants dominate most of the economic life of the land.

Nor are bitter "race conflicts" within the same colour group confined to Asiatics or Africans: they are as frequent among the whites, many of whom are speaking the same or kindred languages and are closely related in descent. The relations between English and Irish, Poles and Russians, Czechs and Germans, Hungarians and Rumanians, Castilians and Catalans, Croats and Serbs, Greeks and Turks, have evoked the same protests against "oppression," the same bitterness and affirmation of incompatibility of national temperaments as ever coloured races voiced against white control.

The position of coloured races is often much better in colonies dependent upon imperial governments than in independent countries where the white element predominates politically. The Negroes in British West Africa or in the French colonies of Guadeloupe and Martinique enjoy a much wider participation in political liberty, in economic and social advancement and educational facilities than the Negroes in the southern United States or in the Union of South Africa. In the latter, the Boer has been an especially hard master for the coloured population; his "colour feeling has something almost religious about it. He considers it his duty to hate black blood in all its manifestations" (Sarah Gertrude Millen). In the parts of South Africa under direct British imperial control, the position of the natives is much better. Cecil Rhodes regarded every educated man irrespective of colour or race as a citizen with a right to vote, but the complete independence granted the Union of South Africa led to a general deterioration of the position of the natives throughout its territory. The South African territories under imperial control, Basutoland, Bechuanaland and Swaziland, protect the status of the natives and their interests far better, and the natives have therefore violently protested all demands for the transfer of the territories from the British empire to the Union of South Africa. On the whole it may be said that the imperial government acts, often together with Christian missionaries, as the protector of native rights and well-being against the white settlers and their claims for self-government. This is the case in Rhodesia and in Kenya.

That colour feeling and resultant colour bars are nothing "natural" or "inherent" has been shown in a number of countries where harmonious relations among races in spite of differences in colour have been established. Such is the case in New Zealand where the small native Maori population enjoys complete equality, or in Brazil where the white population mingles with Negroes, Indians and mulattoes, without any feeling of colour bar. Brazil follows therein the example of Portugal where a strong African element, largely composed of imported Negro slaves, has been completely assimilated and absorbed. At present miscegenation is going on on a large scale in the soviet union. That even in countries with a severe colour bar no "instinctive" rejection of contact exists can be seen in the southern United States where Negroes occupy the position of trusted and intimate house servants.

From the end of the 19th century there has been much irresponsible and unrealistic talk of a great coming conflict of races, a final struggle between the white and the coloured man for the control of the globe. Japan's victorious war in 1894 and the Chinese Boxer revolt induced the German Emperor William II to predict "Asia's struggle against all Europe" and to warn of the "Yellow Peril." A generation later Oswald Spengler, one of Germany's representative thinkers, regarded the great coming decision as a war of the coloured peoples, among whom he counted the Russians, for the control of the globe against the white race. He summoned the white race, as Emperor William had done, to a crusade, under German leadership, against the spectre of a fusion of class war and racial war. At the same time some coloured people began to talk of a united coloured front, or of Asia for the Asiatics, without always explaining which Asiatics should dominate other Asiatics, and Africa for the Africans. None of these slogans, fears and hopes had any foundations in reality. Neither the white nor the coloured races did or could act as a united force with identical interests. In World War I as in World War II Japanese and Chinese interests and their political ideals were as opposed as German militarism and British liberalism. In Korea the Japanese are more hated, in the Malay peninsula the Chinese more feared than any white people. Though the Germans often envisaged a racial war for the conquest of the globe, nevertheless they ultimately fought their racial kin, the British and French, the Norwegians and Dutch, and allied themselves with racially much more distant peoples like the Italians, Magyars, Finns and the Japanese. The leading theoretician of National Socialism, Alfred Rosenberg, praised in *The Myth of the 20th Century* British imperialism in India as a dike against the flood of coloured barbarism and warned Britain in the interests of the white race not to yield to the Indian demands for dominion status. For the self-preservation of Europe, England was to stay in Suez, and Negroes in the United States should be deprived of their political rights and shipped to Africa. Rosenberg proclaimed as the aim of all German policy to "secure the political domination of the white race over the globe." To that end, the white man should not tolerate "any Negroes, any yellow men, any mulattoes, any Jew" in his lands. Though Germany has been leading in racial theories of this kind, there have been isolated individuals in other countries, who shared this vision or welcomed a coming war of colour. But the division of mankind and the lines of conflict have been drawn throughout the modern period, not according to colour, but according to national allegiance and political ideas. Nation fought nation, idea opposed idea, irrespective of colour or race. And many nations, especially the empires of Russia, Britain, the United States and France, included men of many races in a common loyalty.

Though colour and race are in no way a decisive factor in contemporary group conflicts, colour plays a special role, because it renders the conflicting groups easily recognizable, facilitates segregation, places each member irrevocably into his own group and renders the border line much less flexible than in any other order of division. These differences of colour make it easier to impose political, economic, social and cultural restrictions on weaker groups and to keep them underprivileged. These restrictions show a great variety, ranging from minor discriminations in employment and social intercourse to most serious handicaps, even to complete human degradation as with the untouchables under Hindu rule or to total annihilation as with the Jews in Germany.

The most acute colour problems are not found in the relations within empires or within the international world, but in some multiracial countries. There the policy pursued can be either one of segregation, rarely on the basis of equality, mostly on that of privilege or even of legal discrimination, or one of amalgamation. As environment and opportunity shape human character more than heredity, amalgamation is opposed rather from irrational motives than from any rational consideration. Racial segregation often serves as an artificial protection for the status of the poorer classes of the dominant race, as a weapon for the maintenance of privilege. Racial stereotypes are used to rationalize political and economic relations.

A further complication in colour and race relations is introduced by immigration policies, which wish to preserve the racial homogeneity of underpopulated countries and to that end bar the settlement or naturalization of members of certain races. Australia adopted such a "White Australia policy" at the beginning of the 20th century, Canada has barred the immigration of Asiatics, and the Union of South Africa has excluded Indians. The classical country of such an immigration policy is, however, the United States. According to the most reliable source, *A Century of Population Growth*, the white population of the United States in 1790 was, as regards their origins, 82.1% of English, 7.0% of Scotch, 5.6% of German, 2.5% of Dutch, 1.9% of Irish, and 0.6% of French descent. Negroes came to North America as early as 1619; in 1790 they numbered 19.3% of the entire population. The second half of the 19th century brought a large immigration to the United States which fundamentally altered the composition of the population, first in favour of the Irish, and later in favour of eastern and southeastern European elements. At the same time far eastern races began to settle on the Pacific coast. As the "melting pot" could not absorb these new immigrants fast enough, immigration quotas were introduced first in 1921 and then in the Immigration Act of 1924. The census of 1940 showed in a total population of 131,669,275 the following coloured races in the continental United States: 12,865,518 Negroes, 333,969 American Indians, 126,947 Japanese, 77,504 Chinese, 45,563 Filipino, 2,405 Hindus, 1,711 Koreans and 788 others.

Members of these races suffer under various, and often severe, legal or social disabilities. The Immigration Act of 1924 established the exclusion and the inability of naturalization for Asiatic immigrants. The Chinese Exclusion act, which was first passed in 1882, was repealed in 1943 by the congress of the United States as a recognition of China's fight as an ally in World War II, and in 1944 the government of India demanded a similar measure in favour of British Indians. Immigration of Japanese into the United States was for a time regulated by a "Gentlemen's Agreement," but the congress of the United States excluded all Japanese immigration by the Act of 1924.

The events leading to World War II, the extreme use made by the Germans of racial prejudice, the growing acuteness of the dangers of race conflict and of the involved human degradation, again put the demand for equal opportunity and equal rights of all races, irrespective of colour, into the forefront of public interest, for the questions of race and colour relations touch the roots of the social order. The majesty of justice and law, the substance of democracy and liberty, are threatened everywhere by the passions and fears evoked by race prejudice. Christian conscience as well as rational humanitarianism demand the recognition of human dignity and individual rights in every human being, irrespective of class, colour or race. The solution of the problems arising from colour and race forms one of the great tasks set before the generation liquidating World War II, in which both Germany and Japan have put the racial question into the centre of their propaganda.

COLOUR-BLINDNESS, a term applied to a condition of vision in which the number of colours which can be differentiated is markedly less than normal. Many different types have been noted; Schjelderup recognizes at least 18 which need explanation by any theory of colour vision; and there are evidences of an indefinite variety of gradations from full trichromatic vision to total colour-blindness in which all things appear in shades of grey only. However, the data available at present indicates the following types as of principal importance: (1) anomalous trichromatism, involving a minimum of departure from the normal; (2) dichromatism, in which all colours can be matched by mixtures of two, instead of requiring three, elementary stimuli; (3) monochromatism, in which there is no discrimination of wave-length compositions, as such. Colour-blindness may rest either upon congenital and non-remediable conditions, or it may be a consequence of disease or injury to the optic nervous system. In the former case, the characteristics are biometrically more clear-cut than in the latter.

Colour-blindness of the first two types listed above is difficult to detect under ordinary conditions of life, because of the skill with which the affected individual utilizes brightness cues in judging the colours of objects. However, when presented with appropriately selected pigments, or with spectral stimuli, he may make egregious errors or show an easily measurable departure from normal. When an anomalous trichromat is required to match a spectral yellow with a mixture of spectral red and green, he may require either more red or more green than the normal, corresponding to the protanomalous and deuteranomalous conditions, respectively. For the protanomalous, reds are reduced in brightness as well as colour value, and the anomalous trichromats, in general, show weaknesses of the colour sense in the form of high thresholds, easy fatigability, increased contrast effects, and the like. It seems probable that anomalous trichromatism merely constitutes an extreme variant of normal trichromatic vision, which naturally differs in its exact characteristics from one individual to another.

Dichromatism represents the most common form of colour-blindness, being a characteristic of about 4% of males and about one-tenth this proportion of females. It shows the properties of a sex-linked character in the Mendelian scheme of heredity. These statements apply primarily to the two forms which are known as protanopia and deuteranopia, respectively. Tritanopia, a rarer dichromatic condition, is associated with pathological rather than with hereditary defects. Both of the first two forms are characterized by an inability to distinguish between reds and greens, when these colours are adjusted to the same brightness, for a given individual. In both types, a narrow region of the spectrum, having a wave-length lying somewhere between 490 and 500 $\mu\mu$, matches a white or grey, although for the normal observer this region is a slightly bluish green.

The brightness of the spectrum at the long-wave (red) end is very markedly reduced in the case of the protanope, yielding a distorted visibility curve, as compared with the normal. The deuteranope has a curve which is approximately the same as that of the normal trichromat. It is a general rule that colour matches or equations which are established by the latter are valid for the former, a fact which is taken to indicate that dichromatism is derived from trichromatism by the simple dropping out of a colour component. Tritanopia, or "blue-blindness," involves a confusion between blue and yellow, with a neutral band in the yellow region of the spectrum. It is associated with detachment of the retina. Data from cases of monocular colour-blindness indicate that the colour sensations of the protanopes and deuteranopes are confined to yellow, grey and blue. The tritanopes presumably see the spectrum in terms of red, grey, and green.

Monochromatism is a condition in which all objects or stimuli appear to be of the same colour—various shades of grey. In practically all cases, there is an accompanying condition of day-blindness or photophobia, confirming the view that monochromatism is referable to complete functional loss of the retinal cone system, which is responsible for chromatic discrimination in general. Vision is thus restricted to the rod system, which is achromatic even in the normal individual.

For a more detailed discussion of the facts and theories of colour-blindness, *see* J. H. Parsons *An Introduction to the Study of Colour Vision,* Part II. (1924). (L. T. T.)

COLOURED HEARING, a particular form of synaesthesia, which manifests itself by the appearance in consciousness of colours (or various shades of grey) whenever certain sounds are heard. These colours are most frequently associated with tones of the musical scale. For some individuals each tone of the scale has its specific colour; for others all of the tones within certain regions of the scale will have the same colour. It is seldom, however, that two people agree as to the colour they associate with the same tone or region of tone. It has been estimated that coloured hearing occurs in about 5% of the population.

COLOUR IN ARCHITECTURE refers to the use of special pigments to create colour effects in the appearance of a structure, whether applied purely as decoration, like paint, or built in as integral elements of the construction.

The range of available materials is wide. Bricks may be had in natural tones running from reds through the greys, whites, blacks and brown. Terra-cotta is burnt clay either unglazed or covered with coloured glazes fired on to the piece itself. Mosaic in glass, stone or marble, permits the widest range of tone and pattern, for it is frankly an application of small elements, each pure in colour, to a large composition on a flat or rounded surface. Marbles in every conceivable tone have always been favourite elements in the embellishment of buildings; the greenish limestones so popular in Italy, the warm, golden-coloured stones of France, the rich Kato or Kasota stones of western America may also be mentioned here. The granites present blacks, greys, rich reds and purples; and glass can be obtained in all shades. Metals, such as zinc, lead, copper and gold combined with alloys, such as bronze, are fertile with possibilities. Woods, either stained to emphasize their natural colour, or painted, allow further latitude. Paint, either mixed with water as a wash, or combined with oil as a more permanent covering, has been the usual resource in finishing a building. On roofs, the slates, brown, grey, green and purple, vie with tiles of baked earth.

USE OF COLOUR IN THE PAST

Historically, the monotone has been widespread since the days of the Italian Renaissance (*see* RENAISSANCE ARCHITECTURE). In Italy such fragments of Greek and Roman architecture as were then found apparently induced the artists of the period to assume that little colour had been employed by the ancients. Although the normal instinct of the Italians, as was later evidenced, tended towards the employment of interesting variations of colour, the classic palace of the 14th and 15th centuries developed into a stone structure, serious in composition and of a distinctly severe monotone in colour. In earlier centuries the cathedrals of Venice, Palermo, Siena and Florence used a play of marble and mosaic inlays that gave great distinction to their façades. In Venice, in particular, the strong Byzantine influence retained colour and decorations such as marked the Doges' palace and many of the stately houses along the canals. Throughout Italy, coincident with the severe perfection of such admirable buildings as the Farnese palace in Rome, came the delightful work of P. Lombardi in the Santa Maria dei Miracoli in Venice, the sgraffito decoration of Peruzzi in Rome, the terra-cottas of the della Robbias in Florence. In all these buildings the artists, fortunately emancipated from the distinction of architect and painter, gave expression to their talents in the production of structures agreeable in colour as well as form.

In spite of these agreeable variations the masters of the Renaissance, who were ultimately to inspire architects throughout Europe and America, swept on to a clear type of design. This tradition leads directly to the present and has consistently maintained so strong a check on the designer that the mere consideration of colour on an exterior is often met with shock and suspicion. So powerful has this influence been that in every capital of Europe and the Americas greyish-white stone structures decorated with carvings of the same materials are commonplace. Occasionally red, and more recently buff, brick buildings are seen, but it is fair to assume that the theory of the greyish mass is dominant. Before analysing the records antedating the Renaissance it may be interesting to note that in most of the countries in whose capitals traditional work was built the popular expressions were vastly different. In Spain, particularly in the south, the Moorish reactions produced houses brilliantly painted in primary colours, quite similar to the vigorous handling of the Dutch peasants' dwellings. Climatic conditions may, in part, be responsible for the striking appearance of the Dutch towns, but it is apparent that where no restraint existed, experiment has been permitted and a most delightful result obtained. Sweden and Norway made similar essays, which were also somewhat analogous to the brilliant tones of the Russian peasant buildings. Throughout Bohemia, Poland, Hungary and Austria, are similar evidences of painted wood and plaster, all, to be sure, in the smaller buildings in contrast to the chaste grey of the aristocratic town structures. It is quite clear that in European countries where the influence of Byzantium and the East was strong, colour has ever been dear to the populace and has been expressed quite as freely on the façades as in the interiors of their buildings.

Greece.—The theory that the buildings of Greece were of white marble has of course been shattered since the early part of the 19th century by the researches of Schliemann and countless other archaeologists, which have proved that the decorative features of the Greek temples, the mouldings, metopes, sculptures and especially the non-structural elements were brilliantly painted. Part of the restorations are necessarily conjectural, but sufficient evidence is available to show that the great Greek monuments must have been strikingly beautiful in brilliant colours contrasting with the purity of the marble mass. It is equally obvious that to the modern eye, trained to accept whiteness as perfection, the actual Greek masterpieces would appear garish and startling. A serious attempt at restoration has been made in the new art museum in Philadelphia where, under the direction of Leon Solon, a Greek design has been executed with terra-cotta in such colours as were probably employed on the Parthenon. In Rome, more particularly in the residential buildings, the Greek conception prevailed and in the excavations of Pompeii and Herculaneum the brilliant contrasts of painted plaster, coloured marbles and mosaics clearly indicate a tendency that must have been quite as marked in Greek domestic work of approximately the same epoch.

Asia.—In Asia two powerful influences were evident. Byzantium, the capital of Rome during the 4th century, exerted great power not only in Greece and the neighbouring countries of the Balkans, but indirectly in Russia and Italy proper. Reflecting the richness of Persia, Egypt and the East in general, Byzantium (*see* BYZANTINE AND ROMANESQUE ARCHITECTURE) poured on the West a stream of versatility and imagination more particularly reflected in the lavish use of strongly coloured mosaics. Ravenna still represents a glorious contribution to the history of the use of that particular medium. Further east, China had for centuries produced works of art in painting, sculpture and architecture (*see* CHINESE ARCHITECTURE) which were particularly notable in the epochs marking a lull in European cultural activity. The Mongol invasion of the 12th century had done more than conquer Persia and its great empire. Chinese forms, decorative motifs, were promptly absorbed in Persian decoration and some of the influence of China through Persia found its way to Spain. India likewise had developed a rich heritage of architecture (*see* INDIAN ARCHITECTURE; INDONESIAN AND FARTHER INDIAN ART) coloured no doubt by both China and Persia in proportion to the invading successes of their various rulers. All this truly eastern art expressed itself vigorously in sumptuous colour arrangements: in the buildings by the use of burnt clays, in lacquers by the lavish use of gold, crimson, etc., and quite noticeably in the magnificent costumes embroidered on the richest silk and satin. Marco Polo's amazement at the glories spread before his eyes in his travels through Persia, Turkestan and China was a sincere acknowledgment of the existence of something at least unusual to a Venetian in the days of the glory of his native city.

Gothic Architecture.—In Europe with the development of Gothic architecture (*q.v.*) it was evident that some of the richness of the East would remain. Curiously enough, the fact that the Gothic sculptured reliefs were quite as brilliantly painted as their prototypes in Greek Art is equally ignored. The interiors of the Sainte Chapelle in Paris and the restorations of some of the earlier châteaux in the Loire district indicate what the Gothic painted decoration must have been. Much of the Gothic sculpture of the 13th century was fully painted though, to be sure, the actual monuments retain little indication of colour apart from the brilliant stained glass (*q.v.*). It is evident that this desire for expression in colour would appear in varied forms in different peoples and throughout their histories. The Spanish iron work (*see* IRON IN ART) of the 16th century, possibly the finest in Europe, is likewise enriched with reds, blues and gold, all handled with the boldness of master craftsmen. Brussels is noteworthy for its great *Place* surrounded by stone structures now quite dark with the patina of age, but superbly ornamented with gold decorations.

Primitive peoples are lovers of colour in precise relationship to their independence of so-called civilized contacts. The artistic expression of the tribes of Central Africa, the natives of Polynesia, the Incas of South America, the Mayas of Central America, the American Indians and, finally, the Esquimaux, is shown in bold patterns of pure colour which cover the most sacred structures and also the boats, tents and domestic vessels. In Asia, the Assyrians produced magnificent tile decorations which are among the gems of the Louvre collection. Egypt in its constant unfolding of its treasures from the royal tombs proves the freedom and versatility of her artists (*see* EGYPTIAN ARCHITECTURE). The furniture, pottery, glass, jewellery, fabrics, indicate an understanding of the combination of colour and form that is almost incredible. In Persia the magnificent blue dome of Ispahan, the tile, lacquers, rugs of Persian history from the Sassanian period to our day are additional indications of an instinct for colour that has persisted through the historic races of the world.

CONTEMPORARY PRACTICE AND THEORY

In approaching contemporary architecture, one is faced with certain preconceived theories as to what is acceptable. If an architect ventures to experiment, even though he directly copies an example of accepted historic reputation, he risks making his building conspicuous. The tradition of the monotone has developed so uniformly that the very knowledge of how to experiment seems to be a lost art. The painter theoretically equipped to handle colour has withdrawn to his studio and in his own restricted dignity produces canvases that may or may not eventually decorate a building. Where the public might gain from the exercise of his ability he refrains, not necessarily from choice but for the obvious reason that where all buildings are monotonous there is no need of a colourist.

The New Architecture.—Granting that tradition has restrained development and that under existing conditions extensive use of colour is impossible, a new factor of enormous influence has appeared. The tall building on a comparatively narrow street in one of our big cities can no longer employ the decorative forms so lovingly and superbly handled by the masters of the past (*see* ARCHITECTURE). Two reasons are evident: copying any man's work intended for a particular place or period is not only false but a stamp of inability in design; the detail, charming in a structure 40 ft. in height is ludicrous in one 400 ft. higher. If the detail, as much of the earlier American sky-scraper architecture shows, is merely inflated to suit the increased distance from the eye the fallacy is no less obvious. The decoration of the tall building must produce the same agreeable effects of rhythm, symmetry, picturesqueness, sparkle or whatever basic theories the designer wishes, with quite new mediums. Flat surfaces take the place of the obsolete cornices, and colour in surfaces, in proportion to the distance from the observer, marks the accents that the artist desires. The practical question of material, whether the effect will be produced in burnt clay or terra-cotta, bricks covered with glazes baked under high temperatures, mosaic or glass, will depend, in large measure, on the ingenuity of the designers themselves. What seems to be particularly vital, however, is the conception of the use of colour as a part of the structure and not as merely applied ornament.

The dream of a coloured city, buildings in harmonious tones making great masses of beautiful pattern, may be less of a vision if the enterprising city developer realizes what it means. There is evident economy of effort in the application of colour in lieu of carved decoration which cannot be seen; and the novelty of a structure distinguishable from its neighbours has a practical value which must appeal without question to the designer and his public. The precise manner of handling colour, whether in masses, adapted as contrasts to the major tone of the building, as accents only, or in the entire structure by reason of its basic material, depends again on the programme of the creative designer; but a positive conception of the employment of colour cannot countenance mere spots of bright tiles, marbles or other substances used to relieve the sobriety of a façade. The individual must learn what media fit his taste and are adapted to the conditions of his work.

The classic conception of colour was that functional elements should be in base colours, particularly where stone and metal were employed, and that only decoration should be toned. In modern construction, where the entire façade is applied to a skeleton frame of concrete or steel, the design would be false if the artist persistently emphasized classicism where all construction is evidenced on the façade. As he creates his design, if he is willing, he can attempt accents and effects quite in keeping with contemporary building practice.

In recent years little of actual value has been produced that would indicate broad acceptance of the need of colour on buildings. The Radio City buildings in New York, striking as they are in mass and arrangement, carry on the classic principle of grey masses relieved by richly decorated sculptures and entrance features. They do not indicate a departure from the norm of the stone block.

In exposition architecture, however, the public has been privileged to see what might be accomplished with the architects encouraged to experiment. Here the painters have been asked to cooperate. In Chicago, in 1933–34, while the results were somewhat confused due to a lack of organization in scheme, the effect was nevertheless striking and had a considerable influence on the many visitors. In New York in 1939–40, a more carefully analyzed colour scheme, using mural paintings to a degree before unknown and accepting a policy of separating the Fair into broad zones of colour—gold, blue, red, white,—produced a superb effect of mass, that at night, with the added attraction of lights carefully set to produce accents on trees, flowers, and the building blocks, developed a substantial result in the use of colour on buildings.

It is important to note the fact that the painters helped materially to accomplish this effect. Paint was the main element, for the use of more substantial materials could not be general in view of the cost. To the public the Fair in New York demanded comparison with the white Exhibition of Chicago in 1893, which captivated the eye as an expression of neo-classicism, and where no colour of any consequence appeared. The World's Fair in San Francisco in 1939–40 also was designed with similar concentration on brilliant colour masses. The possibilities of colour in large masses have been established.

COLOUR INDEX, in astronomy, the difference between the visual magnitude and the photographic magnitude of a star. Since the ordinary photographic plate is proportionately more sensitive to blue light and less to red, this gives a measure of the colour of star. The colour index ranges from about −0·5 mag. for the bluest (hottest) stars to more than 2.0 mag. for the reddest stars.

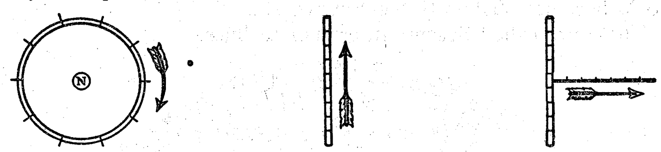
COLOURING MATTERS: *see* DYES, NATURAL; and DYES, SYNTHETIC.

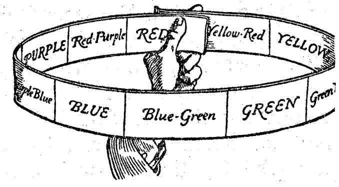
COLOUR MEASUREMENT (MUNSELL SYSTEM). The first essential to the application of the Munsell Colour System is a clear understanding of the three dimensions of colour, and once having grasped the simple logic of these, the practical advantages of the system will be manifest. Colour has three dimensions—*Hue, Value,* and *Chroma,* which fully and accurately describe any colour as readily as the three dimensions of a box describe its length, width, and height. The idea of the three dimensions of colour may be expressed thus:



HUE — Measurement around a circle
VALUE — Measurement up a vertical pole
CHROMA — Measurement on a horizontal away from a vertical pole

With these three simple directions of measurement well in mind, there need be little confusion in comprehending what is meant by colour measurement.

Hue.—This first dimension is defined by A. H. Munsell as, "The quality by which we distinguish one colour from another, as a red from a yellow, a green, a blue, or a purple." Suppose that a spectrum is cast by a prism, or a section of a rainbow. It is true that it contains all visible hues, merging one into the other by indistinguishable degrees—but always in a fixed order. Now imagine that such a spectrum is fixed or printed on a band of paper and that it begins at one end with red and going through all possible hues, it arrives back at red again at the other end. The hues are unevenly divided and they merge one into the other by indistinguishable degrees. But, preserving the order of these hues, divide them into equal steps, as a ruler is divided into inches, by selecting familiar colours—red, yellow, green, blue, purple. These may be called the Principal hues but between each of them another division is made, where each merges into the other. These may be called yellow-red, green-yellow, blue-green, purple-blue, and red-purple, and they will be known as Intermediate hues because they are intermediate or half-way between the Principal hues. The five Principal and five Intermediate hues may be called the major hues. Now, if this band is bent into a circular hoop, so that the red at one end meets and laps the red at the other end, there has been constructed a perfect scale of hue in the circular form, with the five Principal hues opposite the five Intermediate hues. The circle of hues with the five Principal hues and five Intermediate hues is shown in this form in the accompanying colour plate. The selection of five colours for the Principal hues is based on their complementary hues as determined by "after image." The five Principal hues and their complements, the five Intermediate hues, divide the hue



circle into ten parts—visually equidistant one part from another and readily expressed by the decimal system. So it is that when one states the first dimension of a colour, one is referring to its position on this circular scale of hues. In writing a colour notation, this first dimension is expressed by the initial letter of the hue—R for red, a Principal hue, and BG for blue-green, an Intermediate hue.

These ten steps being decimal numbers, may, of course, be infinitely subdivided and it may frequently happen that a given colour does not fall exactly on any of these ten divisions of hue, but somewhere between two of them. Allowance has been made for this by dividing each of the steps of the Principal and Intermediate hues into ten further divisions—called Special Intermediate hues. These ten subdivisions represent about as fine a variation of hue as even a trained eye can distinguish, and it would be obviously futile, for practical purposes, to carry it further. The numerals run from 1 to 10, 5 always marking a Principal hue or an Intermediate hue and 10 always falling half-way between a Principal and an Intermediate hue. Thus the system has a series of numerals denoting any practical step or gradation between one hue and another and in writing a colour notation, of which one of these special Intermediate hues is a part, the numeral is given, denoting the position of the hue on this scale, before the letter which stands for the nearest Principal or Intermediate hue, thus 7 R, 3 YR, 2 Y. The ten major hues then are expressed: 5 R, 5 YR, 5 Y, etc. The notation 10 R may also be expressed as Red Yellow-Red, it being half-way between these two hues, similarly 10 Y becomes Yellow Green-Yellow, etc.

These are called Second Intermediate hues.

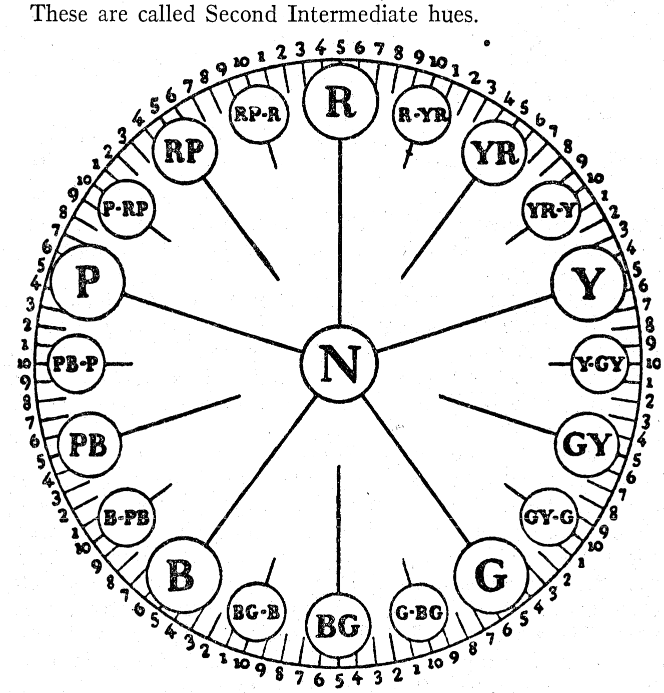


Diagram showing the 5 Principal Hues, the 5 Intermediate Hues, the 10 Second Intermediate Hues, and the 80 Special Intermediate Hues (indicated by the numerals, 1, 2, 3, 4, and 6, 7, 8, 9), in the 100 Hue circuit.

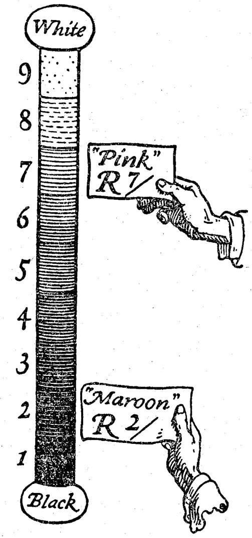
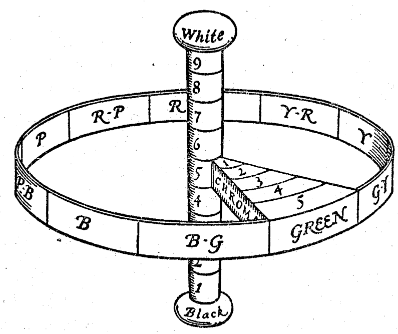
It should be remembered that the hue Red embraces all reds whether light or dark, weak or strong, its hue merely determines its point on the spectrum hue circle.

Value.—This is the second dimension and is probably the simplest to understand. It is, according to Mr. Munsell's definition, "The quality by which we distinguish a light colour from a dark one." Note that the first dimension did not tell whether a colour was light or dark. It told, for example, that it was red and not green, but there may be a light red and a dark red, and it is the function of this dimension of Value to tell how light or how dark a given colour may be. For this purpose a scale of Value is needed, which may be imagined as a vertical pole or axis to the circle of Hues, black at the lower end, representing total absence of light, and white at the top, representing pure light, and between these a number of divisions of grey regularly graded between white and black. This gradation could also be infinite. Since pure black is unattainable, it is called zero and the scale begins with the darkest grey as one, numbering the steps up to nine, which is the lightest grey. Pure white, which is also unattainable, may be called ten. In the practical use of the scale of Value, therefore, there are but nine steps and the middle one of these is five—which is referred to as Middle Value. The Value scale is shown in this form in the accompanying colour plate with proper divisions between black and white. In writing a colour notation this dimension of Value is expressed by a numeral, which denotes at which step on the scale of Value the colour falls. This numeral is written above a line, as B 6/ for example, by which is meant that this particular blue, regardless of its other qualities, is as light or as dark as the sixth step upon the scale of Value. A colour such as is called "maroon" is an example of a red which is low in value, because it is dark, and what is called a "pink" is a red which is high in value, because it is light.



Chroma.—When it is stated that the colour is blue or yellow or green, and that it is dark or light, two of its important qualities are indicated—its Hue and Value, but this by no means describes it completely. It may be said of a flower that it is red and that it is light, but it may also be said that a certain brick is red and also light, and yet there is a notable difference between their respective colours, if they are placed side by side. Both may be red and of the same Value, but the flower is strong in colour and the brick is weak in colour, or greyer. It is this difference which is measured on the dimensions of Chroma. This dimension is the measure of the strength or weakness of a colour. The scale of Value may be referred to in the convenient and easily understood form of a vertical pole, which represents the neutral axis of all the circle of Hues and is, of itself, of no colour, but is pure grey. Around this pole may be placed the band representing the scale of Hue and then any one of these hues on the circumference of the band may be imagined as growing inward toward the grey pole in the centre, growing greyer or weaker in colour strength until it reaches this centre pole and loses its colour entirely. This gives a visualization of the idea of the dimension known as Chroma. By dividing these bands into regular measured steps, one has a scale upon which the strength of colour may be measured. This dimension of Chroma is written in a colour notation by means of a numeral below a line, which denotes the step upon the Chroma scale at which it falls, thus /2, /4, /8, /10, etc.

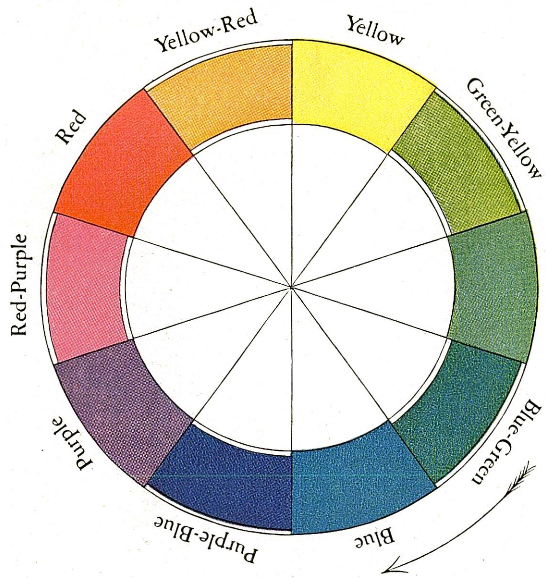


Needless to say, all of the Hues may be thus measured on this dimension at right angles to the vertical pole and grading from grey, step by step away from the pole to greater and greater strength of colour.

A complete Chroma chart of red is shown on the colour plate; on this chart the vertical scale of Value is repeated to emphasize its position in relation to Chroma.

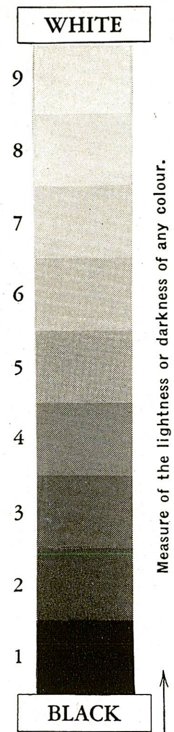
There are two important facts which should be considered. First, colours differ by nature in their Chroma strength, some being much more powerful than others. The strongest red pigment used, for example, is approximately twice as powerful as the

COLOUR MEASUREMENT

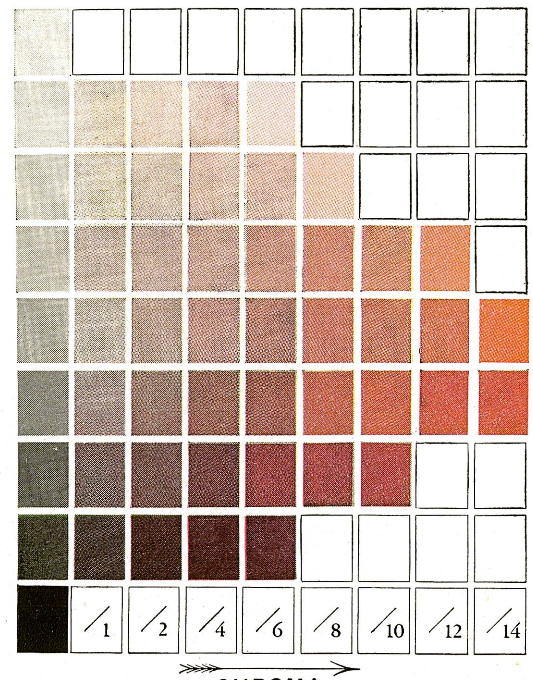


HUE

Quality that distinguishes one colour from another.



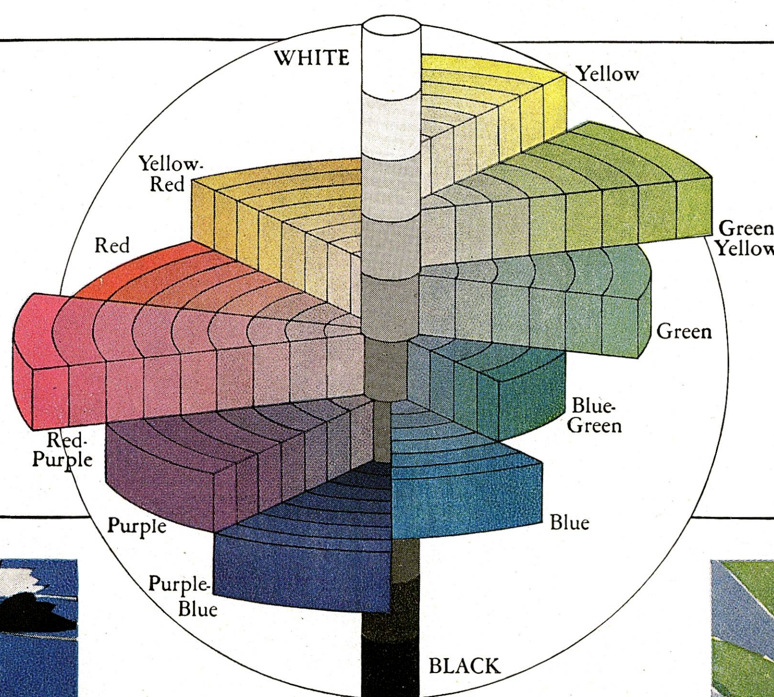
VALUE



CHROMA

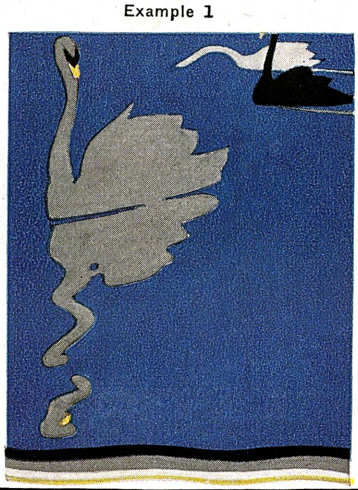
Measure of the strength or weakness of a colour.

At the right is a projection showing the Principal and Intermediate Hues arranged radially in ten equal divisions about the vertical scale of Value in the same order as the Hue circle above. For simplicity, Hues are shown only at the Value in which they reach their strongest Chroma. A complete Tree would show each Hue developed completely from black to white, as shown in the red Chroma chart above.



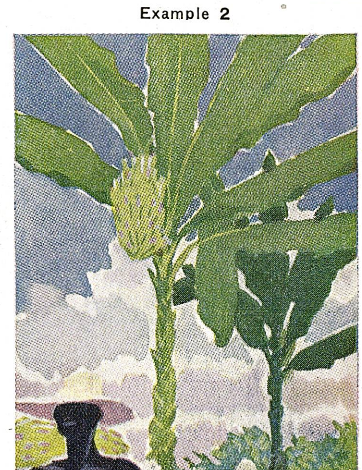
THE COLOUR TREE

Example 1



(1)
Purple-blue with grey and small areas of the complementary yellow. Note the yellowish hue of the grey, a result of simultaneous contrast.

Example 2



(2)
A free use of a number of complementary hues, purples and green-yellows predominating.

strongest blue-green pigment and the red pigment will, therefore, require a correspondingly greater number of steps on a longer path to reach grey. The second fact is that all colours do not reach their maximum Chroma strength at the same level of Value. It can be readily comprehended, for example, that the strongest yellow pigment is by nature much lighter, or higher in Value, than the strongest blue pigment and, therefore, the complete Chroma paths of these two colours will each touch the neutral pole at different values.

The form, which conveys most completely the character of colour qualities and dimensions governing the range of pigments in regular use, has been conceived by A. H. Munsell as a "Colour Tree." The "Colour Tree" has for its trunk the vertical scale of Value and the branches represent the different hues arranged radially about the trunk, these branches varying in length with the Chroma strength of each hue. A colour tree is shown in this form in the accompanying colour plate—the vertical scale of Value in the centre with the ten major hues are shown only at the Value level at which they reach their strongest Chroma. If each hue was shown at every level of Value the figure would become a solid with the strong colours outside gradually becoming greyer until they reach the grey Value scale.

Each of the three dimensions by which any colour may be measured has been described, and also how each is written in a colour notation. It remains only to put these separate notations together and to write a complete notation embodying all three dimensions. For example, given a certain colour to measure and define, it is found that upon the scale of Hue it is Purple-blue. Upon comparing it with the scale of Value, it is seen to be but three steps from the bottom, and two steps away from the neutral grey pole upon the scale of Chroma. A complete notation for this colour would, therefore, be written PB 3/2. It is scarcely necessary to point out the practical advantages of such a system of definite measurement and notation over the vague and variable terms in general use, borrowed from the animal, mineral, and vegetable kingdoms, such as plum, olive, fawn, mouse, etc., of which no two persons ever have quite the same idea.

The Use of Colour.—Contrast in Value is, perhaps, the most important factor in a composition or design. Value difference alone without regard to Hue or Chroma may make or mar the result. Value contrast will make lettering or type, for example, legible or illegible. A colour of middle Value will be least distinguishable on another colour of equal Value and the greater the contrast in Value the better the legibility.

Maximum contrast is obtained by the use of colours of extremely strong Chromas if they differ sufficiently in Value from black or white, or one another. Some examples of this form of contrast would be a yellow of extreme Chroma on a black; a low value purple-blue on white; a strong yellow on dark blue.

It is also useful to know the relative power of colours. Of course in considering the power of a colour it is impossible to think of it without a background colour and the contrast of Value and Chroma must be considered.

A strong yellow on a black field is an excellent example of maximum visibility. Although certain other factors have a bearing on the case, this visibility may be attributed to the extreme contrast plus the power of the yellow. The power of a colour may be considered as the product of the Value times the Chroma. The magnitude of the product is a good indication of the worth of a colour from the attention or attraction standpoint. Thus, a bright, strong yellow-red would be considered as a powerful colour because of the large product resulting from its high Value and strong Chroma.

For example, in terms of the Munsell notation a yellow-red at its present extreme Chroma would be YR 7/13 with a power product of 91 (7 x 13), whereas the strongest red R 4/14 has a power product of only 56. The strongest available yellow Y 8/12 will have a power of 96, a little higher than the yellow-red.

The simplest use of colour is the monochrome, by which one hue alone is used in its many combinations of Value and Chroma. Some of the pleasantest colour harmonies are in the group called "neighbouring" or analogous colour schemes which utilize a series of hues in their sequence on the chromatic circle.

Complementary colour schemes offer great varieties of colour relationships from the strongest to the weakest contrast, depending on the Value and Chroma adjustment. When complementary colours are used together they have the effect of making each other more brilliant. This should be borne in mind in selecting the proper Value and Chroma, because if the same Value and Chroma of each colour is used, an unpleasant condition of vibration between the two colours will occur.

If one colour of a pair of complementaries is weakened in Chroma, the other will appear still brighter by contrast. Complementary pairs may be used in all the steps from low to high Value and weak to strong Chroma, depending on the purpose of a design. More than one pair of complementaries may be used in a composition and possibilities in this group are limited only by the ingenuity and taste of the designer.

In summing up, remember that while genius may work in violent colour combinations, those of lesser talent must play safe. Satisfactory results may be achieved if colours of low Value and weak Chroma are used for larger areas and the small areas are contrasted with colours of high Value and strong Chroma.

Two examples of the use of colour are shown in the accompanying colour plate. The first of these shows the use of purple-blue with grey and small areas of its complementary yellow. The purple-blue is low in Value and moderate in Chroma as it occupies the larger area of the design. Its complementary yellow is high in Value and strong in Chroma. The grey shown in this example appears to be a yellow very weak in Chroma—this is the result of simultaneous contrast, the large area of purple-blue causing the grey to appear yellow (its complement) in comparison. The second example shows a free use of a number of complementary hues, purples and green-yellows predominating.

The context of this article is principally a revision and condensation of "A Practical Description of the Munsell System" written by T. M. Cleland for the Strathmore Paper Company. Material has also been used from "A Color Notation" by A. H. Munsell, and "Munsell Manual of Color" by F. G. Cooper. The section on "Use of Colour" and the two sketches, by Rudolph Ruzicka are from "Three Monographs of Color" published by the Research Laboratories of International Printing Ink Corporation, a division of Interchemical Corporation. Article and colour plate arranged and designed by Arthur S. Allen.

COLOUR MILL, a machine used in mixing and grinding paints. Its history may be traced back to the time when man first discovered that paint was made more tractable, and consequently furnished a more beautiful surface, by thoroughly grinding the contents. He secured two flat stones, placed the paint on the upper surface of the bottom stone, and milled it by rotating the top stone by hand. This method was slow and tiresome, and finally the principle was applied to a sort of gristmill type of which our present mills are a direct descendant.

Colour mills, or paint mills, fall into two general classifications: (1) those designed to grind or pulverize dry colours or dry paints, (2) those designed to grind paste paints and ready-mixed or liquid colours. The dry colour mills are divided into three groups: (1) The ball mill, which consists of a large cylinder made of cast iron, steel or bronze, and contains a quantity of balls, of similar metal, which pulverize the colours as the cylinder rotates; (2) The buhrstone mill, which is similar to the old-fashioned gristmill; (3) The disintegrator, which powders the dry colour by forcing it through closely set steel discs revolving at a tremendous speed. This is the most modern type of dry colour mill.

It is necessary to grind paint thoroughly in order to "wet" each pigment particle with the so-called paint vehicle, to break up the agglomerates of pigment particles, and to expel the occluded air. In the case of the fine oil colours, artists' colours and inks, the pigment particle itself is actually ground finer. Thus the *desiratum* of the grinding procedure is the creation of paints perfect in texture and supreme in beauty of colour.

The paste and ready-mixed paint mills are of five types: (1) the stone mill, (2) the roller mill, (3) the pebble mill, (4) the iron mill, (5) the colloid mill. The most widely used of these is the stone, or buhrstone, mill. It is made of two flat, round stones, which are usually cut from Virginia or North Carolina buhrstone, French buhrstone, or Esopus stone, which is softer than buhrstone. The top stone is stationary and has a hole or eye in its centre, the size of which depends on the size of the mill. The lower stone, which rotates, is solid and adjustable, which means that it can either be forced up hard against the top stone, or that any desired clearance between the two stones can be maintained. The paint to be ground is dropped through the eye of the top stone and a grinding action is accomplished by the rotation of the lower stone, which forces the paint between the grinding surfaces of the two stones.

Stone mills vary in size from 8 in. in diameter, for laboratory use, to 6 ft., although the sizes in general commercial use range from 15 to 36 inches. Some are water-cooled and others have no cooling device, and others are also made in "tandem form" which consists of two mills in one, for double grinding. Grooves about $\frac{1}{8}$ in. deep are cut into the grinding surfaces of the stones in such a manner as to give to the paint a scissor-cutting action between the stationary and revolving stones. For producing the most beautiful and delicate colours, the water-cooled 15 or 20 in. stone mills are used, the paint being reground until, when tested, it is found to be absolutely speckless.

Roller mills are constructed with one, three, or five chilled steel rollers, the three-roller type being the most widely used. These mills grind the paint by pulling it between the closely set rollers. Printing inks and the finest of enamels are ground on this type of mill and in many cases colours are ground and reground several times in order to produce the finest possible texture.

The pebble mill is constructed with a large cylinder holding 55% paint and 45% pebbles. By rotating the cylinder the pebbles fall through the paint and break up the agglomerates or lumps. This type of mill is generally used for grinding paints in the ready-mixed form, whereas stone or roller mills are generally used for grinding in paste form. The iron mill operates on the same principle as the stone mill, except that the grinding surface is smaller and of iron. This type is practically obsolete as paint "grinders," but is still being used to "feed" stone mills.

Colloid mills, which are the most recently developed, are high speed mills grinding by forcing the paint through the minute clearance formed by the swiftly revolving steel "rotor" and the stationary steel "stator." The faces of the "rotor" and "stator" are machined with such precision that they can be adjusted to form an exact clearance of $\frac{1}{2,000}$ in. throughout their entire circumference. This mill is more of an emulsifier than a grinder, and is not being used extensively in the paint trade.

(G. W. C.)

COLOUR-MUSIC is the term most frequently employed to designate an art which makes use of varying light or lights as its principal means of expression. The first mention of such an art was made in the eighteenth century. From very ancient times, however, certain analogies had been observed between colours and sounds and particularly between the principal colours of the rainbow and the seven notes of the diatonic scale. The analogy between colour harmony and sound harmony was remarked upon by Aristotle in his *De Sensu,* while in the sixteenth century Arcimboldo, a Milanese painter, invented a system of colour harmony based upon a colour scale analogous in its order to the musical scale.

That there was some mysterious fundamental relationship between colours and sounds was a natural assumption in an age which was given to philosophizing upon the "Music of the Spheres." No doubt Kepler's *The Harmonies of the Universe* considerably influenced Sir Isaac Newton, whose sponsorship of the analogy gave it an authority which it has continued to possess to this day. Newton was struck by an analogy between the relative spaces occupied by the principal colours of the spectrum and the ratios of the notes of the diatonic scale, but as this observation depended entirely on the deviation of the particular prism he employed his conclusions were inaccurate, and it is probable that he himself later realized the nature of his mistake. Without question, however, his arbitrary division of the spectrum into seven principal colours has misled numberless colourists and it was not until late in the nineteenth century that it was proposed to develop an art of light entirely independent of the art of music.

The undulatory theory of light first propounded by Dr. Thomas Young in the Bakerian lecture before the Royal Society in 1801, and later incorporated into the general theory of electro-magnetism in the hands of Clerk Maxwell and others, provided a new mathematical foundation upon which the indefatigable analogists might once more erect their specious systems. The measurement of the wave lengths of visible radiation, the curious fact that the frequency limits of visible radiation lie within the approximate compass of one octave, the fundamental similarity of the physical behaviour of electric waves and that of mechanical sound waves (namely, the similar laws of reflection, refraction, interference, etc.) all contributed towards an increasing confidence in the intimate correspondence between the two groups of phenomena. Only such great physicists as Helmholtz seemed to be able to perceive the deep divergences between the two and to refer at last to the weakest point in the argument of the analogists, namely, to the radically different construction and characteristic response to stimuli of the two organs of sense involved, the eye and the ear.

Louis Bertrand Castel (1688–1757) was probably the first to propose an art of colour-music. Born at Montpellier, November 11, 1688, he became a Jesuit and was recognised as one of the most eminent mathematicians of his day. He first describes his *La Musique en Couleurs* in 1720. *Esprits, Saillies et Singularités du Père Castel,* published after his death in 1763, contains a chapter, "Clavessin pour les Yeux," in which Castel states his general theory of colour-music, and describes a colour clavessin so constructed that the keys not only actuated the tongues for plucking the strings but also revealed certain transparent coloured tapes. Presumably it was his intention to place sources of light behind these.

Castel pursued his experiments with immense enthusiasm and wrote as intelligently about the subject as anyone ever has, but he was inevitably scorned by his contemporaries and almost forgotten by those who followed him. The fact remains that if anything ever comes of colour-music, Castel will hold the position of the great pioneer who first explored the ground. He is the Giotto or Guido d'Arezzo of colour-music.

D. D. Jameson wrote a singular little pamphlet on colour-music in 1844. He proposed a notation and gives examples. Apparently he constructed an instrument of some kind and gave demonstrations. He employed glass containers filled with coloured liquids and projected light through these filters into a room lined with tin plates. Mechanically controlled shutters were used.

A prophetic passage occurs in a book called *Music and Morals,* by the Rev. H. R. Haweis (1875)—"And here I will express my conviction that a colour-art exactly analogous to the Sound-art of music is possible. . . . Nor do I see why it should not equal any in the splendour of its results and variety of its applications."

Bainbridge Bishop of Essex County, New York State, having read Chevreul and Field, built (1877), a projection instrument which formed part of a house organ, by means of which he could blend colours on a small screen simultaneously with the playing of music, by attaching levers and shutters to the keys and directing first daylight and later the light from an electric arc through coloured glass.

William Schooling in an article in the *Nineteenth Century* (July, 1895), described an art of colour-music on the lines of the sound analogy, and proposed to use various vacuum-tubes, with intensity control in conjunction with a keyboard. This article was written in 1893.

In the same year Professor Alexander Wallace Rimington (1854–1918) had independently conceived the idea of a colour organ which he patented and constructed. It was completed in 1893 and he gave a private demonstration of its powers at the old St. James's Hall, London, on June 6th, 1895. A complete account of his theories and experiments, and of the colour-organ may be found in his book *Colour-Music: The Art of Mobile Colour* (1911).

The project was next considered by Louis Favre, in his *La Musique des Couleurs et les Musiques de l'Avenir* (1900). In the same year E. G. Lind, F.A.I.A., discussed a music-colour system and a projection instrument in *The Music of Color and the Number Seven.*

Mary Hallock Greenewalt, an American pianist, is one of the ablest experimenters of the present time. Though not insisting on a combined art of light and sound, she has spent most of her labours in the attempt to achieve such an aesthetic unity and her many patents and instruments are directed mainly to this end.

Thomas Wilfred, born in Denmark in 1889, began experimenting in 1905 and is perhaps the most active of contemporary colour-musicians. Proceeding on independent lines he has from the first refused to be misled by the sound analogy. In 1919 he completed his first important colour-projector in America, where he now resides, and this he named "The Clavilux." He has given colour concerts throughout the United States, and during 1925 he gave concerts in Paris, London and Copenhagen. Wilfred's procedure is to project upon a screen an even flood of light into which he introduces fantastic figures which rhythmically move and at the same time alter their form and colour.

In Australia, Alexander Burnett Hector has for some years experimented with various forms of colour-music. His first colour-organ made use of ordinary incandescent lamps combined with Geissler and X-ray tubes. M. Luckiesh, an American illuminating engineer, has also given the subject considerable attention and has experimented with various instruments for the production of mobile colour effects.

Other experimenters have been M. Carol-Bérard and M. Valère Berneird in France and Leonard C. Taylor, Claude Bragdon and Adrian Bernard Klein in England. The last named has constructed an instrument embodying optical means for the production of coloured light by prismatic dispersion, the addition of white light to monochromatic light, control over wave-length and luminous intensity. The projector possesses an electrically operated key-board and is well suited to experimental work in all forms of colour-music.

Before discussing the theoretical requirements for an art of colour-music brief reference should be made to the phenomenon of colour audition (synaesthesia), whereby many musicians associate different keys with different colours. One of the earliest scientific investigations of this phenomenon is that recorded by Francis Galton in his *Inquiries into Human Faculty* (1883).

The "coloured hearing" of Scriabin, the Russian composer, led him to compose his *Prometheus, the Poem of Fire,* for which he wrote an accompaniment of changing coloured light. It was performed in Moscow in 1911, with a colour-projection apparatus which apparently failed to function, and some years later (March 20, 1915), at Carnegie Hall, New York, with a "Clavier à Lumières," when, however, the results were not impressive.

Will colour-music as a means of expression ever be accorded the dignity of one of the great arts? At present it is impossible to say. Yet there seems no reason why the aesthetic enjoyment derived from the perception of the unity of a musical composition, its parts having unfolded in time, should not be aroused, equivalently, by observation of the construction of the various colour motifs, of combinations of sequences, and of the logical development of these, in a composition of light. The view is sometimes expressed that colour has little or no interest when it is divorced from form or familiar shape, but the literature of the subject is full of enthusiastic reports by those who have witnessed demonstrations of colour-music.

A great physicist, Prof. Albert A. Michelson, referring to the colour effects familiar to those who use optical instruments has written in his *Light Waves and their Uses* (1903), "Indeed, so strongly do these colour phenomena appeal to me that I venture to predict that in the not very distant future there may be a colour art analogous to the art of sound—a colour-music in which the performer seated before a literally chromatic scale, can play the colours of the spectrum in any succession or combination, flashing on a screen all possible gradations of colour, simultaneously or in any desired succession, producing at will the most delicate and subtle modulations of light and colour, or the most gorgeous and startling contrasts and colour chords! It seems to me that we have here at least as great a possibility of rendering all the fancies, moods and emotions of the human mind as in the older art."

COLOUR PHOTOGRAPHY: *see* PHOTOGRAPHY.

COLOUR PRINTING. The introduction of colour printing is obscure, and the claims of the Chinese and Japanese cannot be discounted, for it is probable that these peoples were practising the methods of colour block printing, which they follow to-day and for which they are famed throughout the world, long before the inception of printing from movable types. The use of coloured inks was not common with the early printers, but, strangely enough, the very first books printed at Mainz in the 15th century were decorated with initials in colour. The "42-line Bible," believed to be the first book printed from movable type, contained initials in red, some printed and others drawn in the spaces left for the purpose; whilst the later works produced at Mainz had initials in both red and blue, the Psalter of 1457 being the most famous of these. Colour printing, therefore, may be said to have commenced with the birth of the typographic printer's art. The desire to rubricate the new method of producing books in the early days is not to be wondered at when it is recalled that printing took the place of the beautifully decorated written books produced in the scriptoriums—works of art which call for the admiration of the world as evidence of unstinted patience and skill given to what was often a life's work. In 1486, the famous schoolmaster printer of St. Albans produced a book which contained woodcuts of armorial designs printed in red, blue and brown, but strange to relate, when yellow was introduced it was put in by hand. This was the first specimen of English printing (and the last for over 200 years) in which coloured inks were introduced.

Early in the 16th century a new method of colour printing from wood blocks, called chiaroscuro, was introduced. This consisted of a black outline to which tints were added. There is uncertainty about the inventor of this process, both Germany and Italy claiming the credit for its invention. It found great favour on the Continent. About this period, what might be called stencilling was introduced. This was used principally in the production of playing-cards. About the year 1630 the method of obtaining prints from copper-plates, into which the design was incised (intaglio) was practised. There are a number of colour prints in the British Museum produced by this process, the method entailing the rubbing of coloured inks into hollows cut below the surface, and, when the plate was completely inked, passing it through a press, thereby obtaining an impression on a sheet of paper. The 18th century saw great developments in the art of colour printing. New methods were invented, and it was at this period that three-colour mezzotint prints were produced by a German of French extraction, named Le Blon, he being the first to apply the principles of the three primary colours (without, of course, the aid of photography). His method was to dissect the original painting into its primary colour and tints, and make a separate mezzotint plate for each colour; these he printed in the respective coloured inks one on top of the other and, when the three impressions were registered into each other, they produced a result approximating the original picture. Le Blon's process was largely practised by others after his death in Paris, in 1741. In 1718 an Englishman named Kirkall worked a process which had as its key a mezzotint plate, the colours being added by means of wood blocks. He also reverted to the original method of preparing an intaglio plate, dabbing the colours on to the plate by hand. This method of colour printing is still used for producing costly prints for art dealers. About the end of the 18th century a large number of mezzotints, stipples and line engravings in colour were produced, the best of which now command fabulous prices.

Early in the 19th century, chiaroscuro printing was revived by William Savage, and some of his prints contained as many as 30 colours. At this time, Senefelder's invention of lithography was applied to colour reproduction, when the picture was printed in flat tints. It was not until midway through the century that the superimposing of colour was attempted, and became known as chromo-lithography. In 1834, the first colour prints by George Baxter were published. The method employed in producing this class of colour work, now known as Baxter prints, was by the use of an intaglio key plate which was printed in black or brown, to which was added a number of colours printed from wood or metal blocks. Colour printing from woodcuts and line blocks was carried on until the introduction of what is now known as the three-colour process—a method in daily use by letterpress printers. In the latter half of the 19th century chromo-lithography began to make rapid strides, and collotype, a beautiful process, was developed to meet the demands of art dealers for a high standard of colour printing. (*See* COLLOTYPE.) Mainly due to the application of photography and the advance of mechanical science, great developments have taken place in colour printing within the last half century.

Printing Methods.—The basic methods by which prints are obtained may be summarized under three headings: *relief printing, intaglio printing* and *planographic printing.* Each of these methods has its own peculiar characteristics and each possesses certain qualifications for the production of work of a distinctive character, and it is not unusual to find a combination of two, or even three in modern reproductions.

Relief Printing.—This is generally known as letterpress printing and embraces impressions obtained from relief surfaces; such as type, woodcuts, line blocks and half-tone blocks.

Type.—When type is printed in colour, it is usual for the compositor to set up the matter complete, and then take out the lines or initials which have to be printed in colour. The space left blank by the removal of the lines or initials is filled up with "furniture," *i.e.,* material of the same width and length but lower in depth than type so that it will not print. The matter is then made portable by locking it into an iron frame, called a chase, by means of a series of wedges. The types which have been removed are placed in another chase, and are made to register, *i.e.,* fit the places left blank in the main forme; this is also done by making up with furniture. Proofs are then pulled of the two formes for the purpose of registering the one into the other. Great care has to be exercised in each printing when putting the sheets through the machine in order that the colours will print where they are required.

Woodcuts.—The production of woodcuts may be called a handicraft and is seldom used for present day commercial requirements, although attempts are being made to revive it in certain quarters, particularly in the form of cutting the design on linoleum. The method in this instance is to cut an outline of the design in relief and take impressions from the block which is "offsetted," *i.e.,* a wet impression is transferred to as many blocks as there are colours to be printed to complete the design. The cutter removes with a sharp knife those parts of the block that will not be required for a particular colour of ink in which it has to be printed. This manner of preparing colour printing blocks is mainly confined to amateurs and students of art schools.

Line Blocks.—The making of line blocks is a photo-mechanical process. The artist's drawing, which must be in line or stipple, is placed on the copy-board of a camera, specially made for the purpose, to which a prism is attached. This enables the image to be reversed on the photographic plate when the exposure is made. When developed and dried, the negative is placed in contact with a piece of metal (usually zinc) which has been coated with a sensitized solution of albumen and potassium bichromate. The negative and the plate are then placed in a screw frame to hold them in close contact during exposure to light. The light penetrating the white lines on the negative, hardens the sensitized coating and when sufficient exposure has been made the plate is washed; the parts which have been acted upon by light remaining hard whilst the parts not acted upon wash away. The parts which remain on the plate represent the design. This is then protected by an acid-resisting material and the plate placed in an acid bath which etches away the unprotected parts of the plate, leaving the lines and stipple as represented in the design standing in relief. Numerous operations take place before the plate is mounted on wood to make it type high to meet the printer's requirements. The outline is known as a key-plate, and colours are added as required, either by photographic means or by the offset method. Tints of the colour in which the block is to be printed are produced by means of stipple, or lines made on the plate before etching. Many of the delightful colour illustrations in Kate Greenaway's, Walter Crane's and Randolph Caldecott's books are printed from woodcuts or line blocks.

Three-colour.—This process is used for the reproduction of paintings of carpets and other colour subjects and is an adaptation of what is known as the half-tone process. A photographic negative of the subject is taken through a cross-lined screen which breaks up the picture into innumerable little dots, varying in number and size according to the grading of the screen, and the tones contained in the picture. It is by the three-colour process that a large amount of colour printing for commercial purposes is produced. When photographing a painting, however, the colours and their component tints are scientifically separated. This is done by placing in the camera a piece of coloured optical glass called a colour filter, representative of one of the fundamental colours of the spectrum, through which the light passes before reaching the specially prepared photographic plate. Different coloured filters are required for each colour sensitive negative. The object of the filter is to keep from being recorded on the negative the colours and their tints which are not complementary to the inks in which the printing blocks are to be printed. For the blue printing plate a red filter is used, for the red plate a green filter, and for the yellow plate, a blue filter; and when, as is usual at the present day, a fourth colour is used, another filter is employed which is of an amber tint. This fourth colour block may be printed in grey or black, which greatly assists in overcoming the difficulties met with in obtaining a correct rendering of the tones and colours in the original picture and, at the same time, materially helps the colour printer in producing clean and regular results throughout a long run.

In making colour plates the ruled screen, which breaks up and provides the necessary reticulation required for a printing surface, is turned round so that the dots are at a different angle for each colour. When the screen negatives are developed they are photographically printed on to a piece of metal, usually copper, and etched in a similar manner to that employed in making line blocks. Before a set of colour blocks is in a condition to be sent to the printer, however, a vast amount of artistic and painstaking work has to be done by etchers who endeavour, by means of repeated immersions in the etching bath, to obtain results in the finished print approximating to the original painting. To obtain the best results from half-tone blocks, a paper with a glossy surface, known as art paper, must be used. Objection, however, is frequently made to the glare of this coated paper but experiments are being made to make blocks which will print satisfactorily on a matt (*i.e.,* non-glossy) paper and recent results give reason to hope that this will materialize in the near future.

Relief Printing Machines.—The types of machine used for colour printing by relief methods are numerous, but they may be divided into two categories: (1) Platen machines, where the impression is obtained over the whole of the printing surface at the same moment; (2) Cylinder machines, where the pressure extends along the whole length of the sheet but with only about a ½in. contact with the printing surface.

Platen Machines.—Those generally known as "heavy" platens are most suitable for colour printing. The forme or plate is securely fixed in an iron frame called a chase, and placed on the "bed" in a perpendicular position, the inking rollers passing over the face of the forme, thus inking the surface. The ink, which is of a buttery consistency, is stored in a trough, and can be regulated according to the supply required. A sheet of paper is placed (usually by hand) on to the guides fixed on to the platen, which is flat and moves up with a rocking motion to get the impression from the inked plate. The platen then rolls back, and the printer removes the printed sheet with his left hand and places it on a board fixed to the machine, at the same time placing another sheet in position on the platen as it begins to make its upward movement. Sheets of about 22½in. by 17½in. can be printed on this type of machine, but great skill is required to place the sheet accurately into the guides, which if not done, will prevent the subsequent colours from registering, *i.e.*, fitting each other so that the finished print is sharp and clean, and the colour values of the original are faithfully reproduced.

Cylinder Machines.—These are used for large sheets and a heavy class of work. In this instance, the formes or plates are placed in a horizontal position and fixed securely on the bed of the machine which moves to and fro. During the travel the plates are inked by a series of rollers held in brackets. These receive their supply of ink from a slab to which the ink has been transferred from a duct, a trough which can be regulated to supply the amount of ink necessary. Working in conjunction with the bed on which the forme is placed is a large cylinder, secured in brackets, which rotates as the bed makes its to-and-fro movement, carrying with it a sheet of paper which has been placed in lays. This is taken by means of a "gripper," which automatically takes the sheet round the cylinder, and thus obtains the impression from the plates. The sheets are then mechanically deposited on to a board, where they are piled up one on top of the other until they are removed by the printer. On this class of machine, sheets ranging from 22½in. by 17½in. to 60in. by 40in., and sometimes larger, are printed. There are special machines for printing two, three or four colours before the sheet is delivered, but these are not used for the best class of work, although fair commercial results are obtained by this method, generally known as multi-colour printing.

By whichever type of machine the work is printed, a great deal of work requiring care and skill is necessary before the actual printing of the sheet commences. The blocks have to be made type high, and this is done by the skilful fixing of pieces of paper below the wood mount so that the printing plate will present an even surface to the inking rollers in order that the plate may be correctly inked. This is called underlaying. Another operation, called overlaying, is necessary. Briefly, this means the cutting out and pasting together of pieces of paper and fixing them on the machine in such a way that the requisite amount of pressure will be brought to bear upon the different tones contained in the plate. Thus, the solids would be represented by the thickest parts of the overlay, the middle tones correspondingly less, and the high lights just sufficient to make the impression firm and no more. The treatment of the ink also requires attention, in order that each colour should print clearly on the top of the previous one. Care is likewise required to protect the sheets from the effects of changing temperature; while the adjustments of the machine have to receive special attention in order to ensure that each of the colours will register, otherwise the work would be spoiled.

Intaglio Printing.—The intaglio method of producing prints is theoretically an ideal one since it produces the tones of an original in a similar way to that in which many artists obtain "weight" in a picture—by applying varying amounts of colour. In other words, solids in an intaglio print have a greater quantity of ink than the middle tones and high-lights, the latter being practically plain paper. The method applicable to this process may be divided into two sections: *hand work* and *mechanical.* The first includes engravings, etchings, aquatints, mezzotints and photogravure. Each process has a distinctive characteristic and special method of preparing the plate, which it is necessary to understand when dealing with colour prints commanding high prices.

Line Engraving.—The method of preparing plates for line engraving is as follows: a carefully prepared piece of copper is coated with a varnish on to which the design is drawn or transferred. The drawing is then gone over line by line with a liner or graver which cuts furrows into the metal plate. Various shapes and sizes of gravers are used according to the character of the line required, the incisions varying in depth and width according to the nature of the drawing. The greatest care, therefore, must be taken to preserve the surface of the plate from damage, since the slightest scratch will print.

Stipple Engraving.—In this method the plate is obtained by etching the copper or zinc sheet, which is covered with a wax acid resist, the work being produced on the plate by means of dots of various sizes and forms made by needles. These remove the wax coating and leave the metal bare. The plate is placed in a bath of diluted nitric acid and the bare metal is etched away. The parts which will appear as white in the print are protected by the wax. After necessary touching up has been done the plate is ready for printing.

Etchings.—As the term suggests, etchings are obtained from plates on which the work has been bitten below the surface. The method of making the plate is somewhat similar to that followed in stipple engraving. A selected plate is coated with an acid-resisting preparation—a composition of wax, the design being drawn upon this with a steel point which removes the wax and leaves the metal bare. A mordant (*i.e.*, acid) is then applied and etches away the metal where the steel point has removed the wax. Repeated application of the acid is required, the darker tones requiring more than the lighter. *Aquatints.* A plate for aquatint printing is covered evenly with powdered resin or bitumen. This is done by placing the plate in a box where resin or bitumen is agitated. The dust falls on to the plate which is then heated, melting the grains of powder which run together, and leaving the surface partially protected. This forms an acid-resisting ground. The subject to be reproduced is either drawn or transferred to the ground. The edges and back of the plate are stopped out with some acid-resisting liquid and after the first etch the parts of the picture which are to be white are stopped out, and the plate is again placed in the acid bath. This is repeated until all the tones are treated. The plate is then removed from the bath, washed and dried. Aquatint is often used along with etching, the subject being first etched, and the lines protected, before adding the aquatint grounds and proceeding with the additional etchings.

Mezzotints.—This is probably the ideal intaglio process for producing colour prints. It is not an etching process but one which is entirely dependent upon the skill of the artist. A flat and highly polished sheet of copper is roughened all over with what is called a rocking tool. This is from 2in. to 3in. broad and made with varying degrees of fine teeth. The tool is rocked backwards and forwards in every direction over the face of the plate until the plate is a mass of sharp teeth. An impression taken from the plate at this stage would yield a solid black velvety print. The subject is then drawn or traced on to the "rocked" plate. A tool called a scraper is employed to get a surface with different gradations of tones, from high lights to solids. This is done by expertly scraping away the grain or tooth from the plate in a greater or less degree, according to the strength of the tone required. When the grain is completely removed the high lights will appear white in the print, the deepest tones being represented by the natural grain obtained by the rocking tool.

Photogravure.—The making of a photogravure plate is somewhat similar to that adopted in aquatint, where the copper-plate receives a ground of resin or bitumen, but, instead of drawing the design on the ground, a special photographic print is employed. What is known as a carbon tissue is made, *i.e.*, a mixture of gelatin and carbon or pigment being made and a thin film of this spread on a piece of paper. When this is dry it is treated with potassium bichromate, which after drying is exposed to light under a reversed photographic positive of the subject. Gelatin thus treated with bichromate and dried becomes sensitive to light, and acquires the property of becoming insoluble in hot water wherever light has acted upon it; thus the layer of gelatin is penetrated by the light and rendered insoluble to varying depths according to the proportional strength of the light passing through the positive. This printed carbon tissue is soaked in cold water and pressed upon the prepared plate. Warm water is then applied, and as the gelatin not affected by light remains soluble, it dissolves, the paper support coming away at the same time, leaving a tone mould or relief of the subject affixed to the plate. This, along with the resin ground, constitutes the acid resist. The plate is then subjected to a series of etchings by a suitable mordant.

Intaglio Plates.—The printing of intaglio plates is indeed an art, calling for great skill, extreme patience, a high artistic sense and much experience. The general principle in inking a plate is to rub the colour all over it with what is called a "dabber," *i.e.,* a piece of blanket made into a pad. Care must be taken to get the ink into the deepest hollows as well as into the lightest tones. During this work the plate is kept warm by placing it on a stove. The surplus ink is then carefully wiped off the surface of the plate by cloths varying in degrees of fineness. Discretion must be used by the printer in wiping the plate, some parts requiring more than others. When producing colour prints the colours are painted on the plate by small dabbers or paper stumps, *i.e.,* a piece of suitable paper rolled in the shape of a pencil and dipped into the special colour required. This is then dabbed into the tones in the plate in accordance with the scheme of the original picture which the printer follows. When all the colours are filled in, the plate is wiped and polished, the finishing touch being given by the palm of the hand. It is then ready for the impression to be taken. This is done by placing the inked plate on the bed of what is known as a copper-plate press. A piece of special damped paper is placed upon the face of the plate, which is then backed with a soft packing and the impression obtained by running the plate and paper under a steel cylinder. Extreme care has to be taken in removing the print from the plate. It is by these intaglio processes that the high-priced prints sold by art dealers are produced. Usually, about 20 colours are used in a colour print, and frequently it takes at least a day to obtain a print.

Machine Photogravure.—Thanks to the progress of mechanical science, within recent years it has been made possible to apply the principles of photogravure (intaglio) to every day use, more particularly in the production of magazines and supplements to newspapers. This method of printing has made greater advances in America and on the Continent than in Great Britain, although excellent work is done in England where probably the best examples of colour work are produced. This method of reproduction masquerades under many titles, *i.e.,* gravure, machine photogravure, rotogravure, intaglio printing and sometimes photogravure. The method of preparing the printing surface is similar to that of photogravure; a photographic print is taken on a film of sensitized gelatin spread over a sheet of paper and mixed with a coloured pigment. To provide the necessary reticulation, in place of the resinous ground employed in hand photogravure, a photographic copy of a ruled screen is incorporated on the carbon tissue along with the design and then transferred to the copper-plate or cylinder, the latter being generally used. The plate is then mechanically etched and sent to the press room for printing.

Machines.—The machines used are of two types. One is the flat-bed machine, where the plate is flat and placed on a bed over which a cylinder carrying a sheet of paper travels, thus obtaining the impression. The inking and cleaning of the plate are done mechanically. The other variety is the rotary machine where the paper receives its impression when travelling between two cylinders, one of which bears the work and the other provides the necessary impression. This style is in most general use. The etched cylinder runs in a bath of volatile ink, and as it rotates a fine and delicately adjusted knife, called a "doctor," scrapes the surplus ink off the surface. This falls back into the trough, leaving the cylinder clean. The paper is either fed in by hand or supplied from a reel or web, this passing between the printing and pressure cylinders. Frequently both sides of the paper are printed before it is automatically cut up into sheets. Colour reproductions by this method require a distinct cylinder for each colour, the separation of colours being obtained in the same manner as that in the making of three-colour blocks. Great difficulty, however, is experienced due to register troubles in obtaining results equal to those by other printing processes. Experiments are continually being made, and no doubt in time colour reproductions will become part of the ordinary day's work of the gravure printer, instead of being confined to one or two firms who have made colour work a speciality.

Planographic Printing.—This, as the term denotes, means surface printing, such as lithography, and possibly collotype might be included.

Lithography.—The basic principle of this process is the antipathy of water to grease. A design is drawn or transferred on to a level stone or a sheet of metal which must be free from grease. This must also be water-absorbing. Upon a dry surface the lithographic artist either draws or paints the design in an ink of a greasy nature, with a pen or brush. The stone is then prepared for printing by gumming, rolling up with printing ink, and etching; the effect being that, when the printing surface is damped over with water and a roller charged with printing ink passed over the stone, the design which has rejected the water will accept the ink from the roller, while the clean parts of the stone which have absorbed the water repel the ink. A sheet of paper is then brought into contact with the stone and run through a press, thus an impression of the design is transferred to the sheet. The first attempts at colour printing by this process were obtained by printing flat tints. According to the number of colours in the picture, offsets were transferred on to as many stones as the number of colours required, and the parts of the design which had to be printed in a particular colour were painted in, following the practice of the engravers who cut woodcuts for colour printing. The next development was to print colours on the top of each other. This was done by stippling, and demanded great skill and patience. When the original picture was handed over to the lithographic artist he would first make an intricate tracing of the original, detailing every variation in form and colour; after drawing on the stone an elaborate key to scale, he proceeded to paint in the parts which had to be solid, and the graduated tints by making dots with a pen in circular formation, varying the sizes and spaces between them according to the tones and tints of colour he desired to reproduce. Thus, in each of the stones which represented a separate printing, he would incorporate a particular colour and its component tints. When the drawing of the various colours was finished, which would sometimes take weeks, proofs were taken on a hand press and alterations made where necessary. It was by this means that certain colours in their various hues would be obtained; *i.e.,* super-imposing blue on yellow produced a green; violet was obtained by printing blue on the top of red; and so on. The drawing was done with a black ink, but this did not affect the colour to be printed as it only provided the means by which the design is absorbed by the stone, each stone being printed separately in a different coloured ink. The colours were registered into each other by means of marks called "register marks." When artists use the lithographic process to reproduce their own work, they sometimes draw the design by freehand direct on the stone. Few lithographic artists are capable of doing this, the usual practice being to trace the original and reduce it to the size required by scaling. Another method is to use grained stones on which the artist works with crayons. It is by this means that chalk drawings are reproduced. Stippling is a tedious and laborious operation calling for great proficiency and many years of training. Many chromo-lithographic prints had as many as 25 printings, and good lithographic prints, produced in the early part of the 19th century, now command high prices.

Photo-Lithography.—As the demand for speed became greater mechanical means were adopted, and hand work has now largely been superseded by photographic methods, by which either a transfer taken from a specially prepared half-tone relief block is put on the printing surface, or what are known as photo-litho transfers are employed. The modern practice is to make screen colour negatives in the same way as those made for three-colour printing. The lithographic printing plate is coated with albumen and ammonium bichromate, the negative being placed in contact with it, and exposed to light. When sufficient exposure has been given, the plate is washed and the part of the sensitized coating which has been acted upon by light remains on the plate, and from this impressions are obtained. A different stone or plate is required for each colour and the sheet of paper passes through the press or machine for each printing. Reproducing pictures by this process has materially reduced the number of printings, seven or eight being the average number required.

Lithographic Machines.—The work is proved upon a press carrying the stone or plate on which, when damped and inked, a sheet of paper is placed opposite marks and backed with a few sheets of paper or other material. A hinged frame with a sheet of leather or metal called a tympan is then lowered on to the stone and run through under a scraper. Small editions can be printed on a press but when a large number of copies are required a machine, either flat-bed or rotary, is used.

Flat-bed.—By this method, the stone is placed on the carriage and levelled up to a certain height so that the proper inking may be given to the stone and the necessary pressure obtained to transmit an impression of the design from the stone to the paper. This is done by passing the sheet round a cylinder which is supported by brackets and runs in unison with the bed. At the crown of the cylinder there are boards to hold the paper, each sheet is laid into guides and by means of grippers, the sheet is carried by the cylinder over the stone. Behind the cylinder an apparatus is attached for automatically damping the stone as it passes to and fro, while in front of the cylinder there is a series of inking rollers which supply the necessary ink. The printed sheets are either taken off by hand or mechanically by "flyers" and deposited on to the delivery board.

Rotary.—This type of machine has a plate stretched round one cylinder, with apparatus for automatically damping and inking. The sheets are fed into the machine and taken round the impression cylinder by means of grippers, and thus the impression of the design is transferred to the paper. This type of machine allows for higher speed than the flat-bed and is mainly used for poster printing. Both these methods are rapidly giving way to what is called "offset." By the offset method the sheet of paper does not come in direct contact with the plate upon which the design is drawn, but transfers an inked impression to a sheet of rubber stretched round an auxiliary cylinder, when, as the machine rotates, the paper comes into contact with the rubber cylinder from which it receives its impression. The chief feature of the offset principle is that paper with a rough surface, or even fabric, can be printed, often adding additional quality to the print. This process has made rapid strides, and has, without doubt, great possibilities as a colour printing process.

Collotype.—Collotype is claimed to be the ideal colour reproductive process. Prints produced by this process command higher prices than those obtained by other processes, with the exception of hand intaglio methods. In this instance, no mechanical reticulation such as that obtained by the use of a screen, is required. The necessary grain is provided by the natural drying of the gelatin and cannot be distinguished by the naked eye. Continuous tone negatives are used, and these are retouched, to provide the proper colour rendering, by workers with a keen appreciation of colour and its analysis. It is then photographically printed on a sensitized film of gelatin floated on a glass plate about ½in. thick. It is then washed in running water, and the parts mostly affected by the light, which has passed through the negative, are hard and insoluble, whilst those which have only been partially affected are more or less soluble according to the intensity of light which has passed through the negative on to the sensitized gelatin film. The surface is, more or less, water-absorbent, and consequently resists the ink in varying degrees. There is no mechanical printing process more capable of giving finer reproductions of coloured subjects. It reproduces the atmosphere of the original picture with remarkable fidelity, whilst its capacity for giving depth of colour and quality is unsurpassed by any other printing method. The average number of printings is seven or eight.

Collotype Machines.—The machines used for collotype printing are similar to a flat-bed lithographic machine, but no damping is required. In fact, damp is the greatest enemy with which the collotype printer has to contend. It is seldom possible to obtain more than 1,000 copies from a plate. No printer of experience would care to prophecy by what particular method colour printing would be produced in the future. Experience has proved that each method adapts itself to its own particular field, and seldom does a new method entirely supplant processes which have proved successful. Since the 1880s great strides have been made in developing colour printing processes, and, with the aid of the engineer, machines are constantly being adapted to meet the demands for finer and more accurate results. Many colour prints are produced by a combination of the different methods of reproduction. (*See* PRINTING; PHOTO-ENGRAVING; COLLOTYPE; LITHOGRAPHY.)

COLOURS, FAST. The dyestuffs producing the fastest shades upon textile materials are the "vat" dyes of the anthraquinone and indigoid classes, more especially the former. (*See* DYES, SYNTHETIC.)

COLOURS, MILITARY. The term "colours" is a colloquial expression embracing the standards and guidons carried by cavalry regiments and the colours proper carried by infantry regiments and certain other arms. Like all national and tribal flags, colours are symbols embodying the spirit of the people who fight under them. The origin of these symbols can be traced to the dim beginnings of history, a fact which is confirmed by recent excavations in India bringing to light evidence that there was a "cult of the standard" over 5,000 years ago. These primitive symbols were made of metal or wood. They are frequently mentioned in the Bible: "The children of Israel shall pitch every man by his own standard, with the ensigns of their fathers' house" (Num. ii., 2). It is not until just prior to the Christian era that we find standards made of cloth, silk or damask. The standards of Julius Caesar's army were made of metal, usually surmounted by an eagle, a practice copied later by the French.

Twofold Purpose of Colours.—These military flags have always had a twofold purpose: (*a*) to serve as visible rallying points on the field of battle; and (*b*) as distinguishing marks of persons of superior social status. Before the introduction of long-range weapons it was impossible to locate one's leader in the confusion and dust of battle unless his distinctive insignia was held aloft. Sometimes the insignia or ensign could not be seen, so the bugles, trumpets, drums, fifes, and, later, bands, usually played some music round the standard to assure the fighting men, through the sense of hearing, that the standard was still flying. This employment of flags and music is aptly stated in the Chinese *Book of War*, written 500 B.C.—"The drum and bell are used because the voice does not carry; the flag is used to assist the sight." To lose the standard, therefore, often meant that one's leader was lost, or at least there was no assurance that he was still leading, which caused the troops to become dispirited. The importance of "keeping the flag flying" was very great, but the conspicuity attendant upon the carrying of it increased the mortality of colour- or standard-bearers as long-range weapons became more efficient. The mortality of colour-bearers in the Crimean War was tremendous and this was the last European war in which British colours were carried. They were, however, carried in the Zulu War of 1877–79, when Lieuts. Melvill and Coghill of the 1st battalion, 24th Regiment (now the South Wales Borderers) endeavoured to save the Queen's colour at the notorious Isandlwana disaster on Jan. 22, 1879. Colours were last carried at the Battle of Laing's Nek on January 28, 1881, in the first Boer War. During the Russo-Japanese War, 1904–5, both sides carried colours. During the World War colours were not taken into action but identification was obtained by means of small flags during the day and by coloured flares at night. As regards the second purpose, that of being employed as distinguishing marks, early evidence of this may be seen in the sculptures unearthed at Nineveh which show two designs of standards attached to the yoke of the chariot of Darius. The continuity of this idea finds expression in all ages in the personal standard of royal personages and the nobility, and, in a lesser degree, in the flags used to denote the headquarters of higher commanders of the fighting services at the present time. Early military flags were of two main types: (*a*) the "personal," borne in feudal armies where service was rendered to the immediate overlord, and (*b*) the "national" or "standardized" as borne by national or standing armies. In the British service the transition period lasted from 1661, when Charles II. created the standing army, until 1743 when a clothing warrant stated "No Colonel to put his arms, crest, device, or livery, in any part of the appointments of his regiment." This abolished the "personal" aspect of the colour. The same warrant directed the "number of the rank of the regiment" to be painted in the centre of the regimental or second colour, thereby inaugurating the "regimental" aspect.

Modern Colours.—Present-day colours are the direct descendants of the mediaeval baron's banner. The baron's regiment consisted of companies under knights. Later the baron's flag became the "colonel's colour" and the knights' banners the "company colours." The baron's banner was usually square and bore his coat-of-arms. The banner of a person under the rank of knight-banneret was swallow-tailed like a guidon; this also bore the knight's coat-of-arms. Variety was the predominant note at this period and "standardized" colours were not introduced until about 1620 when Gustavus Adolphus regularized his cavalry, and ordered that each regiment should have eight troops, with a standard to each troop, each regiment having all its standards of one pattern and bearing similar devices. During the Commonwealth both Parliamentarian and Royalist forces adopted the standardized pattern of colours. In 1661, Charles II. issued a warrant to provide "twelve colours or ensigns for our Regiment of Foot Guards." In the same year he issued a further warrant for another regiment of Foot Guards then at Dunkirk, for "twelve colours of the same sort as those of Colonel Russell's Regiment," thereby pursuing the policy of standardization by ordering the same number of the "same sort" for both regiments. These warrants are also important from the fact that they authorized for these two regiments—which were amalgamated in 1665 to form the Grenadier Guards—the royal badges which they carry, in rotation, on their regimental colours at the present day. During the early part of William III.'s reign a reorganization of infantry took place by which they fought in three divisions, pikemen in the centre and musketeers on the flanks. The colours were therefore reduced to three per regiment and the cavalry standards were also reduced to the same number. In 1707 the pikemen were abolished as a tactical division and this caused the colours to be reduced again to two per regiment. Many regiments appear to have kept up their three colours until 1743 when George II. issued a warrant in drastic terms. This warrant was not very clear on many points and it was followed by another in 1751, under which each regiment was to have only two colours, viz., the first, or king's colour, to be the Great Union (except for Foot Guards), and the second, or regimental colour, to be of the colour of the facing of the regiment, with the Union in the upper canton, except those regiments faced with red or white, whose second colour was to be the red cross of St. George, in a white field and a union in the upper canton. In the case of the Foot Guards, the king's standard (crimson) is the first colour, and the second is the Great Union. Several line regiments were also authorized to bear "royal devices and ancient badges" on their colours. This warrant, the first of its kind, was revolutionary, and made a definite break with the past. It became the foundation of all subsequent warrants and, in fact, with slight modifications, is in force to-day. Although it permitted only two colours to be borne a few regiments acquired a third, particularly those which served in India between 1780 and 1806. These third colours were, however, definitely abolished in 1835. (T. J. E.)

British Colours in 1940.—Modern mechanization of the cavalry has necessitated a reduction in the number of regiments of that arm, some of the older regiments being combined in pairs. Where that occurred the combined unit bears the flags of both the old regiments. The Household Cavalry and the Dragoon Guards carry standards, the Dragoons have guidons. All are of crimson silk damask and are emblazoned with various badges. Royal arms and badges are borne on the standards of the Household Cavalry, regimental badges are placed on the standards and guidons of the other regiments. Lancer and hussar regiments have no standards. Each infantry regiment, with the exception of the rifle regiments, carries two colours; the first, or king's colour, and the second, or regimental colour. In the regiments of Foot Guards the king's colour is of crimson silk damask and bears some royal device which has been assigned to the regiment as a badge. The regimental colour is the national Union flag, with a regimental badge on the centre. The first colour of the other infantry regiments is the Union flag, with the title of the regiment on the centre. The second colour carries the regimental badges on a background of the colour of the facings of the uniform, except that when the facings are scarlet or white, the colour has the red cross of St. George on a white field. It should be noted that all regiments having the word "Royal" in the title have blue facings. The rifle regiments carry no colours. The royal crest, a crowned standing lion, forms the finial of the staff of all colours and standards. Colours of units of the Indian army and of Dominion troops follow the general rules for British regiments.

Battle Honours.—In addition to the distinctive badges pertaining to the different regiments, colours and standards in the British army bear the battle honours which have been earned. These honours are of two kinds, (1) a symbol or badge, (2) the name of a battle or campaign in which the regiment participated. The first battle honour granted was "Emsdorff," authorized in 1768 for the 15th Hussars for its distinguished services at that battle in 1760, where it defeated and captured five battalions of French infantry with their colours. In 1784 the word "Gibraltar" was authorized to be borne on the regimental colour of each regiment that had taken part in the defence of Gibraltar under Sir George Elliot (1779–83). In addition to the word "Gibraltar," a castle and key to symbolize that famous fortress is now embroidered on the colours. "Minden" was authorized in 1801. In 1802 the Sphinx, as a badge, was granted to the regiments which had taken part in the Egyptian campaign of the preceding year. In 1811 an order recognized and regulated the custom which had gradually come into being and in due course authorization was given for campaigns prior to Emsdorff, the earliest so recognized being "Tangier, 1662–80," borne on the colours of the Queen's Royal West Surrey regiment and the 1st Royal Dragoons. In addition to the castle and key for Gibraltar and the sphinx for Egypt a mural crown is used when the defence of a city is commemorated, a dragon for the campaign in China and either a tiger or an elephant for service in Indian wars. A rare badge is the naval crown granted for services afloat. One example is the Welch Regiment, which served as marines under Admiral Rodney in the West Indies in 1782. Another is the Queen's Royal West Surrey which served aboard the fleet under Admiral Howe in the victory of the "Glorious First of June," 1794. At first these battle honours were placed on both the king's and the regimental colours, but since 1844 they are on the second colour only with these exceptions; (a) the Foot Guards, who place their honours on both colours; (b) the Honourable Artillery Company, whose honours are on the king's colour only; and (c) the ten selected honours of the World War, which are placed on the king's colour in accordance with an order of 1922. Lancers and hussars, having no colours or standards, place their battle honours on the drum covers; rifle regiments paint them on their drums and place them on their cap badges.

COLOURS IN OTHER ARMIES

United States of America.—In March of 1779 the army regulations called for two colours for each regiment, one to be "the standard of the United States," the same throughout the army; the other a regimental colour varying according to the facings of the uniform. In other words the British system was adopted on paper, but it was not carried into effect. The Revolutionary War ended before any of these flags were issued. The colours actually carried were a heterogeneous collection issued by the different States or donated by individuals. It is doubtful whether the national flag, the Stars and Stripes, was carried by troops in that war, certainly not with any official authorization. In 1787 the one regiment then in existence was furnished one colour, showing the coat-of-arms of the United States and that plan was followed for subsequent regiments until 1834 when the artillery was furnished with two colours, one, the regimental, having a red background, the other, the national flag. In 1841 the same system was extended to the infantry, but it was not until 1895 that the cavalry was given a standard of the Stars and Stripes. The regimental colour in those days had the arms of the United States. After the World War (1914–18) the regimental colour was changed by replacing the shield, crest and motto of the United States by the regimental devices on a background in the colour of the facings, red for artillery and engineers, yellow for cavalry, blue for infantry, etc. The battle honours are carried on silk streamers made in the same colours as the ribbons of the different campaign medals, each streamer being inscribed with the principal battles of that war in which the regiment participated. The streamer is attached to the staff of the regimental colour only, just below the spearhead finial. The regiments which were decorated with the fourragère by the French for particularly brilliant services in the World War, attach a fourragère to the staff. Each company has a guidon inscribed with the company letter and regimental number. The background is in the colour of the facings, except cavalry guidons, which are red and white in two horizontal stripes.

France.—The military colours of France had their origin in the 15th century, when Charles VII and Louis XI organized royal foot troops among the burghers of cities in their effort to curb the power of the nobles, and unify the country. These troops usually carried banners bearing the arms or device of the parish, surmounted by a white cross. From that time until the Revolution the colours of the infantry in the French army bore a white cross. In 1791 the Assembly prescribed that the "first flag of each regiment will hereafter carry the three national colours," blue, white and red, charged with the number of the regiment and the motto "Discipline et Obéissance à la loi." It was not until 1803, however, that the colours were arranged in the familiar three vertical stripes, there was no systematic arrangement before that year. Prior to the Revolution the staff of each colour was surmounted by a fleur-de-lis. Under the First Republic a spearhead was used. When Napoleon became Emperor he used the Roman eagle standing on a thunderbolt, and that became the most important part of the standard, so that the entire device, eagle and flag, was known as an "Eagle." Under Louis Philippe the Gallic cock was used as a finial. Napoleon III returned to the eagle of his uncle, while the Third Republic uses a spearhead, bearing the monogram "RF." There is but one colour for each regiment, the tricoloured flag of France, bearing the number of the regiment within laurel wreaths and the inscription "La République Française" on one side. On the other side is "Honneur Patrie" and the names of the most important battles in which the regiment has participated. Prior to the World War only four such names were permitted, now the number has been doubled. Attached to the staff, just below the spearhead, is a "cravate," on which are placed the decorations which the regiment has earned for specially meritorious services in action, the Legion d'Honneur, Medaille Militaire, Croix de Guerre, or perhaps a fourragère. The fourragère is a cord, similar to an aiguillette, in the colours of the ribbon of one of the above mentioned decorations.

Germany.—German troops do not carry the national flag. In the days of Frederick the Great, Prussian regiments bore a white flag on which was a black eagle from the coat-of-arms of Prussia. That was typical of all German troops, as each principality and kingdom used the local coat-of-arms on the colours of their own regiments. This practice lasted until the National Socialist government abolished all territorial subdivisions. Now the regimental flag shows an iron cross with a swastika in each corner of the flag. On the centre of the cross is the badge of Nazi Germany, a black eagle standing on a swastika, within a wreath of oak leaves. The field of the flag varies according to the arm of service, white for infantry, yellow for cavalry, red for artillery, pink for mechanized infantry, etc. The eagle on a swastika forms the finial of the staff. Colours of foot troops are square, motorized and mounted regiments carry guidons.

Spain.—Each regiment in the Spanish army carries one colour, the national flag having the coat-of-arms on the centre. Since the victory of the Nacionalistas in the Civil War, the old flag of the monarchy has been restored, with the coat-of-arms of Ferdinand and Isabella, in a revised form to show all five of the ancient kingdoms comprising modern Spain. There are, however, many exceptions to this rule, as all older regiments are authorized to carry the colours they formerly bore, in some cases as far back as the 17th century. These ancient colours are of two kinds, (1) the red raguled saltire cross of Burgundy, the flag used by the armies of the Emperor Charles V in the 16th century, and (2) a purple flag, the most notable of which is the colour of the regiment Inmemorial del Rey, which dates back historically to 1634, and by tradition much earlier. The regiments thus honoured comprise most of the artillery and engineers and the First Royal Infantry regiment. The Fifth Engineers of Valencia and the air service bear the red cross of Burgundy superimposed on the national flag. The staff is always topped by a spearhead, more or less decorated.

Belgium, Portugal, Italy, Japan.—Other nations follow the French and Spanish custom by using the national flag for the only colour carried by a regiment. The Belgians embroider in gold the battles for which the regiment was decorated for distinguished services, and place the decoration itself on the cravate. The Portuguese use a knot of silk ribbon in the colours of the decoration which has been awarded. This is attached to the staff above the flag. Italian colours also have a cravate, called "nastro" in Italian. The colour carried by the Japanese is the rising sun with 16 rays.

Nothing is placed on it except the regimental title.

Johnson, *The Flags of our Fighting Army* (1919); V. Wheeler-Holohan, *A Manual of Flags* (1933); Gherardi Davis, *Regimental Colours in the War of the Revolution* (1907, for old U.S.A. colours); Gilbert Grosvenor and William J. Showalter, "Flags of the World," in *National Geographic Magazine* (1934); A. Maury, *Emblèmes et Drapeaux de la France* (1904). (R. E. WY.)

COLOUR-SERGEANT, a rank peculiar to the British army, created in 1813 at Wellington's request, and till 1915 the senior N.C.O. of a company. One particular duty of the colour-sergeant is that of "Attending the Colours." The original distinctive badge was a "Colour supported by two cross swords and ensigned with a Crown" worn above the chevrons on the tunic. In 1915 a new rank, that of warrant officer class 2, was created and generally the senior of the colour-sergeants of a double company was promoted thereto.

COLOURS OF ANIMALS. This is a subject at once of considerable aesthetic appeal and of high scientific interest. Many of the most beautifully coloured objects in nature are animals or are derived from animals. On the scientific side, there are questions of the physical and chemical basis of animal coloration, and of its value, if any, in the economy of the organism. Colour, indeed, has figured importantly in nearly every branch of biology: in biochemistry, physiology, pathology, histology, taxonomy and genetics, both of animals and plants; as well as in psychology, both human and comparative. In general, the colours of animals are the result of two chief causes: (a) the minute structure of materials, chiefly ones on the body surface (the so-called physical or structural colours); (b) the presence of substances which possess colour independently of the arrangement of their particles (chemical or pigmental colours).

STRUCTURAL COLOURS

The physical principles of total reflection, interference, scattering and to some extent, diffraction, all familiar in the inanimate world, are encountered also among tissues and tissue products of animals.

Total reflection of light, imparting whiteness to animal structures, often arises from the separation of finely divided structural materials by air spaces in the way that whiteness is conferred upon snow. Examples of this are seen in the whiteness of feathers, fur and hair, and in the wings of certain butterflies. Secretions or deposits in animal tissues may also contribute to the whiteness of total scattered reflection, examples being colloidally dispersed fatty or lipoid materials, calcium carbonate in the skeletons of numerous molluscs, crustaceans, corals, echinoderms and protozoans, silica in sponges, proteinaceous materials in various serous membranes, deposits of white pterins in the wings of pierid and other butterflies and silvery aggregates of crystalline guanine or other purine materials (*q.v.* infra) in numerous invertebrates and in fishes' scales.

Disintegration of white light into its spectral components occurs in animal structures chiefly through interference, wherein the incident light penetrates and is reflected back through successive thin-layered films or laminae to give striking iridescence, even in diffuse light. Iridescent interference colours are very common in certain animal structures, including the wing scales of *Morpho* and other butterflies, the brilliant rainbow hues observed in the feathers of humming-birds, peacocks, pheasants, etc., in the wing covers of many beetles, the outer skin of reptiles, nacreous surfaces of Pearls and in molluscan shells and the setae or bristles of numerous marine worms (*e.g., Aphrodite*). The brilliant lustre of human or other mammalian hair and its iridescent appearance in direct sunlight is due to the same phenomenon, the light being reflected in its disintegrated components by minute transparent scales which surround each individual hair. Pure prismatic refraction of light in animals is probably very rare, and limited to cases wherein direct beams of light encounter certain microcrystalline deposits. Diffraction by natural gratings or regular fine parallel striations is not uncommon among certain insects, but is perceptible only when a direct beam of light strikes such structures at an angle. Studies with the electron microscope have confirmed the presence of such natural diffraction gratings in some insects, notably the elytra or wing coverings of certain iridescent beetles.

Very common in animals is the display of blue colours, arising not from blue pigments but from scattering of reflected light by finely dispersed colloidal systems, lying over layers of dark melanin deposits. Examples of these structural blues are numerous. Blue eyes, wherein the turbid stroma of the iris overlies the dark membrane or uvea, may be simulated by placing disks of agar gel or dried collodion film upon a black surface. The blue skin about the head and neck of the cassowary or on the face and buttocks of certain primates results from the scattering of light by colloidally dispersed materials in the skin, overlying an absorbing layer of melanin pigment beneath. The gorgeous blues of the integument of various reptiles and fishes could be added to the many other examples of structural blue.

Two types of structural coloration may be combined, *e.g.,* diffraction and interference. In many other cases, the two underlying causes, structural and pigmental, are superimposed. Most of the greens found in fishes, amphibia and reptiles do not really depend upon the presence of a green pigment, but result from the association, within the tissues, of black and yellow. The otherwise sombre colours of black or brown pigment, when suitably reinforced structurally, may give rise to a resplendent glitter.

THE CHEMISTRY AND PHYSIOLOGY OF ANIMAL PIGMENTS

The visible range of light is selectively affected by reflection from or transmission through materials, only if the latter contain structural units whose size or vibrational frequencies lie between 3000Å and 7000Å. Those physical structures in the biological world which may disintegrate white light into spectra have already been considered; namely, very thin, finely spaced laminations, or closely placed ridges or striations, or very fine, colloidally dispersed micelles which scatter incident light, reflecting only the blue rays, these being the most refrangible.

This brings the discussion to a consideration of the chemical pigmentary compounds which, irrespective of physical orientation, selectively absorb a part of the light and reflect or transmit the unaffected fraction. Since the word pigment is based upon a Latin verb meaning "to paint," its original significance obviously had to do with the use of colouring matters for human ends. Those coloured substances were called pigments which were used as such. In transferring the term to the living world, this functional connotation has for some reason been abandoned. Any coloured substance which can be extracted from an animal or plant, regardless of its function, forthwith becomes a pigment. Owing to long-established precedent, this somewhat illogical use of the term will be employed in the present article, though a more recent word, biochrome, will be used as an alternative.

The colour of a compound depends upon the selective absorption of incident light within definite wave lengths, the unabsorbed residue being reflected or transmitted to the eye. This capacity to absorb visible light is due, in turn, to varying kinds and degrees of chemical unsaturation, or unfulfilled valencies, located in so-called chromophores (colour-carrying groups) within the molecule (*see* DYES). These areas of special molecular activity arise from reduction in the relative speed or frequency of motion on the part of one or more pairs of the compound's many rapidly vibrating electrons. Indeed, sufficient modification in the speed of electronic vibration imparts to the entire molecule a degree of special vibratory motion or chemical resonance. And this phenomenon, in the modern view, is the basis of colour manifestation.

Consider, as a crude analogy, a long horizontal cord or chain (representing a chemical compound), suspended just above or below the view of an observer looking through a long, narrow slit placed parallel to it (representing the visible spectrum of light). If, at certain points or links of the chain, threads be attached, and if these threads be given rhythmic jerks by an operator, the whole length of the chain will be thrown into a series of waves. As a result, portions of the chain will come into view through the slit, at heights and intervals depending upon the intensity and frequency of the pulses imparted to the chain at the various points of focus. Obviously, rapid, gentle pulls at a number of points of the chain would give the observer a resonance pattern of many rapid undulations of minor calibre, while more vigorous jerks at one or two points would reveal through the slit slower, higher wave pulses, and so on.

A molecular chainlike compound in a resonating condition absorbs, by internal interference or frictional forces, that critical fraction of incident light whose wave length corresponds with the resonance-frequency peculiar to the compound. The absorbed light is converted into heat, and the residual portion which emerges is of a complementary colour. Thus, if the resonance involves short, rapid waves (corresponding with rapid undulations in the analogous chain seen through a slit) the shortest visible light waves will be absorbed, *i.e.,* those of the violet and blue spectral region, and the compound will appear yellow. Red substances, having slightly longer resonance values, similarly extinguish light in the blue and green, while blue or green compounds result from cancellation of light in the red or orange realm. Black substances absorb all light equally and completely.

The colours of most chemical compounds are not of spectral purity, but include all of the visible light excepting the absorbed fraction; the colour of a molecule depends upon the dominant wave length, or that of maximum transmission.

There is good ground for the view that colour and chemical reactivity, and hence the potential metabolic value of a pigment to an organism, are parallel expressions of the same underlying molecular property of unsaturation. This is a reason for the careful consideration of the physicochemical attributes of biochromes and for continued researches regarding their metabolic position in the animal organism.

The more important biochromes of animals may be grouped into classes whose molecules are without combined nitrogen and others which contain this element.

Of the non-nitrogenous pigments, by far the most important, the most conspicuous and the most widely distributed are the carotenoids or polyenes. Indeed these are among the most widely distributed of all biochromes. Chromolipoids, naphthoquinones, anthraquinones and flavones represent other nitrogen-free pigments which occur in animals, but these are limited in distribution, and but little is known of their physiological attributes.

In the nitrogenous group are several pigments of very diverse chemical nature and metabolic position. The tetrapyrrolic pigments include both the porphyrin class, present in the blood of many animals, and the bile pigments, occurring in many secretions and excretory products; the dark melanins occur in skin, hair and other parts, and represent metabolic end-products. Several purines, while usually white or silvery in appearance, are included as biochromes or pigments because they contribute to the total colour of numerous lower animals; similarly the pterins, which are derivatives of pyrimidine, are frequently white, but may often be yellow in colour; the lyochromes or flavines, detectable in the tissues of all or nearly all living organisms, are identified with certain important biocatalysts; finally the indole derivatives, which are somewhat limited in any conspicuous manifestation are, like the melanins, purines and pterins, end-products of metabolism.

In the following treatment are outlined the chemical configuration, colour, source and metabolic features, insofar as the latter are known, of some representative animal biochromes comprised in these groups. Lastly, a few of many miscellaneous coloured compounds will be considered, whose chemical structure is yet imperfectly known.

Carotenoids (Fig. 1).—These red, orange, or yellow pigments, whose numbers of known compounds is constantly increasing, are of such wide distribution throughout the living world as to be nearly universal. The carotenoids are insoluble in water, but may be readily dissolved in alcohol, ether, chloroform and the various other organic fat-solvents. They show pronounced and consistent crystalline habits, and in solution, exhibit usually two, often three, but in some cases only a single absorption band, characteristically in the violet to blue, sometimes extending into the green region of the visible spectrum. They are readily bleached by light and by exposure to atmospheric oxygen, are unstable also in the presence of mineral acids, their chloroform solutions giving dark blue coloration upon treatment with concentrated sulphuric acid.

The chromophore grouping, or chemical configuration responsible for the colour, is the long chain of alternating points of unsaturation, or so-called conjugated double-bond structure, represented in the formula given for β-carotene. A number of carotenoid hydrocarbons share this constitutional formula $C_{40}H_{56}$. Carotenes and xanthophylls ($C_{40}H_{56}O_n$ . . .) occur together in many organisms, and may be separated on the basis of their preferential solubilities in certain solvents, and by differential adsorption from solution upon packed columns of relatively inert powders, such as chalk, sugar, alumina, magnesium oxide, etc., wherein the pigments appear as distinct coloured bands or zones. They may then be resolved into individual components by chemical extraction of each mechanically isolated zone.

These pigments occur in plant organisms ranging from the simplest types, *i.e.*, bacteria, fungi and algae, to the most highly evolved flowering plants. Animals from simple Protozoa to the highest mammals, including man, contain carotenoids, although the tissues, and notably the blood sera of a number of mammals, are almost or entirely devoid of these pigments. The livers of some of such species often yield carotenoids, and it is known that the lives of these animals depend upon a supply of carotene or its metabolic derivative, vitamin A. Carotenoids are relatively more concentrated in ovaries or eggs, some testes, liver (or liver-like analogue in invertebrates), skin, eyes and milk. Outstanding common examples of visible carotenoid pigmentation are in the legs, body-fat and eggs of domestic poultry, the bright red, orange and yellow feathers of many birds, similarly coloured wing covers of numerous insects, and the milk-fat of cattle. In some animals, a high degree of specificity exists for the absorption of either the hydrocarbon (carotene) class or the oxygenated (alcoholic or xanthophyllic) type of carotenoid. The horse, for example, absorbs through the intestine only carotenes, from green food containing an ample supply of both kinds of carotenoid. The hen, on the other hand, stores only members of the xanthophyll class; many fishes and marine invertebrates likewise store only xanthophyllic carotenoids, rejecting in the faeces or otherwise totally disposing of the carotenes. Other animals, including the frog and man, assimilate and store both classes in depot-fat.

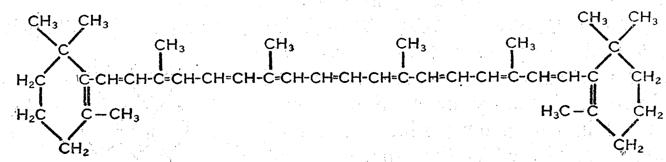

FIG. 1.—β-CAROTENE

Strikingly beautiful displays of carotenoids are encountered in the skins of numerous amphibians, notably among salamanders, many species of fish, and countless marine invertebrates, especially among the echinoderms (sea stars and brittle stars), molluscs, ascidians (sea squirts), crustaceans, the tissues of coelenterates including many anemones and corals and many species of marine worms. The gorgeous blue and green, some gray or chocolate tones, violet and near-black pigments of certain crustaceans, naked molluscs and sea stars are in many instances due to carotenoids in chemical conjugation with protein. Denaturation of the protein by immersion of the specimen in boiling water or in alcohol unmasks the bright red colour of the carotenoid involved. Hence the familiar red colour of boiled lobsters. Marine animals commonly derive their rich supplies of carotenoids directly or indirectly from the countless microscopic plants. Even carnivorous fishes and flesh- or mud-eating invertebrates from the great unlighted depths frequently exhibit rich pigmentation, derived ultimately from supplies of carotenoids long since generated in lighted waters and buried in the ocean floor.

A yellow condition of the skin, known as xanthosis, carotenaemia or artificial jaundice may follow excessive eating of carotenoid-rich foods such as carrots or oranges; the condition, less common in adults than in children, is unaccompanied by pathological symptoms and disappears when excessive supplies of carotenoids are withheld from the diet.

Hens and fish mobilize body carotenoids in their eggs during laying (or spawning) season, with an obvious diminution of the yellow biochrome from its former conspicuous position in the skin. Males of these species may continue to exhibit the pigmentation, however, those of many species showing an actual enrichment of the colour during the reproductive period.

Naphthoquinones (Fig. 2).—These compounds, occurring in many plants, are yellow, orange, red or purple in colour, soluble in various organic solvents, and have found considerable use as dyes for fabrics. Their occurrence in any conspicuous degree among animals seems to be limited to the echinoids (sea urchins and sand dollars) whose spines, shell and thin skin are consequently rendered distinctly red, purple and in some instances green by echinochromes. Red aggregates of this class of biochrome are found in the body fluid, inner lining of the shell, and in the lining of the alimentary tract of numerous species of echinoid, and some members bear the dye also in distinct masses within the jelly surrounding the eggs.

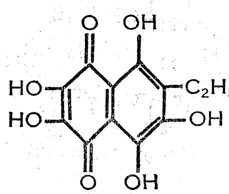

FIG. 2.—ECHINOCHROME

Like other quinones, echinochromes are mildly oxidizing, and lose their colour when treated with chemical reducing agents. They assume different colours also according to the acidity or alkalinity of their surroundings. The purple or red colour of sea urchins is consistent with the faintly alkaline condition of the tissues and calcareous shell. The antihaemorrhagic factor, vitamin K, is a naphthoquinone of yellow colour. Other naphthoquinones are reported to possess vitamin K potency as well. Echinochrome has been assigned a role as respiratory stimulant for sea urchin eggs. It is believed by some investigators to cause stimulation of the spermatozoa of certain species of sea urchins and to attract the latter to the eggs.

The diverse coloration of spines, tests and other structures of certain species of sea urchin are attributable to the presence of mixtures of echinochrome and a chemical homologue, spinochrome, in various proportions. Studies of crystalline melting point, absorption spectrum and other properties indicate that a number of different echinochromes exist.

Anthraquinones (Fig. 3).—A large number of brilliantly coloured compounds which have found wide application as dyes and chemical indicators of acidity or alkalinity are included in this group. Like the naphthoquinones, with which they share a common chromophoric structure, they may be chemically reduced by certain reagents. Carminic acid is the red biochrome constituting about 10% of the product cochineal, obtained from the female scale insect *Coccus cacti,* found in Mexico and Central America. The pigment imparts permanent red colours to mordanted wool and silk. Kermesic acid from another scale insect, *Coccus ilicis,* is yellow-red in water, and violet-red in acid solutions; it is employed as a dye as is carminic acid, from which its chemical structure differs in only a minor way. Laccaic acid is isolated from lac dye or lac-lac, the solid exudation of East Indian lac insects, *Coccus laccae.* This scarlet or carmine-red dye possesses a constitution similar to that of the above-named compounds. While these conspicuous anthraquinones are beyond doubt derived by scale insects from the plants upon which they feed, no information is yet available relative to their metabolic path or possible physiological role.

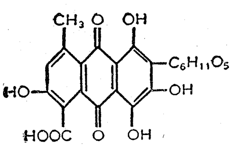

FIG. 3.—CARMINIC ACID

Flavones (Fig. 4).—Considerable chemical study has been devoted to this large group of coloured compounds which occur in a wide variety of plants and in a few insects which feed upon such plants and assimilate some of the pigment. These compounds impart yellow colours to flowers and other plant parts. The chemical properties of a yellow biochrome isolated from the wings of a butterfly, *Melangaria galatea,* correspond closely with those of the plant pigment quercitin. The chemically related anthocyanins, which are the red, violet and blue compounds often seen in blossoms, fruit and leaves of plants, are occasionally encountered in certain dipterous and hemipterous insects and their larvae, commonly in the albuminoid inclusions of fat cells. None of these classes of biochromes has been shown to fulfill particular physiological functions in animals, although they are believed to be involved in certain biochemical oxidations in the plants which synthesize them.

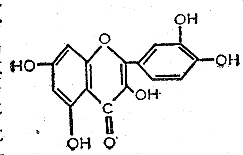

FIG. 4.—QUERCITIN

Tetrapyrroles.—*A. Porphyrin Compounds (Fig. 5).*—Porphin is the parent compound of the whole class of nitrogenous water-soluble biochromes under discussion in this subsection. Bearing side chains of various lengths composed of carbon, hydrogen, and frequently oxygen, linked to different carbon atoms of the four pyrrole nuclei, porphyrins are represented in the green photosynthetic chlorophylls of plants and in animal haemoglobins. Haemoglobins are conjugation products between a protein body, globin, whose composition varies with the species, and a porphyrin, haem, $C_{34}H_{32}O_4N_4Fe$, whose pyrrolic nitrogen atoms are attached to an atom of iron. Haemoglobins are present in the red blood cells of mammals, birds, reptiles, amphibians and fishes, and in the circulatory fluids of numerous invertebrates, notably among the worms, and in scattered members of the arthropod, echinoderm and molluscan phyla. Having the unique capacity to combine with atmospheric oxygen in lungs, gills or other respiratory surfaces of the body, and to again release it among tissues of lower oxygen content, haemoglobins thus serve as respiratory catalysts. These compounds are responsible for the pink to red colours observed in combs and wattles of birds and the skin of man and other primates, notably that covering portions of the face, buttocks and genital regions of baboons.

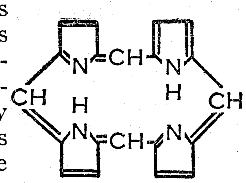

FIG. 5.—PORPHIN

Other biochromes chemically allied to the haem compounds are cytochrome, the red oxidation enzyme which occurs in minute concentrations in nearly all cells; catalase, an enzyme of similar distribution which accelerates the breakdown of hydrogen peroxide; pinnaglobin, a brown compound which serves as a respiratory aid in the mollusc *Pinna squamosa;* chlorocruorin is a green pigment which plays a similar role in the blood of tube-building annelid worms; a red compound, helicorubin, is encountered in the liver and gut of some snails, and actineohaematin is responsible for some of the beautiful red colours of sea anemones. The physiological functions, if any, of the latter two pigments have not been clarified.

Numerous porphyrins are present in secretory and excretory products of animals, and others may be extracted from ancient deposits such as coal, petroleum and mud from long-buried strata of the ocean floor. Many porphyrins are readily isolated, crystallized and identifiable by their manifestation of spectral absorption bands at given positions in the visible spectrum.

Oöporphyrin is responsible for the red flecks upon the eggshells of the plover. The shell of the emu egg is coloured by a biliverdin, found also in the skeleton of the blue coral *Heliopora caerulea.* The remarkable turaco bird excretes a copper salt of uroporphyrin in its quill-feathers. This red pigment, known as turacin, is readily leached out of the feathers by water containing traces of alkali. A similarly occurring green porphyrin in feathers of the turaco is turacoverdin. Certain molluscs excrete coloured porphyrins in the material of their shells. Bonelline, obtained from alcoholic extracts of the worm *Bonellia viridis,* is an alkaline biochrome giving blue solutions in acids; its properties have led to its inclusion among the pyrrole pigments. The chemical structure of so-called enterochlorophyll found in the liver of numerous molluscs, crustaceans and even in the digestive gland of carnivorous sea stars, has not been determined.

B. Bile Pigments (Fig. 6).—Among the metabolic breakdown products of haem or allied biochromes is a series of yellow, green, red or brown nonmetallic tetrapyrroles arranged in open-chained molecules typified by the simplest synthetic member bilane. Small quantities of the red compound, bilirubin ($C_{33}H_{36}O_4N_6$), its green oxidation-product biliverdin, and various other chemically homologous products occur in normal tissues, and may be conspicuous in excretory and secretory products under certain pathological circumstances.

Various compounds of the bile-pigment series are encountered in birds and in lower animals. Oöcyan, closely related to bilirubin, imparts a blue or blue-green colour to the eggshells of numerous birds. Pterobilin is a blue pigment observed in many pierid butterflies' wings, and other insects and their larvae exhibit or excrete allied compounds. The liverlike organs of numerous invertebrates seem to lack bile pigments, containing instead porphyrin compounds, exemplified by helicorubin in some molluscs and crustaceans. Certain leeches, nourished by the blood of vertebrates, contain blue-green, red or brown bile pigments in their blood, probably as a result of the breakdown of ingested haemoglobin.

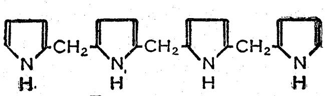

FIG. 6.—BILANE

The sea anemone *Actinia equina* carries beneath the outer skin and at the base of the foot a green pigment believed to be biliverdin which occurs also in other anemones. The dark red or violet biochrome encountered in the strikingly coloured anemone *Calliactis parasitica* has been termed calliactine. It is a natural indicator, being yellow-brown in acid, becoming golden to orange in less acidic solutions, and changing to blue, violet and finally red in alkalis. It can be crystallized in a pure state as blue-violet rosettes of needles which, when dissolved in dilute aqueous solutions, exhibit characteristic absorption bands, according to the acidity or alkalinity of the solvent. Calliactine is easily and reversibly oxidized and reduced, which fact suggests its possible function in oxidative metabolism. Certain molluscs display colours in their tissues or shells which are attributable to the presence of biochromes of the bile-pigment class. Examples are the red compound, rufine, in the snail *Arion rufus,* another red colouring matter in the shells of abalones and some turban shells, called rufescine, and a blue-green one in another species of abalone. The purple colour of the offensive, mucous-laden ink of the sea slug *Aplysia* (*Tethys*) is due to a pigment, aplysiopurpurin, closely similar to mesobiliviolin, conjugated with protein material as are other pigments, including mesobilirhodin and urobilin which accompany it. Numerous fishes among the Belonidae and Cottidae bear strikingly blue-green coloured skeletons. The green pigment in the bones and scales of the garfish *Belone belone* is a bile pigment, related to biliverdin.

Melanins (Fig. 7).—Dark colours, indicating the presence of melanin pigment, are observed in mammalian hair and eyes and in the skin and scales of numerous fishes and reptiles, the ink of cephalopods, various tissues of numerous other invertebrates and in skin-moles of man and black tumorous growths of various mammals. Melanin, an end-product of metabolism, is formed as a result of serial oxidation and polymerization of tyrosine or similar phenolic compounds. This oxidation by dissolved atmospheric oxygen is catalyzed by an enzyme tyrosinase. Chemically reversible yellow, orange or red stages in the successive oxidation are followed, if uninterrupted, by a final intensely black product. Some white or albino animals may lack the enzyme tyrosinase in its active form, or they may have means of excluding the enzyme and the substrate, tyrosine, from each other. Completely white or red variants of the anemone *Metridium senile,* for example, fail to develop melanin in their tissues as do brown variants of their species. But upon death, or upon grinding of the tissues of such an albino animal, the macerated material blackens rapidly with the formation of melanin.

Pale yellow, tawny, buff, red and brown colours of hair are due to melanin in intermediary phases of formation or in relatively finely divided condition. The importance of dark, light-absorbing sublayers of melanin in intensifying structural blues or iridescent colours has been mentioned. Genetic or photically induced melanization of human skin serves an important function in protecting underlying tissues from injurious sunrays.

Certain fishes exhibit a striking ability to synthesize and store in their skins more melanin when kept on dark backgrounds than do members of the same species maintained in pale surroundings, all of the specimens receiving the same amount of incident light from above. (See *Adaptive Colour Change,* below.)

Black or brown melanins or melanoproteins are to be observed in numerous invertebrate animals in addition to those mentioned. Certain of the worms, numerous crustaceans and many classes of molluscs exhibit melanism in the integument. The red intermediate compound, formed during the transformation of tyrosine to melanin (*see* formula) is hallachrome, which is encountered also in the marine worm *Halla parthenopaea.* It is green in alkali beyond pH 8.3. This biochrome may be reversibly oxidized and reduced; it is said to stimulate increased respiration in certain invertebrate eggs. Its original precursor may be either tyrosine or tryptophane. Red or yellow uranidines, found in sponges, corals, medusae, holothurians (sea-cucumbers) annelid worms and tunicates, are believed to be chemically related to the melanins.

Urochrome, the principal yellow pigment of urine, is considered to be a modified melanin. In certain diseases, melanin precursors cause urine to darken as oxidation occurs on standing (melanuria, alkaptonuria).

Indole Derivatives (Fig. 8).—Certain similarities between katabolic features applying to the two amino acids, tyrosine and tryptophane, lead next to a consideration of the biochromes derived from the latter compound. Like melanins, the indole derivatives are excretory products of certain animals, but in contrast to melanins, their distribution as pigmentary compounds is relatively limited. Unlike the dark, sombre melanins, too, numerous indole compounds are of striking red, green, blue or purple colours. Indigo occurs as a glucoside in many plants of Asia, the East Indies, Africa and South America. It has long been used as a blue dye. While the pigment itself does not occur in healthy animals, certain chemical derivatives of it are found in secretory and excretory products.

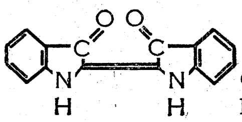

FIG. 8.—INDIGO

Hallachrome, the red pigment in the epidermis of a marine worm, has been discussed. This compound, as well as the chromogen of human melanuria, which is probably a derivative of 5,6-dehydroxy indole, may be generated from the breakdown of either of the common amino acids, tyrosine or tryptophane.

Tyrian purple, a purple of the ancients, is 6–6′–dibromindigo obtained by the irradiation of a glandular secretion of several species of gastropod molluscs of the genera *Murex* and *Purpura.* While this red-violet dye has long been employed commercially in certain countries, its physiological use to the animals producing it is obscure. In all probability it is an excretory product.

Purines (Fig. 9).—The members of the purine class of compounds are hardly to be considered as true pigments, since they are usually white crystals. But they often contribute to the colour scheme of lower vertebrates and invertebrates, hence their inclusion in the section. The position of purines as excretory products is amply illustrated by the large amounts of guanine in the excrement of birds, and of uric acid in that of reptiles. Uric acid has also been found in the yellow sheets of mucous excreted by sea anemones. The brilliant whiteness of some anemones, notably the white variant of *Metridium senile,* results partly from microcrystalline deposits of uric acid in the tissues. These crystalline aggregates are especially noticeable in the mesenteries. Other purines, such as xanthine, have been reported as occurring in the wings of pierid butterflies. Mention has already been made of the notable deposition of guanine crystals in the leucophores or iridocytes of fishes, contributing a whiteness, or often a brilliant silvery appearance to extensive areas of the skin. Note has also been made of the ability of some fishes to vary the quantities of deposited guanine in proportion to the lightness of the background upon which they are living. Purine compounds constitute part of the complex nucleic acids which abound in the nuclear material of all cells; it is therefore presumed that they play an indispensable part in cell metabolism. The purine compound hypoxanthine exercises a specific stimulating and accelerating effect upon the growth of embryonic tissues of the chick.

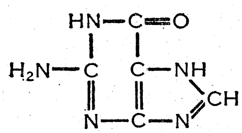

FIG. 9.—GUANINE

Pterins (Fig. 10).—Closely related to the purines, and formerly classed among them, are the so-called pterins, which derive their name from their notable appearance and primary chemical isolation from the wings of certain species of butterflies, wherein they are sometimes accompanied by purines. Pterins are encountered as white, yellow, orange or red granules in association with the wing material, and contribute the yellow colour to the body-integument of numerous wasps.

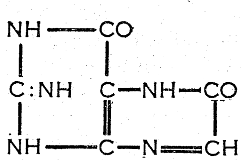

FIG. 10.—XANTHOPTERIN

The pterins are soluble in aqueous solutions, often more so in the presence of ammonia, and insoluble in the usual organic solvents. Leucopterin is a white compound obtained from *Pieris brassicae* and *P. napi,* and has been found accompanied by other pterins in other species. Xanthopterin is a

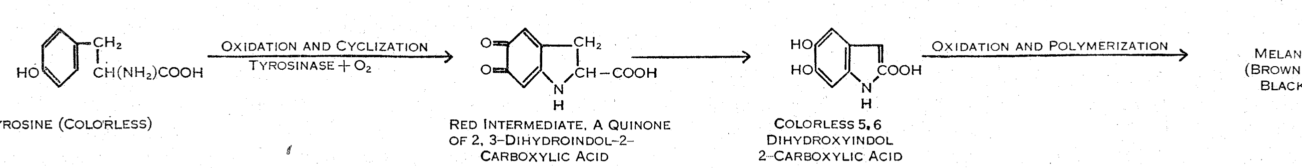

FIG. 7.—TYROSINE (COLOURLESS) CONVERTED TO MELANIN PIGMENT

yellow biochrome responsible for the yellow colour in the wings of *Gonepterix rhamni* and other butterflies, and in the abdominal skin of wasps (*Vespa* spp.). It occurs also in human urine, and therefore is often called uropterin. This compound has been found to be effective in preventing nutritional anaemia in rats and in young salmon. No physiological roles other than their excretory character have been recognized in the other pterins which occur in Lepidoptera; the colourless compounds guanopterin and mesopterin may be accompanied by chrysopterin, an orange compound, or by a red homologue erythropterin; the latter imparts conspicuous red colours to the wings of several species. The red biochrome in the eyes of the fruit fly, *Drosophila melanogaster*, of great interest and usefulness to geneticists, is believed to be related to the pterin class.

Lyochromes or **Flavines (Fig. 11)**.—This class of yellow, greenly fluorescent, water-soluble biochromes is very widely distributed in plant and animal tissues, although their presence in very small amounts renders their colour unappreciable in animals save following appropriate chemical extraction. Although synthesized by bacteria, yeasts and the green plants, the lyochromes, notably lactoflavine (riboflavine), which is identical with vitamin B_2, is not manufactured by animals, which thus depend upon plant material for their ultimate supply of this important factor. Lactoflavine, conjugated with a protein, has been shown to be identical with the yellow oxidizing enzyme described by O. Warburg and W. Christian in 1932. The enzyme is capable of combining with molecular oxygen, whereupon the yellow colour develops. It may then release this element for intracellular oxidation processes, with simultaneous loss of colour. The colour is again restored by fresh supplies of oxygen. Blood, milk, eggs, liver, kidney and muscle contain appreciable quantities of the biochromic catalyst. Physiologically, a nutritional lack in the supply of lactoflavine leads to impairment of cellular respiration, retardation in growth of young mammals, and to cataract in the eyes of mice, chickens and monkeys. The compound is not stored in quantity and is a normal excretory product. This flavine has been encountered in somewhat concentrated amounts in the Malpighian tubules of insects, which obtain it from fresh vegetable material. The larvae of mosquitoes responsible for carrying yellow fever fail to develop normally, or to complete their metamorphosis if deprived of flavine and purine.

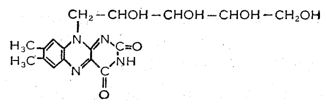

FIG. 11.—LACTOFLAVIN

MISCELLANEOUS BIOCHROMES

There are many animal colouring matters whose constitutions remain unknown. Of these, only a few of the more conspicuous examples will be mentioned.

Chromolipoids are a class of yellowish, reddish or brown fat-soluble biochromes often encountered in the fat-droplets of eggs and other cells and in other lipoid-rich tissues. These compounds have often been mistaken for both melanins and carotenoids. They are believed to be derived from partially oxidized fatty acids, phospholipids or other lipoid compounds, perhaps in ways similar to those in which commercial fats may gradually become discoloured on being heated or after long standing in air.

Haemocyanin is the respiratory catalyst encountered in the plasma of molluscan and crustacean blood. It is colourless in the reduced condition, but assumes a blue colour upon exposure to oxygen, with which it combines. During the circulation of the blood, the oxygen carried in combination with haemocyanin is released to the tissues requiring it. Chemically, haemocyanin is composed of a large protein complex bound to copper, whose presence is responsible for the blue colour of the oxidized molecule.

Haemerythrin is an iron-containing proteinaceous biochrome present in the blood of gephyrean worms, serving there as a reversible oxygen carrier just as do haemoglobin, chlorocruorin and haemocyanin. The blood containing haemerythrin is pale when in the reduced condition, but red or reddish-brown when oxygenated.

Vanadium chromogen occurs in blue, green or orange aggregates within the corpuscles of the blood of tunicates. Chemically this unique biochrome series represents protein combined with vanadium in various stages of oxidation. Owing to the presence of rather remarkable amounts of dilute sulphuric acid in the corpuscles of these animals, the biochrome readily yields its combined oxygen to surrounding tissues.

Numerous coelenterates exhibit brilliant pigmentation, the chemical nature of which is as yet very imperfectly known. For example, the lasting red pigment in skeletons of the corals *Corallium rubrum* and *Tubipora musica,* and the red, orange and yellow colouring matters of many other alcyonarian skeletons are chemically obscure.

USES OF COLOURS TO ANIMALS

Under this head are two distinct classes of problems: (a) the value of the colours as such to the organisms possessing them; (b) the value to the organisms of the substances giving rise to these colours. The one case has to do with the value of appearance to the animal, regardless of how this is brought about; the other case with the utilization for one or another function of substances which happen to be coloured. Any discussion of these matters must include black and white pigments among the substances influencing colour. The second of these classes of problems has already received some attention, in connection with the chemistry and physiology of animal pigments. As there stated, some of these coloured substances have a high physiological importance to the organism, in relation to their respiratory function, or as products of fundamental metabolic processes.

One service which the pigments or biochromes render to the organism is the protection of certain tissues, notably the retina and central nervous system, from the rays of the sun. Here should be mentioned, too, the dense layer of pigment cells (chromatophores) which lines the peritoneum of many fishes and some other vertebrates. The function of such a layer is not certain, though it may well relate to the protection of the viscera from sunlight. The cephalopod molluscs, when disturbed, discharge a dense cloud of black ink (melanin) into the water. This is commonly interpreted as a smoke screen, serving to baffle pursuers.

As already stated, white in the animal kingdom is sometimes due to special white substances (guanine, etc.) deposited in the tissues; in other cases to the mere lack of coloured substances, the place of these being taken by air. This is notably true of the hair of white mammals and the plumage of white birds. The colours of arctic animals belong in a later section of this discussion, since the importance of these animals' appearance is probably a real factor in the evolution of their colour. However, the suggestion has often been made, and with some plausibility, that a white plumage or pelage is of value in retarding the radiation of heat. Consistent with this view is the fact that some of these animals lay aside their white garb and assume a darker one during the summer. It is possible that in these cases both factors, the concealing and the heat-conserving one, are operative.

Concealing Coloration (Procryptic and Anticryptic Coloration).—The optical principles which became familiar to the world after World War I, under the name of camouflage, have probably been utilized in the animal kingdom from the time that predators began to rely upon their sight in hunting their prey. Naturalists were doubtless early impressed by the widespread existence of protective coloration, since any collector of living specimens, vertebrate or invertebrate, is constantly balked in his search for objects which, as he may know, lie before his very eyes. The prevailing sandy hue of desert animals, and the frequency of green in animals inhabiting trees are familiar to the field naturalist. Less familiar are special cases where extensive areas of black, volcanic rock in the desert have called forth appropriate darkening effects in animals which, in surrounding areas, display the prevailing pale hue. Such facts serve to refute any general explanation of the pallor of desert animals as due either to the direct effects of solar radiation or to the animal's need of reflecting this from its surface. The importance of the principle of protective coloration as a factor in evolution was fully recognized by Darwin and some of his contemporaries, and it soon became one of the standard examples of the working of natural selection. It required considerable sophistication for zoologists of a later generation to reject the plain testimony of their senses and to dismiss the protective coloration theory as unfounded. However, more extensive knowledge, including experimental evidence that protective coloration does in reality protect, led to a return, more nearly, to the views of Darwin and his followers. If one had to do, in these cases, merely with a general resemblance in colour between the organism and its more familiar environment, one might seek for some direct physical or chemical influence of the latter upon the former, as has been done by more than one critic of natural selection. But one frequently has to do with a striking resemblance in pattern, *i.e.,* in the distribution of pigment upon the animal's surface such as frequently to match in detail features of the more habitual background which the animal occupies. Some of the most striking cases of this sort are to be found in the special fauna of the *Sargassum* or floating seaweed of certain areas of the tropical Atlantic. Here are animals, belonging to several different subdivisions of the animal kingdom, not only displaying the colours of the seaweed itself, carefully reproduced, but even copying the white patches of the encrusting bryozoan by which this is conspicuously mottled. In certain of these organisms, too, the skin is extended into long fleshy appendages which closely imitate similar structures upon the fronds of the weed. It is hardly likely that these resemblances would be attributed to chance by anyone who had actually seen these organisms together under natural conditions. Furthermore, any naturalist with much field experience knows that correspondences of this sort are far from being rare or exceptional. Specific resemblances to particular natural objects, *e.g.,* to leaves, sticks or stones, or to other animals, occur with convincing frequency, while even the spider which seems to mimic the excrement of birds is difficult to interpret in any other terms. We must add to these resemblances in colour and structure the frequent occurrence of appropriate instincts controlling the attitude assumed by the animal, or imposing quiescence or movements of a sort calculated to deceive the enemy. The walking stick, for example, would not be duly protected by its form, unless it also behaved like a stick and reduced its movements to a minimum.

Another class of camouflage principles was later in being recognized than those which have to do with general conformity to background, or resemblance to specific objects in this. Here colours or patterns which make the organisms inconspicuous or unrecognizable must be considered, regardless of background. For the recognition of these principles, chief credit must be given to the American artist, Abbott H. Thayer (*q.v.*), whose discoveries in this field were first announced in 1896, but were not given wide publicity until 1909 (G. H. Thayer, *Concealing Coloration in the Animal Kingdom.*) The first of these principles is that of counter-shading or obliterative shading, which had, however, been clearly stated by E. B. Poulton a few years earlier. This is a generalization of the fact that in the great majority of animals, both terrestrial and aquatic, the dorsal surface of the body is more heavily pigmented than the ventral, while there is a gradient of decreasing pigmentation from one to the other. Thayer called attention to the fact, which he illustrated by solid models, that such a distribution of pigment makes for minimum visibility, when the animal is lighted, as it most commonly is, from overhead. Another principle, stressed by Thayer, which has been widely adopted in the camouflage both of animals and of ships, is that of ruptive and secant patterns. In such cases the natural continuity of the body's outline has been broken up by intrusions of black or white or other pigment at the margins, or a less conspicuous general colour scheme of the body has been nullified to the observer by conspicuous markings which are quite irrelevant to this. The effect is to render an object so treated unrecognizable, even though it remains in full view. Under the name coincident disruptive colouring, H. B. Cott discussed a class of cases in which disruptive patterns were carried continuously through regions of the body which are not morphologically continuous, *e.g.,* pigmented bars which run crosswise upon the hind legs of a frog, but are evident only when the animal's legs are doubly folded in the resting position. Similar pigmented stripes, disposed longitudinally, frequently include the eye. They divide the body into two or more longitudinal sections and tend to render it unrecognizable as a single organism of familiar form.

Adaptive Colour Change.—Many animals, belonging to several of the major subdivisions of the animal kingdom, are able to conform their shades (as lighter or darker) or in some cases their actual colours, to those of the backgrounds on which they happen to lie. These changes are mediated through the eyes and the central nervous system, in some cases involving the endocrine glands. The effector organs are special cells in the skin or elsewhere, known as chromatophores. The most familiar of these are black, white, yellow and red. Colour changes of this type have been most fully investigated in fishes, amphibia and reptiles among the vertebrates, and in crustacea and the cephalopod molluscs among the invertebrates. The literature in this field has become very extensive.

Colour changes resulting from chromatophore action are of two chief sorts: (1) rapidly ensuing changes, often induced within a few minutes, or even seconds. These are brought about by the aggregation or dispersion of pigment granules within the chromatophores. The aggregated condition results in a withdrawal of much of the pigment from view, and thus to a paling of the animal. On the other hand, the dispersion of pigment leads to a darkening of the chromatophores, and thus of the surface of the body as a whole. These processes are frequently, but incorrectly, referred to as contraction and expansion of the chromatophores, whereas the outlines of the chromatophores are commonly little affected.

The second type of color change (2) usually involves an increase or decrease in the number of chromatophores present, as well as in the actual amount of pigment contained in the individual chromatophores. Such changes result from more prolonged subjection of the animal to the same stimuli which call forth the more familiar, immediate responses. In either case, it is important to note that the shade assumed, or the amount of pigment produced, is dependent not upon the absolute degree of illumination to which the animal is subjected, but upon the albedo of the background, *i.e.,* to the ratio of reflected to incident light. For one species of fish (*Girella nigricans*) it was determined that the amount of melanin present at the end of four months was about twice as great in specimens kept on black as in those which had been kept on white, while the amount of the white pigment, guanine, was four times as great in the latter as in the former. The differences in appearance, moreover, were much greater than these figures would seem to indicate. The black-adapted specimens were nearly dead black, the white-adapted ones were very pale gray.

Evidence that this capacity for pigmentary adjustment to background may be of lifesaving value to fishes has been obtained experimentally. Large numbers of fishes which differed widely in the extent to which this adjustment had been carried were subjected to the attacks of fish-eating birds and of larger fishes. It was found that the ratio of less-adapted to more-adapted fishes among the casualties was consistently high, averaging about two to one. Aside from such tests, however, the mere existence of the mechanism for adjustable coloration would seem to constitute strong evidence for the effectiveness of protective coloration. For this complicated mechanism has been evolved independently in several unrelated branches of the animal kingdom. Furthermore, so far as aquatic animals are concerned, no plausible function except concealment has ever been suggested. To clinch this argument more completely, it may be pointed out that the adjustment of some fishes to their backgrounds includes pronounced and appropriate changes in the disposition of light and dark areas on the skin (*i.e.,* in the pattern), which can have no significance except as affecting appearance. The old familiar objection to the protective coloration theory that many of the presumed predators are not known to possess colour vision loses its force completely in the face of these facts. It is possible, however, that in some terrestrial animals, *e.g.,* lizards, the colour changes are secondarily concerned with the absorption or reflection of heat rays from the sun. This may be an important matter in desert species.

Warning (Aposematic) Coloration.—Many animals, especially among insects, which are themselves edible and inoffensive, have developed a superficial resemblance to other species, often widely unrelated to themselves, which are avoided by predators, owing to the possession of repellent or dangerous characteristics (*see* MIMICRY). This earliest discovered (Batesian) type of mimicry is believed to be supplemented by another (Müllerian) type, in which a number of species of animals that are equally obnoxious appear to have adopted a common, conspicuous livery, supposed to be recognized by predators as belonging to animals which had better be left alone. Thus, we have the warning colours of wasps and many other insects which are protected by stings, offensive scent glands, etc., of certain frogs which are known to be poisonous, and indeed of a wide variety of animals belonging to various groups. Experiments by a number of naturalists provide reasons for believing that birds, monkeys and perhaps some other animals do exercise choice in the selection of insects and tend to reject those having certain brightly coloured patterns. The results of such experiments are not wholly consistent, however, and the efficacy of warning coloration is perhaps more limited than has been claimed.

Recognition Colours.—This term has been applied to certain cases in which conspicuous markings are displayed, that may serve to identify an animal in the eyes of another of the same species, either at the time of mating or when they are flocking together for mutual protection. The white flag of the retreating cottontail rabbit, and the showy rumps of some of the deer are examples which are frequently cited in this last connection. According to A. R. Wallace, however, a large proportion of the differences of colour pattern which distinguish one species of birds or of insects from another are to be interpreted as recognition marks.

COLOUR AND SEX

In many species of animals the sexes differ more or less widely in colour. The most familiar examples of this are to be found among the birds, fishes and insects, although instances may be cited from some other of the major groups of animals. In cases where one sex is more highly coloured or more ornate than the other, it is usually the male which is so characterized. Much study has been devoted to the relation between sex hormones and the colours and other secondary sexual characters of animals, particularly of birds. In this group, as a rule, the castrated male retains the plumage colours of the normal animal, sometimes even to an exaggerated degree. The spayed female, on the other hand, takes on the colours of the male, and this may happen, without operation, as a result of disease of the ovary. These facts make it evident that the colours of the male in such species may develop in the absence of any hormone from the testis, while the colours of the normal female require the presence of a hormone from the ovary. The part played by the latter is further illustrated by the production of feminized males by grafting ovarian tissues into castrated cocks (capons).

In some birds and fishes these sexual differences of colour become greatly emphasized during the breeding season, diminishing or disappearing during the periods of sexual inactivity.

In the Spring a fuller crimson comes upon the robin's breast;
In the Spring the wanton lapwing gets himself another crest.

Among birds, these changes in plumage are usually due to the replacement of feathers, following the spring moult, less frequently to the shedding of the deciduous tips of feathers. In some cases, both among birds and mammals, it has been shown that the onset of moulting may be hastened or delayed through artificial control of the diurnal period of illumination. Shortening of this in the summer may lead to an earlier assumption of the winter plumage (or pelage), while the spring moult may be hastened by lengthening the period of daylight in the winter. In general, these alternations of plumage are not dependent upon the presence of sex hormones, and may follow their normal course in castrated birds. The same cannot be said, however, of the seasonal colour changes of some other parts, such as the bill and certain areas of skin, which are more likely to be under hormonal control. So far as known, the brilliant colours which are displayed in the spring by the males of many species of fresh-water fishes are hormonally controlled. They fail to appear in castrated males, while these same colours may be induced in females through the injection of the male hormone. In the latter case, actual quantitative increases of pigment may result, which persist for some time after the hormone treatment has been discontinued. In general, the nature and extent of the hormonal control of secondary sexual characters varies greatly from one organism to another. In insects such control seems to be lacking, sexual differences being more directly controlled by the hereditary complex, without the intermediation of hormones.

A question quite different from that of the physiological basis of sexual colour differences is that of the utility of these colours, if any, to the organism. Are the gorgeous colours of male birds, for example, of advantage to the wearers of these colours? Darwin, as is well known, answered this question in the affirmative with his hypothesis of sexual selection. The showy characters of the male plumage, he contended, arose through the continued selection by the females of more ornate mates. Darwin was able to point to cases among birds in which competitive display by the males and selection by the females seemed to be incontrovertible facts. And the extraordinary perfection to which certain colour schemes have been carried (*e.g.*, in the secondary wing feathers of the male argus pheasant) speaks for a level of aesthetic appreciation which certainly would not have been expected in a bird. However, the range of phenomena which can reasonably be explained by this sexual selection theory is certainly much less extensive than Darwin supposed, and in those cases for which it is regarded as relevant, the theory has undergone considerable changes in its formulation (*see* SELECTION and COURTSHIP OF ANIMALS). One alternative explanation which was offered by A. R. Wallace to account for certain sexual differences of coloration in birds would seem to have considerable inherent probability. Wallace contended that part of this difference might be due to the modification of the brooding female in the direction of concealment, the male being in less need of such protection. Indeed, the suggestion has been made by others that it might be advantageous to the species for the male to be more conspicuous during the nesting season in order to divert the attention of predators from the (at that time) biologically more important female.

All in all, it must be admitted for a considerable proportion of sexual differences in coloration that no explanation can be found and, indeed, that perhaps no explanation of a bionomic nature is called for. Knowledge of the animal's metabolism, when this is attained, will perhaps be sufficient. And it might be added, that the same conclusion is probably justified in regard to much of the coloration of animals in general. One does not inquire how minerals such as cinnibar or malachite benefit from their respective hues and the question may be equally irrelevant in the case of many animals.

COLOUR VISION: *see* VISION or SIGHT.

COLSTON, EDWARD (1636–1721), English philanthropist, the founder of Colston's Charity and a generous donor to other foundations in his native city of Bristol and elsewhere, was born at Bristol on Nov. 2, 1636, and died at Mortlake, near London, on Oct. 11, 1721. His father was a keen Bristol merchant and an ardent Royalist. Edward Colston was educated at Christ's Hospital, London, of which school he was later on governor and a generous benefactor. He made his fortune in trade with the West Indies and in a sugar refinery which he established in Bristol, and though he was domiciled in London he spent much time in his native city. There he endowed (1708) "Colston's Charity" for the education of 100 boys in the principles of the Church of England. This school, built on Augustine's Back, was subsequently removed to Stapleton, Gloucestershire. Almshouses, homes for sailors and other schools in Bristol were endowed by him, and he made many benefactions to London hospitals and schools.

Colston, who was in the habit of bestowing large sums yearly for the release of poor debtors and the relief of indigent age and sickness, and who gave (1711) £6,000 to increase Queen Anne's Bounty Fund for the augmentation of small livings, was always keenly interested in the organization and management of his foundations; the rules and regulations were all drawn up by his hand, and the minutest details of their constitution and economy were dictated by him. He was a high churchman and Tory.

See T. Garrard, *Edward Colston, the Philanthropist* (4to, Bristol, 1852); G. Pryce, *A Popular History of Bristol* (1861).

COLT, SAMUEL (1814–1862). American inventor, born July 19, 1814, at Hartford, Conn. Colt ran away to sea at 16, sailing from Boston, Aug. 2, 1830, for India. During this voyage he whittled a wooden model of the Colt revolver. (*See* PISTOL.) He had several metal models made between 1831 and 1835.

Colt's invention was a single-barrelled pistol or rifle having a many-chambered rotating breech which was turned, locked and unlocked by cocking.

He took out English and European patents in 1835, and United States Patent No. 138, Feb. 25, 1836. On March 5, 1836, the Patent Arms Manufacturing Co., of Paterson, N. J., was formed to manufacture and sell Colt's arms. The first military use of Colt arms was in the Seminole War in 1837. They were also used by the Texas Rangers in the war between Texas and Mexico. Lack of general acceptance of the new weapons, however, caused the Patent Arms company to fail in 1842.

Colt then turned to the invention of electrically-discharged submarine mines. He also conducted a telegraph business which utilized the first cable ever laid under water.

As a result of the Mexican War, 1846–48, Captain Walker was sent to Colt with a government order, dated Jan. 4, 1847, for 1,000 revolving pistols. These were made at the factory of Eli Whitney at Whitneyville, Conn. Colt established his own plant at Hartford in the latter part of 1847. He moved twice, until in 1855 he set up the largest private armory in the world on the site of the present Colt plant.

Colt developed beyond any maker before him the manufacture of interchangeable parts, and the production line as we know it. He also had advanced ideas concerning working conditions and employee welfare. His invention netted him one of the outstanding fortunes of the period. He died at Hartford, Jan. 10, 1862. (C. T. H.)

COLTON, a city of San Bernardino county, California, U.S.A., 55 mi. E. of Los Angeles; served by Southern Pacific, Santa Fe, Union Pacific and Pacific Electric railways. The population was 8,014 in 1930 and 9,686 in 1940. Citrus, grapes and other fruits and garden produce are packed and shipped from there. The largest Portland cement plant in the west is there; also concrete pipe and conduit manufacturing, citrus by-products plant, flour and feed mills, car shops, candy plant, large fruit refrigeration plant and various other industries. It was settled about 1860 and incorporated in 1887.

COLT'S-FOOT, the popular name of a small herb, *Tussilago Farfara,* a member of the family Compositae, which is common in Great Britain in damp, heavy soils. It has a stout, branching, underground stem, which sends up in March and April scapes about 6 in. high, each bearing a head of bright yellow flowers. The fruits bear a soft, snow-white, woolly pappus, somewhat like that of the dandelion. The leaves, which appear later, are broadly cordate with an angular or lobed outline, and are covered on the under-face with a dense white felt. They are smoked in cases of asthma.

In eastern North America the colt's-foot has become extensively naturalized, having the appearance of a native plant, along banks, roadsides and the shores of streams from Nova Scotia to Minnesota and southward to Pennsylvania.

COLUGO: *see* FLYING LEMUR; GALEOPITHECUS.

COLUMBA, SAINT (Irish, *Colum*) (521–597), Irish saint (also Columkille "of the church"), was born on Dec. 7, 521, at Gartan in Co. Donegal. His father, Feidlimid, was a member of the reigning family in Ireland and was closely allied to that of Dalriada (Argyll). His mother Eithne was descended from the king of Leinster. To these connections as much as to his piety and ability he owed his immense influence. Columba studied under the distinguished Finian of Moville (at the head of Strangford lough) and Finian of Clonard, and *c.* 551 was ordained priest. During his residence in Ireland he founded a number of churches and the famous monasteries Daire Calgaich (Derry), on the banks of Lough Foyle, and Dair-magh (Durrow) in King's county.

In 563 Columba with 12 disciples established himself on the island of Hy or Iona, where he erected a church and a monastery, and in 565 applied himself to the task of converting the Picts. By his preaching, his holy life and miracles he converted the whole of northern Scotland and established many monasteries there, the monastery of Iona being regarded as the mother house and its abbots as the chief ecclesiastical rulers even of the bishops. Columba, in his character of chief ecclesiastical ruler, gave formal benediction and inauguration to Aidan, the successor of Conall, as king of the Scots. He accompanied that prince to Ireland in 575, and took a leading part in a council held at Drumceat in Ulster, which determined the position of the ruler of Dalriada with regard to the king of Ireland. The last years of Columba's life appear to have been spent mainly at Iona, where he was already revered as a saint. He died on June 8, 597.

Several Irish poems are ascribed to Columba, but they are manifestly of a later age. Three Latin hymns may be attributed to the saint with some degree of certainty.

The life of St. Columba by Cuminius, who became abbot of Iona in 657, was enlarged by Adamnan, who became abbot in 679. These narratives were supplemented by the notices given by Bede. *See* W. Reeves, *Life of St. Columba, written by Adamnan* (1857); W. F. Skene, *Celtic Scotland,* vol. ii. "Church and Culture" (1877).

COLUMBAN (543–615), Irish saint and writer, was born in Leinster, and educated in the monastery of Bangor, Co. Down. About 585 he left Ireland with 12 other monks, and established himself in the Vosges, in an ancient fortification called Anagrates, the present Anegray in the department of Haute-Saône. He then built the abbey of Luxeuil, for the congregation of which he drew up his rule. His enemies accused him before a synod of French bishops (602) for keeping Easter according to the Celtic usage, and a powerful conspiracy was organized against him at the court of Burgundy for boldly rebuking King Theuderich II. and the queen-mother Brunhild. Being forcibly removed from his monastery, with St. Gall and other monks he withdrew to Switzerland, where he preached to the Suebi and Alamanni. Finally he was forced to retire to Italy, where he founded the monastery of Bobbio in the Apennines, where he died on Nov. 21, 615. His writings, which include some Latin poems, prove him a man of learning, acquainted with the Latin and Greek classics.

St. Columban's writings were published by Patrick Fleming in his *Collectanea sacra Hiberni* (Louvain, 1667), and reproduced by Migne, vol. lxxxvi. *See* further, Wright's *Biographia Literaria;* and U. Chevalier, *Repertoire des sources hist.*

COLUMBANI, PLACIDO, Italian architectural designer, who worked chiefly in England in the latter part of the 18th century. He belonged to the school of the Adams and Pergolesi, and like them frequently designed the enrichments of furniture. He was a prolific producer of chimney-pieces, which are often mistaken for Adam work, of moulded friezes, and painted plaques for cabinets and the like. There can be no question that the English furniture designers of the end of the 18th century, and especially the Adams, Hepplewhite and Sheraton, owed much to his graceful, flowing and classical conceptions, although they are often inferior to those of Pergolesi. His books are still a valuable storehouse of sketches for internal architectural decoration. His principal works are:—*Vases and Tripods* (1770); *A New Book of Ornaments* (1775); *A variety of Capitals, Friezes and Corniches, and how to increase and decrease them, still retaining their proportions* (1776).

COLUMBARIUM, originally a pigeon house, and so still used, particularly of the large, round, tower-like structures common in many districts in France; a dove cote. The term is also, and more commonly, applied to a sepulchral building containing many small niches for funerary urns. Columbaria were the most common places for the disposal of the ashes of the dead in imperial pre-Christian Rome, except for the very wealthy. Many have been excavated and are one of the most fruitful sources of Latin inscriptions. Columbaria were erected by societies, gilds, the slaves and freedmen of great families and similar associations. They usually took the form of an open court, the walls of which contained the arched niches for the urns. Occasionally they were treated with considerable architectural splendour as in the columbarium of the freedmen of Livia in the Via Appia, Rome (early first century A.D.). In modern times, with the revival of cremation, there has come a new development of columbaria in connection with the great crematories, the most famous example being that surrounding the crematory of Hanover, Germany.

For Roman columbaria *see* R. Lanciani, *Ancient Rome in the Light of Recent Excavations,* chap. iii. (1889); G. Rivoira, *Roman Architecture,* Fig. 29 (1925).

COLUMBIA, a city near the centre of Missouri, U.S.A., about 10m. N. of the Missouri river, at an altitude of 720ft.; the county seat of Boone county. It is on Federal highways 40 and 63, and is served by the Missouri-Kansas-Texas and the Wabash railways. The population was 10,392 in 1920 (18·5% Negroes) and in 1940 was 18,399 by the federal census. It is in a region of diversified agricultural interests; has large flour mills and several other manufacturing industries; is the seat of the University of Missouri, the Christian college for women (Disciples), Stephens college and the Bible college of Missouri (Disciples); and is the headquarters of the State teachers' association. In the quadrangle on the campus is the monument of gray granite from the grave of Thomas Jefferson, designed by him and bearing the famous inscription he wrote for it. It was given to the university by his descendants when Congress erected the monument now standing on his grave. Columbia was settled about 1821, and was incorporated as a city in 1826.

COLUMBIA, a borough of Lancaster county, Pennsylvania, U.S.A., amid beautiful scenery on the Susquehanna river (a mile wide at this point), 80 mi. W. by N. of Philadelphia. It is on the Lincoln highway, and is served by the Pennsylvania and the Reading railways. The population in 1940 was 11,547 by the federal census. Columbia is a busy trading and shipping centre, and has numerous and varied manufacturing industries, with an output in 1939 valued at $7,186,400. Columbia was settled by Quakers in 1726 and was incorporated in 1814. It was one of the places considered by the congress in 1790 for the permanent site of the national capital.

COLUMBIA, the capital of South Carolina, U.S.A., and the county seat of Richland county, on the Congaree river, in the geographical centre of the state. It is on federal highways 1, 21 and 76; is served by the Atlantic Coast line, the Columbia, Newberry and Laurens, the Seaboard Air line and the Southern railways; a municipal airport is located 3½ miles southeast of the post office.

The population in 1930 was 51,581 (37·8% Negroes) and was 62,396 in 1940. Suburbs just outside the city limits add 28,000 to the metropolitan population.

The city is beautifully situated on a bluff above the river. Wide streets, many trees and fine public buildings make it very attractive. The state house is built of granite from near-by quarries and has specimens of over 50 species of trees on its grounds. Columbia is the centre of a rich agricultural and forest district. It has important manufactures, especially of cotton goods, cottonseed oil, fertilizer and machinery. The output of its 175 industries in 1939 was valued at $30,000,000. The assessed valuation of property is over $20,000,000. The University of South Carolina, chartered in 1801 as South Carolina college, and opened there in 1804, has an enrolment of over 2,000. Among the other educational institutions are Columbia college (1854); Columbia Bible college; Benedict college (1870), for Negroes of both sexes; Allen university (1870), for Negroes of both sexes; and Lutheran Theological Southern seminary (1829). The state penitentiary and the state insane asylum are there. In 1786, when the site was still largely forest, it was chosen for the capital, and a town was laid out, which was governed directly by the legislature until 1805, when it was incorporated as a village. A city charter was secured in 1854. On Feb. 17, 1865, Gen. Sherman entered Columbia, and that night a fire broke out which destroyed most of the city. From June 1862, until the close of the war, the buildings of the university (then the college) were used by the Confederate government for a hospital.

COLUMBIA, a city of Tennessee, U.S.A., 46 mi. S. by W. of Nashville, on the Duck river; the county seat of Maury county. It is on federal highway 31, and is served by the Louisville and Nashville and the Nashville, Chattanooga and St. Louis railways. The population in 1920 was 5,526 (35% Negroes); it was 7,882 in 1930 and 10,579 in 1940. It is in a fine farming region, where tobacco, corn, wheat, alfalfa and potatoes are grown, and many mules are raised. Phosphate rock is mined within 12 miles. The city has a large mule market. Its factories include flour mills, a cannery, a cotton mill and plants making furniture, work clothes and lighting fixtures. Columbia was settled about 1807 and incorporated in 1822. In 1862–63 it was Gen. N. B. Forrest's base of operations, and during Gen. Hood's Nashville campaign (Nov.–Dec. 1864) it was occupied alternately by federal and Confederate troops. James K. Polk began there (1820) to practise law.

COLUMBIA RIVER, the largest river flowing into the Pacific ocean from the western continent, is one of the world's great hydroelectric power streams. More than 30% of the potential hydro power of the United States is located within its watershed.

The Columbia river rises in the ice fields of the Rocky mountains in British Columbia (50° N., 116° W.), about 80 mi. N. of the international boundary, and flows northwest for about 170 mi. to lat. 52°, where it turns sharply south, nearly encircling the Selkirk mountains. It enters the United States near the northeast corner of Washington. Through Washington the Columbia flows circuitously, in what is called the Big Bend, to its junction with the Snake, its largest tributary. Not far below it turns west and forms the boundary between Washington and Oregon for about 325 mi. Ice of the glacial period, which extended as far south as the Big Bend, greatly modified its course, once the line of the series of lakes now in the Grand Coulee.

The total area drained by this system is 259,000 sq.mi., of which 220,300 are in the United States. The total length of the river is about 1,210 mi. The mean flow at its mouth is about 280,000 sec.ft. (maximum about 1,250,000)—approximately eight times the mean flow of the Colorado at Yuma, and nearly double that of the Nile at Assuan. The fall through 400 mi. in Washington is over 1,000 ft.

Numerous rapids in the upper river afford many hydroelectric power sites. The Columbia's mouth is the only deepwater harbour between San Francisco and Cape Flattery, a distance of 770 mi. Tides are perceptible 140 mi. up the river. The mean tide at Astoria is about six feet, and the average tidal flow at the mouth is about 1,000,000 sec.ft.

Early development in the river basin was confined to navigation and irrigation. Navigation improvement has been developed by the U.S. war department, while irrigation has been handled for the most part by the department of the interior. A project for a 30-ft. channel 300 ft. wide, from Portland to the sea, was authorized in 1911, and a 35-ft. channel 500 ft. wide in 1928. A lock was completed at Cascade rapids in 1898, and an 8-mi. canal was built in 1918 around Celilo falls. Principal irrigation developments have been the Yakima project, irrigating slightly more than 500,000 ac. in 1941, with water from one of the Columbia's principal tributaries, and the Vale-Owyhee project in the Snake river basin.

First surveys for complete utilization of the river system were begun by the war department in 1927. In 1933 construction of the first two of a series of multiple-purpose dams was begun at Bonneville, Ore., 140 mi. from the ocean, and at the juncture of Grand Coulee with the present course of the river 450 mi. above Bonneville.

Because the river's power potentialities are peculiarly suited to the needs of electrolytic and electric furnace operations, government economists planned development of the northwest as a light metals manufacturing centre.

Bonneville dam, completed in 1937 for the dual purpose of navigation improvement and ultimate generation of 518,400 kw. of electricity, comprises a spillway 1,090 ft. long between the Washington shore and Bradford island, and a powerhouse and navigation lock between the island and the Oregon shore. With completion of a 27-ft. channel from Portland to Bonneville in 1942, the lock will permit ocean vessels to ascend the river 192 mi. As a result of navigation improvement, tonnage on the river above Bonneville increased from 417,000 to 700,000 between 1939 and 1940.

Grand Coulee dam, first operated in 1941, was designed to supply water for the Columbia basin irrigation project and for generation of 1,944,000 kw. of electric power. The dam is 3,000 ft. long at its crest, and the height from bedrock is 550 ft. The spillway has a capacity of 1,000,000 cu.ft. per sec.

On Aug. 20, 1937, congress passed an act establishing the Bonneville power administration as agency for the transmission and sale of power generated at Bonneville. A presidential executive order signed Aug. 26, 1940, made the agency the transmission and marketing unit for Grand Coulee power.

By June 30, 1941, the combined generating capacity of both dams had reached a total of 214,400 kw., and a total of 322,000 kw. had been contracted to retail power distribution agencies and electrometallurgical and electrochemical industries. Nearly 1,400 mi. of high-voltage transmission system had been constructed. Complete generator installation at Bonneville was scheduled for 1943.

COLUMBIA RIVER HIGHWAY begins at Astoria, Oregon, and ends at Pendleton, 336 mi. distant in the same State. Of this mileage 202 mi. are paved and 134 mi. are of oiled rock or gravel. It runs within sight of the Columbia river practically all the way, sometimes along its lower banks and sometimes along rocky walls at great heights above the stream, often passing by tunnel through projecting mountain spurs. Portland, Hood River, The Dalles and Umatilla and also the great snow-crowned peaks, Multnomah Falls and Mt. Hood are points of interest along its course. It is part of the old "Oregon Trail" made famous by the Astor family and is one of the most notable scenic highways in America.

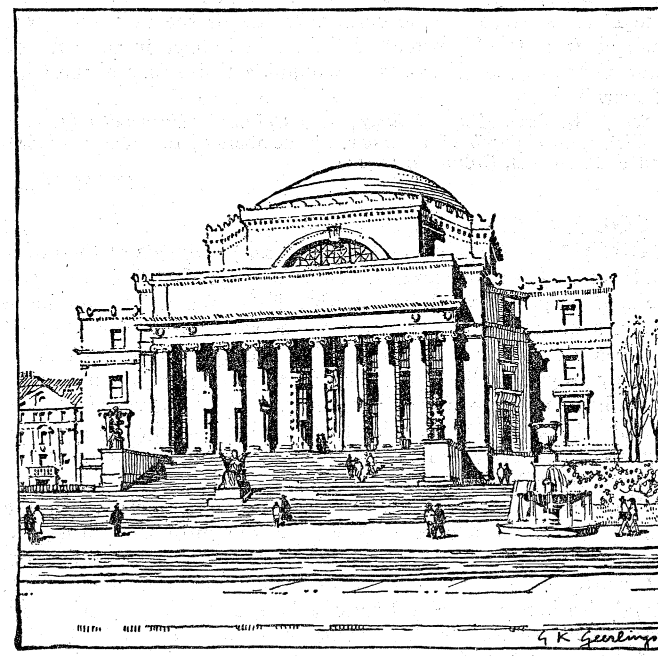
COLUMBIA UNIVERSITY, one of the oldest and most important of the higher institutions of learning in the United States, situated for the most part on Morningside Heights, New York city. It embraces Columbia college, founded as King's college in 1754; a school of medicine (the College of Physicians and Surgeons) founded 1767, removed in 1928 to a site on the Hudson above 165th Street where, in conjunction with the Presbyterian hospital and allied institutions, it forms the nucleus of a great medical centre; school of law (1858); school of engineering, organized as school of mines in 1863; school of architecture (1881); graduate facilities of political science (1880), philosophy (1890) and pure science (1892); school of journalism (1912); school of business (1916); school of dental and oral surgery (1916); school of library service (1926). Closely affiliated to it and incorporated in its educational system are the College of Pharmacy (1829), in West 68th Street; Teachers college, founded in 1886, as the New York College for the Training of Teachers, and essentially a part of the university since 1895; Barnard college (for women) founded in 1889, and essentially a part of the university since 1900; Bard (formerly St. Stephen's college), Annandale-on-Hudson (for men) founded in 1860, and essentially a part of the university since 1928, New York Post-Graduate Medical School, founded in 1882 and essentially a part of the university since 1931. Reciprocal relations also exist between the university and Union Theological Seminary, thus practically adding to the university a theological faculty.

In co-operation with the Ministry of Education in Porto Rico the university in 1924 assumed responsibility for educational and scientific work of the school of tropical medicine on the island of Porto Rico. Three research institutes are connected with the university, the Institute of Educational Research, the Institute of Cancer Research and the De Lamar Institute of Public Health. Courses in university extension are open to men and women who can give only a portion of their time to study, but who desire to pursue subjects included in a liberal education. These courses, as such, do not lead to degrees. Under university extension there is also an Institute of Arts and Sciences which conducts a series of lectures and recitals of a popular nature. Women are admitted by all faculties of the university with the exception of that of engineering. Since 1900 a summer session has been held for six weeks. Teachers and others, under the direction of the Teachers college, are afforded an opportunity to pursue courses *in absentia* and so meet some of the requirements for an academic degree or a teacher's diploma.

In 1936 there were in Columbia university in all departments 3,190 instructors and administrative officers, and in the 12 months ending June 30, 1935, 33,495 students were enrolled. Of these, roughly one-third were registered in the 1935 summer session; more than one-third in the degree-granting schools and faculties during the academic year 1935–1936. In addition to the resident students there were 676 non-resident students in home study and 1,986 non-resident students in extra-mural and special courses. The numerous university publications include works embodying the results of original research published by Columbia University Press; "Studies" published in the form of a series by each of several departments; various periodicals edited by some members of the faculty, such as *The Romanic Review, The Germanic Review, The Political Science Quarterly,* etc. and several papers or periodicals, published by the students, among which are the *Columbia Spectator,* a daily paper, the *Columbia Law Review* and the *Columbia Jester.*

With one exception the 69 buildings of the university on Morningside Heights have been erected since 1896. They include besides the several department buildings and laboratories, two library buildings, a university hall (with gymnasium), Earl Hall (for social purposes), St. Paul's chapel (dedicated in 1907), President's house, Faculty house, faculty residential halls, residence halls for men and for women, and four centres of foreign interests, the Maison Française, the Casa Italiana, the Deutsches Haus, and the Casa de las Españas. The library contains about 1,520,000 volumes exclusive of duplicates and unbound pamphlets.

The highest authority in the government of the institution is vested in a board of 24 trustees, vacancies in which are filled by co-optation; but the immediate educational interests are directed largely by the members of the university council, which is composed of the president of the university, the dean and elected representatives from the faculty of each school. The alumni of the university have been given a definite part in the government of the institution by an agreement under which six of the 24 trustees are elected on alumni nomination. The productive endowment of the university, including the endowments of Teachers college, Barnard college, College of Pharmacy, Bard College, and New York Post-Graduate Medical School had a book value in 1936 of $85,749,434, which, added to the property occupied for educational purposes, made a total capital holding of $144,336,580. The tuition fees to the students in the several schools range from $400 to $545. The total budget appropriations for the maintenance of the work of the whole educational system of the university for the year 1936–1937 were $14,840,633.25.



LOW MEMORIAL LIBRARY

The library, one of the first five buildings to be erected on the present site of the college when it removed to Morningside Heights in 1896, was the gift of Seth Low, at that time president of the institution. The statue half way up the steps represents Alma Mater

The charter granted by the Crown in 1754, for the establishment of King's college, was so free from narrow sectarianism as to name ministers of five different denominations for ex-officio governors, and provide that the governors should not "exclude any person of any religious denomination whatever from equal liberty and advantage of education or from any of the degrees, liberties, privileges, benefits or immunities of the said college on account of his particular tenents in matters of religion." The purpose of the institution as set forth by its first president, Dr. Samuel Johnson (1696–1772) was about as broad as that now realized.

In 1756 the erection of the first building was begun at the lower end of Manhattan island, near the Hudson, and the institution prospered from the beginning. From 1776 to 1784, during the Revolutionary War, the exercises of the college were suspended and the library and apparatus were stored in the New York city hall. In 1784 the name was changed to Columbia college, and an act of the legislature was passed for creating a State university, of which Columbia was to be the basis. But the plan was not a success, and three years later, in 1787, the act was repealed and the administration of Columbia was entrusted to a board of trustees of which the present board is a successor. In 1857 there was an extensive reorganization by which the scope of the institution was much enlarged, and at the same time it was removed to a new site on Madison Avenue between 49th and 50th Streets.

From 1890 to 1895 much reorganization and centralization in its administration was effected. In 1896 the name of Columbia university was adopted, and in the autumn of 1897 the old site and buildings were again abandoned for new, this time on Morningside Heights. In 1912 the corporate title of the university was changed from the "Trustees of Columbia College in the City of New York" to the "Trustees of Columbia University in the City of New York."

See J. B. Pine, *King's College, now Columbia University* (1896); *A History of Columbia University*, by members of the faculty (1904) and F. P. Keppel, *Columbia* (1914).

(N. M. B.)

COLUMBIDAE: *see* DOVE; PIGEON.

COLUMBINE, any plant of the genus *Aquilegia* of the crowfoot family (Ranunculaceae). They bear slender, delicate, long-stalked, deeply divided leaves with blunt segments, and loose panicles of handsome, drooping, blue, white or yellow flowers, which are characterized by having all the five petals spurred.

They grow in woods and thickets, and often in alpine meadows. Some horticultural varieties are well known in cultivation. There are about 75 species of columbine, natives of north temperate regions, together with numerous varietal forms and crosses developed by cultivation.

The 20 odd species found in North America, chiefly in the Rocky Mountain region, rank among the most beautiful wild flowers of the continent, several of which, including the following, are widely cultivated. The eastern columbine (*A. canadensis*), called also honeysuckle and rock bells, found in dry woods from Nova Scotia to North-West Territories and southward to Florida and Texas, with nodding, scarlet and yellow flowers, an inch or more across, is a favorite spring wild flower. The Rocky Mountain columbine (*A. coerulea*), with handsome, erect, blue and white flowers, 2 in. or more across and spurs 2 in. long, is the state flower of Colorado.

The golden columbine (*A. chrysantha*), found from western Texas to Arizona, grows 3 ft. to 4 ft. high, with clear yellow flowers, sometimes 3 in. across and very slender spurs about 3 in. long. The Sitka columbine (*A. formosa*), which ranges from Utah and northern California to Montana and Alaska, has nodding red and yellow flowers, about 2 in. across, with short, thick spurs.

The common columbine of California is a form of this, with pendulous, scarlet flowers and short spurs.

Columbine, in pantomime (*q.v.*), is the fairy-like dancer who is courted by Harlequin. In the mediaeval Italian popular comedy she was Harlequin's daughter. (*See* COMMEDIA DELL' ARTE.)

COLUMBITE, a rare mineral consisting of iron niobate, $FeNb_2O_6$, in which the iron and niobium are replaced by varying amounts of manganese and tantalum respectively, the general formula being $(Fe, Mn)(Nb, Ta)_2O_6$. It was in this mineral that Charles Hatchett discovered, in 1801, the element niobium, which he himself called columbium after the country (Columbia or America) whence came the specimen in the British Museum collection which he examined. It crystallizes in the orthorhombic system, and the black, opaque crystals are often very brilliant with a sub-metallic lustre. Hardness 6; sp. gr. 5·3. With increasing amount of tantalum the specific gravity increases up to 7·3, and members at this end of the series have been given the name of *tantalite* ($FeTa_2O_6$). These minerals occur as crystals and compact masses in granite and pegmatite.

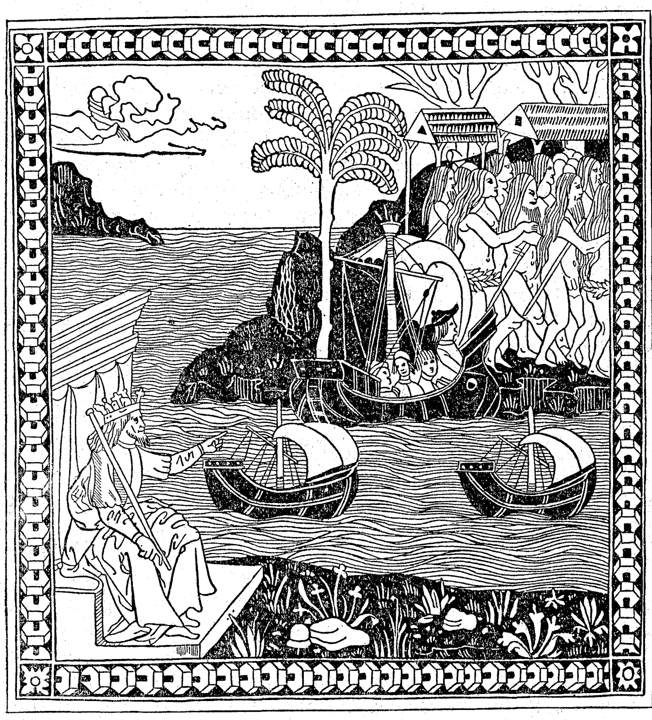
COLUMBIUM or **NIOBIUM,** a metallic chemical element, which has, as yet, found little application in the arts. First observed in 1801 by C. Hatchett in a New England mineral, since named columbite, it was identified by Rose in 1844. The metal was first prepared by Blomstrand (1866) by reducing its chloride with hydrogen. Later its oxide was reduced, by Moissan in the electric furnace in contact with carbon and by Goldschmidt by the use of aluminium powder.

Columbium, whose symbol is Cb or Nb, is a steel-grey metal, atomic number 41, atomic weight 93·1, of specific gravity 7·06 and melting point 1,950° C. It has nearly the same hardness as wrought iron in massive pieces, is malleable and may be welded. It burns on heating in air, is scarcely attacked by hydrochloric or nitric acid, but is soluble in warm concentrated sulphuric acid. It is related to vanadium and tantalum chemically and occurs associated with the latter most frequently in nature; the chief minerals being tantalite, columbite, fergusonite and yttrotantalite. With other elements it is found in pyrochlor, euxenite and samarskite. Three oxides of columbium are known, namely the *dioxide*, Cb_2O_2, the *tetroxide*, Cb_2O_4, and the *pentoxide*, Cb_2O_5, whilst a fourth oxide, *columbium trioxide*, Cb_2O_3, has been described by E. F. Smith and P. Maas (1894).

Columbium tetroxide, Cb_2O_4, is obtained as a black powder when the pentoxide is heated to a high temperature in a current of hydrogen. It is unattacked by acids. Columbium pentoxide, Cb_2O_5, is obtained from columbite after the removal of potassium tantalifluoride. (*See* TANTALUM.) The mother liquors are concentrated, and the double salt K_2CbOF_5, H_2O, which separates, is decomposed by sulphuric acid, or by continued boiling with water. The pentoxide is a white amorphous infusible powder, which when strongly heated in sulphuretted hydrogen, yields an oxysulphide. Several hydrated forms are known, yielding salts known as columbates. A percolumbic acid, $HCbO_4 \cdot nH_2O$, has been prepared by P. Melikoff and L. Pissarjevski (1899), as a yellow amorphous powder by the action of dilute sulphuric acid on the potassium salt, which is formed when columbic acid is fused in a silver crucible with eight times its weight of caustic potash.

Columbium trichloride, $CbCl_3$, is obtained in needles or crystalline crusts when the vapour of the pentachloride is slowly passed through a red-hot tube. When heated in a current of carbon dioxide it forms the oxychloride $CbOCl_3$, and carbon monoxide. Columbium pentachloride, $CbCl_5$, is obtained in yellow needles when a mixture of the pentoxide and sugar charcoal is heated in a current of air-free chlorine. It melts at 194° C (H. Deville) and boils at 240·5° C. It is decomposed by water, and dissolves in hydrochloric acid. Columbium oxychloride, $CbOCl_3$, formed when carbon tetrachloride and columbic acid are heated together at 440° C, forms a white silky mass which volatilizes at about 400° C. It deliquesces in moist air, and is decomposed violently by water. Columbium pentafluoride, CbF_5, is obtained when the pentoxide is dissolved in hydrofluoric acid. It is only known in solution; evaporation of the solution yields the pentoxide. The oxyfluoride, $CbOF_3$, results when a mixture of the pentoxide and fluorspar is heated in a current of hydrochloric acid. It forms many double salts with other metallic fluorides. These double salts belong to an isomorphous series in which fluorine is replaced atom by atom by oxygen, *e.g.*, K_2TiF_6, H_2O, K_2CbOF_5, H_2O and $K_2WO_2F_4$, H_2O.

COLUMBUS, CHRISTOPHER (*c.* 1446 or 1451–1506) (in Spanish, CRISTOBAL COLÓN), was the eldest son of Domenico Colombo and Suzanna Fontanarossa, and was probably born at Genoa, the exact date of his birth being uncertain. According to the *Life of Columbus* by his son Ferdinand (a statement supported by Las Casas), young Christopher was sent to the University of Pavia, where he studied astronomy, geometry and cosmography. Yet, according to the admiral's own statement, he became a sailor at fourteen. Evidently this statement, however, cannot mean the abandonment of all other employment, for in 1470, 1472 and 1473 we find him engaged in trade at Genoa, following the family business of weaving, and (in 1473) residing at the neighbouring Savona. In 1474–75 he appears to have visited Chios, where he may have resided some time, returning to Genoa perhaps early in 1476. Thence he seems to have again set out on a voyage in the summer of 1476, perhaps bound for England; on Aug. 13, 1476, the four Genoese vessels he accompanied were attacked off Cape St. Vincent by a privateer, one Guillaume de Casenove, surnamed Coullon or Colombo ("Columbus"); two of the four ships escaped, with Christopher, to Lisbon. In Dec. 1476, the latter resumed their voyage to England, probably carrying with them Columbus, who, after a short stay in England, claims to have made a voyage in the northern seas, and even to have visited Iceland about Feb. 1477. This last pretension is disputed, but it is perhaps not to be rejected, and we may also trace the Genoese about this time at Bristol, at Galway, and probably among the islands west and north of Scotland. Soon after this he returned to Portugal, where (probably in 1478) he married Felipa Moñiz de Perestrello, daughter of Bartholomew Perestrello, a captain in the service of Prince Henry the Navigator, and one of the early colonists and first governor of Porto Santo.



THE FIRST PICTORIAL VERSION OF COLUMBUS' DISCOVERY OF AMERICA
This woodcut, executed in the year Columbus returned to Spain after his discovery of America, shows the three boats that made up the expedition. After a woodcut in "La lettera dellisole che ha trouato nuouamente il Re dispagan," Florence. 1493

About 1479 Columbus visited Porto Santo, here as in Portugal probably employing his time in making maps and charts for a livelihood, while he pored over the logs and papers of his deceased father-in-law, and talked with old seamen of their voyages, and of the mystery of the western seas. He seems step by step to have conceived that design of reaching Asia by sailing west which was to result in the discovery of America. In 1474 he is said to have corresponded with Paolo Toscanelli, the Florentine physician and cosmographer, and to have received from him valuable suggestions, both by map and letter, for such a Western enterprise. (The whole of this incident has been disputed by some recent critics.) He had perhaps already begun his studies in a number of works, especially the *Book* of Marco Polo and the *Imago Mundi* of Pierre d'Ailly, by which his cosmographical and geographical conceptions were largely moulded. His views, as finally developed and presented to the courts of Portugal and Spain, were supported by three principal lines of argument, derived from natural reasons, from the theories of geographers, and from the reports and traditions of mariners. He believed the world to be a sphere; he underestimated its size; he overestimated the size of the Asiatic continent. And the farther that continent extended towards the east, the nearer it came towards Spain. Nor were these theories the only supports of his idea. Martin Vicente, a Portuguese pilot, was said to have found, 400 leagues to the westward of Cape St. Vincent, and after a westerly gale of many days' duration, a piece of strange wood, wrought, but not with iron; Pedro Correa, Columbus's own brother-in-law, was said to have seen another such waif at Porto Santo, with great canes capable of holding four quarts of wine between joint and joint, and to have heard of two men being washed up at Flores "very broad-faced, and differing in aspect from Christians." West of Europe, now and then, men fancied there hove in sight the mysterious islands of St. Brendan, of Brazil, of Antillia or of the Seven Cities. In his northern journey, too, some vague and formless traditions may have reached the explorer's ear of the voyages of Leif Ericson and Thorfinn Karlsefne, and of the coasts of Markland and Vinland. All were hints and rumours to bid the bold mariner sail towards the setting sun, and this he at length determined to do.

QUEST FOR A PATRON

For the promotion of the plan the concurrence of some state or sovereign was necessary. Columbus, on the accession of John II. of Portugal, seems to have entered the service of this country, to have accompanied Diego d'Azambuja to the Gold Coast, and to have taken part in the construction of the fort of St. George at El Mina (1481–82). On his return, he submitted to King John his scheme for reaching Asia by a western route across the ocean. The king was interested in the rival scheme (of an eastern or south-eastern route round Africa to India) initiated by the Genoese in 1291, and revived, for Portugal, by Prince Henry the Navigator; but he listened to the Genoese, and referred him to a committee of council for geographical affairs. The council's report was adverse; but the king, who was inclined to favour the theory of Columbus, assented to the suggestion of the bishop of Ceuta that the plan should be carried out in secret and without its author's knowledge. A caravel was despatched; but it returned after a brief absence, the sailors having lost heart, and refused to venture further. Upon discovering this treachery, Columbus left Lisbon for Spain (1484), taking with him his son Diego, the only issue of his marriage with Felipa Moñiz, who was by this time dead. He departed secretly;—according to some writers, to give the slip to King John; according to others, to escape his creditors.

Columbus next betook himself to the south of Spain, and while meditating an appeal to the king of France, opened his plans to the count (from 1491, duke) of Medina Celi. The latter gave him great encouragement, entertained him for two years, and even determined to furnish him with three or four caravels, to carry out his great design. Finally, however, being deterred by the consideration that the enterprise was too vast for a subject, he turned his guest from the determination he had come to of making application at the court of France, by writing on his behalf to Queen Isabella; and Columbus repaired to the court at Cordova at her bidding (1486). It was an ill moment for the navigator's fortune. Castile and Leon were in the thick of that struggle which resulted in the final conquest of the Granada Moors; and neither Ferdinand nor Isabella had time as yet to give due consideration to Columbus's proposals. The adventurer was indeed kindly received; he was handed over to the care of Alonso de Quintanilla, whom he speedily converted into an enthusiastic supporter of his theory. He made many other friends, and among them Beatriz Enriquez, the mother of his second son Fernando. But the committee, presided over by the queen's confessor, Fray Hernando de Talavera, which had been appointed to consider the new project, reported that it was vain and impracticable.

From Cordova Columbus followed the court to Salamanca, having already been introduced by Quintanilla to the notice of the grand cardinal, Pedro Gonzalez de Mendoza, "the third king of Spain"; the latter had befriended and supported the Genoese, and apparently arranged the first interview between him and Queen Isabella. At Salamanca prolonged discussions took place upon the questions now raised; the Dominicans of San Esteban entertained Columbus during the conferences (1486–87). In 1487 Columbus, who had been following the court from place to place (billeted in towns as an officer of the sovereigns, and gratified from time to time with sums of money towards his expenses), was present at the siege of Malaga. In 1488 he was invited by the king of Portugal, his "especial friend," to return to that country, and was assured of protection against arrest or proceedings of any kind (March 20): he had probably made fresh overtures to

King John shortly before; and in the autumn of 1488 we find him in Lisbon, conferring with his brother Bartholomew and laying plans for the future. We have no record of the final negotiations of Columbus with the Portuguese Government, but they clearly did not issue in anything definite, for Christopher now returned to Spain (though not till he had witnessed the return of Bartholomew Diaz from the discovery of the Cape of Good Hope and his reception by King John), while Bartholomew proceeded to England with a mission to interest King Henry VII. in the Columbian schemes. If the London enterprise was unsuccessful (as indeed it proved), it was settled that Bartholomew should carry the same invitation to the French court. He did so; and here he remained till summoned to Spain in 1493. Meantime Christopher, unable throughout 1490 to get a hearing at the Spanish court, was in 1491 again referred to a *junta,* presided over by Cardinal Mendoza; but this *junta,* to Columbus' dismay, once more rejected his proposals; the Spanish sovereigns merely promised him that when the Granada war was over, they would reconsider what he had laid before them.

Columbus was now in despair. He at once betook himself to Huelva, a little maritime town in Andalusia, north-west of Cadiz, with the intention of taking ship for France. He halted, however, at the monastery of La Rabida, near Huelva, and still nearer Palos, where he seems to have made lasting friendships on his first arrival in Spain in Jan. 1485, where he especially enlisted the support of Juan Perez, the guardian who invited him to take up his quarters in the monastery, and introduced him to Garcia Fernandez, a physician and student of geography. Juan Perez had been the queen's confessor; he now wrote to her in urgent terms, and was summoned to her presence; and money was sent to Columbus to bring him once more to court. He reached Granada in time to witness the surrender of the city (Jan. 2, 1492), and negotiations were resumed. Columbus believed in his mission, and stood out for high terms; he asked for the rank of admiral at once ("Admiral of the Ocean" in all those islands, seas, and continents that he might discover), the vice-royalty of all he should discover, and a tenth of the precious metals discovered within his admiralty. These conditions were rejected, and the negotiations were again interrupted. An interview with Mendoza appears to have followed; but nothing came of it, and before the close of Jan. 1492, Columbus actually set out for France. At length, however, on the entreaty of the queen's confidante, the Marquesa de Moya, of Luis de Santangel, receiver of the ecclesiastical revenues of the crown of Aragon, and of other courtiers, Isabella was induced to determine on the expedition. A messenger was sent after Columbus, and overtook him near a bridge called "Pinos," 6 m. from Granada. He returned to the camp at Santa Fé, and on April 17, 1492, the agreement between him and their Catholic majesties was signed and sealed.

As his aims included not only the discovery of Cipangu or Japan, but also the opening up of intercourse with the grand khan of Cathay, he received a royal letter of introduction to the latter. The town of Palos was ordered to find him two ships, and these were soon placed at his disposal. But no crews could be got together, in spite of the indemnity offered to criminals and "broken men" who would serve on the expedition; and had not Juan Perez succeeded in interesting in the cause the Palos "magnates" Martin Alonso Pinzon and Vicente Yañez Pinzon, Columbus' departure had been long delayed. At last, however, men, ships and stores were ready. The expedition consisted of the "Santa Maria," a decked ship of 100 tons with a crew of 52 men, commanded by the admiral in person; and of two caravels; the "Pinta" of 50 tons, with 18 men, under Martin Pinzon; and the "Niña," of 40 tons, with 18 men, under his brother Vicente Yañez, afterwards (1499) the first to cross the line in the American Atlantic.

THE NEW WORLD DISCOVERED

The First Voyage.—The adventurers numbered 88 souls; and on Friday, Aug. 3, 1492, at eight in the morning, the little fleet weighed anchor, and stood for the Canary islands. An abstract of the admiral's diary made by Las Casas is yet extant; and from it many particulars may be gleaned concerning this first voyage. Three days after the ships had set sail the "Pinta" lost her rudder; the admiral was in some alarm, but comforted himself with the reflection that Martin Pinzon was energetic and ready-witted; they had, however, to put in at Teneriffe, to refit the caravel. On Sept. 6, they weighed anchor once more with all haste, Columbus having been informed that three Portuguese caravels were on the look-out to intercept him. On Sept. 13, the westerly variations of the magnetic needle were for the first time observed; on the 15th a meteor fell into the sea at four or five leagues distance; soon after they arrived at those vast plains of seaweed called the Sargasso Sea; while all the time, writes the admiral, they had most temperate breezes, the sweetness of the mornings being especially delightful. On the 17th the men began to murmur; they were frightened by the strange phenomena of the variation of the compass, but the explanation Columbus gave restored their tranquillity. On the 18th they saw many birds, and a great ridge of low-lying clouds; and they expected to see land. On the 20th they saw boobies and other birds, and were sure the land must be near. In this, however, they were disappointed; and thenceforth Columbus, who was keeping all the while a double reckoning, one for the crew and one for himself, had great difficulty in restraining the evil-disposed from the excesses they meditated. On the 25th Martin Alonso Pinzon raised the cry of land, but it proved false, as did the rumour to the same effect on Oct. 7, from the "Niña." But on the 11th the "Pinta" fished up a cane, a pole, a stick which appeared to have been wrought with iron, and a board, while the "Niña" sighted a branch covered with berries; "and with these signs all of them breathed and were glad." At ten o'clock on that night Columbus himself perceived and pointed out a light ahead, and at two in the morning of Friday, Oct. 12, 1492, Rodrigo de Triana, a sailor aboard the "Niña," announced the appearance of what proved to be the New World. The land sighted was an island, called by the Indians Guanahani, and named by Columbus San Salvador. It is generally identified with Watling island. The same morning Columbus landed, richly clad, and bearing the royal banner of Spain. He was accompanied by the brothers Pinzon, bearing banners of the Green Cross (a device of the admiral's), and by a great part of the crew. When they all had "given thanks to God, kneeling upon the shore, and kissed the ground with tears of joy, for the great mercy received," the admiral named the island, and took solemn possession of it for their Catholic majesties of Castile and Leon. At the same time such of the crews as had shown themselves doubtful and mutinous sought his pardon weeping, and prostrated themselves at his feet.

This voyage resulted in the discovery of the islands of Santa Maria de la Concepcion (Rum Cay), Fernandina (Lond island), Isabella (Crooked island), Cuba or *Juana* (named by Columbus in honour of the young prince of Spain), and Hispaniola, Haiti, or San Domingo. Off the last of these the "Santa Maria" went aground, owing to the carelessness of the steersman. No lives were lost, but the ship had to be unloaded and abandoned; and Columbus, who was anxious to return to Europe with the news of his achievement, resolved to plan a colony on the island, to build a fort out of the material of the stranded hulk, and to leave the crew. The fort was called La Navidad; 44 Europeans were placed in charge. On Jan. 4, 1493 Columbus, who had lost sight of Martin Pinzon, set sail alone in the "Niña" for the east; and two days afterwards the "Pinta" joined her sister-ship. A storm separated the vessels, and Columbus did not reach the island of Santa Maria in the Azores until Feb. 18. Here he was threatened with capture by the Portuguese governor, who could not for some time be brought to recognize his commission. On Feb. 24, however, he was allowed to proceed, and on March 4 the "Niña" dropped anchor off Lisbon. The king of Portugal received the admiral with the highest honours. On March 13 the "Niña" put out from the Tagus, and two days afterwards, Friday, the 15th, she reached Palos.

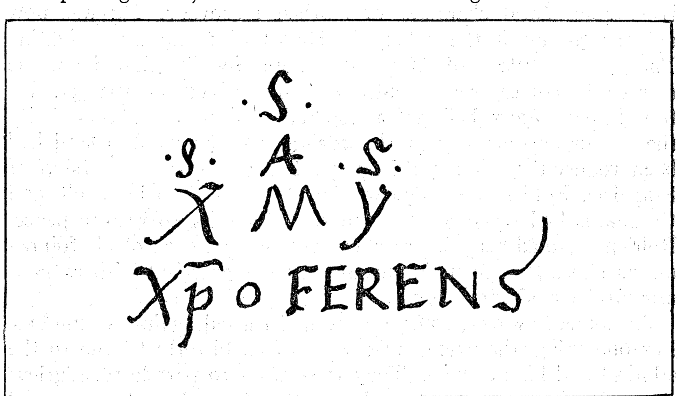
The court was at Barcelona; and thither Columbus proceeded. He entered the city in a sort of triumphal procession, was received by their majesties in full court, and, seated in their presence, related the story of his wanderings, exhibiting the "rich and strange" spoils of the new-found lands,—the gold, the cotton, the parrots, the curious arms, the mysterious plants, the unknown birds and beasts, and the Indians he had brought with him for baptism. All his honours and privileges were confirmed to him; the title of Don was conferred on himself and his brothers; he rode at the king's bridle; he was served and saluted as a grandee of Spain. A new and magnificent scutcheon was also blazoned for him (May 4, 1493), whereon the royal castle and lion of Castile and Leon were combined with the five anchors of his own coat of arms. On May 3–4, Alexander VI. granted bulls confirming to the crowns of Castile and Leon all the lands discovered, or to be discovered, west of a line of demarcation drawn 100 leagues west of the Azores, on the same terms as those on which the Portuguese held their colonies along the African coast. A new expedition was got ready to secure and extend the discoveries already made.

Second Voyage.—After several delays the fleet weighed anchor on Sept. 24, 1493. It consisted of three great carracks (galleons) and 14 caravels (light frigates), having on board over 1,500 men, besides the animals and materials necessary for colonization. Twelve missionaries accompanied the expedition, under the orders of Bernardo Buil or Boil, a Benedictine; Columbus had already been directed (May 29, 1493), to endeavour to Christianize the inhabitants of the islands, to make them presents, and to "honour them much," while all under him were commanded to treat them "well and lovingly," under pain of severe punishment. On Oct. 13, the ships, which had put in at the Canaries, left Ferro; and on Sunday, Nov. 3, after a single storm, an island was sighted to the west, which was named Dominica. Northwards from this the isles of Marigalante and Guadalupe were next discovered and named; while on the north-western course to La Navidad those of Montserrat, Antigua, San Martin, Santa Cruz and the Virgin Islands were sighted, and the island now called Porto Rico was touched at, hurriedly explored, and named San Juan Bautista. On Nov. 22, Columbus came in sight of Hispaniola, and sailing westward to La Navidad, found the fort burned and the colony dispersed. He decided on building a second fort, and coasting on 30 m. east of Monte Cristi, he pitched on a spot where he founded the city of Isabella.

COLONIZATION

The climate proved unhealthy; the colonists were greedy of gold, ignorant and mutinous; and Columbus, whose inclination drew him westward, was doubtless glad to escape the worry and anxiety of his post, and to avail himself of the instructions of his sovereigns as to further discoveries. On Feb. 2, 1494 he sent home, by Antonio de Torres, that despatch to their Catholic highnesses by which he may be said to have founded the West Indian slave trade. He established the mining camp of San Tomaso in the gold country of central Hispaniola; and on April 24, 1494, having nominated a council of regency under his brother Diego, and appointed Pedro Margarit his captain-general, he again put to sea. After following the southern shore of Cuba for some days, he steered southwards, and discovered (May 14) the island of Jamaica, which he named Santiago. He then resumed his exploration of the Cuban coast, threaded his way through a labyrinth of islets which he named the Garden of the Queen (Jardin de la Reyna), and, after coasting westwards for many days, became convinced that he had discovered continental land. He therefore caused Perez de Luna, the notary, to draw up a document to this effect (June 12, 1494), which was afterwards taken round and signed (the admiral's steward witnessing) by the officers, men and boys of his three caravels, the "Niña," the "Cordera," and the "San Juan." He then stood to the south-east, and sighted the island of Evangelista (now Isla de los Pinos), revisited Jamaica, coasted the south of Hispaniola, and on Sept. 24, touched at and named the island of La Mona, in the channel between Hispaniola and Porto Rico. Thence he had intended to sail eastwards and complete the survey of the Caribbean Archipelago; but he was exhausted by the terrible tear and wear of mind and body he had undergone (he says himself that on this expedition he was 33 days almost without sleep), and on the day following his departure from La Mona he fell into a lethargy that deprived him of sense and memory, and had well-nigh proved fatal to life. At last, on Sept. 29, the little fleet dropped anchor off Isabella, and in his new city the admiral lay sick for five months.

The colony was in a sad plight. Every one was discontented, and many were sick, for the climate was unhealthy and there was nothing to eat. Margarit and Boil had deserted the settlement and fled to Spain, but ere his departure the former, in his capacity of captain-general, had done much to outrage and alienate the



COLUMBUS CIPHER. THE INTERPRETATION OF THE SEVEN-LETTERED CIPHER, ACCEPTING THE SMALLER LETTERS OF THE SECOND LINE AS THE FINAL ONES OF THE WORDS, SEEMS TO BE SALVE CHRISTUS, MARIA, YOSEPHUS. THE NAME CHRISTOPHER (CHRISTOFERENS) APPEARS IN THE LAST LINE

Indians. The strongest measures were necessary to undo this mischief, and, backed by his brother Bartholomew, Columbus proceeded to reduce the natives under Spanish sway. Alonso de Ojeda succeeded by a brilliant *coup de main* in capturing the cacique Caonabo, and the rest submitted. Five ship-loads of Indians were sent off to Seville (June 24, 1495) to be sold as slaves; and a tribute was imposed upon their fellows, which must be looked upon as the origin of that system of *repartimientos* or *encomiendas* which was afterwards to work such mischief among the conquered. In Oct. 1495 Juan Aguado arrived at Isabella, with a royal commission to report on the state of the colony; here he took up the position of a judge of Columbus's government; and much recrimination followed. Columbus decided to return home; he appointed his brother Bartholomew *adelantado* of the island; and on March 10, 1496 he quitted Hispaniola in the "Niña." The vessel, after a protracted and perilous voyage, reached Cadiz on June 11, 1496, where the admiral landed, wearing the habit of a Franciscan. He was cordially received by his sovereigns, and a new fleet of eight vessels was put at his disposal. By royal patent, moreover, a tract of land in Hispaniola, of 50 leagues by 20, was offered to him, with the title of duke or marquis (which he declined); for three years he was to receive an eighth of the gross and a tenth of the net profits on each voyage; the right of creating a *mayorazgo* or perpetual entail of titles and estates was granted him; and his two sons were received into Isabella's service as pages.

DISCOVERY OF SOUTH AMERICA

Third Voyage.—Meanwhile, however, the preparing of the fleet proceeded slowly, and it was not till May 30, 1498 that he set sail with his main fleet of six ships—two caravels had already been sent on ahead. From San Lucar he steered for Porto Santo, Madeira, and Gomera, despatching three vessels direct from the Canaries to Hispaniola. He next proceeded to the Cape Verde islands, which he quitted on July 5. On the 31st of the same month, being greatly in need of water, and fearing that no land lay westwards as he had hoped, Columbus had turned his ship's head north, when Alonzo Perez of Huelva saw land about 15 leagues to the south-west. It was crowned with three hill-tops, from which circumstance, and in fulfilment of a vow made at starting (to name the first land discovered on this voyage in honour of the Trinity), the admiral named it Trinidad, which name it yet bears. On Wednesday, Aug. 1, he beheld for the first time the mainland of South America, the continent he had sought so long. It seemed to him but an insignificant island, and he called it Isla Santa. Sailing westwards, next day he saw the Gulf of Paria (named by him the Golfo de la Ballena), into which he was borne at immense risk on the ridge of waters formed by the meeting of the sea and the Orinoco estuaries. For several days he coasted the continent, esteeming as islands the various projections he saw, and naming them accordingly, nor was it until he had realized the volume poured out by the Orinoco that he began to perceive the truly continental character of his last discovery. He was now anxious to revisit the colony in Hispaniola; and after sighting Tobago, Grenada, and Margarita, made for San Domingo, the new capital of the settlement, where he arrived on Aug. 31. He found that affairs had not prospered well in his absence. By the vigour and activity of the *adelantado,* the whole island had been reduced under Spanish sway; but under the leadership of Francisco Roldan the malcontent settlers had risen in revolt, and Columbus had to compromise matters in order to restore peace. Roldan retained his office of chief justice; and such of his followers as chose to remain in the island were gratified with *repartimientos* of land and labour.

At home, however, court favour had turned against Columbus. For one thing, the ex-colonists were often bitterly hostile to the admiral and his brothers. They were wont to parade their grievances in the very court-yards of the Alhambra, to surround the king when he came forth with complaints and reclamations, to insult the discoverer's young sons with shouts and jeers. Again, the queen began to criticize severely the shipment of Indians from the new-found lands to Spain. And once more, there was no doubt that the colony itself, whatever the cause, had not prospered so well as might have been desired. Ferdinand's support of Columbus had never been very hearty, and his inclination to supersede the Genoese now prevailed over the queen's friendliness. Accordingly, on May 21, 1499, Francisco Bobadilla was appointed governor and judge of Hispaniola during royal pleasure, with authority to examine into all complaints. Columbus was ordered to deliver up his charge to Bobadilla, and to accept whatever the latter should deliver him from the sovereigns. Bobadilla left Spain in June 1500, and landed in Hispaniola on Aug. 23.

Columbus, meanwhile, had restored such tranquillity as was possible in his Government. With Roldan's help he had beaten off an attempt on the island of the adventurer Ojeda, his old lieutenant; the Indians were being collected into villages and Christianized. Gold-mining was profitably pursued; in three years, he calculated, the royal revenues might be raised to an average of 60,000,000 reals. The arrival of Bobadilla, however, speedily changed this state of affairs. On landing, he took possession of the admiral's house and summoned him and his brothers before him. Accusations of severity, of injustice, of venality even, were poured down on their heads, and Columbus anticipated nothing less than a shameful death. Bobadilla put all three in irons, and shipped them off to Spain. Alonso Vallejo, captain of the caravel in which the illustrious prisoners sailed, still retained a proper sense of the honour and respect due to Columbus, and would have removed the fetters; but to this Columbus would not consent. He would wear them, he said, until their highnesses, by whose order they had been affixed, should order their removal; and he would keep them afterwards "as relics and as memorials of the reward of his service." He did so. His son Fernando "saw them always hanging in his cabinet, and he requested that when he died they might be buried with him." Whether this last wish was complied with is not known.

A heart-broken and indignant letter from Columbus to Doña Juana de Torres, formerly nurse of the infante Don Juan, arrived at court before the despatch of Bobadilla. It was read to the queen, and its tidings were confirmed by communications from Alonso Vallejo and the alcaide of Cadiz. There was a great movement of indignation; the tide of popular and royal feeling turned once more in the admiral's favour. He received a large sum to defray his expenses; and when he appeared at court, on Dec. 17, 1500, he was no longer in irons and disgrace, but richly apparelled and surrounded with friends. He was received with all honour and distinction. The queen is said to have been moved to tears by the narration of his story. Their majesties not only repudiated Bobadilla's proceedings, but declined to inquire into the charges that he at the same time brought against his prisoners, and promised Columbus compensation for his losses and satisfaction for his wrongs. A new governor, Nicolas de Ovando, was appointed, and left San Lucar on Feb. 13, 1502, with a fleet of 30 ships, to supersede Bobadilla. The latter was to be impeached and sent home; the admiral's property was to be restored; and a fresh start was to be made in the conduct of colonial affairs. Thus ended Columbus's history as viceroy and governor of the new Indies which he had presented to the country of his adoption.

HIS LAST ADVENTURE

The Fourth Voyage.—His hour of rest, however, was not yet come. Ever anxious to serve their Catholic highnesses, "and particularly the queen," he had determined to find a strait through which he might penetrate westwards into Portuguese Asia. After the usual inevitable delays his prayers were granted, and on May 9, 1502, with four caravels and 150 men, he weighed anchor from Cadiz, and sailed on his fourth and last great voyage. He first betook himself to the relief of the Portuguese fort of Arzilla, which had been besieged by the Moors, but the siege had been raised before he arrived. He put to sea westwards once more, and on June 15 discovered the island of Martinino (probably St. Lucia). He had received positive instructions from his sovereigns on no account to touch at Hispaniola; but his largest caravel was greatly in need of repairs, and he had no choice but to abandon her or disobey orders. He preferred the latter alternative, and sent a boat ashore to Ovando, asking for a new ship and for permission to enter the harbour to weather a hurricane which he saw was coming on. But his requests were refused, and he coasted the island, casting anchor under lee of the land. Here he weathered the storm, which drove the other caravels out to sea, and annihilated the homeward-bound fleet, the richest that had till then been sent from Hispaniola. Roldan Bobadilla perished with others of the admiral's enemies; and Fernando Columbus, who accompanied his father on this voyage, wrote long afterwards, "I am satisfied it was the hand of God, for had they arrived in Spain they would have never been punished as their crimes deserved, but rather been favoured and preferred."

After recruiting his flotilla at Azua, Columbus put in at Jaquimo and refitted his four vessels; and on July 14, 1502 he steered for Jamaica. For several days the ships wandered painfully among the keys and shoals he had named the Garden of the Queen, and only an opportune easterly wind prevented the crews from open mutiny. The first land sighted (July 30) was the islet of Guanaja, about 40 m. east of the coast of Honduras. Here he got news from an old Indian of a rich and vast country lying to the eastward, which he at once concluded must be the long-sought-for empire of the grand khan. Steering along the coast of Honduras, great hardships were endured, but nothing approaching his ideal was discovered. On Sept. 12 Cape Gracias-a-Dios was rounded. The men had become clamorous and insubordinate; not until Dec. 5, however, would he tack about and retrace his course. It now became his intention to plant a colony on the river Veragua, which was afterwards to give his descendants a title of nobility; but he had hardly put about when he was caught in a storm, which lasted eight days, wrenched and strained his crazy, worm-eaten ships, severely, and finally, on Epiphany Sunday 1503, blew him into an embouchure which he named Belem or Bethlehem. Gold was very plentiful in this place, and here he determined to found his settlement. By the end of March 1503 a number of huts had been run up, and in these the *adelantado* (Bartholomew Columbus), with 80 men, was to remain, while Christopher returned to Spain for men and supplies. Quarrels, however, arose with the natives; the cacique was made prisoner, but escaped again; and before Columbus could leave the coast he had to abandon a caravel, to take the settlers on board, and to relinquish the enterprise of colonization. Steering eastwards, he left a second caravel at Puerto Bello; he thence bore northwards for Cuba, where he obtained supplies from the natives. From Cuba he bore up for Jamaica, and there, in the harbour of San Gloria, now St. Ann's bay, he ran his ships aground in a small inlet still called Don Christopher's cove (June 23, 1503).

The expedition was received with great kindness by the natives, and here Columbus remained upwards of a year, awaiting the return of his lieutenant Diego Mendez, whom he had despatched to Ovando for assistance. During his critical sojourn here, the admiral suffered much from disease and from the lawlessness of his followers, whose misconduct had alienated the natives, and provoked them to withhold their accustomed supplies, until he dexterously worked upon their superstitions by prognosticating an eclipse. Two vessels having at last arrived for his relief, Columbus left Jamaica on June 28, 1504, and, after calling at Hispaniola, set sail for Spain on Sept. 12. After a tempestuous voyage he landed once more at San Lucar on Nov. 7, 1504. As he was too ill to go to court, his son Diego was sent thither in his place, to look after his interests and transact his business. Letter after letter followed the young man from Seville—one by the hands of Amerigo Vespucci. A licence to ride on mule-back was granted him on Feb. 23, 1505; and in the following May he was removed to the court at Segovia, and thence again to Valladolid. On the landing of Philip and Juana at Coruña (April 25, 1506), although "much oppressed with the gout and troubled to see himself put by his rights," he is known to have sent off the *adelantado* to pay them his duty and to assure them that he was yet able to do them extraordinary service. The last documentary note of him is contained in a final codicil to the will of 1498, made at Valladolid on May 19, 1506. By this the old will is confirmed; the *mayorazgo* is bequeathed to his son Diego and his heirs male, failing these to Fernando, his second son, and failing these to the heirs male of Bartholomew; only in case of the extinction of the male line, direct or collateral, is it to descend to the females of the family; and those into whose hands it may fall are never to diminish it, but always to increase and ennoble it by all means possible. The head of the house is to sign himself "The Admiral." A tenth of the annual income is to be set aside yearly for distribution among the poor relations of the house. A chapel is founded and endowed for the saying of masses. Beatriz Enriquez is left to the care of the young admiral. Among other legacies is one of "half a mark of silver to a Jew who used to live at the gate of the Jewry, in Lisbon." The codicil was written and signed with the admiral's own hand. Next day (May 20, 1506) he died.

After the funeral ceremonies at Valladolid, Columbus's remains were transferred to the Carthusian monastery of Santa Maria de las Cuevas, Seville, where the bones of his son Diego, the second admiral, were also laid. Exhumed in 1542, the bodies of both father and son were taken over sea to Hispaniola and interred in the cathedral of San Domingo. In 1795–96, on the cession of that island to the French, the relics were re-exhumed and transferred to the cathedral of Havana, whence, after the Spanish-American War of 1898 and the loss of Cuba, they were finally removed to Seville cathedral, where they remain. The present heir and representative of Columbus belongs to the Larreategui family, descendants of the discoverer through the female line, and retains the titles of admiral and duke of Veragua.

In person Columbus was tall and shapely. The only authentic portrait of him is that which once belonged to Paulus Jovius, and is still in the possession of the de Orchi family (related to Jovius by female descent) at Como. It shows us a venerable man with clean-shaven face, thin grey hair, high forehead, sad thoughtful eyes. It bears the inscription *Columbus Lygur. novi orbis repertor.*

COLUMBUS, a city of Georgia, U.S.A., 100m. S.S.W. of Atlanta, at the head of navigation on the Chattahoochee river; the county seat of Muscogee county. It is on Federal highway 80, and is served by the Central of Georgia, the Seaboard Air Line, and the Southern railways, and by river steamers to Apalachicola, on the Gulf of Mexico. The population was 31,125 in 1920 (29·2% negroes), and was 53,280 federal census in 1940. Including suburbs, there were over 65,000 persons living within 3m. of the county court house. Phoenix City and Girard (Ala.) lie just across the river, which is spanned by two concrete highway bridges. Columbus is one of the leading industrial centres of the South, with 100 plants making 200 different articles. Most of them are operated by electricity, generated from the falls of the river, which drops 362ft. in 34m. just above the city. The cotton mills have over 555,000 spindles. Other leading manufactures are brick, tile, concrete pipe, fertilizer, ice-making and refrigerating machinery, cotton gins, textile machinery, agricultural implements, cane mills, engines, boilers, shafting and pulleys, log skidders, doors, bank and office furniture and other lumber products. The output of the factories within the city in 1939 was valued at $60,000,000, and there are many plants just outside the corporate limits. The assessed valuation of property for 1940 was $39,569,005. Columbus has a large export trade in cotton, and is the shipping point also for the pecans, peanuts, dairy products, live stock and diversified crops grown in the vicinity.

Columbus was founded in 1828 by the State of Georgia, as an outpost on the border of the Indian lands and as a vantage point from which to utilize the water-power and the transportation facilities of the river. It was laid out by the State engineers, with avenues and streets 99–164ft. wide and ample reservations for public squares and buildings. The cotton-gin industry was established in 1832; the textile industry in 1837. This was the point of embarkation for troops from the south-east during the Mexican War. During the Civil War the city ranked next to Richmond in the manufacture of supplies for the Confederate Army. On April 16, 1865, after Lee had surrendered, it was captured by a Union force under Gen. James Harrison Wilson. Hydro-electric development was begun about 1900. The first cotton-mill worked by electricity was in Columbus, and it was here artificial ice was made on a commercial scale. Columbus was also the first city in the South to establish municipal graded schools, and the first in the country to provide industrial training as part of its public-school system. In 1922 it adopted a commission-manager form of government. Muscogee county also is governed by commission.

At Ft. Benning, 8m. S. of Columbus, is the infantry school of the U.S. Army. The reservation, selected partly for its variety of terrain, consists of 97,000 ac. along the river, and the personnel numbers about 35,000.

COLUMBUS, a city of Indiana, U.S.A., on the east fork of the White river, 41m. S.E. of Indianapolis; the county seat of Bartholomew county. It is on Federal highway 31, and is served by the Big Four and the Pennsylvania railways. The population in 1930 was 9,935; in 1940 it was 11,738. The city is surrounded by a fine farming region. Its manufactures include leather, textiles, lumber, handles, iron castings, transmission, metal furniture, radios, auto parts, meat packing and diesel engines.

COLUMBUS, a city of northeastern Mississippi, U.S.A., on the Tombigbee river, near the Alabama state line; the county seat of Lowndes county. It is on federal highways 45 and 82, and is served by the Columbus and Greenville, the Mobile and Ohio, the Southern and the Frisco railways. The population in 1930 was 10,743, and was 13,645 (51·2% Negroes) in 1940 by the federal census. The city ships cotton, hay, cattle and hardwood lumber; has a large floral industry; and the output of its cotton and lumber mills, veneer and brick plants, marble works and other manufacturing industries was valued in 1939 at $3,330,000. The dairy industry is developing rapidly; three large cheese factories began operations in the county early in 1928. The Mississippi State college for women (enrolment, 1,140 in 1941) was established there in 1884.

At Starkville, 25 mi. W., is the Mississippi state college.

De Soto in 1540 crossed the Tombigbee river near the site of Columbus. The land was ceded to the United States by the Choctaw Indians in 1816, and the first log cabin was built in 1817. In 1821 the city was incorporated, and Franklin academy, the first free public school in the state, was established. During the Civil War the Confederate government maintained a large arsenal there, and in 1864 the city was for a short time the capital of the state. After the battle of Shiloh it was a hospital centre. About 1,500 soldiers were buried in Friendship cemetery, where on the first "decoration day" (April 25, 1866) the women of Columbus inaugurated the custom of placing flowers on northern and southern graves alike.

COLUMBUS, a city of eastern Nebraska, U.S.A., on the Loup river, just above its junction with the Platte, 87 mi. W. of Omaha; the county seat of Platte county. It is at the intersection of the Lincoln and the Meridian transcontinental highways, and is served by the Union Pacific and the Burlington railways. The population in 1930 was 6,898; in 1940 it was 7,632 by the federal census. It is the centre of a fertile farming region that raises corn, wheat, alfalfa, hogs, cattle and poultry, and has several factories. The city was founded about 1857.

COLUMBUS, the capital of Ohio, U.S.A., near the centre of the state, at the confluence of the Scioto and the Olentangy rivers; a port of entry and the county seat of Franklin county. It is on federal highways 23, 33, 40 and 62; has three airports; and is served by the Baltimore and Ohio, the Chesapeake and Ohio, the New York Central, the Norfolk and Western and the Pennsylvania railways and by two transcontinental air lines, American Airlines and Transcontinental & Western Air. The area is 39·5 sq.mi. The population in 1940 was 306,087. The city lies on a level plain. The state house, constructed between 1839 and 1859 at a cost of $1,400,000, is a dignified building in Doric style (304 by 184 ft., with a rotunda 158 ft. high) of gray limestone from a local quarry, set in a square of ten acres. On the Scioto river, near the capitol, a civic centre development includes these structures: city hall, American Insurance Union Citadel (the city's tallest skyscraper, 555·5 ft.), City Safety building, U.S. post office and court house, Ohio departments of state building, Central high school and Columbus auditorium. The centre flanks a graceful bend of the Scioto for a distance of three city blocks. A planning commission was created in 1920, and zoning ordinances are in force. The water supply is obtained from the Scioto river by means of the Griggs dam (1904–05) and the O'Shaughnessy dam (1922–24), impounding respectively 1,500,000,000 and 5,000,000,000 gallons. Both dams are in parklands of great beauty owned by the city. Filtering and softening plants and a municipal electric-light plant were completed in 1908. Natural gas is available from the fields of eastern Ohio. The city has 81 public and 24 parochial schools; libraries aggregating 1,500,000 volumes to which the public has access; 540 mi. of paved streets; 806 mi. of sewers; 11 hospitals; three municipal markets; and 1,200 ac. in public parks. The state fairgrounds of 150 ac. are just 2½ mi. from the centre of the city. Columbus is the seat of the Ohio State university, of Capital university (1850) including the Evangelical Lutheran theological seminary, of the state penitentiary and of state institutions for the insane, the feeble-minded, the blind and the deaf. There are three daily papers, including the *Ohio State Journal* (estab. 1811), which is widely known throughout the country. The private philanthropic agencies of the city are financed jointly through a "community fund," with an annual budget of over $600,000. Columbus is the home of Battelle Memorial institute, one of the world's largest research agencies, and several other organizations conducting research in metallurgy, fuels, ceramics, business and agriculture. The city's assessed valuation of property in 1940 was $369,637,850.

Ohio State university occupies a beautiful campus 3 mi. N. of the state house. Its campus and farm cover 1,400 ac., and the total value of its plant is more than $25,000,000. Its magnificent stadium (opened in 1922), in a 92 ac. tract on the bank of the Olentangy, covers 10 ac. and has 72,000 seats. Within the city limits is Ft. Hayes (formerly Columbus barracks), which in 1922 became headquarters of the 5th corps area of the U.S. army. In East Columbus, on a reservation of 281 ac., is one of the three general reserve depots of the army.

Columbus has a large trade in coal from the Ohio fields in the neighbourhood, and in wool, livestock, grain and other agricultural products. Its jobbing market serves a territory in which there are 30,000 dealers and 1,622,000 consumers. The manufacturing industries are important and diversified, with an aggregate output in 1937 valued at $169,717,720. Among the leading manufactures are iron and steel products (notably mining machinery and steel railway cars), shoes, glass, teeth, flour, cereal products, caskets, aeroplanes, fire fighting equipment, coated fabrics and agricultural implements. There are several meat-packing plants.

Postal receipts in 1940 amounted to $3,998,284; bank debits to individual accounts in 1940 were $2,164,073,254.

This region was opened to settlement in 1787. In 1797 the first log cabin within the present limits of Columbus was built at Franklinton, on the west bank of the Scioto, which became the county seat when Franklin county was organized in 1803. Through the enterprise of four citizens who offered the general assembly land for a state house and a penitentiary on the higher ground east of the Scioto, that site was chosen for the seat of government, and in 1812 a town was there laid out on the "refugee lands" appropriated by congress for Canadians and Nova Scotians who had sympathized with the colonies in the recent struggle. It was named after Christopher Columbus, because "to him we are primarily indebted in being able to offer the refugees a resting place." The first state house, a plain two-story brick building, was completed in 1814. The borough of Columbus was incorporated in 1816; it became the county seat in 1824; and in 1834, when the population was 3,500, it was incorporated as a city. In 1860 the population was 18,554; in 1880, 51,647; in 1900, 125,560. Franklinton was annexed in 1871, and the area was increased by successive additions of territory in every decade thereafter. The present charter (Jan. 1, 1916) provides for a mayor as executive, a legislative council of seven elected at large, a nonpartisan ballot, the recall of elected officials and the referendum. In the flood of 1913 about 100 lives were lost in Columbus, three bridges were destroyed, more than 4,000 dwellings were flooded and some 20,000 persons were temporarily homeless. As a protection against future floods the channel of the Scioto has been widened and revetments have been built.

COLUMELLA, LUCIUS IUNIUS MODERATUS, of Gades, writer on agriculture, contemporary of Seneca the philosopher, flourished about the middle of the 1st century A.D. His extant works treat of the cultivation of all kinds of corn and garden vegetables, trees, flowers, the vine, the olive and other fruits, and of the rearing of cattle, birds, fishes and bees. They consist of the twelve books of the *De re rustica* (the tenth, which treats of gardening, being in dactylic hexameters in imitation of Virgil), and of a book *De arboribus,* the second book of an earlier and less elaborate work on the same subject.

Bibliography.—The best complete edition is by J. G. Schneider (1794). Of a new edition by K. J. Lundström, the tenth book appeared in 1902 and *De arboribus* in 1897. The tenth book was edited in 1920 by J. P. Postgate in the *Corp. Poet. Lat.* There are English translations by R. Bradley (1725), and anonymous (1745); and treatises, *De*

HISTORICAL DEVELOPMENT OF THE COLUMN FROM ITS ORIGIN IN ANCIENT EGYPT TO MODERN TIMES

Columellae vita et scriptis, by V. Barberet (1887), and G. R. Becher (1897), a compact dissertation with notes and references to authorities. *See* also W. E. Heitland, *Agricola* (Cambridge, 1921).

COLUMN, in architecture, a vertical support, round or polygonal in plan, in contradistinction to a pier (*q.v.*), usually rectangular in plan. Occasionally the word is used for any vertical support. The earliest columns were undoubtedly simple tree trunks; large wooden columns, tapered, with the small end down, were a characteristic feature of the Aegean architecture (*see* WESTERN ASIATIC ARCHITECTURE: § *Knossos,* vol. 23, p. 526), as in the palace at Knossos (*c.* 1500 B.C.); contemporary frescoes show that such columns were common and were used, not only structurally but as cult objects (the Lion Gate at Mycenae, *c.* 1200 B.C., shows two lions flanking such a column). The Hittites, the Assyrians and the Egyptians in their smaller works also used wooden columns for which many stone bases exist. In modern times wooden columns play an important part in the monumental architecture of China and Japan, when they are usually covered with brilliantly coloured lacquer. Stone bases are almost universally used with wooden columns in order to preserve the wood from damp. Those of Assyria and the Hittites are richly decorated. Stone capitals are also sometimes found.

Stone columns furnish the greatest architectural opportunities, however, and they have been favourite architectural motives in many styles. Primitive types of stone columns, probably derived by cutting the corners off square, rock-cut piers, a form which may have resulted in the invention of the flute (*q.v.*), are to be found in the polygonal shafts of the temple at Deir-el-Bahri, and the tombs of Beni Hassan, in Egypt, both from the third millennium B.C. The Greeks evidently developed their columns from two sources; one a modification of Aegean prototypes, which, changing material from wood to stone, reversed the direction of the taper so that the smaller end was up in a growth which gave rise to the Doric order (*see* ORDER). The other a development from Asiatic sources, is more slender, and has a high, decorated base and a much enriched capital (*q.v.*). This development produced the Ionic and Corinthian orders. Almost all Greek columns are fluted.

Etruscan structural columns were largely wooden. The decorative representations remaining in stone tombs show types both Greek and Oriental. Under the Roman empire the Greek orders were much used and further developed, but owing to the fact that the shafts were frequently marble monoliths, fluting was often omitted. Renaissance columns generally follow classic precedent, but additional decoration, in the form of ornamental banding and heavy rustication, occasionally appears. The taper of all classic and Renaissance columns is produced with a curved profile known as the entasis (*q.v.*).

Although most columns thus far noted are monolithic, or built with drums (horizontal stones the entire width of the column, set one above the other), columns were often built of small stones or brick, and in the mediaeval period this type became almost universal. Small columns, however, remained monolithic. Mediaeval columns are generally without taper or entasis.

In Mohammedan countries columns follow either Byzantine or classic tradition, with, however, many changes in the capitals. But in India there is a separate and characteristic type of column design. Indian columns are extremely varied and complex, and much broken up horizontally and vertically by many small mouldings and sinkages, occasionally further enriched with fantastic sculpture. (*See* BASE, CAPITAL, ENTASIS, ORDER and the articles on Architectural History.) (T. F. H.)

COLUMNIST, one who is responsible for a stipulated amount of writing, humorous or semi-serious in character, on a daily newspaper. Originally this material was confined to the editorial page as a relief from its serious nature, but it now occurs in the sports section, if the writer's trend is in that direction, or on a page devoted to various types of feature writing. The columnist may do all his own writing or he may depend to a greater or less extent upon contributors, in which case he acts as editor of the column. In either case he maintains a running commentary on contemporary life. He attacks its shams and hypocrisies and especially the individuals who best epitomize them, and in so doing has a variety of tools at his disposal, including jokes, jingles, light verse, short editorials, paragraphs, anecdotes, humorous mottoes, reminiscences and short essays. He may be obviously humorous, subtly so, cynical or satirical or any combination of these, but the result must be entertaining; his own personality must always shine through and his personal bias be apparent. Since the success of the column depends upon the utter freedom of expression of the writer he escapes the ordinary editorial restrictions.

COLURE, in astronomy, either of the two principal meridians of the celestial sphere, one of which passes through the poles and the two solstices, the other through the poles and the two equinoxes; hence designated as *solstitial colure* and *equinoctial colure,* respectively. (From Gr. *κόλος,* shortened, and *οὐρά,* tail).

COLUTHUS or **COLLUTHUS,** of Lycopolis in the Egyptian Thebaid, Greek epic poet, flourished during the reign of Anastasius I. (491-518). According to Suidas, he was the author of *Calydoniaca* (probably an account of the Calydonian boar hunt), *Persica* (an account of the Persian wars), and *Encomia* (laudatory poems). These are all lost, but his poem in some 400 hexameters on *The Rape of Helen* was discovered by Cardinal Bessarion in Calabria. It is a poor imitation of Homer. It related the history of Paris and Helen from the wedding of Peleus and Thetis down to the elopement and arrival at Troy.

The best editions are by Van Lennep (1747), G. F. Schäfer (1825), E. Abel (1880).

COLVIN, JOHN RUSSELL (1807–1857), lieutenant-governor of the North-West Provinces of India during the mutiny of 1857, was born in Calcutta on May 29, 1807. Passing through Haileybury he entered the service of the East India Company in 1826. In 1836 he became private secretary to Lord Auckland, and his influence over the viceroy has been held partly responsible for the first Afghan war of 1837; but it has since been shown that Lord Auckland's policy was dictated by the secret committee of the company at home. In 1853 Colvin was appointed lieutenant-governor of the North-West Provinces by Lord Dalhousie. On the outbreak of the mutiny in 1857 he had with him at Agra only a weak British regiment and a native battery, too small a force to make head against the mutineers. A proclamation which he issued was censured at the time for its clemency, but it followed the same lines as those adopted by Sir Henry Lawrence and subsequently followed by Lord Canning. Exhausted by anxiety and misrepresentation he died on Sept. 9, just before the fall of Delhi.

His son, SIR AUCKLAND COLVIN (1838–1908), followed him in a distinguished career in the same service, from 1858 to 1879. He was comptroller-general in Egypt (1880–82), and financial adviser to the khedive (1883–87), and from 1883 till 1892 was back again in India, first as financial member of council, and then, from 1887, as lieutenant-governor of the North-West Provinces and Oudh. He was created K.C.M.G. in 1881 and K.C.S.I. in 1892, when he retired. He published *The Making of Modern Egypt* in 1906, and a biography of his father, in the "Rulers of India" series, in 1895. He died at Surbiton on March 24, 1908.

COLVIN, SIR SIDNEY (1845–1927), English literary and art critic, was born at Norwood, London, on June 18, 1845, and died on May 11, 1927. He was scholar and then fellow of Trinity college, Cambridge. In 1873 he was elected Slade professor of fine art at Cambridge; he was four times re-elected, and from 1876 to 1884 was director of the Fitzwilliam museum. From the date of his fellowship in 1868 onwards he had contributed many articles to the reviews and to the *Encyclopædia Britannica* on the fine arts. In 1873 he met Robert Louis Stevenson, and formed a friendship which endured until Stevenson's death. The story of this friendship is told in the *Vailima Letters,* which appeared under Colvin's editorship in 1890. Colvin also edited the Edinburgh edition of Stevenson's works and two further volumes of letters in 1895 and 1911. In 1884 he was appointed keeper of the prints and drawings in the British museum. In addition to the reorganization of the system, which made the rich collections of the museum more readily available to students and to the general public, he arranged for the acquisition of numerous precious collections before their value was generally realized. He was knighted on his retirement in 1921.

Among his works are: *Landor* (1881); *Keats* (1887); *Early History of Engraving in England* (1905); *Memories and Notes* (1921).

See E. V. Lucas, *The Colvins and Their Friends* (1928).

COLWYN BAY, municipal borough, Denbighshire, Wales, on the Irish sea, 40½ mi. W.N.W. of Chester by the L.M.S.R. Pop. (est. 1938) 21,240. Area, 9.6 sq.mi. The town grew rapidly after 1918, until it became virtually continuous with Old Colwyn and Rhos-on-Sea, with which it is linked by a promenade 3 mi. long. It is a seaside resort and a centre for excursions in north Wales. It was incorporated in 1934. Many local beauty spots are corporation property. To the southeast (2½ mi.) is Llanelian-yn-Rhos, famous for its "cursing well" (*Ffynnon Elian*). The name Colwyn is that of the lords of Ardudwy, the narrow tract of country between the mountains and the sea in west Merionethshire.

COLY, a small group of African birds about 12 in. long, with crested heads, finchlike bills, short, rounded wings and long tails. The six species are all included in the genus *Colius,* which constitutes the peculiar order Coliiformes and family Coliidae. They are somewhat related to trogons and swifts (*qq.v.*). They are often called mousebirds, probably from their habit of creeping along the boughs of trees with the whole tarsus applied to the branch. They generally have a dun or slate-coloured plumage that sometimes brightens into blue or is diversified with white or chestnut. All toes are ordinarily directed forward, and it is reported that they sleep hanging upside down. They feed almost wholly on the fruits, but occasionally take insects. All the species belong to the Ethiopian region. There are six species. The commonest is *C. striatus,* with some 16 races, ranging from Ethiopia to Capetown and west to northern Nigeria and the lower Congo; *C. macrourus* occurs in thornbrush and semiarid country from Senegal to Ethiopia, south to Tanganyika; *C. indicus* is found throughout South Africa; *C. colius,* in western South Africa; the other two species occur in Angola and Kenya. (G. F. Ss.)

COLZA OIL, a nondrying oil obtained from the seeds of *Brassica campestris,* var. *oleifera,* a variety of the plant which produces Swedish turnips. Colza is extensively cultivated in France, Belgium, the Netherlands and Germany; and, especially in the first-named country, the expression of the oil is an important industry. In commerce colza is classed with rape oil, to which both in source and properties it is very closely allied. It is a comparatively inodorous oil of a yellow colour, having a specific gravity varying from 0.912 to 0.920. The cake left after expression of the oil is a valuable feeding substance for cattle. Colza oil is extensively used as a lubricant for machinery and for burning in lamps.

COMA, in medicine, a complete and prolonged loss of consciousness from which a patient cannot be roused. There are various degrees: in the slighter forms the patient can be partially roused only to relapse again into a state of insensibility; in the deeper states, the patient cannot be roused at all. Coma may arise abruptly from: (1) concussion, compression or laceration of the brain from head injuries, especially fracture of the skull; (2) alcoholic and narcotic poisoning; (3) cerebral haemorrhage, embolism and thrombosis. It may also supervene in diabetes, uraemia, general paralysis, meningitis, sleeping and sleepy sickness, cerebral tumour and acute yellow atrophy of the liver. The depth of insensibility to stimulus is a measure of the gravity of the symptom; thus the conjunctival reflex and even the spinal reflexes may be abolished, the only sign of life being the respiration and heartbeat. A characteristic change in respiration known as Cheyne-Stokes breathing occurs prior to death in some cases. *Coma Vigil* is a state of unconsciousness met with in the algide stage of cholera and some other exhausting diseases. The patient's eyes remain open, and he may be in a state of low muttering delirium.

The word "coma" which is used in astronomy for the envelope of a comet and in botany for a tuft, though spelled the same in English, is derived from a different Greek word.

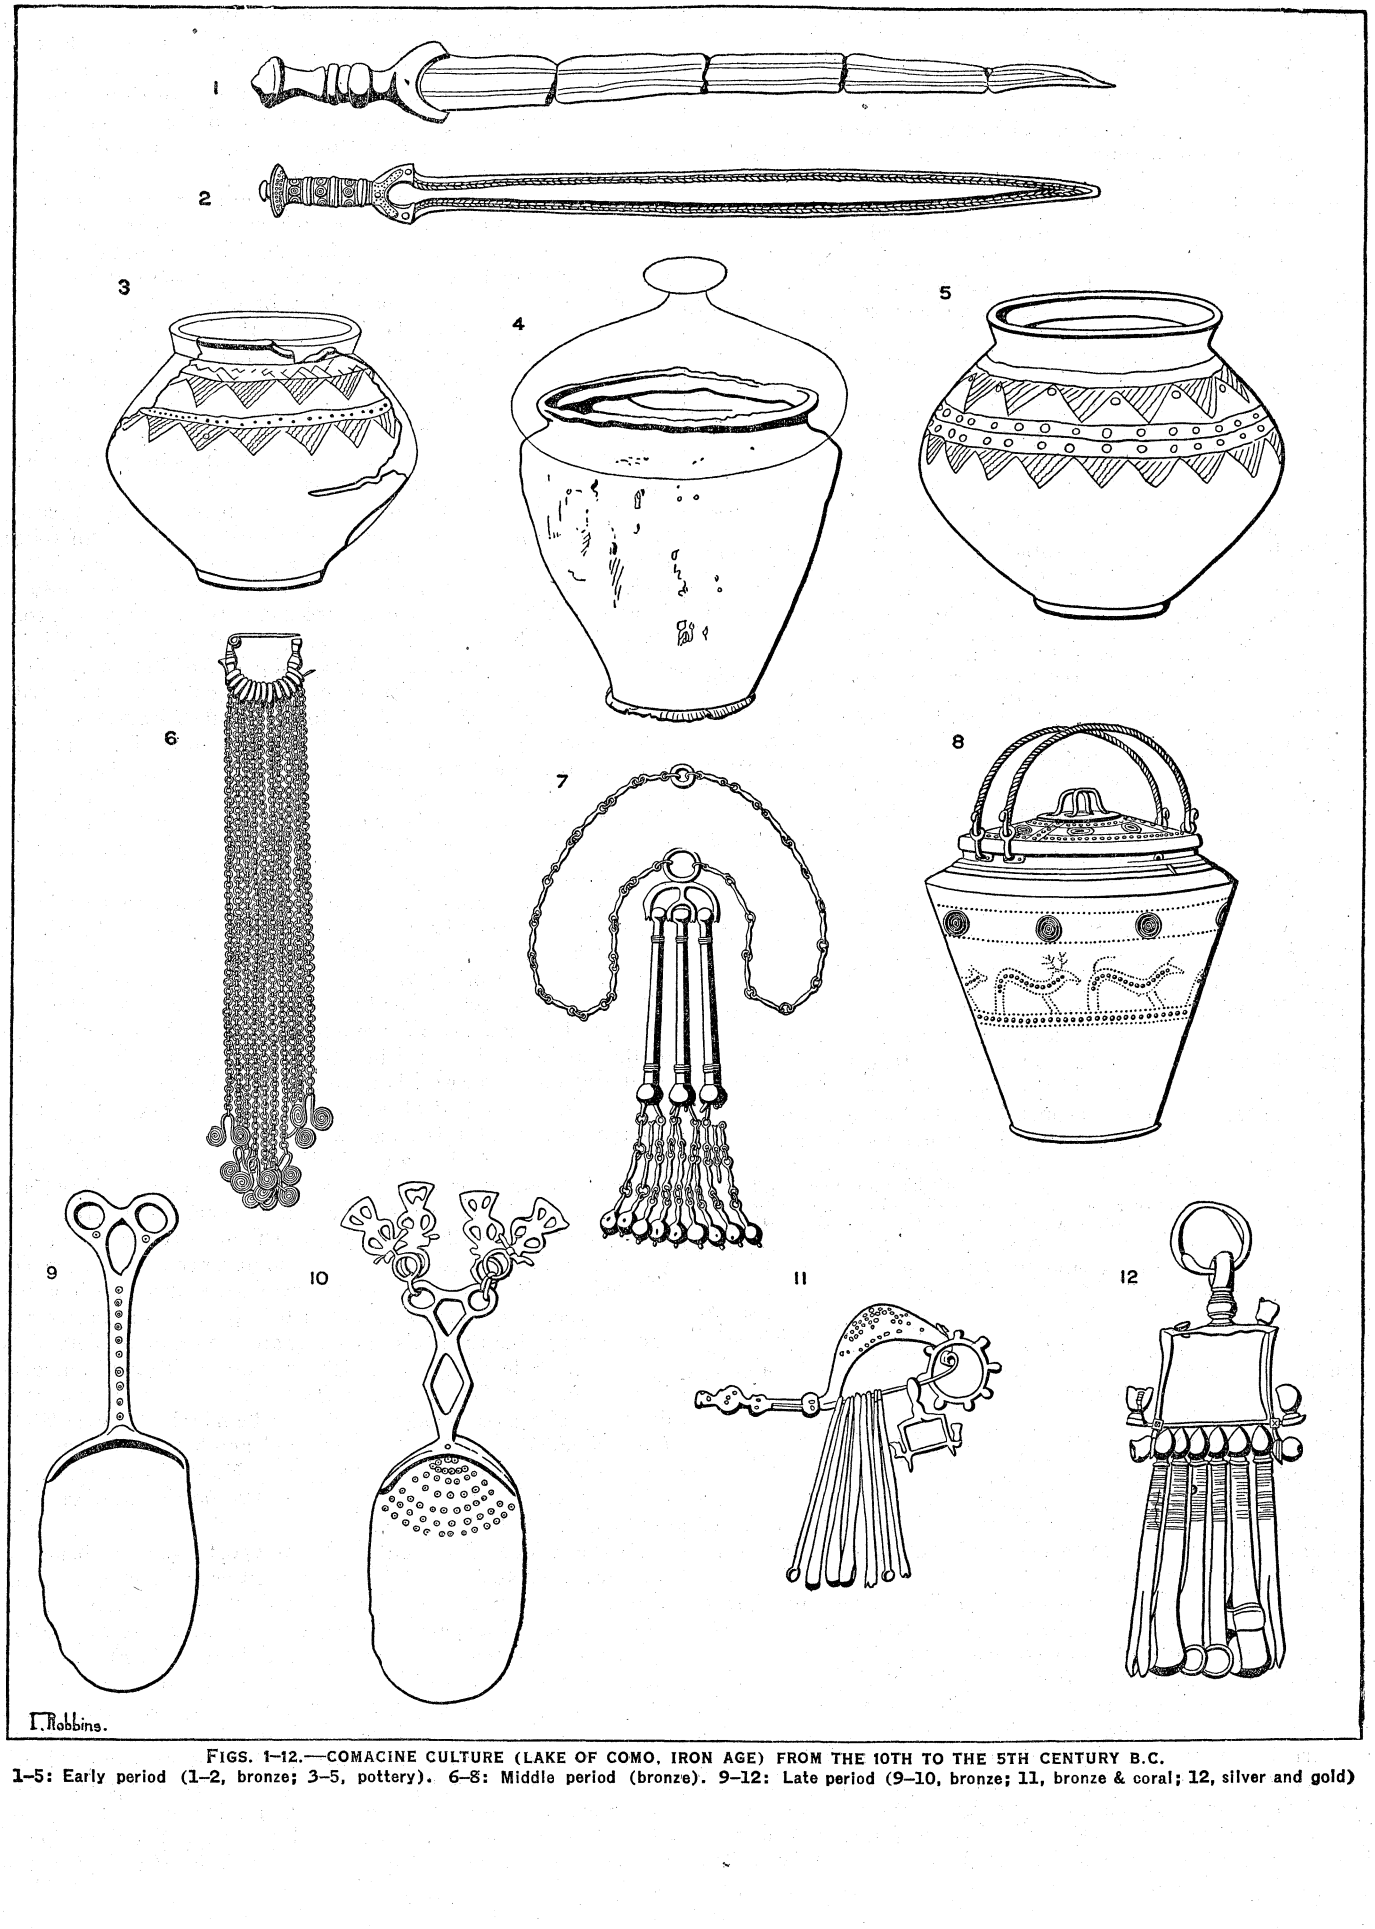
COMA BERENICES ("Berenice's hair"), in astronomy, a constellation of the northern hemisphere; it was first mentioned by Callimachus, and Eratosthenes (3rd century B.C.), but is not included in the 48 asterisms of Ptolemy.

COMACCHIO, a town of Emilia, Italy, province of Ferrara, 30 mi. E.S.E. by road from the town of Ferrara, on the level of the sea, in the centre of the lagoon of Valli di Comacchio, just north of the present mouth of the Reno. Population (1936) 9,141 (town); 13,894 (commune). It is built on 13 different islets, joined by bridges, and its industries are fisheries and saltworks. Comacchio appears as a city in the 6th century, a fortress owing to its central position in the centre of the lagoons. It was included in the "donation of Pippin"; it was taken by the Venetians in 854, but afterward came under the archbishops of Ravenna; in 1299 it came under the house of Este. In 1597 it was claimed by Clement VIII as a vacant fief. *See* also SPINA.

COMACINES, THE, may be defined as the people who lived in the Iron Age all round the Lake of Como, and on the adjoining lakes of Lugano and Varese. They are close relatives of the Golasecca tribes near Lago Maggiore but show some points of difference from them (*see* GOLASECCA). The records for the Como region begin much earlier than for the Somma plateau on the Ticino. At Malgesso near Varese, and at Albate, Moncucco, San Fermo and Villa Nessi, four sites clustered at the south end of the Lake of Como, have been found objects which, though few, yet demonstrate that there were settlements here at the very opening of the Iron Age, made by a branch of those cremating peoples who came over the Venetian Alps in successive waves between 1200 and 1000 B.C., and who must be judged on this evidence to have found their way into Lombardy as early as into any other region. Their march westward was probably by way of the Val di Sole and the Valtellina. They buried, like the Villanovans and all the other cremating invaders, in pottery jars, which contained the ashes of the deceased and a few small objects or personal ornaments. Weapons and larger objects might be placed adjoining the jar, which was often enclosed in a shelter of rough slabs as shown in fig. 13. The archaeology of the Iron Age in the region of Como and Varese falls into three well-defined periods. From the 12th century to about 750 B.C. is the Early period, contemporary with the two Benacci stages of Bologna. The Middle period is the correlative of the Arnoaldi period of Bologna, equivalent to the Golasecca civilization of 750 to 500 B.C.; and the Late period runs from 500 B.C. down to the Gaulish invasions of the 4th century. A fair amount of material representative of all this time has been discovered and chronicled by local archaeologists, whose records have been published for the last 50 years in the *Rivista archeologica della provincia di Como*. So far as the objects have been collected in any one place they may be seen in the municipal museum of the town of Como.

In the Early period, represented by the cemeteries of Moncucco, Villa Nessi and San Fermo, very archaic *fibulae* have been found which can hardly be later than the 12th century B.C., of types familiar in other parts of Italy at Pianello, Timmari and Bismantova. A certain number of the Comacines had thus arrived at their new homes simultaneously with the establishment of the earliest Villanovans in Etruria and Latium. The ossuary employed for burial was, however, not the Villanovan urn but a pottery *situla* or spherical *olla,* as seen in Nos. 3–5 of the plate. All the pottery of this stage is of the rough hand-made style seen in these examples, often incised with bands and chevrons formed by rows of dots. Apart from pottery, the most important objects of the Early period are the weapons, particularly the bronze swords. All belong to types which must have been imported from north of the Alps. There was one instance of the antennae-handled sword, well known as a transalpine product, which occurs on a number of different sites in north Italy as well as in Etruria. More remarkable than this, however, are the examples figured as Nos. 1 and 2 in the plate, which are not familiar elsewhere in Italy. No. 2, a famous sword from Bernate near Como, is a definitely Hungarian model, which may be matched by one lately found at Sondrio in the Valtellina and another from Serravalle near the Ticino. Another foreign type is No. 1, from Moncucco, closely resembling a sword found at Colico on the northern edge of the Lake of Como.

To the Middle Comacine period of 750 to 500 B.C. belong a few graves at Rebbio and Albate, as well as sporadic finds from sites nearer to the Po; but the principal material is derived from 40 graves at Valtravaglia, situated on Lago Maggiore though belonging by its affinities rather to the Varese district than to Golasecca. The pottery of Valtravaglia, exhibited in the museum of Como, has a misleading appearance, for it looks exceedingly primitive, being hand-made and incised with simple geometrical patterns. The ossuaries were of the *olla* shape with resemblance to Golasecca forms, as well as to those of Moncucco; *fibulae* were of unmistakable forms of the 7th and 6th centuries; weapons were completely absent. Ornamental art of the Middle period is well exemplified by the ribbed *fibula* with hanging chains, the



FIGS. 1–12.—COMACINE CULTURE (LAKE OF COMO, IRON AGE) FROM THE 10TH TO THE 5TH CENTURY B.C.
1–5: Early period (1–2, bronze; 3–5, pottery). **6–8:** Middle period (bronze). **9–12:** Late period (9–10, bronze; **11**, bronze & coral; **12**, silver and gold)

necklace of bronze chains with poppyhead pendants, and the engraved *situla,* all shown in the plate. This *situla* was found on the Adda at Trezzo a little east of Monza. Its *pointillé* technique and the style of the animal-drawing are closely comparable to the rude art of the Sesto Calende *situla* (*see* GOLASECCA).

The Late Comacine period is considerably influenced by the Etruscans, whose products began to penetrate into the Lake region about 500 B.C., before which time they were quite unknown there. Bronze palettes such as those shown in Nos. 9 and 10 of the Plate are an Etruscan invention; they were used for shifting the ashes and placing the incense on the sacrificial fire. A gaudy set of manicuring implements on a chatelaine of massive silver picked out with gold (No. 12) is of late Etruscan origin, and a complete series of Etruscan objects was found at Rondineto. Many of the *fibulae,* however, are different from the Etruscan and the Bolognese, belonging to types peculiarly characteristic of the Lake region, many of which are found also in the Italian-speaking Swiss canton of Ticino. No. 11 is a good example of a very popular form.

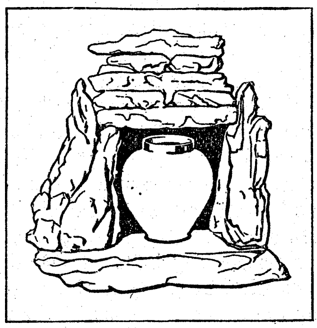


FIG. 13.—PLAN OF A TOMB AT MONCUCCO

Closely connected with the Comacine civilization is that of the

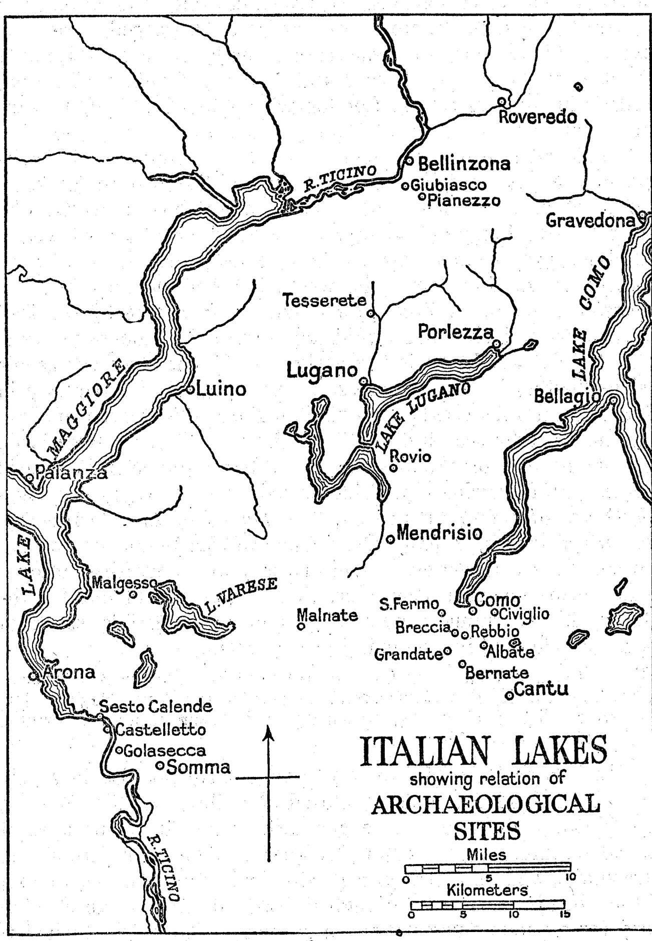

FIG. 14

Canton Ticino as seen in a group of cemeteries clustering about Bellinzona. The burial-rite is inhumation, which has led some authors to regard these people as Ligurian colonists from the western plain of the Po. They exploited their geographical position at the opening of the principal pass then in use, which was not the St. Gotthard but the Val di Mesocco, to become the porters and carriers of a transport service between northern Italy and the head-waters of the Rhine. Through their mediation Etruscan, Greek, Bolognese and Venetian products found their way to Switzerland, western Germany, France, Belgium and even England. Being of a peaceful disposition, these Ligurians possessed no weapons, but they were well provided with ornaments and other objects showing a high standard of luxury. Many of these were obtained from their clients on either side of the Alps, but a certain number were produced locally. In particular the Ticinese developed a primitive but independent style of metal-work, shown at its best in their bronze girdles. These barbaric objects contrast curiously with the sophisticated bronze vessels of Campanian workmanship found in the same graves. The Bellinzona cemeteries begin about 600 B.C. and continue down to the Roman empire. It is to be observed that the Early La Tène (*q.v.*) period 500 to 300 B.C. is free of all Gaulish influence, but the middle La Tène which succeeds this is entirely Gaulish in character.

D. Randall-MacIver, *The Iron Age in Italy,* gives the few original authorities. (D. R.-M.)

COMANA, a city of Cappadocia (frequently called CHRYSE or AUREA, *i.e.,* the golden, to distinguish it from Comana in Pontus; mod. *Shahr*), celebrated in ancient times as the place where the rites of Mā-Enyo, a variety of the great west Asian Nature-goddess, were celebrated with much solemnity. The service was carried on in a sumptuous temple with great magnificence by many thousands of *hierodouloi* (temple-servants). To defray expenses, large estates had been set apart, which yielded a more than royal revenue. The city, a mere apanage of the temple, was governed immediately by the chief priest, who was always a member of the reigning Cappadocian family, and took rank next to the king. The number of persons engaged in the service of the temple, even in Strabo's time, was upwards of 6,000, and among these, to judge by the names common on local tombstones, were many of Persian race. Under Caracalla, Comana became a Roman colony, and it received honours from later emperors down to the official recognition of Christianity. The site lies at Shahr, a village in the Anti-Taurus on the upper course of the Sarus (Sihun), mainly Armenian, but surrounded by new settlements of Avshar Turkomans and Circassians. The place has derived importance both in antiquity and now from its position at the eastern end of the main pass of the western Anti-Taurus range, the Kuru Chai, through which passed the road from Caesarea-Mazaca (mod. *Kaisarieh*) to Melitene (Malatia), converted by Septimius Severus into the chief military road to the eastern frontier of the empire. The extant remains at Shahr include a theatre on the left bank of the river, a fine Roman doorway and many inscriptions; but the exact site of the great temple has not been satisfactorily identified. There are many traces of Severus' road, including a bridge at Kemer, and an immense number of milestones, some in their original positions, others in cemeteries.

BY COURTESY OF THE SMITHSONIAN INSTITUTION

COMANCHE INDIAN OF THE SHOSHONEAN STOCK

See P. H. H. Massy in *Geog. Journ.* (Sept. 1905); E. Chantre, *Mission en Cappadocie* (1898). (D. G. H.)

COMANA, an ancient city of Pontus, said to have been colonized from Comana in Cappadocia, standing on the river Iris (Tozanli Su or Yeshil Irmak). The moon-goddess was worshipped in the city with a pomp and ceremony in all respects analogous to those employed in the Cappadocian city. The slaves attached to the temple alone numbered not less than 6,000. Some slight remains of Comana are still to be seen near a village called Gumenek on the Tozanli Su, 7 m. from Tokat.

COMANCHE, a Plains Indian tribe, close relatives of the Wind River Shoshone of Wyoming. They ranged from this State south-westward into Texas, were active raiders, penetrating into Mexico, and fought the Mexicans, Texans and various tribes consistently. They were among the most nomadic of bison-hunting

Indians. In the historic period their affiliation has been closest with the Kiowa. There remain 1,600 on a reservation in Oklahoma.

COMAYAGUA, a city and former capital of Honduras, Central America, now the capital of the department of Comayagua. Population (1940) 4,758; at one time (1827) it had a population of about 18,000 people. The city lies on the right bank of the Humuya river in a fertile valley 32 mi. long by 16 mi. wide, and is distant from the capital, Tegucigalpa (*q.v.*), about 70 mi. by road. It lies on the line of the proposed transcontinental railway, but, what is more important at the present time, on the highway from Tegucigalpa to the north coast, a route which includes a boat trip across Lake Yojoa to Portrerillos (about 100 mi. from Comayagua), the inland terminus of the National railway. Comayagua boasts a handsome cathedral, dating from 1715, and other public buildings of the colonial era which have fallen into disrepair. The town was founded originally in 1540, with the name of Valladolid la Nueva, by Alonso de Cáceres, under instructions from the Spanish government to found a town midway between the two oceans. The new town soon afterwards became the capital of the province of Honduras, was given the rank of a city in 1557 and became the site of an episcopal see in 1561. In 1827 it was burned by the revolutionaries, suffered from various subsequent battles and in 1880 Tegucigalpa was made the capital.

COMAYAGÜELA, the twin city of Tegucigalpa (*q.v.*), capital of Honduras, from which it is separated only by a narrow river. Comayagüela is to be distinguished from Comayagua (*q.v.*).

COMB. A toothed toilet implement used for cleaning and arranging the hair, and also for holding it in place after it has been arranged; the word is also applied, from resemblance in form or in use, to various appliances employed for dressing wool and other fibrous substances, to the indented fleshy crest of a cock, and to the ridged series of cells of wax filled with honey in a beehive. Hair combs are of great antiquity, and specimens made of wood, bone and horn have been found in Swiss lake-dwellings. Among the Greeks and Romans they were made of boxwood, and in Egypt also of ivory. For modern combs the same materials are used, together with others such as tortoise-shell, metal, india-rubber and celluloid.

There are two chief methods of modern manufacture. A plate of the selected material is taken of the size and thickness required for the comb, and on one side of it, occasionally on both sides, a series of fine slits are cut with a circular saw. This method involves the loss of the material cut out between the teeth. The second method, known as "twinning" or "parting," avoids this loss and is also more rapid. The plate of material is rather wider than before, and is formed into two combs simultaneously, by the aid of a twinning machine. Two pairs of chisels, the cutting edges of which are as long as the teeth are required to be and are set at an angle converging towards the sides of the plate, are brought down alternately in such a way that the wedges removed from one comb form the teeth of the other, and that when the cutting is complete the plate presents the appearance of two combs with their teeth exactly dovetailing into each other. In india-rubber combs the teeth are moulded to shape and the whole hardened by vulcanization.

COMBACONUM or **KUMBAKONAM,** a city of British India, in the Tanjore district of Madras, in the delta of the Cauvery, on the South Indian railway, 194 m. from Madras. Pop. (1941) 67,008. The city is historically interesting as the capital of the Chola race, an old Hindu dynasty, from whom the whole coast of Coromandel, or Cholamandal, derives its name. It has a notable *gopuram,* or gate pyramid, rising to a height of 100 ft. and ornamented with stucco figures. One of its water tanks is traditionally connected with the Ganges by a subterranean passage and as such forms a centre for pilgrims. Brass and other metal wares, silk and cotton cloth and sugar are manufactured here.

COMBE, GEORGE (1788–1858), Scottish phrenologist, was born in Edinburgh on Oct. 21, 1788. After attending Edinburgh high school and university he entered a lawyer's office in 1804, and in 1812 began to practise on his own account. In 1817 his first essay on phrenology was published in the *Scots Magazine;* these and other papers were published in 1819 in book form as *Essays on Phrenology,* which in later editions became *A System of Phrenology.* In 1820 he helped to found the Phrenological Society, which in 1823 began to publish a *Phrenological Journal.* By his lectures and writings he attracted public attention to the subject on the continent of Europe and in America, as well as at home; and a long discussion with Sir William Hamilton in 1827–28 excited general interest.

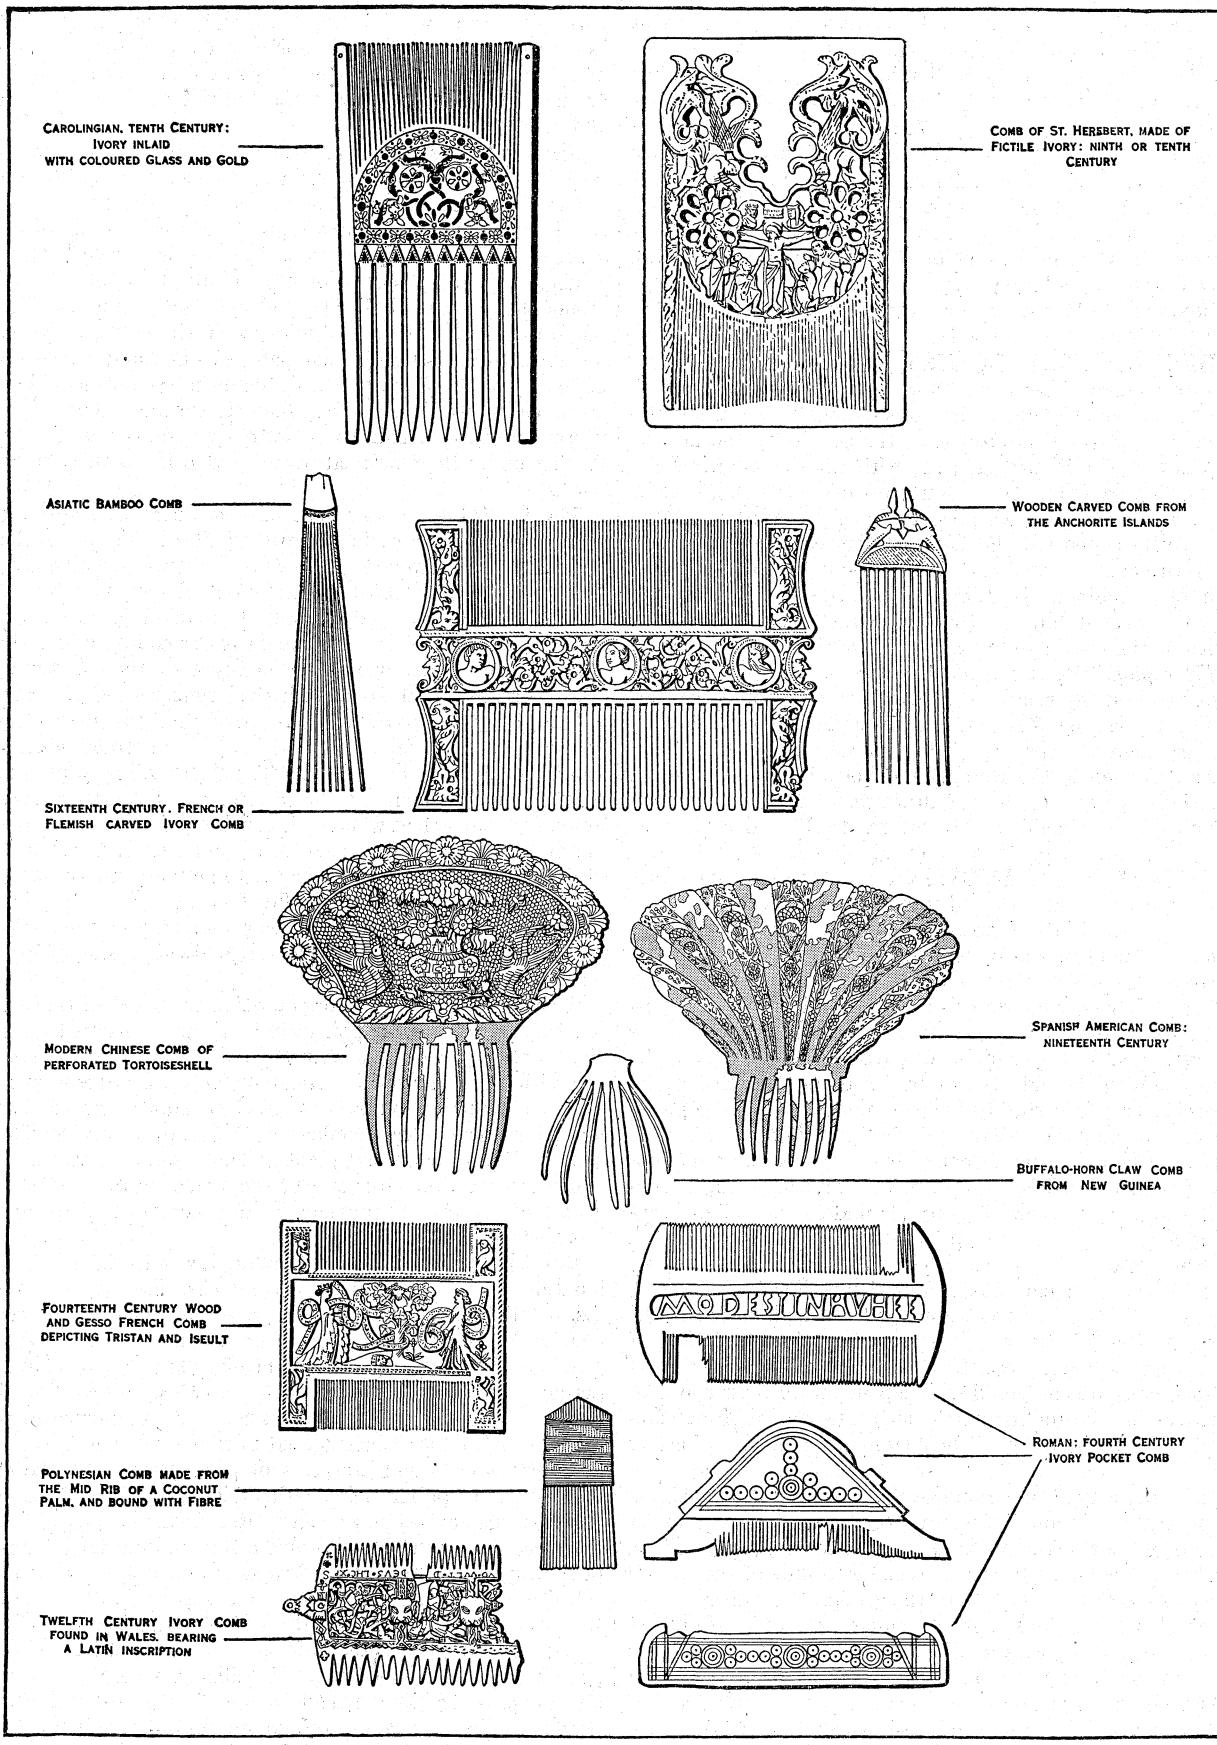
His most popular work, *The Constitution of Man,* was published in 1828. In 1838 he visited America and spent about two years lecturing on phrenology, education and the treatment of the criminal classes. On his return in 1840 he published his *Moral Philosophy,* and in the following year his *Notes on the United States of North America.* In 1842 he delivered, in German, a course of 22 lectures on phrenology in the university of Heidelberg, and he travelled much in Europe, enquiring into the management of schools, prisons and asylums. He married in 1833 Cecilia Siddons, a daughter of the great actress. He was engaged in revising the ninth edition of *The Constitution of Man* when he died at Moor Park, Farnham, on Aug. 14, 1858.

COMBE, WILLIAM (1741–1823), English writer, the creator of "Dr. Syntax," was born in Bristol in 1741. He was educated at Eton, where he was contemporary with Charles James Fox, the 2nd Baron Lyttelton, and William Beckford. William Alexander, a London alderman and his reputed father, bequeathed him some £2,000 (a little fortune that soon disappeared in a course of splendid extravagance which gained him the nickname of Count Combe) and after a chequered career as private soldier, cook and waiter, he finally settled in London (about 1771), as a law student and bookseller's hack. In 1776 he made his first success in London with *The Diaboliad,* a satire full of bitter personalities. Four years afterwards (1780) his debts brought him into the King's Bench; and much of his subsequent life was spent in prison. Periodical literature of all sorts (pamphlets, satires, burlesques, "two thousand columns for the papers," "two hundred biographies,") filled up the next years, and about 1789 Combe was receiving £200 yearly from Pitt, as a pamphleteer. In 1809–11 he wrote for Ackermann's *Political Magazine* the famous *Tour of Dr. Syntax in search of the Picturesque* (descriptive and moralizing verse of a somewhat doggerel type), which, owing greatly to Thomas Rowlandson's designs, had an immense success. It was published separately in 1812 and was followed by two similar *Tours,* "in search of Consolation," and "in search of a Wife," the first Mrs. Syntax having died at the end of the first *Tour.* Then came *Six Poems* in illustration of drawings by Princess Elizabeth (1813), *The English Dance of Death* (1815–16), *The Dance of Life* (1816–17), *The Adventures of Johnny Quae Genus* (1822)—all written for Rowlandson's caricatures. In his later years, notwithstanding a by no means unsullied character, Combe was sought out for the sake of his charming conversation and inexhaustible stock of anecdote. He died in London, June 19, 1823.

Brief obituary memoirs of Combe appeared in Ackermann's *Literary Repository* and in *The Gentleman's Magazine* for Aug. 1823; and in May 1859 a list of his works, drawn up by his own hand, was printed in *The Gentleman's Magazine.*

COMBE or **COOMB,** a term particularly popular in south-western England for a short closed-in valley, either inland on the side of a down or, more generally, when it forms a small coastal feature. It appears in place-names as a termination, *e.g.,* Ilfracombe, and as a prefix, *e.g.,* Combemartin. The etymology of the word is uncertain; in English *combe* or *cumb* is an obsolete word for a "hollow vessel," and a similar meaning is attached to the Teutonic forms *kumm* and *kumme.* The Welsh *cwm,* in place-names, means hollow or valley, and may be compared with *cum* in several Cumbrian and Scots place-names. The Greek κύμβη also means a hollow vessel, and there is a French dialect word *combe* meaning a little valley.

COMBERMERE, STAPLETON COTTON, 1ST VISCOUNT (1773–1865), British field-marshal and colonel of the 1ST Life Guards, was the second son of Sir Robert Salusbury Cotton



BY COURTESY OF THE DIRECTOR OF THE VICTORIA AND ALBERT MUSEUM, LONDON AND THE TRUSTEES OF THE BRITISH MUSEUM

COMBS OF VARIOUS COUNTRIES RANGING IN DATE FROM THE 4TH CENTURY ONWARDS of Combermere Abbey, Cheshire, and was born on Nov. 14, 1773, at Llewenny Hall in Denbighshire. He was educated at Westminster school, and when only 16 obtained a second lieutenancy in the 23rd regiment (Royal Welsh Fusiliers). He served in Cape Colony (1796), India (1797–1800), Ireland (1800), and in the Peninsula (1808–1812). He commanded Wellington's cavalry in Portugal, and fought at Salamanca (1812). His career of active service was concluded in India (1826), where he besieged and took Bhurtpore. For this service he was created Viscount Combermere. In 1855 he was made a field-marshal and G.C.B. He died at Clifton on Feb. 21, 1865.

See Viscountess Combermere and Capt. W. W. Knollys, *The Combermere Correspondence* (1866).

COMBES (JUSTIN LOUIS), ÉMILE (1835–1921), French statesman, was born at Roquecourbe, Tarn, on Sept. 6, 1835. He was a doctor by profession, practising at Pons, Charente-Inférieure. In 1885 he was elected to the senate by the department of Charente-Inférieure. He sat with the democratic Left. On Nov. 3, 1895, he entered the Bourgeois cabinet as minister of public instruction, resigning with his colleagues on April 21 following. He actively supported the Waldeck-Rousseau ministry, and upon its retirement in 1903 he was himself charged with the formation of a cabinet. In this he took the portfolio of the interior, and devoted himself to the struggle with clericalism. The parties of the left in the chamber, united upon this question in the *Bloc republicain,* supported Combes in his application of the law of 1901 on the religious associations, and voted the new bill on the congregations (1904), and under his guidance France took the first definite steps toward the separation of Church and State. The defection of the Radical and Socialist groups induced him to resign on Jan. 17, 1905, although he had not met an adverse vote in the Chamber. He sat in the Briand cabinet of 1915–16 without portfolio. He died on May 25, 1921, at Pons.

COMBINATION IN INDUSTRY. The term combination, in its industrial sense, is used to designate the entire process whereby the competition of rival manufacturers or traders has given place, in the evolution of industry, and is still giving place, to concerted or unified business control and action. The word is not a particularly happy one in this usage, recalling as it does, the Combination laws directed against trade unionism, but no better word has suggested itself as capable of covering every phase of the movement whereby the old type of trade competition disappears and something that is certainly not the old competition appears in its place. The simplest, though not necessarily the least sophisticated, kind of combination is that which occurs where a number of manufacturers or traders, who are rivals in business, meet from time to time and arrive at an "honourable understanding" or "gentlemen's agreement" as to the prices they shall charge or the districts they shall serve. (*See* GENTLEMEN'S AGREEMENT.) These are for the most part casual and always informal.

A more organic form of the same kind of combination is the association of manufacturers or traders for the regulation of prices, output, selling areas, etc. (*See* ASSOCIATIONS, INDUSTRIAL.) These associations are composed of independent business concerns temporarily associated for the particular purpose of limiting competition and are to be distinguished from permanent fusions or mergers.

An intermediate type of combination between the association and the permanent fusion is the profit-pooling agreement under which two or more firms may agree for a term of years to share, in a fixed ratio based upon the pre-agreement profits of the several firms, the combined future profits of the group. From these casual or systematic combinations of independent interests one passes almost insensibly to the various types of consolidation, though in the passage from terminable to permanent combination a great gulf is crossed for only in the most extreme circumstances and in the rarest event will a permanent combination ever again break up into its original components.

"Vertical" and "Horizontal" Combinations.—Permanent combinations are termed consolidations, and of these a distinction may usefully be made between "vertical" consolidations formed of a number of firms engaged in the production of a commodity at various stages of manufacture (*e.g.* coal and iron mining, pig iron, iron and steel, ships); and "horizontal" combinations formed of firms engaged in the same line of manufacture at the same stage of production. From this point the terminology becomes arbitrary and overlapping.

The word "trust," which is used as a popular label for any large business or association of businesses which is suspected of using monopolistic powers, was originally an American form of organization in which "trustees" figured as the controllers and directors of a group of financially centralized enterprises. (*See* TRUSTS for a fuller account and discussion of all kinds of consolidations having monopolistic powers.) In England the term combine is fairly consistently appropriated in popular speech—it seldom if ever appears in the registered title of a company—to horizontal consolidations of firms that were originally of somewhat the same order of importance and which, after their finances are merged and their direction centralized, remain to outward appearances as distinct firms trading under their original names and using their former trademarks.

The Cartel.—Another type of permanent or semi-permanent combination is the cartel, characteristic of but not exclusive to German industrial development (*see* CARTEL), in which the generic idea around which the organization is shaped is frequently the joint selling agency; and yet another manner in which ostensibly competing concerns may be brought under collusive direction is by arrangements under which one or more of the directors of one concern serve on the board of a rival concern and *vice versa.*

"Holding Company."—The particular manner in which a consolidation is effected and afterwards operated gives rise to another range of terminology. "Trust" has already been referred to. "Holding company" is another term in the same class and denotes an arrangement whereby a new limited company is formed to purchase the whole of, or a controlling interest in, the share capitals of each of the companies which are to be merged into one interest. "Absorption" is preferably confined to cases in which a large firm purchases outright a smaller concern, which thereupon disappears as a separate entity, its custom and goodwill passing as far as may be to the purchasing firm.

A very different type of organization from any of the above, yet one that partakes of combination in a reflex sense is the co-operative society (*see* CO-OPERATION) in which consumers associate to establish stores and to a lesser extent factories and workshops from which they can purchase the goods they require, the surplus profits being returned to the members in the shape of dividends on purchases. From the present point of view of concentration and centralized control the co-operative movement must take its place as a part of the general movement from competition towards combinations.

Combinations and the Community.—In the growth of combination as a ruling factor in the conduct of industry and trade, two distinct though related elements may be seen. One is concerted control determining the levels of production and price which were previously the fortuitous resultant of the pursuit of gain by competing individuals; the other is the substitution of a few big businesses for many small businesses and the emergence in the economic field of that concentrated power—over sources of supply, over instruments and processes of production, over the channels of trade, over public policy—that bigness gives. The emergence of conscious control and concentrated financial power in industry has created a new order of problem for the industrial communities of the world, for "the law of demand and supply" can no longer be relied upon to insure that prices and supplies will be about what they ought to be; nor can "the law of struggle and survival" be relied upon to ensure that the industrially more fit will succeed against the industrially less fit. Intelligent control has tremendous advantages over blind struggle if used in the best interests of the producers themselves and the community generally; the problem for the future is whether and how far concerted control and concentrated power will be used aright, and how far it will prove desirable and practicable to control the controllers. For a fuller examination of the social and political problems of combination *see* TRUSTS, also MONOPOLY. (J. H.)

For bibliography, *see* that under TRUSTS.

COMBINATION LAWS, the name given to the British acts of 1799 and 1800, which made trade unionism illegal. Previously combinations of journeymen had only been illegal when, as was frequently the case, parliament had passed special legislation dealing with the organization of the trade, and journeymen's combinations could reasonably be regarded as attempts to interfere with operation of a particular statute. Combinations of workmen to secure the enforcement of such laws (which generally included provisions for the fixing of wage rates) were indeed permissible, and petitions from such combinations were frequently accepted by parliament throughout the first three-quarters of the 18th century. Parliament in addition passed from time to time laws forbidding combinations in particular trades: in 1800, according to Samuel Whitbread, there were 40 such acts. But toward the end of the 18th century, judges began to declare that trade unions were also illegal at common law: and this opinion, together with skilful pressure by employers, led in 1799 to the passing of the first Combination act, which was hurried through all its stages in no more than 24 days. The vigorous protests that it aroused secured the passing of a second act in 1800, but the modifications secured were trifling.

The law, as finally amended, sentenced to three months in jail or to two months' hard labour any working man who combined with another to gain an increase in wages or a decrease in hours, or who solicited anyone else to leave work, or objected to working with any other workman. The sentence was to be given by two magistrates and appeal was forbidden unless "two sufficient sureties in the penalty of £20" were given, which was the more improbable as anyone contributing to the expenses of a person convicted under the act would be fined £10, and the recipient another £5. The removal of a conviction by *certiorari* was forbidden, and defendants could be forced to bear witness against each other. Other clauses forbade employers' combinations, but these were never in any recorded case put into operation. Despite, however, the attractive nature of this act, the employers and the government often preferred to proceed by means of the law against conspiracy, trade unionism being now officially an offense. Thus in 1818 at Bolton two secretaries and the president of a union were sentenced to two and one years of imprisonment respectively for "conspiracy" in calling and attending a meeting of operatives on the request of the employers. In Ireland, according to the evidence given in 1824, the punishments inflicted included public whippings.

The laws were repealed in 1824 as a result of the patient intrigue of the radical tailor, Francis Place (*q.v.*), acting through Joseph Hume, M.P. The repealing bill attracted little attention, and the prime minister, though he supported it, later declared he was ignorant of its contents. The repeal was followed by a rush of strikes and in 1825 an attempt was made to re-impose the acts. This was frustrated by Place's persistent wirepulling and agitation, and the final act of 1825 differed very little from the plain repeal of 1824. The whole story is told by Place, probably with a bias in his favour, in his mss. in the British museum (Add. mss. 27798–9).

See also S. and B. Webb, *History of Trade Unionism* (1898, latest ed. 1920); R. W. Postgate, *The Builders' History* (1923); G. Wallas, *Life of Francis Place* (1925). (R. W. P.)

COMBINATORIAL ANALYSIS. Combinatory analysis is a branch of mathematics dealing with various elementary topics in number theory, algebra, and tactical geometry and extensive developments therefrom. Historically this title includes the beginnings of topics now rightly assigned to number theory, Diophantine analysis, the theory of probability, determinants, group theory, topology, and the theory of aggregates. Even the formulas of the theory of partitions may be included in number theory, and symmetric functions in the theory of forms.

Many of the traditional problems which involve at most the investigation at any stage of a discrete number of possibilities, usually fall under the general designation of combinatorial problems. Among the best developed might be said to be the subjects of triple systems (established on a firm basis by the work of J. Steiner, 1852, and E. H. Moore, 1893); magic squares, Latin squares, the map colouring or four-colour problem, the eight queens problem, the Game of Nim (C. L. Bouton, *Annals of Mathematics,* 2nd ser., vol. i, 1902), unicursal or maze problems, theory of knots, tesselation or parquetry, decimation problems and the Problem of the Virgins. Such subjects as cryptograms, bridge problems, and chess problems, while deeply studied, continue largely unmathematical.

A hint as to the historical sequence (mentioning only conspicuous early investigators) in the development of the elementary fundamental subjects in this field may be afforded by the following bare list: (1) figurate numbers (triangular, square, and polygonal numbers generally, pyramidal, cubic, prismoidal numbers, etc.)—earliest Pythagoreans, Nicomachus (*c.* A.D. 100), Diophantus (*c.* A.D. 250), Pierre de Fermat (1621), J. L. Lagrange and Leonard Euler (1770), K. F. Gauss (1801); (2) the binomial coefficients—reputed Chinese writings of 14th century, Michael Stifel (1544), Henry Briggs (1620), Blaise Pascal (1665), G. W. v. Leibniz (1666), Isaac Newton (1676), John Wallis (1685), Jacques Bernoulli (1713); (3) permutations, combinations, probability—Jacques Bernoulli (1713); (4) symmetric functions—Albert Girard (1629), Abraham de Moivre (1698), Isaac Newton (1707), Edward Waring (1762), Lagrange (1770); (5) determinants—Leibniz (1690), Gabriel Cramer (1750), Lagrange (1773), Gauss (1801), A. L. Cauchy (1815); (6) the application of generating functions to problems in partitions—Euler (1770), N. M. Ferrers (1853), J. J. Sylvester (1882).

Illustrative Examples.—Consider the following simple problem in *permutations* (one of the two traditional uses of the term, here meaning "arrangement"): What numbers of two figures each (in the usual decadic notation) can be formed with the digits, 1, 3, 5, 7? To make the problem precise it must be stated whether repeated use of a digit in the representation of a single number will be permitted. We may obviously form a table as follows:

Tens' digit	1	3	5	7
Units' digit				
1	11	31	51	71
3	13	33	53	73
5	15	35	55	75
7	17	37	57	77

The numbers are all distinct and are clearly $4^2 = 16$ altogether, of which four, those in the "principal diagonal" have repeated digits, leaving $4.3 = 12$ numbers with digits distinct.

Analogous problems in *combinations* are distinguished from problems in permutations in that the arrangement of the elements is now regarded as without significance, attention being devoted merely to which elements are selected. For example: In how many way can two numbers whose sum is even be selected from among the numbers, 1, 2, 3, 4, 5, 6, 8? We note first that both summands must be even or both odd to have an even number as their sum, and that the order of their choice is immaterial.

Again the problem must be made precise by stipulating whether or not two equal summands are to be accepted. Suppose distinct summands only are desired. For odd summands, there are two pairs using the number 1, namely (1, 3), (1, 5) and one more using the number 3, namely (3, 5). There are similarly three pairs using the number 2, namely (2, 4), (2, 6), (2, 8), two new pairs using 4 but not 2, namely (4, 6) and (4, 8), and one remaining pair (6, 8). The total number of pairs is therefore $(2+1)+(3+2+1)=9$.

Two Numerical Functions.—Before making a systematic study of such problems, it is desirable to introduce two numerical functions. The first of these logically, although not historically, is the *factorial function* $n!$ or $\underline{n}$, defined, for $n>1$, as the continued product of the natural numbers up to and including n.

Thus $n!=1.2\ldots(n-1).n$. For each positive integer $n>1$, we have the recursion relation $(n+1)!=(n+1)(n!)$. In conformity with this relation we naturally define $1!$ as 1 and $0!$ as 1, and regard $n!$ for negative integers as not finite. The first few values of $n!$ are given by $0!=1$, $1!=1$, $2!=2$, $3!=6$, $4!=24$, $5!=120$, $6!=720$, $7!=5{,}040$, $8!=40{,}320$, $9!=362{,}880$. The value of $n!$ increases, with increasing n, with extraordinary rapidity. The remarkable size of the answers to certain combinatorial problems due to this fact has interested and astonished generations of schoolboys. For large values of n an approximation of $n!$ is afforded by Stirling's asymptotic formula (1730), which, to give only the leading term, approximates $n!$ by $\left(\frac{n}{e}\right)^n\sqrt{(2\pi n)}$ where e is the "Naperian base," 2.71828. . . . The factorial function $(n-1)!$may be regarded as exhibiting the integral values only of the celebrated *gamma function* (of Euler), $\Gamma(n)$, while $\Gamma(x)$ is defined for complex numbers generally. It is of interest that $\Gamma(\frac{1}{2})=\sqrt{\pi}$, and more generally $\Gamma(x)\ \Gamma(1-x)=\pi/\sin\ (\pi-x)$. Further study of this function leads through the very heart of modern analysis to difference equations, complex functions, definite integrals, contour integration, asymptotic series, etc. In number theory $n!+1$ may be used in Euclid's proof that the number of primes is infinite, and occurs also in Wilson's theorem.

The next function needed is the *binomial coefficient* $\binom{n}{k}$, a numerical function of two independent integers, n, k, and definable in terms of factorials by $\binom{n}{k}=n!\,/\,[(n-k)!\,k!]$, (Newton, 1676), although much older than either factorials or the binomial theorem. The values of $\binom{n}{k}$ may be conveniently exhibited by the so-called Pascal's arithmetical triangle (Apianus, 1527; Michael Stifel, 1544; Blaise Pascal, 1665; and apparently by Chu Shï-kie, 1303), where the $(k+1)$st element counting whether from left to right or from right to left in the $(n+1)$st horizontal row (counting from the top) is $\binom{n}{k}$. The triangle extends downward indefinitely. It starts as follows:

$$\begin{array}{ccccccccccc}
 & & & & & 1 & & & & & \\
 & & & & 1 & & 1 & & & & \\
 & & & 1 & & 2 & & 1 & & & \\
 & & 1 & & 3 & & 3 & & 1 & & \\
 & 1 & & 4 & & 6 & & 4 & & 1 & \\

A table of its values up to n, $k=50$, is given by J. W. L. Glaisher (*Messenger of Mathematics*, 47, 1917, 97–107). The law of formation of a horizontal row from the elements of the row above may be expressed concisely by the conditions $\binom{n}{0}=\binom{n}{n}=1, \binom{n+1}{k}=\binom{n}{k}+\binom{n}{k-1}$. These properties of $\binom{n}{k}$ alone, are used in establishing by complete induction the binomial theorem:

$$(a+x)^n=\binom{n}{0}a^nx^0+\cdots+\binom{n}{r}a^{n-r}x^r+\cdots+\binom{n}{n}a^0x^n$$

for positive integral exponents n. In the theory of combinations $\binom{n}{k}$ is sometimes denoted by ${}_nC_k$, and may then be called "the k-combination of n" or "the number of combinations of n distinct things taken k at a time without repetitions."

Many important and surprising relations hold among these binomial coefficients for which reference may be made to Hagen, *Synopsis der höheren Mathematik* (vol. i, 1891, p. 64 *sqq.*, or Netto, chap. xiii.).

Two Fundamental Problems.—Perhaps the simplest and most fundamental general problem in the subject of permutations may be stated in traditional form as follows: *To determine a systematic method of securing once and only once each possible arrangement* (or "permutation") *of k things selected from among n given distinct things;* (a) *when repetitions are allowed,* (b) *when the things in each arrangement of k things are distinct. Also to determine the number of such arrangements.* In an "arrangement" as here used, the only feature considered is the ordinal count of the distinct objects, *i.e.*, as to which is first, which is second, which is third, and so forth. When repetitions are permitted, one may select the first object for our arrangement in any one of n ways, since one may select any one of the given objects of the set to be the first of the arrangement. This having been done one can again select any one of the n as the second, and so forth, obtaining n^k possible arrangements of exactly k things from among n permutations permitted. For repetitions not permitted, the first is selected in any one of n ways, the second arbitrarily from among the $(n-1)$ left available. This makes $n(n-1)$ ways of selecting this first ordered pair. The third may be chosen as any one of the $n-2$ remaining things, giving $n(n-1)(n-2)$ distinct possible ordered triads, and so forth. The number of distinct arrangements of k distinct elements selected from among n given distinct elements is therefore $n(n-1)\cdots(n-k+1)=n!/(n-k)!$, denoted sometimes by ${}_nP_k$, "the k-permutation of n," or "the number of arrangements (or permutations) of n distinct things taken k at a time without repetitions."

The corresponding problem in combinations is in some ways more fundamental. It may be stated as follows: *To determine a systematic method of securing once and only once each possible combination of k things selected from among n given distinct things:* (a) *when repetitions are allowed,* (b) *when the things in each combination of k things are distinct. Also to determine the number of such combinations.* By a combination is meant a collection without regard to the sequence or order among the elements. Instead of starting afresh as may be done, let us assume that the permutation problem has been solved and a table is before us giving all distinct arrangements of k things selected from among the given n. We may treat to some extent simultaneously cases (a) and (b). The following procedure is analogous to the use of the *Sieve of Eratosthenes* (*c.* 230 B.C.) in the theory of prime numbers. Establish in any arbitrary manner a sequence among the "arrangements" appearing in the table. Take the first arrangement. Note what k things are there contained. Go through the entire table crossing out all other arrangements comprising these same k things and constituting merely rearrangements of this first accepted arrangement. Proceed to the next arrangement that has not yet been crossed out and repeat the process. This is clearly a procedure that never requires one to turn back and re-examine or cross out any arrangement once accepted. All the arrangements that finally remain will constitute also distinct combinations. In case (b) when no arrangement contains repeated elements, the number of distinct arrangements which constitute the same combination is clearly ${}_kP_k=k!$, since it is possible to arrange a given set of k things in exactly $k!$ ways and each of these possible ways must appear once and only once in the table. The entire collection of ${}_nP_k=n!/(n-k)!$ distinct arrangements contains therefore each combination exactly $k!$ times, so that the number of distinct combinations is $(n!/(n-k)!)/k!$, or $\binom{n}{k}$.

Before taking up the count in case (a), the case of combinations with repeated elements, it is convenient to note certain combinatorial relations in a set of integers arranged in increasing order. Consider a set, s, of k distinct numbers selected from among the first $n+k-1$ natural numbers, and let this set be arranged in increasing order. It is to be noted that the hth number in this set, s, $(h=1, 2, \cdots, k)$ cannot be less than h nor more than $n+h-1$. For its smallest value would occur when the first h numbers of the set are consecutive, giving the value h, and its largest value would occur when the last $k-h+1$ numbers are consecutive, giving the value $n+h-1$. If from the hth number of the set we subtract $h-1$, $(h=1, 2, \cdots, k)$, the consequent *derived* set, s', will be arranged in non-decreasing order, and no one of its elements is greater than n. This derived set may contain repeated elements. Two distinct given sets, s, result in two distinct derived sets, s', and conversely distinct derived sets, s', correspond to distinct given ordered sets, s. We may state the following important theorem in partitions. *For each set, s, of k distinct natural numbers arranged in order of increasing magnitude selected from the first $n+k-1$ natural numbers, there is a uniquely determined set s' of k natural numbers arranged in order of magnitude selected with repetitions allowed, from the first n natural numbers, and conversely.* Returning now to case (a) for combinations, we may imagine our original set of n distinct things numbered ordinally from 1st to nth. In each combination of k things selected from this set, the k things retain their ordinal designation, so that each combination may have its k elements arranged ordinally in a unique manner except for repeated elements, among which order is regarded as immaterial. By applying the theorem stated above, we see that the theory of combinations allowing repetitions as considered in case (a) may be replaced by the theory of combinations of k elements selected from an initial set of $n+k-1$ elements, no repetition being allowed. Thus the number of combinations permitting repetition in case (a) is

$$\binom{n+k-1}{k}.$$

Partitions.—A subject at first sight independent of permutations but in fact almost identical with it is that of *partitions*, one theorem in which subject has been mentioned above. This topic is but a phase of the general subject of distributions, being the theory of combinations of summands having a given sum. For compactness in display, it is convenient to formulate the typical problem as follows: In how many ways can the number $m+n$ be represented as the sum of exactly n positive integers? Thus for $n=4$, $m=2$, we have

$$6=3+1+1+1=2+2+1+1,$$

two ways, and for $n=2$, $m=4$, we have $6=5+1=4+2=3+3$, three ways. The following table was given by Euler who studied the recursion relations among the values of this function.

n =	1	2	3	4	5	6	7	8	9	10	11	...
$m=0$	1	1	1	1	1	1	1	1	1	1	1	...
1	1	1	1	1	1	1	1	1	1	1	1	...
2	1	2	2	2	2	2	2	2	2	2	2	...
3	1	2	3	3	3	3	3	3	3	3	3	...
4	1	3	4	5	5	5	5	5	5	5	5	...
5	1	3	5	6	7	7	7	7	7	7	7	...
6	1	4	7	9	10	11	11	11	11	11	11	...
7	1	4	8	11	13	14	15	15	15	15	15	...
8	1	5	10	15	18	20	21	22	22	22	22	...
9	1	5	12	18	23	26	28	29	30	30	30	...
10	1	6	14	23	30	35	38	40	41	42	42	...
.	.	.	.	.	.	.	.	.	.	.	.	

If this partition function be denoted by $P(n, m)$, we have the relations of Euler: $P(1, m)=P(n, 0)=P(n, 1)=1$, $P(n, m)=0$, $(m<0)$, $P(n, m)=P(n-1, m)+P(n, m-n)$, $P(n, m)=\sum_{s=1}^{n} P(s, m-s)$, and of Stern (1840),

$$P(n, m)=P(n-1, m)+P(n-1, m-n)$$
$$+P(n-1, m-2n)+P(n-1, m-3n)+\cdots.$$

From the simplest tactical considerations (Ferrers, 1853) of the horizontal rows and vertical columns of a *point diagram* ("lattice diagram" or "graph") such as the following, one may infer an important general theorem. Here we have twenty points arranged in horizontal rows containing respectively; 5, 4, 4, 3, 2, 2, points and also in vertical columns containing respectively 6, 6, 4, 3, 1, points:

```
. . . . .
. . . .
. . . .
. . .
. .
. .
```

From such observations we have the Theorem of Reciprocity (Sylvester, 1882): *Every partition of n into k positive summands of which the greatest is equal to h, determines a reciprocal partition of n into h positive summands of which the greatest is equal to k.* As immediate corollaries one has: *The number of partitions of n into k parts is equal to the number of partitions of n into parts of which the largest is k;* and, *The number of partitions of n into not more than k parts is equal to the number of partitions of n with no part greater than k.*

Another Problem in Permutations.—Another typical general problem in the domain of permutations and combinations is the following: Given a partition of n, say $n=m_1+m_2+\cdots+m_h$, to determine the number of distinct possible arrangements using all of n given things, each once only, of which m_1 are alike (say of type 1), m_2 are alike, but of another type (say type 2), and so forth, there being in all, h distinct types. Since rearrangements within each type are freely possible, among the total $n!$ possible arrangements of elements, one has $m_1!$ arrangements differing only with respect to interchanges among elements of type 1. These are independent of rearrangements within type 2, and so forth, giving $n!/[m_1!\,m_2!\cdots m_h!]$ arrangements distinct with respect to type. This number is called a *multinomial coefficient* on account of its being the coefficient of $x_1^{m_1}x_2^{m_2}\cdots x_h^{m_h}$ in the expansion of $(x_1+x_2+\cdots+x_h)^n$ in powers of the separate arguments. This is the germ of two lines of investigation, the study of the powerful method of *generating functions* in which the coefficients of the several terms of a power series are interpreted as numerical functions (used throughout MacMahon's treatise), and the study of divisibility of factorials by products of factorials, since the multinomial coefficient is necessarily an integer. (*See* Dickson, *History of Theory of Numbers*, vol. i., ch. ix.) As to generating functions, lack of space and the complexity of the subject require us to dismiss briefly this fundamental tool for research in combinatorial analysis. It is known that

$$(1+x)(1+x^2)(1+x^3)(1+x^4)\cdots=\frac{1}{(1-x)(1-x^3)(1-x^5)(1-x^7)\cdots}$$

is a valid identity for all complex values of x less in absolute value than unity. By imagining the expansion in power series and comparing coefficients, we infer at once that *the number of representations of n as a sum of odd integers allowing repetitions is equal to the number of representations of n as a sum of distinct integers* (allowing both odd and even numbers). De Morgan's theorem illustrating the simplest case of Sylvester's *denumerants*, proved by use of generating functions, states that *the number of representations of n as a sum of the numbers 1, 2, 3, allowing repetitions is equal to the integer lying nearest to* $\frac{1}{12}(n+3)^2$.

Sets and Subsets.—The theory of combinations with distinct elements is identical with the theory of *finite aggregates* or *finite sets*. Many of the concepts apply equally to all well-defined sets whether finite or infinite. There are many grave philosophical difficulties associated with the general definition of set (*see* Whitehead and Russell, *Principia Mathematica*, vol., i., ch. ii., particularly p. 63 *sqq.*), but this concept lies at the basis of modern analysis. (Hobson, *Functions of a Real Variable*, 2nd ed. 1, p. 1-2.) One may at least say that a set is a collection comprising distinct objects of any sort, called *elements* of the set, such that it may be definitely ascertained whether any arbitrarily assigned object is or is not an element of the set. If A and B are sets, A is called a *subset* of B (and B a *superset* of A) if and only if each element of A is an element of B. Thus A is a subset and superset of itself. It is convenient to introduce a unique *null-set* with no elements, which is a subset of every set. Any subset of A which is neither A itself, nor the null-set is a *proper* subset of A. The elements common to two sets A and B constitute the *section* or *logical product* of A and B. The set each element of which is in at least one of the sets A, B, is the *spread* or *logical sum* of A and B. Given three sets A, B, C, the sets A and B are said to be *supplementary in C*, if and only if

A and B have no common element, and C is their spread. In this case only is subtraction possible. We write then $B=C-A$, and $A=C-B$. This notion may be used to demonstrate the theorem, *If $n>k>h$, the number of combinations of n distinct things taken k at a time (without repetitions), which include h specified elements, is equal to the number of combinations of these same n things taken $n-k$ at a time (without repetitions) which exclude each of these h specified things.* In particular for $h=0$, $\binom{n}{k}=\binom{n}{n-k}$. If a set has a finite number, n, of elements, the total number of subsets is 2^n, since each element in turn may independently be included or excluded. Hence $\binom{n}{0}+\binom{n}{1}+\binom{n}{2}+\cdots+\binom{n}{n}=2^n$, as follows also by putting $a=x=1$ in the binomial expansion.

Uniform Correspondences.—If a correspondence is established from a set A to a set B such that for each element of A there is one and only one corresponding element of B, the correspondence determines a *single-valued* (or uniform) *function* "on A to B." This is the sense in which "function" is now used throughout mathematics, after successive extensions through centuries. Here A is the *domain* of the function and B, or the part of B used, is the *range*.

If a correspondence is, furthermore, one-to-one from A to B so as to establish an actual pairing off of elements of A against elements of B, it is *biuniform*. The correspondence then has a unique biuniform *inverse* correspondence K^{-1} from B to A, which determines the same tallying or pairing off. Two sets between which there can exist a biuniform correspondence are said to be *equivalent* or to have the same *cardinal number*. (*See* NUMBER, or Cantor, *Theory of Transfinite Numbers* [trans.], 1915).

When two finite sets A and B have the same cardinal number n, there exist $n!$ distinct biuniform correspondences from A to B. It is sometimes convenient to select one of these correspondences as a *principal* correspondence and by means of it establish a corresponding notation for the two sets. When A and B coincide, this principal correspondence is chosen as merely the *identical* correspondence whereby each element corresponds to itself. A biuniform correspondence within a single set may be called a *substitution* (or "permutation" in the more fundamental sense). The simplest type of substitution is a *circular* or *cyclic* substitution, permuted elements all following in a single cycle. Each element of the cycle may be carried into any other element of the cycle by repeating the given correspondence or its inverse sufficiently often. (Where the cycle contains but a finite number of elements, the inverse is itself obtained by repeating the direct correspondence a certain number of times.) The simplest cyclic substitution after the identity is a *transposition*, by which a single pair of elements is interchanged, and every other element left unaltered. *Each substitution in a finite set may be expressed (in an infinite number of ways) as the result of a finite number of transpositions, but more interestingly, as the result of a finite number of component cyclic substitutions each of which leaves unaltered every element permuted (not left invariant) by any other of the component cyclic substitutions.* Thus each substitution breaks up the given finite set of elements into uniquely determined cycles. A substitution within a finite set is said to be *even* or *odd* according as the number of cycles each with an even number of elements is even or odd. In this connection we have the important theorem: *A substitution in a finite set which is expressible as the result of an even number of transpositions is even, and one expressible as the result of an odd number of transpositions is odd. Each substitution is either even or odd, but never both even and odd.*

Any study of substitutions leads to the consideration of *groups* of substitutions. From this fundamental point of view the theory of permutations (in the sense of arrangements) so far as the case of distinct elements is concerned is a phase of the study of substitutions among elements of subsets of a given set.

Matrices and Determinants.—Given two sets (not necessarily finite), A and B. Let a denote a variable element of A, and b a variable element of B. A set C is called a direct product of A and B (to be distinguished from "logical product") if there is a biuniform correspondence between the elements of C and the ordered pairs (a, b). If the elements of C are independent algebraic variables, then C is called a general *matrix* on (A, B), with elements, x_{ab}, where a determines the (horizontal) *row* and b the (vertical) *column* of the matrix. When A and B have the same cardinal number, the matrix is *square*. If a principal correspondence is chosen between A and B, the notation x_{aa} acquires a meaning. The set of all these variables with repeated subscripts are said to constitute the *principal diagonal* of the square matrix. There need be no preassigned arrangement among the elements of A. Thus, if A consists of the three symbols $+$, $\times$, 0, then there is a general square matrix of nine independent variables, say w_{++}, $w_{+\times}$, w_{+0}, $w_{\times+}$, $w_{\times\times}$, $w_{\times0}$, w_{0+}, $w_{0\times}$, w_{00}, which can be written in any order but of which w_{++}, $w_{\times\times}$ and w_{00} form the elements of the principal diagonal, and for example, $w_{\times0}$, $w_{\times+}$, $w_{\times\times}$ are in the same row (in some order). By a *determinantal product* of the elements of a general square matrix of *order n, i.e.*, with n rows and n columns, is meant a product Πx_{ab} of elements "one from each row and each column," that is, a product of n elements where the first subscripts, a, take on each value in A once and only once, and the second subscripts, b, take on each value once and only once. For example, the following are determinantal products of the matrix given above, $w_{+0}\ w_{\times+}\ w_{0\times}$, $w_{00}\ w_{\times+}\ w_{+\times}$, $w_{\times\times}\ w_{00}\ w_{++}$, but such a product as $w_{+0}\ w_{\times+}\ w_{+\times}$ is not a determinantal product since among first subscripts $+$ appears twice and 0 not at all. The product of the elements of the principal diagonal is always a determinantal product (the *principal* determinantal product). For a finite square matrix of order n, there are $n!$ such determinantal products. (Only n^2-2n+2 are independent [G. Polya, *Arch. d. Math. u. Phys.* [3] 24 [1916], pp. 369–375].) Now each product determines a biuniform correspondence from A to B and hence among the set of symbols used in common by the two sets. This correspondence is that by which the value of a appearing as first subscript in any factor corresponds to the value of b which is the second subscript of this same factor. Thus for a square matrix of finite order, each of the $n!$ determinantal products determines definitely either an even or an odd substitution. The principal determinantal product determines the identical substitution which is even. For $n>1$, there are the same number, $n!/2$, of even as of odd substitutions. To each of the $n!$ determinantal products a sign is attached, $+$, if the substitution it defines is even, $-$, if the substitution is odd. The algebraic sum of all these signed products is defined as the *determinant* of the general matrix. (*See* DETERMINANT.) For a matrix of order nine, the product $x_{27}x_{18}x_{49}x_{66}x_{73}x_{81}x_{35}x_{94}x_{52}$ determines the cycles (2735) (18) (49) (6), with three of an even number of elements. This product is given the minus sign. For the traditional method of determining the sign of a term by counting "permanences" and "inversions," *see* Scott and Matthews, *Theory of Determinants* (2nd ed., 1904, p. 1–14).

Symmetric Functions.—The application of substitution groups to algebra finds a rich development in the Galois Theory of Equations. The simplest topic in this connection, essentially preliminary and incidental to the latter subject, is the theory of *symmetric functions*, fundamentally equivalent to much of the theory of distributions. A symmetric rational integral function of n independent variables $\alpha, \beta, \cdots, \nu$, may be expressed as a sum of terms, each of the form $k\Sigma\alpha^{i_1}\beta^{i_2}\cdots\nu^{i_n}$ where $i_1, i_2, \cdots i_n$ are non-negative integers, where the summation sign, Σ, covers all terms obtainable by transpositions among the variables. The sum $\Sigma\,\alpha^{i_1}\,\beta^{i_2}\cdots\nu^{i_n}$ has a unique term for which $i_1\geqq i_2\geqq i_3\geqq\cdots\geqq i_n\geqq 0$. This is called the *leader*, and the whole sum is called a *monomial sum*. A monomial sum is completely identified by the *specification*, $(i_1, i_2, \cdots i_n)$ of its leader, where the final set of zeros, if any, may be omitted, and where successive equal indices such as $i_a=i_{a+1}=\cdots=i_{a+h-1}$ may be condensed by writing i_a^h. The most important monomial sums are the n *elementary symmetric functions* (1^m), $(m=1, 2, \cdots, n)$ and the infinite sequences of *power-sums*, $s_m=(m)$, $(m=1, 2, \cdots)$, $s_0=n$. It is often convenient to define the symbol (1^m) for $m>n$ as identically zero, thereby enabling many recursion relations to hold universally. Another important fundamental system of symmetric functions is the infinite sequence of *homogeneous product-sums* denoted by h_m where for example, $h_4=(4)+(31)+(2^2)+(21^2)+(1^4)$, and h_m generally is the sum of all monomial sums whose specifications are partitions of m. A system of great interest, relatively little studied in this connection (T. N. Thiele, 1889) is the system comprising in addition to $t_0=1$, and $t_1=(1)/n$, the algebraic semi-invariants, t_m (Arthur Cayley, 1886) definable by the implicit recursion relation

$$s_{m+1}=\Sigma\binom{m}{k}t_{k+1}\,s_{m-k}.$$

Here $t_m(c\alpha, c\beta, \cdots, c\nu)=c^m t_m(\alpha, \beta, \cdots, \nu)$,

$t_m(\alpha+c, \beta+c, \cdots, \nu+c)=t_m(\alpha, \beta, \cdots, \nu)$, $m>1$, but $=t_1(\alpha, \beta, \ldots, \nu)+c$, for $m=1$.

For the relations among these involved in Newton's Identities, Waring's Formulae and the proofs, and generalizations, the reader is referred to treatises on algebra.

The entire subject of symmetric functions acquires new significance when studied from the point of view of *algebraic invariants*. The differential operators of invariant theory are illustrated for example by the Hammond operator, D, used to determine explicit coefficients in certain expansions. (*See* MacMahon.)

The process *transvection* by which concomitants of a system of forms are obtained suggests the use of *multi-linear symmetric functions* of m systems, a subject not yet developed. The set of independent variables $(\alpha, \beta, \cdots, \nu)$ may become infinite in number or even continuously infinite as in the theory of integral equations. Or again all explicit mention of them may be suppressed as in certain algebraic studies, and a general theory including that of symmetric functions be developed, but applicable to much wider domains. Determinants in non-commutative domains have been investigated (*see* LINEAR ALGEBRAS), and this suggests further problems in this line also. Recent studies in symbolic logic and in combinatorial topology present fresh applications of combinatorial principles.

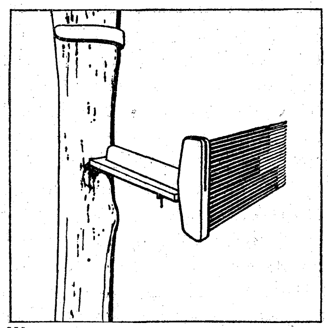
COMBINES. The term "combine" is in popular use throughout Great Britain and the Dominions as a synonym for what is more commonly spoken of in the United States as a "merger." It is employed to denote the large and probably monopolistic concern which results from the permanent "combination" of a number of smaller concerns in the same line of business. The combine is one form of industrial consolidation and is dealt with more fully, along with other forms, under TRUSTS.

COMBING. Prior to the development of mechanical means of fibre-spinning, each fibre was treated in accordance with its nature—more particularly its length. Thus the silk fibre 400 to 600yd. long was readily reeled. The cotton fibre—often not more than an inch in length—was spun on what is known as the spindle-draft system, a comparatively thick sliver of the material, usually drawn from a bundle of the raw material, being actually attenuated into a finer sliver while twist is being inserted, the twist simply controlling the fibres and keeping the thread intact while the fibres are gliding upon one another. On the attenuation's being completed much more twist is inserted, usually to give the maximum strength to the thread. Two fibres—flax and long wool—did not lend themselves to either of these processes, being either too short for reeling or too long for spindle-draft spinning. For flax a process termed "scutching" or "dressing" has been evolved; for wool a process termed "combing." It is interesting to note, however, that the dressing process for flax has been successfully applied to what is termed waste or spun silk, and the combing process (originally worked out for wool) even to comparatively short cotton fibres—for reasons which are obvious when the process of combing is understood.

As Bishop Blaize, a saint of the 4th or 5th century, is the patron saint of the wool-combers, it seems probable that the craft goes back at least into mediaeval times. In its latest form as a handicraft, wool-combing was performed with two combs, one of which, after being heated, was fixed to the "pad-post." The wool to be combed was then lashed by hand into the teeth of this fixed comb, and the fringe hanging from it was then combed by drawing the other comb, also heated, at right angles across the face of the pad-post comb, gradually straightening out all the fibrous mass. After feeding back into the pad-post comb and again combing, the ultimate result was that both combs held equally a straightened fringe of wool fibres. The wool was then drawn off each comb in succession, by hand, as a continuous sliver some three to five feet long, leaving in the comb "milkings" and "backings" which were combed with the subsequent lot, and "noil"—the short fibres actually left in the comb teeth, which were too short to comb again. The combed slivers were then broken up and again combed, this operation being termed "straightening"; little noil was taken out, but the long fibres were arranged longitudinally in a neat sliver from which a parallel-fibre thread—termed a worsted thread—could be spun. Hand-combing was practised as an established craft until about 1860 when the development of the machine comb, interacting with the supply of merino wool from Australia (Botany bay—hence the term Botany wool), resulted in the evolution of an industry turning over many times the weight of material that had been turned over by the hand-combers.



WOOL COMBING AS A HANDICRAFT
A heated comb is seen fixed to a "pad-post," and the wool is lashed into the teeth of the comb. The fringe is then combed by drawing another heated comb through it and the fibres are gradually straightened out on both combs

Cartwright's Invention.—Dr. Edmund Cartwright, a clergyman with an unusually ingenious mind, thought out, about 1785 to 1800, the ideas which underlie the two types of comb at present in use. In the first comb he employed a vertical cylinder or barrel into which the comb teeth were fixed more or less radially, this being the prototype of the various forms of Heilman combs which are now employed both in the short wool and long cotton industries. In the second comb he placed the large carrying cylinder horizontally, charging it with tufts of combed wool overlaid so that on being drawn off a continuous sliver was formed. Thus the idea of hand-combing was imitated, but with circular combs lending themselves to continuity of action.

Other inventors followed Cartwright, but it was not until Heilman, Lister and Holden were at work that the comb showed signs of being a practical success. Heilman and Lister were both practically successful with their "tuft" combs, Heilman employing the vertical and Lister the horizontal circular positions. In a great lawsuit Heilman proved himself to be the first inventor of the "tuft" idea; Lister promptly bought him out and suppressed his vertical cylindrical comb in Britain from about 1854 to 1900, when, French combers having established a large trade with this comb on the Continent and having become the envy of their British competitors, attempts were made to wrest some of the finest wool trade from them, and this necessitated the reintroduction of the Heilman comb for wool. In the meantime, however, a Mr. Donisthorpe, working in Leeds with a man named Noble, evolved another type—now termed the "Noble" comb (*see* WORSTED MANUFACTURE)—and this has proved the best for crossbred and medium Botany wools. It consists of Cartwright's horizontal large circle, with two smaller horizontal circles which work inside the larger circle, touching tangentially, and thus forming two combing positions. The wool is dabbed into the pins of the touching circles, and as in revolving these separate, the combed wool lies between them as a continuous fringe on the inside of the large circle and the outside of the small circle. These two fringes are drawn off by vertical rollers, united together and also to the two corresponding slivers from the other combing position, thus forming what is termed the "top." The short fibres, termed "noil," rest in the teeth of the two small circles inside the large circle. This noil is thrown out with "noil-knives" so that the small combs are freed from fibre in order to proceed continuously with the combing operation in conjunction with the larger circle which has been freed by the drawing-off rollers. The wool which has to follow on for combing is now lifted out of the pins of the large comb, a little more is drawn off and dabbed into the pins of both large and small circles where they impinge, and the combing operation is continued. The Noble comb is not a "tuft" comb, and, with the exception of the dabbing mechanism, is circular and continuous in all its motions. Thus of the practical combs employed for both wool and cotton to-day, three—viz., Lister's, Holden's and Heilman's—are "tuft" combs and one—the Noble—a non-tuft comb. All, however, deliver continuous combed slivers. The Heilman cotton comb, specially designed for the purpose by Nasmith and other cotton engineers, is the only type which has ever been successfully employed for cotton. Only the best cottons—Sea Island, Egyptian and the very best American—are combed. (A. F. B.)

COMBUSTION. This term implies the process of burning and in the popular mind is generally associated with the production of flame (*q.v.*). So far as terrestrial conditions are concerned, it is due to the combination of a combustible substance with oxygen and the consequent evolution of heat. The condition of flame is due to the oxidation of gases or vapours at a very rapid rate so that high temperatures are attained, the molecules concerned thereby becoming highly radiant. Scientifically, the term has a broader meaning and is extended to other oxidations. At atmospheric temperature oxidation of a combustible material generally occurs, if at all, only very slowly, and usually with little outward manifestation. When, however, the temperature is raised, as for example by the application of some external source of heat, the process becomes greatly accelerated, and if the "ignition point" be reached, heat will be developed at a rate greater than that at which it can be dissipated and flame will ensue. Thus, when a lighted match is applied to coal-gas issuing from a jet, the temperature is so raised that self-propellant combination is established between the gas and the oxygen of the air with which it intermingles, flame then appears and is maintained at the jet. Similarly, when coal is heaped on a fire, its volatile constituents liberated by heat mix with the surrounding air and after ignition give rise to flame; the residual coke, consisting largely of carbon, becomes incandescent, its primary oxidation proceeding without flame.

The explanation of the nature of fire or flame was sought in very early times. At first fire was thought to be an element, but as far back as the fourth century B.C. it was demonstrated that air plays an important part in the phenomenon. During the middle ages, however, the notion of an "element of fire" universally prevailed until Francis Bacon classed it among his "phantoms of the market place" as one of those "fictions which spring from vain and false theories" (*Novum Organum*). The first important experimental study of combustion commenced with the Oxford School of Chemistry about 1660 under the leadership of Robert Boyle. With the assistance of his pupil Robert Hooke, he had contrived his "Machina Boyleana," a forerunner of the modern air-pump, and by its aid proved that neither charcoal nor sulphur burns when strongly heated in vessels exhausted of air, although each inflames as soon as air is readmitted. Having found that a mixture of either substance with nitre catches fire even when heated in a vacuum, Boyle concluded that combustion depends upon the action of something common to both air and nitre. He concluded further that, in the calcination of metals a ponderable "fire-stuff" is taken up, thus accounting for the gain in weight already observed by the French physician, Jean Rey, in 1630. Robert Hooke said (*Micrographia,* 1665) ". . . that shining transient body which we call Flame, is nothing else but a mixture of Air, and volatil sulphureous parts of dissoluble or combustible bodies, which are acting upon each other whilst they ascend. . . ."

It was, however, John Mayow, another of Boyle's pupils, who in his *Tractatus Quinque Medico-Physici* (1674) expounded views nearest to those held to-day. In common with Hooke, Mayow regarded heat and light as originating in the motions of particles. By making the now familiar experiment of burning a candle or other substance in a bell jar of air enclosed over water, he observed that the air is diminished in bulk by combustion and that when the flame expires the residual air is inactive and will not support combustion. Also he observed that the respiration of animals in an enclosed space had the same effect, and concluded that respiration and combustion were analogous processes. He therefore postulated the existence of two kinds of particles: (*a*) inflammable particles which exist in all combustible substances, and (*b*) nitro-aerial particles which, originating in the sun, become linked to normal aerial particles (which *per se* are inert) in the upper atmosphere. These particles (*a* and *b*) are mutually so hostile that when suitably brought together they enter into sharp conflict, whereby they are thrown into violent motion the outcome of which is the appearance of fire. Such a view differs from that propounded by A. L. Lavoisier a century later and now held, in that (i.) it did not recognize that common air is a mixture of two physically similar but chemically distinct gases, and (ii.) it regarded combustion only as the interplay and not as the actual combining of two opposite kinds of particles. But for his early death in 1679 Mayow might have discovered the gas now called oxygen.

At the beginning of the 18th century, another view of combustion known as the "phlogiston" theory, originally propounded by J. J. Becher (1635–1681), was developed and promulgated by G. E. Stahl, and soon became universally accepted. According to this theory, all combustible bodies contain at least two "principles"—one of "combustibility" called phlogiston (from the Greek φλογιστός, burnt) which escapes during combustion, and the other of "incombustibility" which remains behind as the ash. More easily combustible substances, *e.g.,* charcoal, were supposed to consist so largely of phlogiston that after its escape during combustion little or no visible residue remains. The inherent defect of the theory was that it did not account for the fact that the products of combustion are invariably heavier than the original substance. This was overcome by ascribing to phlogiston a negative weight. The phlogiston theory dominated chemistry during the greater part of the 18th century but it did not long survive the discovery of oxygen by K. W. Scheele and by J. Priestley; for Lavoisier was able to prove that this gas is really the active constituent of air, and in 1783, after Henry Cavendish's discovery of the composition of water, he correctly interpreted its compound nature as an oxide of hydrogen. In his *Réflections sur le Phlogistique* he denied the existence of phlogiston and propounded his new oxygen theory of combustion. His main contentions were, (1) inflammable substances will burn only in oxygen or where oxygen is present; (2) oxygen is consumed in combustion and, uniting with the substance burnt, causes an increase in weight and a corresponding decrease in the weight of the air used.

Spontaneous Combustion.—In certain circumstances ignition may occur without the application of any external source of heat. Thus, when heaps of finely divided coal or of cotton waste soaked in oil are kept in badly ventilated places, oxidation, proceeding slowly at first, may cause heat to accumulate until ultimately the temperature is raised to the "ignition point," when inflammation occurs. The spontaneous firing of hay-ricks is the result of similar causes.

Slow and Catalytic Combustion.—It has already been mentioned that oxidation of a combustible material can occur at temperatures below those at which flame is developed. Thus, Davy in 1817 discovered that when mixtures of hydrogen and oxygen are passed through a tube heated at temperatures between 360° and 500° C they combine to form water "without any violence and without light." W. A. Bone and his collaborators have found that mixtures of certain gaseous hydrocarbons with oxygen are very reactive at 300° C and in some cases even at

250° C. The rate of such combination is always accelerated by contact of the reacting gases with some foreign material or surface, a phenomenon of the greatest importance in chemistry and known as "catalytic" or "surface" combustion. As a result of these and other researches, it is necessary to distinguish between two possible conditions under which gaseous combustion may occur, viz., (i.) *homogeneously, i.e.,* uniformly throughout the system as a whole, (*a*) at temperatures below the ignition point, slowly and without flame, and (*b*) at temperatures above the ignition point, rapidly and with flame; and (ii.) *heterogeneously, i.e.,* in layers in direct contact with a hot surface.

Incandescent Surface Combustion.—Davy also set out to enquire whether, seeing that the temperatures of flame far exceed those at which solids become incandescent, a body can be maintained in an incandescent state by combination of the gases at its surface without actual flame. He discovered that if a heated platinum wire be plunged into a mixture of coal-gas with air rendered non-explosive by excess of the combustible, the wire immediately becomes red hot and continues so until nearly the whole of the oxygen has disappeared. In 1906 W. A. Bone was able to effect a *flameless incandescent surface combustion* by burning explosive gas–air mixtures in contact with surfaces of ordinary refractory material, which were thereby maintained in a continuous incandescence without flame; and in conjunction with C. D. McCourt he applied this discovery to various domestic and industrial heating operations, including steam raising, etc. The advantages of such a system are, (i.) the combustion is greatly accelerated by the incandescent surface, (ii.) the combustion is perfect with a minimum excess of air, (iii.) the attainment of very high temperature is possible and (iv.) owing to the large amount of radiant energy developed, transmission of heat from the seat of combustion to the object to be heated is very rapid.

Lastly, it should be mentioned that combustion is not necessarily controlled by simple thermal factors but may be profoundly influenced by the electrically charged condition (degree of ionization) of the reactants. Such is probably the case in the ignition of explosive mixtures by electric discharges and also in catalytic combustion.

Gaseous Explosions.—When a combustible gas issuing from an orifice is ignited, a stationary flame is maintained by the active chemical combination of the combustible with the oxygen of the atmosphere with which it intermingles. Should, however, the combustible previously be mixed with air (or oxygen) in suitable proportion, the mixture becomes explosive, and given favourable conditions flame will be propagated through it. When such a mixture is ignited in a confined space, the heat developed raises the gases to a high temperature with consequent rapid increase in pressure. This explosion pressure is the source of power in gas- and petrol-engines.

In order that a gaseous mixture may be explosive it is necessary that the percentage of the particular combustible present should lie between certain limits. Also, in order to initiate flame the mixture must be raised locally at least to its ignition temperature. In neither case are these conditions constant, but they are dependent on the temperature and pressure of the mixture and also on its environment. Usually, however, they can be reasonably well defined; thus at atmospheric temperature and pressure the following figures have been found:

	Hydrogen and air		Carbon monoxide and air		Methane and air	
	Lower limit	Upper limit	Lower limit	Upper limit	Lower limit	Upper limit
Limits of inflammability (volume percentage of combustible gas in air) . . .	4·1	75·0	12·8	72·0	5·4	14·8
Ignition temperatures (approximate) . .	570° C		680° C		660° C	

It should also be borne in mind that in certain cases the electrically charged state of the gases may play an important rôle in the initiation of flame.

Propagation of Flame.—In the case of mixtures of "limit" composition, the heat liberated by oxidation of the combustible is just sufficient to raise adjacent layers of gas to the "ignition temperature," flame being propagated only very slowly. When richer mixtures are exploded the nature of flame movement is dependent on circumstances. Thus if a mixture be ignited at the *open* end of a tube which is closed at the other end, an initial slow "uniform movement" usually occurs, its velocity being dependent on (1) the composition of the mixture, (2) its temperature and pressure, (3) the nature and diameter of the tube employed, (4) the direction of flame propagation, and (5) the source and character of the ignition. Flame movement so initiated usually proceeds at uniform velocity for a certain distance and its termination is marked by a period of accelerated vibrational flame movement which may in certain cases give rise to detonation. When a mixture is ignited near the *closed* end of a tube the forward movement of the flame is continuously accelerated until ultimately detonation may be set up. It should also be mentioned that, when an explosive mixture is ignited in a state of turbulence, as in a gas engine, the rate of normal flame propagation (and hence pressure development) is much more rapid than if the mixture were stagnant.

Detonation.—When detonation (Fr. *l'onde Explosive*) occurs, flame is propagated at an enormously high velocity (*c.* 2,000 to 3,000 metres per second), each successive layer of the explosive mixture concerned being ignited by adiabatic compression in an explosion wave. In such circumstances chemical reaction is more intense and of much shorter duration than in normal combustion; in addition, the pressure in the wave is much greater than that developed in ordinary explosions, thus accounting for its shattering effect. It is set up when a sufficiently explosive mixture is ignited by means of a detonator (*e.g.,* a fulminate charge) or in circumstances such that an advancing flame is exposed to the effects of compression waves. When once established, the velocity of the wave is constant and within wide limits unaffected by the material and diameter of the tube employed, being solely dependent on the nature of the explosive mixture, its temperature and pressure.

(For heats of combustion, *see* THERMOCHEMISTRY.)

See W. A. Bone and D. T. A. Townend, *Flame and Combustion in Gases* (1927); R. T. Haslam and R. P. Russell, *Fuels and their Combustion* (1926). (D. T. A. T.)

COMEDY, the general term applied to a type of drama the chief object of which, according to modern notions, is to amuse. It is contrasted on the one hand with tragedy and on the other with farce, burlesque, etc. As compared with tragedy it is distinguished by having a happy ending (this being considered for a long time the essential difference), by quaint situations, and by lightness of dialogue and character-drawing. As compared with farce it abstains from crude and boisterous jesting, and is marked by some subtlety of dialogue and plot. It is, however, difficult to draw a hard and fast line of demarcation, there being a distinct tendency to combine the characteristics of farce with those of free comedy. This is perhaps more especially the case in the "musical comedy," which has been popular in Great Britain and America since the later 19th century, where true comedy is frequently subservient to broad farce and spectacular effects.

The adjective "comic," which strictly means that which relates to comedy, is a modern usage generally confined to the sense of "laughter-provoking." The phenomena connected with laughter and that which provokes it, the comic, have been carefully investigated by psychologists, in contrast with other phenomena connected with the emotions. It is generally agreed that the predominating characteristics are incongruity or contrasts in the object, and shock or emotional seizure on the part of the subject. It has also been held that the feeling of superiority is an essential, if not the essential, factor; thus Hobbes speaks of laughter as a "sudden glory." Physiological explanations have been given by Kant, Spencer and Darwin. Modern investigators have paid much attention to the origin both of laughter and of smiling, babies being watched from infancy and the date of their first smile being carefully recorded. For an admirable analysis and account of the theories *see* James Sully *On Laughter* (1902). (*See* DRAMA, HUMOUR, CARICATURE, etc.)

COMENIUS or **KOMENSKY, JOHANN AMOS** (1592–1670), a famous writer on education, and the last bishop of the old church of the Moravian and Bohemian Brethren, was born either at Comna, or at Niwnitz, in Moravia. Having studied at Herborn and Heidelberg, and travelled in Holland and England, he became rector of a school at Prerau, and later of a school at Fulnek. In 1621 the Spanish invasion drove him into Poland. Soon after he was made bishop of the Moravians. While teaching Latin at Lissa, he published *Pansophiae prodromus* (1630), a work on education, and *Janua linguarum reserata* (1631), the latter being produced in 12 European languages, and in Arabic, Persian and Turkish. He subsequently published similar works, as the *Eruditionis scholasticae janua* and the *Janua linguarum trilinguis.* His original method of teaching Latin and Greek consisted in giving, in parallel columns, useful sentences in the vernacular and the languages to be taught. In some of his books, as the *Orbis sensualium pictus* (1658), pictures are added; this work is, indeed, the first children's picture-book. In 1638 Comenius was requested by the Government of Sweden to draw up a scheme for the management of its schools; and a few years after he was invited to join the commission that the English parliament intended to appoint for the reform of education. He visited England in 1641, but the disturbed state of politics prevented the appointment of the commission, and Comenius left for Sweden where the minister, Oxenstjerna, employed him in the organization of Swedish schools. He died Nov. 15, 1670, at Amsterdam.

Comenius was disgusted at the pedantic teaching of his own day, and insisted that the teaching of words and things must go together. Languages should be taught, like the mother tongue, by topical conversation—pictures and objects should be used. In his course he included singing, economy, politics, world-history, geography, science and the arts and handicrafts.

As a theologian, Comenius was influenced by Boehme. His religious zeal is manifested in his semi-educational work, *The Labyrinth of the World and the Paradise of the Heart,* ed. Lutzom (Temple classics, 1905). The *Great Didactic* was edited by M. W. Keatinge (1910). Comenius also published three historical works—*Ratio disciplinae ordinisque in unitate fratrum Bohemorum, Historia persecutionum ecclesiae Bohemicae* (1648), and *Martyrologium Bohemicum. See* C. von Raumer, *Geschichte der Pädogogik* (1857); D. J. G. Carpzov, *Religionsuntersuchung der Böhmischen und mährischen Bruder* (1742); S. S. Laurie, *John Comenius* (1881).

COMETS. In addition to the planets and their satellites, the sun's retinue contains a very large number of comets. These are distinguished from the planets in three ways: (1) their orbits, instead of being appreciably circular, like those of the planets, are elongated ellipses, which, in the majority of cases, are almost parabolic; (2) their masses are exceedingly small compared with those of the major planets, and are probably much less even than those of the minor planets; (3) they are generally surrounded by hazy or nebulous envelopes; these are styled the "coma" when their outline is nearly circular, or the "tail" when it is greatly extended. The name "comet" is derived from the Greek and Latin words for "hair," from a fancied resemblance between the tails of comets and long hair streaming in the wind. The terms for them used in China and Japan, translated "besom star," may come either from a comparison between a comet's tail and the bundle of twigs in a broom, or from a fancied resemblance between the motion of a comet's tail across the constellations and that of a broom over a floor.

Distances and Periods of Comets.—The distances of comets from the sun vary within enormously wide limits; the comets 1880 I. and 1887 I. approached within 90,000 miles of the sun's surface, and several other comets approached almost as closely. The greatest distance to which comets recede from the sun can only be given vaguely; but it seems to be a large fraction of the distance (25 millions of millions of miles) that separates us from the nearest fixed star. Indeed, in a few cases comets are found to be moving in hyperbolic orbits, which implies that they may pass beyond the sun's control into that of some other star; but such cases are exceptional. The periods of comets, that is, the times required to accomplish a single revolution in their orbits, likewise vary enormously; the shortest known period is that of Encke's comet, three and one-third years, whilst the longest is in the neighbourhood of a million years. The average periods of comets are very long, certainly many thousands of years, and the number of comets of long period that approach the sun in a century is about 300 (making some allowance for undetected ones). The majority of these show no appreciable deviation from a parabolic orbit, and we are probably not overestimating their average period if we put it at 40,000 years. We thus obtain 120,000 as the total number of comets in the solar system, which makes them by far the most numerous class of objects in the system; the minor planets are probably to be reckoned by thousands, but the highest estimate of their number is about 50,000.

Comets in Ancient Times.—Comets appear at irregular intervals, and their rapid, capricious movements, combined with the occasional size and brilliance of their tails, have caused them to be regarded with mingled interest and apprehension. Since the belief was long prevalent that the movements of the heavenly bodies influenced the affairs of men, it is not unnatural that comets were regarded as particularly potent in such influences; later they were associated with plague, famine and war. These erroneous ideas had, however, the useful result of causing the movements of comets to be noted with great care. Many such notices have come down to us, especially in the Chinese annals; they have been useful in enabling the history of Halley's comet to be carried back 2,000 years, and in giving probable identifications of a few other comets.

There were two schools of opinion concerning the nature of comets in early times; one regarded them as true celestial bodies, the other as vaporous exhalations within the earth's atmosphere. The former view was held by the Roman philosopher, Seneca, who made the sagacious forecast: "Some day there will arise a man who will demonstrate in what regions of the heavens the comets take their way; why they journey so far apart from the other planets; what their size, their nature." Unfortunately European astronomers for many centuries exhibited less sagacity than Seneca, and adopted the view that comets were atmospheric exhalations, though this was capable of easy refutation by the fact that comets shared in the daily revolution of the heavens, rising and setting like the stars. The erroneous view had the effect of causing very little attention to be paid to the positions of comets among the stars, so that up to the 16th century the European cometary records are far inferior in accuracy to the Chinese ones. It was one of the useful achievements of Tycho Brahe to establish, by comparison of observations made at two distant observatories, that comets are more remote than the moon, so that they must be regarded as heavenly bodies.

ORBITS OF COMETS

Law of Gravitation Applied to Comets.—It was impossible to ascertain the true orbits of comets till the law of gravitation had been established. Newton proved that under a force that diminished in proportion to the inverse square of the distance, a body could describe any of the curves known as "conic sections," that is, the circle, ellipse, parabola or hyperbola. It was soon recognized that the observed movements of comets could be explained on the hypothesis that they were travelling round the sun in elongated ellipses or in parabolas, being visible for only a small portion of their orbits in the neighbourhood of the sun. Newton himself applied the new principle to the brilliant comet of 1680; subsequently he obtained the assistance of Halley, who in 1704 collected the observations of 24 comets, commencing with that of the year 1337, and calculated their orbits; he made the preliminary assumption that they were moving in parabolas, since this simplified the work. All parabolas are of the same shape, so that tables can be constructed that are available for all cases; the same assumption is still made in calculating the orbits of new comets, since it is known to be true in the majority of cases.

On collecting the orbits thus found, Halley noticed that there were three, those of 1531, 1607 and 1682, that were moving in paths that were practically identical. The intervals between their appearances were not exactly equal, the first being longer by 15 months; but Halley saw that this could be readily explained by the disturbing action of the large planets, Jupiter and Saturn; in the case of elongated orbits a small change of velocity has an exaggerated effect on the period. Examination then revealed records of another appearance of the same comet in 1456. It was confidently and correctly assumed that all four apparitions belonged to a single body, whose return might be expected about 1758. The fact of a comet's return was now established for the first time. There had been some conjectured cases earlier; but they were erroneous, the orbits not having been deduced on correct principles. Halley's prediction was justified by the result, the comet having returned in 1759 and again in 1835 and 1910.

Comets of Short Period.—Halley called his comet a "Mercury among comets," supposing that it had the shortest period of any; this has been known to be incorrect since the discovery of Encke's comet early in the 19th century. This is the true "Mercury of comets," its period being three and one-third years. More than 60 other comets are known whose periods are less than 80 years. These divide themselves naturally into four groups, to which are given the names of the four giant planets. There is not much doubt that there is some connection between each group and the planet whose name it bears. Jupiter's family is much the largest, containing some 50 members, whose periods lie between 3·3 and 8·9 years; the mean is 6·38 years, which is 0·538 of Jupiter's period; the orbits of most of the members pass close to that of Jupiter. Saturn's family has four members; their periods lie between 13·1 and 17·7 years; the mean is 14·9 years or 0·57 of Saturn's period. Uranus has only two comets; the mean period is 36·6 years, or 0·44 of Uranus's. Neptune has the considerable family of nine comets, including that of Halley; their mean period is 70·9 years, or 0·43 of Neptune's. The connection of the first family with Jupiter is not disputed; his influence on many of its members has been considerable. But the connection of the other planets with their families is not universally recognized. There seems to be a good case for assuming connection; the divisions between the families are well marked, and the mean period of each family is about half that of its planet; this implies that their *aphelia* (the points of their orbits furthest from the sun) are near the orbits of their respective planets; no other comets are known with periods of less than 120 years, except those in the four families. The nature of the connection between the planets and their families will be discussed in the section "Origin of Comets."

Our knowledge of the short-period comets may be said to date from 1819. There were a few cases before that when a parabolic orbit was found not to satisfy the observations, and an elliptical one was deduced. The following is a list of them: Lahire's comet 1678, period 5·38 years; Grischow's comet 1743 I., 6·73 years; Helfenzrieder's comet 1766 II., 4·5 years; Messier's comet 1770 I. (now known as Lexell's comet), 5·6 years; Montaigne's comet 1774 (now known as Biela's comet), 6·77 years; Pigott's comet 1783, 5·89 years. In many of these cases the observations were rough, and the period considered doubtful; it had not been verified by the return of the comet. We now know that Biela's comet was seen again in 1806, 1826, etc., but this had not then been recognized.

Encke's Comet.—On Nov. 26, 1818, Pons, an assiduous comet hunter at Marseilles, found a telescopic comet that was observed for 40 days; J. F. Encke, a celebrated German astronomer, undertook the study of its orbit, and found that it was an ellipse with a period of 3·3 years, which was then, and still remains, the shortest known cometary period. Encke was able to prove, by laborious calculation of the disturbances produced by Jupiter, that comets seen in 1786, 1795 and 1805 were identical with it; he predicted the circumstances of its return in 1822, which were exactly verified. From that day to the present time, the comet (which bears Encke's name, owing to his brilliant work upon it) has been observed at every return. There is only one other comet that has a similar unbroken record, namely Halley's comet. The reason in the case of Encke's comet is that it passes within 31 million miles of the sun, which is much closer than the other comets of short period; it is then so brightly lit up that it is usually an easy object to observe. It has also been fortunate in having a succession of able mathematicians, Encke, von Asten and Backlund, to calculate the disturbances in its orbit. One peculiarity noticed by Encke was that, after making allowance for planetary disturbances, the period was getting shorter by two and one-half hours each revolution. It was conjectured that this might arise from a "resisting medium" in space, which slightly retarded the comet's motion; it can be shown that such a retardation brings the comet nearer the sun and shortens its period. Against this suggestion is the fact that other short-period comets do not show the effect; but it can be replied that Encke's comet passes nearer to the sun than they do, and the medium would probably be denser there. A more serious objection is that the effect has gradually diminished in amount; it lost 20% in 1858, another 20 in 1868, 28% in 1895, and there was a further loss about 1905, bringing the amount down to one-ninth of what it was before 1858.

It is worth while to exhibit the changes in the period by giving a table of the dates of *perihelion passage* (that is, the time when the comet is nearest to the sun). These are given in Greenwich civil time; after each perihelion up to 1871 is given the interval in days to the 18th following perihelion, about $59\frac{1}{2}$ years later (equal to five revolutions of Jupiter and two of Saturn, so that their disturbing action nearly repeats itself after the interval). It will be seen that the interval suffers a rapid diminution at one part of the table, but remains almost stationary towards the end of it; it is easy, with the aid of this table to predict future returns within less than a day.

Perihelion	Interval (days)	Perihelion	Interval (days)

Encke's comet is generally easier to see before perihelion than after it; the approach to the sun causes its envelopes to expand till they become very diffused and faint. This comet makes occasional close approaches to Mercury, whose perturbations of its motion afford the best determination of Mercury's mass; Backlund deduced the value of one nine-millionth of the sun or one twenty-seventh of the earth, a smaller value than that previously adopted.

Other Comets of Jupiter.—The aphelion point of the orbit of Encke's comet lies 84 million miles inside Jupiter's orbit. The other members of Jupiter's comet family make much closer approaches to it, occasionally penetrating within its satellite system. The smallness of cometary masses is demonstrated by the absence of any disturbance to the motion of the satellites, whereas the comet's orbit suffers great changes. The orbit of Lexell's comet of 1770 underwent such changes both in 1767 and 1779 that its previous and subsequent paths were outside our sphere of vision. Other comets that have undergone large disturbances from Jupiter are d'Arrest's in 1860, Brooks's in 1886, Wolf's in 1875 and 1922; curiously enough, in this latter comet the second perturbations almost exactly reversed the first, and sent the comet back to its former path.

Space forbids a full account of all the members of the Jupiter family; two of the more interesting members are selected as specimens. The first is Biela's comet; this was seen in 1772 and 1805, but its orbit was not definitely fixed till Biela and Gambart found it independently in 1826. Its period was found to be six and three-fourths years, and its orbit intersected that of the earth, a fact which caused much groundless alarm at its return in 1832; this, however, was the occasion of a useful popular brochure on this comet, and comets in general, by the famous Arago. The return of the comet in 1839 was not seen, the comet being badly placed. In 1846 the surprising discovery was made that it had split into two comets, which travelled side by side at a nearly constant distance. The division of a comet into two equal portions is a very rare occurrence, though several cases of the separation of small fragments are known; it has, however, been conjectured that the family of brilliant sun-grazing comets that appeared in 1843, 1880, 1882, 1887, were separated portions of a single comet. The two portions of Biela's comet appeared again in 1852, somewhat further apart. Their non-appearance in 1859 excited no surprise, since they were badly placed in the sky; but early in 1866 their calculated position was favourable, yet in spite of careful search nothing could be found; nor have they ever again been seen as comets. Their presence has been manifested in the shape of showers of meteors; displays of these, moving in the same path as the comet, occurred on Nov. 27, 1872, and again in Nov. 1885, 1892 and 1898.

The disappearance of Biela's comet is evidence of the transitory nature of short-period comets. Two other comets, Brorsen and Tempel I., have likewise been lost; both were observed at a sufficient number of returns up to 1879 to ensure accuracy in the determination of the orbits and periods, but neither has been seen since 1879.

The other Jupiter comet selected for description is that discovered by Pons in 1819, and found to have a period of 5·6 years; it was not seen again till 1858, when it was found by Winnecke, so that it bears a double designation. It may perhaps be identical with Helfenzrieder's comet of 1766, but this has not yet been proved. The point of interest in this comet is the notable change in its period and perihelion distance, produced by Jupiter's action. The perihelion distance from the sun in millions of miles was 37 in 1766, 72 in 1819, 77 in 1875, 82 in 1886, 86 in 1898, 90 in 1909 and 1915; there was then an abrupt increase of six million miles up to 96½ in 1921 and 1927. The period has now increased to six years, almost exactly half that of Jupiter, and there are large disturbances by Jupiter every alternate revolution. The perihelion point was inside the earth's orbit up to 1915, but then went two million miles outside it. Showers of meteors connected with this comet were seen in June 1916, and June 1927. On June 26, 1927, it approached the earth within three and one-half million miles. This is the second nearest cometary approach on record; the nearest is that of Lexell's comet in 1770 within one and one-half million miles. The comet Pons-Winnecke was clearly visible to the naked eye in 1927, and its nucleus appeared like a small star; its diameter was not greater than some two miles.

Comets of Saturn and Uranus.—The best known member of Saturn's family is Tuttle's comet, discovered in 1858, and then found to be identical with Mechain's comet of 1790. Its period is 13½ years, and it has been seen at every return since 1858.

The more interesting of Uranus's two comets is Tempel's comet, found in 1866. Its period is one-third of a century, and its orbit coincides with that of the "Leonid" meteors, which are seen in November to radiate from the "sickle" of Leo. There were brilliant displays of these in 1833 and 1866, but that of 1899 was much poorer, since perturbations by Jupiter had diverted their course away from the earth. This comet is the first (following the order of increasing period) whose motion is retrograde, or opposed to that of the planets. It has not been seen at any other return, unless it be identical with one seen in China in 1366; if identical, it has greatly diminished in splendour; it was a conspicuous naked-eye object in 1366, but a feeble telescopic one in 1866. Le Verrier has made researches on the previous history of this comet, and concluded that it made a close approach to Uranus in A.D. 126. At present their orbits are separated by 35 million miles. The comet was not seen in 1899. Stephan's comet of 1867 is the other member of the Uranus family; this also has not been observed again.

Neptune's Comets.—Neptune's family is much larger and better observed than that of Uranus. It has nine members, of which five have been observed at a second apparition. Halley's comet heads the list; this has been traced back to 240 B.C. by computing the planetary perturbations. At every return except that of 163 B.C. it has been identified with an actually observed comet. There is a possible identification in 467 B.C.; both the Chinese annals and Aristotle (in *Meteorologica*) record this comet: the latter adds that a large meteor fell (at Aegos Potami) while the comet was visible; this increases the probability that it was Halley's comet, since it is one of those that approach near enough to the earth to give meteor showers. The apparition of this comet in A.D. 1066 is recorded on the Bayeux tapestry. The head of the comet passed across the sun in 1910, but was absolutely invisible, demonstrating the very small amount of matter contained in it. The earth probably passed through the tail at that time; but there was little, if any, evidence of its presence. There was a similar passage of the earth through the tail of the great comet of 1861; no phenomenon was noticeable beyond a diffused glare, demonstrating the very small density of the tails of comets. Four other members of Neptune's family have been seen on their second visit; these are (1) Pons-Brooks, 1812 and 1884; (2) Olbers, 1815 and 1887; (3) Westphal, 1852 and 1913; (4) Brorsen-Metcalf, 1847 and 1919. These are inferior to Halley's comet in brightness, but superior to most of the Jupiter comets. Three of the Neptune family have retrograde motion; these are Halley's comet, the Pons-Gambart comet 1827 II., and Ross's comet 1883 II.

The influence of Neptune on his comet family in the present position of their orbits is very small. The least distances between the orbits of Neptune and the different comets are given in terms of the distance from the earth to the sun:—for de Vico's comet it is four units; for the comets Pons-Brooks and Pons-Gambart six units; for Halley's and the Brorsen-Metcalf comet eight units; for the comet 1921 I. (Dubiago) it is ten units; for the other three comets, Olbers, Westphal and Ross, it is about 18 units. It must, however, be remembered that the influence at a given distance increases as we go further from the sun, since the solar influence is very small in those outer regions. Thus Neptune is never less than ten units from Uranus, yet it disturbs it noticeably. It is probable that disturbances by Jupiter have gradually changed the orbits of these Neptune comets, and that they once came much closer to Neptune.

It is possible to trace evidence of comet families still further from the sun. There are no comets known with periods between about 80 and 120 years; then we have the following group of four comets: (1) 1862 III. (Tuttle), period 119 years; this is the comet associated with the August meteors; (2) Barnard's comet, 1889 III., period 128·3 years; (3) Mellish's comet, 1917 I., period 145·0 years; (4) the comet Grigg-Mellish, 1907 II., identified by E. Weiss with that of 1742, the period being therefore 164·3 years. This last is the only comet outside the Neptune family that has been observed at a second return. There is a possible fifth member of the family; the comets of 1532 and 1661 have such similar orbits, that identity is suspected; if so, the period is 128·3 years. This family gives some ground for suspecting the existence of an extra-Neptunian planet with period about 335 years and distance 48·2 units. It is noteworthy that both Lowell and Gaillot deduced the existence of a planet at about this distance from small unexplained perturbations of Uranus. There is some evidence for another comet family with periods near 400 years, which would give 1,000 years for the associated planet. Prof. G. Forbes strongly supports the existence of this planet from cometary statistics, but it is far more doubtful than the 335-year one.

Comets of Long Period.—We pass on to the comets whose orbits are scarcely distinguishable from parabolas. There has been considerable controversy as to whether these are to be regarded as true members of the solar system or stray wanderers from outside it. The matter is, however, capable of being settled by simple considerations. The relative motions of the stars, including the sun, are of the order of several miles per second; a comet entering the sun's sphere of influence with such a speed would travel not in a parabola, but in a strongly marked hyperbola. No comets have been observed to travel in such orbits, and it is safe to conclude that they do not come to the solar system from outside. The suggestion has been made that the number of comets in interstellar space is very large, and that we see only those exceptional ones that happen to enter the sun's sphere of influence with zero relative velocity, all others passing too far from the sun for us to see them. This suggestion rests on a fallacy. The number of comets with no thwart velocity, but with velocity in the line between them and the sun, would be far greater than the number with zero velocity in both directions; the former would pass through our sphere of vision equally with the latter, and their orbits would be of the markedly hyperbolic form that has never been observed.

This conclusion is strengthened by another consideration. If comets came to the solar system from outside, we should meet more coming from the direction towards which the solar system is moving (not far from the bright star Vega) than from the opposite direction. Now on tabulating all the comets that have appeared since 1700, and excluding those with periods less than 1,000 years (since their orbits have probably been modified by planetary perturbations), it appears that, up to the year 1862, 63 comets came from the hemisphere containing the solar apex, and 76 from the opposite one. Between 1862 and 1927 the numbers are 61 and 96 for the two hemispheres. It should be noted that comets coming from the anti-apex hemisphere are somewhat better placed for northern observers than those from the apex one; but this consideration should have less weight in the more recent period, in which there have been several careful comet-observers in the southern hemisphere. The figures show that there is certainly no excess of comets from the apex hemisphere, and therefore that they do not come from outside the system.

Origin of Comets.—On examining the comets of long period that have appeared since 1700, we find that 139 had *direct* motion (that is, in the same direction as the planets) and 157 had *retrograde* motion; there is thus no preference for direct motion in these comets. This makes it very difficult to form any theory to explain their origin; if they date back to the same epoch as the formation of the family of planets, we should expect that the direction of motion which is so strongly favoured in the one case (there are no exceptions among the planets, but there are a few among the satellites) should prevail in the other likewise. But the statistics show that the preference is slightly in the other direction. It must be admitted that there is no satisfactory theory of the origin of the comets of long period. We may postulate a solar origin for the family of sun grazing comets that appeared in 1843, 1880, 1882, 1887. The phenomena of solar prominences indicate that matter is frequently being driven off from the sun at high speed. If the speed of ejection is less than 383 miles per second (the speed for motion in a parabola) such matter will return to the sun; but planetary perturbations may suffice to cause it to miss the solar surface and continue to circulate round it in a long ellipse. It seems, however, scarcely possible to postulate a solar origin for the numerous comets whose paths do not approach the sun within a distance of 100 million miles; and we must leave the question of their origin as one to which we cannot at present return an answer.

A suggestion is, however, possible in the case of the short-period comets. The explanation generally adopted is that they were formerly long-period comets that happened to pass very near to one of the giant planets, and suffered large perturbations, which reduced their periods to their present value. It is easy to calculate that only a few comets would pass close enough to Jupiter in a million years to suffer such a great change in their orbits. This does not appear to be at all adequate to keep up the supply, in view of the rapid wastage that is going on. In the last century we have witnessed the definite disintegration of Biela's comet, while those of Brorsen and Tempel I. have probably suffered a like fate. An alternative theory was suggested by R. A. Proctor about 1870. He suggested that the comets in question had been expelled from the planets to whose families they belong at a time when these planets were still in a semi-sunlike state. This involves the conclusion that these comets have been travelling in their present orbits for millions of years; it is difficult to accept this, but it does not seem to be impossible that the giant planets may still be in a condition to expel comets. The radiometric researches of Lampland, Coblentz and others have proved that their outer cloud-layers are cold; but since their cloud-mantles are thousands of miles thick, this is not inconsistent with a state of great activity (perhaps of a volcanic character) lower down. In fact many of the disturbances seen in their atmospheres, such as the great red spot on Jupiter and the bright spots on Saturn in 1876 and 1903, are proofs of the existence of sources of energy at a great depth in their atmospheres, where solar energy could not penetrate. There does not appear to be any impossibility in the hypothesis that occasional discharges of torrents of matter may take place at speeds sufficient to carry the matter away from the planet. The necessary speed in miles per second is $37\frac{1}{2}$ for Jupiter, $22\frac{1}{2}$ for Saturn, $13\frac{1}{4}$ for Uranus, $13\frac{3}{4}$ for Neptune. Such speeds may appear improbable, but the capture theory involves much greater improbabilities. The expulsion theory gives a possible explanation of the non-occurrence of retrograde orbits in the Jupiter family, while we meet them in the Uranus and Neptune families. The speed of expulsion necessary for retrograde motion would be 50 miles per second from Jupiter, but only a third of this for the outer planets. It may be noted that the outer planets would soon cease to be the controllers of the families of which they were the parents. The paths of such of them as came into our sphere of visibility would necessarily approach that of Jupiter; on the occasions of such approaches, the powerful attraction of Jupiter would modify the comets' orbits by degrees, till they no longer made near approaches to the orbits of their parent planets. On this view the year A.D. 126, assigned by Le Verrier as the date of capture of Tempel's comet of the Leonid meteors, would be the date of the expulsion of the comet and the meteors from Uranus.

THE PHYSICAL NATURE OF COMETS

When predicting the circumstances of the return of a periodic comet, the assumption is made that no force is acting upon it except the gravitational attraction of the sun and planets. The assumption is justified by the fact that in all such cases where the previous appearances of the comet have been well observed, and where the perturbations have been carefully computed, the prediction is close to the truth. On the other hand, study of the tails of comets shows that they are acted on by a repulsive force from the sun, which is in many cases much stronger than the gravitational force. It is concluded that the tail is composed of matter in a much more finely divided state than the head, and that the head is made up of fairly large lumps, for which the repulsive force is negligible compared with the gravitational. We are led to the same conclusion in two other ways.

First, the matter driven out into the tail is clearly lost to the comet, whose attraction is quite inadequate to bring it back from the great distances to which it is sent; but large comets, like that of Halley, continue to emit new tails at each approach to the sun. Hence the head must have reservoirs to contain this gas, and give some of it off at each approach. Meteoric masses, when analysed, are often found to contain hydrogen and other gases, so that it is reasonable to conclude that a comet's head is formed of similar masses.

Secondly, when orbits were calculated for the leading showers of meteors, it was found in many cases that they agreed closely with the orbit of some comet, and in the case of the Leonid meteors the year of maximum display, 1866, coincided with the perihelion passage of the comet. Since we do not see meteors unless they enter the earth's atmosphere, we can see only the meteors belonging to those comets whose orbits approach that of the earth; but we may infer their existence in other cases. The meteoric lumps are probably some feet in diameter, comparable with those large meteoric masses that have fallen to earth from time to time; specimens are exhibited at the Natural History Museum, South Kensington, and elsewhere. Lumps of a much smaller size would hardly retain a plentiful supply of gas for thousands of years, such as we infer to have been given out by Halley's comet from the accounts of immense tails at many of its returns. We cannot imagine the diameter of the lumps to run into miles since some sign of them would then have been visible when that comet transitted the sun in 1910.

There are two suggestions as to the nature of the repulsive force that drives out the tail; these are radiation pressure and electrical repulsion. The amount of the accelerative action has been measured by taking photographs at short intervals, and noting the outward movement of luminous knots in the tail; estimates as high as 80 times that due to gravity have been obtained, which is higher than the acceleration that radiation pressure could produce. There is another proof that other forces are at work in driving out the tail. It is easy to prove that all matter driven from the comet's head by solar action would leave the head along the line from the sun to the comet; but it is quite common for the tail to consist of several streamers radiating from the head like a fan, the outer ones making a considerable angle with the line from the sun.

The force expelling these streamers must be situated in the head, and electrical repulsion is the most probable solution. Morehouse's comet of 1908 was a specially favourable one for studying tail formation; it would seem that most of the matter leaves the head on the sunward side, but is soon bent back by the solar repulsive action. The action is like that of the jets in a fountain, shot up by water pressure, and curved downwards by gravity. When looking at the congeries of jets in the fountain we see that their outline is parabolic; in just the same manner we frequently see a series of parabolic hoods on the sunward side of the comet's head. These hoods are clearly shown in the photographs of Morehouse's comet of 1908, and in the drawings of those of 1874 and 1881.

The emission of tail matter is not continuous, but intermittent; in Morehouse's comet, and in Halley's (1910) the photographs showed discarded tails, with a space between them and the new tail. Halley's comet also lost its tail on Jan. 24, 1836, and there were rapid changes of appearance, which would seem to have had their seat in the nucleus. Holmes's comet of 1892 exhibited very remarkable changes, which were the more notable since it was distant from the sun, in the middle of the zone of asteroids. It suddenly attained naked eye visibility, though it had been equally well placed for observation for some weeks without anything being seen of it. There must have been something of the nature of an explosion in the nucleus, causing a great outrush of diffused matter which at first was very bright, but grew fainter as it expanded till it could no longer be discerned; then a second outburst took place, repeating the course of the first on a smaller scale. The comet was seen again in 1899 and 1906, but it never repeated the remarkable outbursts of its first apparition.

The comet of 1744 had six divergent tails; this was looked on at that time as very abnormal, and those who did not see the comet received the accounts with incredulity. But photographs show that multiple tails are quite common, though the outside ones are seldom so conspicuous as in 1744.

Comets in the Spectroscope.—The spectroscope indicates that most of the light of the nucleus is reflected sunlight; but most of that from the gaseous envelopes gives a spectrum of bright bands. These have been identified with those of carbon monoxide, cyanogen and hydrocarbons. At a moderate distance from the sun (half the earth's distance, or less) the spectrum of sodium usually becomes visible; it was conspicuous in Wells's comet of 1882, and gave the comet a yellowish colour. When a comet comes very near the sun, as in the great comet of 1882, the spectrum of metals, including iron, becomes visible. It will be remembered that iron is an important constituent of many meteors. The Russian astronomer, Theodore Bredichin, published a theory of comets' tails in which he postulated a hydrogen composition for long straight tails, a hydrocarbon one for those of intermediate type, and iron or other heavy substance for short, highly curved tails. The spectroscope hardly confirms this in details, since it does not reveal the presence of pure hydrogen; moreover, spectroscopic photographs taken with a prismatic camera do not indicate notable difference between the compositions of neighbouring tails.

Gradual Diffusion of Cometary Matter.—There are two distinct ways in which cometary material becomes scattered; the tails evidently consist of very finely-divided matter, either gas or fine dust, since here the non-gravitational forces predominate over gravitation. But meteors continue to follow gravitational orbits; hence they consist of much larger particles, similar to those forming the comet's head, on which we have seen that gravitation is in control. The large dispersion of the meteors away from the comet's head is surprising, and must have taken a long time to complete. Thus in both the November Leonid shower (Tempel's comet), and the August Perseid one (Tuttle's comet), the meteors form a complete ring round the whole orbit, though they are more densely packed in the neighbourhood of the comet. So also the Aquarid meteors of May, whose connection with Halley's comet is admitted, travel in paths separated from that of the comet by many millions of miles. The cause of the beginning of this scattering action is obscure, but once it had started it would proceed with accelerated pace, since the attraction of the sun and planets on the different portions would henceforth be appreciably different. We become aware of the existence of meteors only when they enter the earth's atmosphere; hence only a small minority of comets yield visible meteors; but from analogy we may infer their existence with confidence in the case of all the periodic comets. It is more doubtful whether comets with sensibly parabolic orbits are accompanied by meteor swarms.

There are two ways in which comets may cease to exist as such. Either the meteors in the head may lose all their gas (this appears to be the case with Biela's) or these meteors may become so diffused and scattered as to lose all semblance of unity and coherence. We have no actual experience of the dissolution of a comet in the latter manner; in fact the coherence of the heads of some comets is surprisingly great, and seems to indicate some unknown force holding the constituents together. Thus the comet Pons-Winnecke has been known since 1819, and has made several close approaches to Jupiter; further it has given rise to a meteor shower, which was well seen in June 1916. Yet when the comet approached very near the earth, in June 1927, its nucleus was seen to be very small, not more than two miles in diameter according to Prof. V. Slipher and M. Baldet.

Bibliography.—Practically all handbooks of astronomy have chapters on comets; reference can be made here only to books dealing specially with them; the first two books are of a popular character:—

George F. Chambers, F.R.A.S., *The Story of the Comets* (Oxford, 1910); Mary Proctor, F.R.A.S., *The Romance of Comets* (London and New York, 1926).

J. G. Galle, *Verzeichniss der Elemente der bisher Berechneten Cometenbahnen* (1894), contains orbits of comets from 372 B.C. to A.D. 1893, with copious notes in German. A sequel to Galle's *Cometenbahnen,* continuing it to A.D. 1925, published as vol. xxvi. part 2, of Memoirs of British Astronomical Association (Perth, 1925).

Bengt Strömgren, *Tables for a motion in parabolic orbits,* vol. xxvii. part 2, of Memoirs of British Astronomical Association (Perth, 1927).

Prof. H. C. Plummer, *Introductory Treatise on Dynamical Astronomy* (Cambridge, 1918), contains much useful matter relating to orbits, but needs mathematical knowledge.

Prof. Charles P. Olivier, *Meteors* (Baltimore, 1925). The association of meteors to comets is very close; there is much relating to comets in this book.

John Williams, *Observations of comets (in China) from 611 B.C. to A.D. 1640* (1871). A. Pingré, *Cométographie; ou Traité historique et théorique des Comètes* (1783), contains much interesting matter relating to ancient and mediaeval comets, but is probably accessible only in libraries.

A full and simple description of the method of finding orbits, both elliptical and parabolic, was given by Dr. G. Merton in the Monthly Notices of the Royal Astronomical Society for June 1925. Nothing is needed with it beyond a nautical almanac and logarithm tables (or, if preferred, a calculating machine). (A. C. D. C.)

RECENTLY OBSERVED COMETS

1. Halley's comet, May 4, 1910. Halley in 1704 was the first astronomer to establish the fact of a comet's periodic return and to calculate its elliptical orbit. His calculations were verified by the reappearance of the comet in the years 1759, 1835 and 1910
2. Brooks's comet, November 11, 1911. In 1911 this comet was easily visible to the naked eye and had a long tail
3. Morehouse's comet, November, 1908. Discovered in that year by Daniel Walter Morehouse, then of the Yerkes observatory. The tail formation of the comet is clearly shown here; a series of parabolic hoods may be seen on the sunward side of the head of the comet
4. Halley's comet as seen on April 27, 1910. This comet, called by its discoverer, because of its short period, the "Mercury among comets," is a member of the Neptune family. Its history can be traced in Chinese annals as far back as the year 240 B.C.
5. Pons-Winnecke comet, June 23, 1927. A member of the Jupiter family of comets, named after Pons, who discovered it in 1819, and Winnecke, who rediscovered it in 1858. The photograph shows the comet at a distance of four million miles from the earth. Stars are visible through the transparent cometic envelope. This comet's orbit is changed every alternate revolution
6. Comet Finsler, photographed with the 24-inch reflector of the Yerkes Observatory by Dr. G. Van Biesbroeck on August 5 and 6. This comet was discovered in the morning of July 4, 1937 by Dr. P. Finsler of Switzerland. It reached its closest approach to the earth on August 9 when the distance was forty-five million miles.

POPULAR U.S. COMIC STRIPS

1. "Superman," by Jerry Siegel and Joe Shuster
2. "Popeye," created by Elzie Segar
3. "The Gumps," originated by Sidney Smith and continued after his death by Gus Edson
4. "Li'l Abner," by Al Capp
5. "Mutt and Jeff," by Bud Fisher
6. "Mickey Mouse," by Walt Disney

COMET-SEEKER, a small telescope adapted especially to searching for comets: commonly of short focal length and large aperture, in order to secure the greatest brilliancy of light.

COMIC OPERA, which in its broadest significance may be regarded as including any kind of opera or musical play of a humorous character, in its more restricted and more commonly received meaning, implies an opera light in character, based on an amusing subject and having spoken dialogue. (*See* MUSICAL COMEDY.)

COMIC STRIP. The remote ancestry of the American serial comic would include the figures of "The Rake's Progress" and "Marriage à la Mode" of Hogarth, the work of Rowlandson and Cruikshank, and the "Robert Macaire" of Daumier and Philipon. The indigenous product first found expression in the back pages of the American magazines of the latter half of the 19th century. Conspicuous and enduring examples of this early work were Palmer Cox's "The Brownies," a series of drawings depicting the astonishing adventures of a race of benevolent little people, akin to the fairies; and the sketches of A. B. Frost. It was in the '90s that the comic serial found its way into the newspapers. "The Yellow Kid," a creation of that decade, contributed to the coinage of the term "Yellow Journalism." "The Yellow Kid" is generally credited to R. F. Outcault. Frederick Burr Opper, E. M. Hawarth, T. E. Powers, Gene Carr, creator of "Lady Bountiful," and Carl Schultz, creator of "Foxy Grandpa," were other outstanding comic artists of the period. Somewhat later came the "Bird Center" cartoons of John T. McCutcheon, racy of the soil of the Mid-West. Many successful comic strips have been reproduced as animated cartoons (*see* MOTION PICTURES: *Animated Cartoons*). "Bud" Fisher's "Mutt and Jeff" has been a striking example of the longevity of comic strips, as is Sidney Smith's "The Gumps," continued after his death in 1935 by other artists. Among well-known contemporary comic serials are, or have been, "Mr. and Mrs." started by the late Clare Brigg and continued by others; H. T. Webster's "The Timid Soul," "Poker Portraits," and "Trailer Tintypes"; "The Thimble Theatre," with its famous character "Popeye," by Elzie Segar (1894–1938); Fontaine Fox's "The Toonerville Trolley"; Frank Willard's "Moon Mullins" and William De Beck's "Barney Google."

COMINES, PHILIPPE DE, SIEUR D'ARGENTON (*c.* 1445–1509), French statesman and historian, was born at the castle of Comines, in Flanders. He was brought up at the court of his godfather, Philip V., duke of Burgundy, and in 1464 was taken into the service of Charles the Bold, count of Charolais. When in 1468 Charles, now duke of Burgundy, detained Louis XI., king of France, at Péronne, Comines brought about a reconciliation between the two princes; in 1472 Louis persuaded him to desert the duke's service for his own, made him chamberlain, loaded him with honours and estates and in 1476 appointed him seneschal of Poitou. After Louis's death in 1483 Comines was at first one of the counsellors of the regent, Anne of Beaujeu, but he was justly suspected of intriguing against the regency, with the dukes of Bourbon and Orleans, was banished from court, and in 1486 was imprisoned at Loches for some months in one of the cages used by his old master, Louis XI. On March 24, 1488, he was sentenced to the confiscation of a quarter of his property and was confined to one of his estates for ten years; but he was soon taken into favour again by Charles VIII., and employed as ambassador on various missions. He died in Oct. 1509 at Argenton, an estate acquired through his marriage with Hélène de Chambes.

The *Mémoires,* which he wrote in his latter years, earn for Comines the title of one of the greatest historians of his age; his portrait of Louis XI. is one of the classics of history.

The first part of the *Memoires, Cronique et hystoire du roy Louis onziesme, faicte et composée par Philippe de Comines,* written between 1489 and 1491, was first printed in 1524; the second part, *Croniques du roy Charles huytiesme,* was written between 1495 and 1498, and printed in 1528. Seven mss. are known, derived from a single holograph. Later editions were issued by D. Sauvage (1552), D. Godefroy (1649) and Lenglet Dufresnoy (London 1747). More recent editions are by B. de Mandrot (1901–03) and J. Calmette (3 vols. 1924–25). The first English translation was made by T. Danett, *The Historie of Philip de Commines* (1596, repr. 1897).

See H. Timpe, *Étude sur la vie et les mémoires de Philippe de Comines;* and for a detailed bibliography Ulysse Chevalier, *Répertoire des sources historiques du moyen âge, Bio-bibliographie.*

COMITIA, the name applied to the most formal types of gathering of the sovereign people in ancient Rome, is the plural of *comitium,* the old "meeting-place," on the north-west of the Forum. The Romans had three words for describing gatherings of the people. These were *concilium, comitia* and *contio.* Of these *concilium* could be applied to any kind of meeting and might be employed to denote an organized gathering of a portion of the Roman people such as the *plebs,* and in this sense is contrasted with *comitia,* which when used strictly should signify an assembly of the whole people.

Popular phraseology did not conform to this canon, and *comitia,* which gained in current Latin the sense of "elections" was sometimes used of the assemblies of the *plebs.* The distinction between *comitia* and *contio* was more clearly marked. Both were formal assemblies convened by a magistrate; but while, in the case of the *comitia,* the magistrate's purpose was to ask a question of the people and to elicit their binding response, his object in summoning a *contio* was merely to bring the people together either for their instruction or for a declaration of his will as expressed in an edict. The earliest *comitia* was organized on the basis of parishes (*curiae*) of patricians only, and was known in later times as the *comitia curiata.* The *curia* voted as a single unit and thus furnished the type for that system of group-voting which is found in the popular assemblies. The organization which gave rise to the *comitia centuriata* was the result of the earliest steps in the political emancipation of the plebs. Three stages in this process may be traced. In the first place the plebeians gained rights of ownership and transfer, and could thus become freeholders of land and of the appurtenances of this land (*res mancipi*). This legal capacity rendered them liable to military service as heavy-armed fighting men, and as such they were enrolled in the military units called *centuriae.* When the enrolment was completed the whole host (*exercitus*) was the best organized and most representative gathering that Rome could show. It therefore became invested with voting powers, and for two centuries (508–287 B.C.) was the dominant assembly in the state. But its aristocratic organization, based on property qualifications which gave the voting power to the greater landowners, prevented it from being a fitting channel for the expression of plebeian claims. Hence the plebs adopted a new political organization of their own. The tribunate called into existence a purely plebeian assembly, the *concilium plebis,* firstly, for the election of plebeian magistrates; secondly, for jurisdiction in cases where these magistrates had been injured; thirdly, for presenting petitions on behalf of the *plebs* through the consuls to the *comitia centuriata.* This right of petitioning developed into a power of legislation. The Hortensian law (287 B.C.) recognized the right of resolutions of the *plebs* (*plebiscita*) to bind the whole community. The plebeian assembly was organized on the basis of the territorial tribes in 471 B.C. This change suggested a renewed organization of the whole people for comitial purposes. The *comitia tributa populi* was the result and appears as a legislative body in 357 B.C.

In spite of the formal differences of these four assemblies and the fact that patricians were not members of the plebeian body, the people expressed its will equally through all, although the mode of expression varied with the channel. This will was in theory unlimited. It was restricted only by the conservatism of the Roman, by the condition that the initiative must always be taken by a magistrate, by the *de facto* authority of the Senate, and by the magisterial veto which the Senate often had at its command (*see* SENATE). There were no limitations on the legislative powers of the *comitia* except such as they chose to respect or which they themselves created and might repeal. In spite of the creation of *quaestiones perpetuae* (permanent commissions), they never lost the right of criminal jurisdiction, derived mainly from the right of appeal (*provocatio*) against the decisions of magistrates. Finally, the assemblies elected to every magistracy, with the exception of the Dictator and the Interrex. The distribution of these functions amongst the various *comitia,* and the differences in their organization were as follows:—

The *comitia curiata* in the later republic became a merely formal assembly. Its main function was that of passing the *lex curiata* necessary for the ratification both of the *imperium* of the higher magistracies of the people, and of the *potestas* of those of lower rank. This assembly also met, under the name of the *comitia calata,* and under the presidency of the pontifex maximus, to perform certain religious functions. For the purpose of passing the *lex curiata,* this *comitia* was in Cicero's day represented by but thirty lictors. The *comitia centuriata* could be summoned and presided over only by the magistrates with *imperium.* The consuls were its usual presidents for election and for legislation, but the praetors summoned it for purposes of jurisdiction. It elected the magistrates with *imperium* and the censors, and alone had the power of declaring war. According to the principle laid down in the Twelve Tables, capital cases were reserved for this assembly. It was not frequently employed as a legislative body after the two assemblies of the tribes, which were easier to summon and organize, had been recognized as possessing sovereign rights. The internal structure of the *comitia centuriata* underwent a great change during the republic. In the early scheme the First Class and the *equites* together could always outvote the rest, having 98 centuries against 95. The newer plan has been interpreted in different ways but the essential fact was that it reduced the combination of *equites* and *prima classis* to a minority by a fresh distribution of the classes and centuries over the tribes. In 88 B.C. a return was made to the more aristocratic system by a law passed by the consuls Sulla and Pompeius. But this change was not permanent.

The *comitia tributa* was in the later republic the usual organ for laws passed by the whole people. Its presidents were the magistrates of the people, usually the consuls and praetors and, for purposes of jurisdiction, the curule aediles. It elected these aediles and other lower magistrates of the people. Its jurisdiction was limited to monetary penalties.

The *concilium plebis,* although voting, like this last assembly, by tribes, could be summoned and presided over only by plebeian magistrates, and never included the patricians. Its utterances (*plebiscita*) had the full force of law; it elected the tribunes of the *plebs* and the plebeian aediles, and it pronounced judgment on the penalties which they proposed. The right of this assembly to exercise capital jurisdiction was questioned; but it possessed the undisputed right of pronouncing outlawry (*aquae et ignis interdictio*) against anyone already in exile.

There was a body of rules governing the *comitia* which were concerned with the time and place of meeting, the forms of promulgation and the methods of voting. The *comitia curiata* and the two assemblies of the tribes met within the walls, the former in the Comitium, the latter in the Forum (*q.v.*), or on the Area Capitolii; but the elections at these assemblies were in the later Republic held in the Campus Martius outside the walls. The *comitia centuriata* was by law compelled to meet outside the city, and its gathering place was usually the Campus. Promulgation was required for the space of 3 *nundinae* (*i.e.,* 24 days) before a matter was submitted to the people. The voting was preceded by a *contio* at which a limited debate was permitted by the magistrate. In the assemblies of the *curiae* and the tribes the voting of the groups took place simultaneously, in that of the centuries in a fixed order. In elections as well as in legislative acts an absolute majority was required, and hence the candidate who gained a mere relative majority was not returned.

The *comitia* survived the republic. The last known act of comitial legislation belongs to the reign of Nerva (A.D. 96–98). After the essential elements in the election of magistrates had passed to the Senate in A.D. 14, the formal announcement of the successful candidates (*renuntiatio*) still continued to be made to the popular assemblies. Early in the 3rd century Dio Cassius still saw the *comitia centuriata* meeting with all its old solemnities (Dio Cassius, lviii. 20).

COMITY: *see* INTERNATIONAL LAW, PUBLIC.

COMMA, originally, in Greek rhetoric, a short clause, something less than the "colon"; hence a mark (,), in punctuation, to show the smallest break in the construction of a sentence (Gr. κόμμα, something stumped or cut off, κόπτειν to strike). The mark is also used to separate numerals, mathematical symbols, and the like. Inverted commas, or "quotation-marks," are placed at the beginning and end of a sentence or word quoted, or of a word used in a technical or conventional sense; single inverted commas are used for quotations within quotations.

In music, comma is the name for the extremely small and purely theoretical intervals of sound resulting from the slightly different vibration numbers which may be possessed by one and the same note, according to the different ways in which it is arrived at by the process of tuning up or down from some other note.

COMMAND, in military engineering, the height measured vertically of the crest of a fortified work above the natural surface of the surrounding ground. In military organization it is used, in a general sense, to mean the whole number of troops under a particular officer's command, *e.g.,* "General A's command," especially when comprised of fractions of different units or formations. In a specific sense it is applied in the British and Indian armies to the highest and largest nature of commands which exist in peace time. These are on a territorial basis, and in them are stationed a varying number of divisions and brigades. The troops at home are distributed among the Aldershot, Eastern, Northern, Scottish Southern and Western Commands, besides certain "districts." The commands are usually sub-divided territorially into "areas." The army in India is divided territorially into the Northern, Western, Eastern and Southern Commands.

COMMANDANT. A military commander of a place or body of men, irrespective of his substantive rank, which varies with the size and importance of the place or force. Sometimes "commandant" forms part of a title, *e.g.,* "colonel-commandant." In the French army a commandant is the battalion commander (*see* OFFICERS).

COMMANDEER (from the South African Dutch *kommanderen,* to command), properly, to compel the performance of military duty in the field, especially of the military service of the Boer republics (*see* COMMANDO); also to seize property for military purposes; hence used of any peremptory seizure for other than military purposes.

COMMANDER. Any officer vested with the command of a force, formation, unit or detachment of troops, whether in the navy or in the army.

COMMANDERY, a division of the landed property in Europe of the Knights Hospitallers (*see* ST. JOHN OF JERUSALEM). The property of the order was divided into "priorates," subdivided into "bailiwicks," which in turn were divided into "commanderies"; these were placed in charge of a "commendator" or commander. The word is also applied to the emoluments granted to a commander of a military order of knights.

COMMANDO, a Portuguese word meaning "command," adopted by the Boers in South Africa for military and semi-military expeditions against the natives. More particularly a "commando" was the administrative and tactical unit of the forces of the former Boer republics, "commandeered" under the law of the constitutions, which made military service obligatory on all males between the ages of 16 and 60. Each "commando" was formed from the burghers of military age of an electoral district.

COMMEDIA DELL' ARTE, name given to the mediaeval Italian comedy in which the plot was written out, but the dialogue was improvised by the actors. The name *commedia dell' arte all' improvviso* means, therefore, a comedy improvised by the actor gild (*arte*) or profession. Certain characters recur almost invariably in these plays (*e.g.,* Arlecchino, the Captain, the Doctor), and are the prototypes of the Punch and Judy show, and the Clown, Harlequin, Columbine and Pantaloon of the pantomime. The influence of the *commedia dell' arte* can, indeed, be traced throughout European art and literature. (*See* DRAMA: *The Modern National Drama: Italy.*)

See Winifred Smith, *The Commedia dell' Arte* (New York, 1912).

COMMEMORATION, a celebration of some past event, especially the ceremonial closing of the academic year at Oxford university. This consists of a Latin oration in commemoration of benefactors and founders; of the recitation of prize compositions in prose and verse, and the conferring of honorary degrees upon English or foreign celebrities. "Commencement" is the term for the equivalent ceremony at Cambridge, and this is also used in the case of American universities.

COMMENDATION, approval, a recommendation of one person to the favour of another. *Commendatio* is the liturgical term for the office commending the souls of the dying and departed to the mercies of God. In feudal law it was applied to the act by which a freeman placed himself under the protection of a lord (*see* FEUDALISM). In ecclesiastical law the commendation, or grant *in commendam* of benefices was made temporarily until a vacancy was filled up, and frequently to persons who, by defect of age or orders, were for the time being debarred from receiving institution. The practice of granting benefices *in commendam* to laymen, or, in the case of monasteries, to secular clerks who enjoyed their revenues and privileges for life, or to bishops to hold with their sees, became very general in the later middle ages, especially on the continent. In 1836 the tenure of benefices *in commendam* in England was forbidden by act of parliament.

COMMENTARII, notes to assist the memory, memoranda. This original idea of the word gave rise to a variety of meanings: notes and abstracts of speeches for the assistance of orators; family memorials, the origin of many of the legends introduced into early Roman history from a desire to glorify a particular family; diaries of events occurring in their own circle kept by private individuals—the day-book, drawn up for Trimalchio in Petronius (*Satyricon,* 53) by his *actuarius* (a slave to whom the duty was specially assigned) is quoted as an example; memoirs of events in which they had taken part drawn up by public men—such were the "Commentaries" of Caesar on the Gallic and Civil wars, and of Cicero on his consulship. Different departments of the imperial administration and certain high functionaries kept records, which were under the charge of an official known as *a commentariis* (cf. *a secretis, ab epistulis*).

The *Commentarii Principis* were the register of the official acts of the emperor. These must be distinguished from the *commentarii diurni,* a daily court-journal. At a later period records called *ephemerides* were kept by order of the emperor; these were much used by the Scriptores Historiae Augustae (*see* AUGUSTAN HISTORY). The *Commentarii Senatus,* only once mentioned (Tacitus, *Annals,* xv. 74) are probably identical with the *Acta Senatus* (*q.v.*). There were also *Commentarii* of the priestly colleges. Mention should be made of the *Commentarii Regum,* containing decrees concerning the functions and privileges of the kings, and forming a record of the acts of the king in his capacity of priest.

See the exhaustive article by A. von Premerstein in Pauly-Wissowa, *Realencyklopädie* (1901); Teuffel-Schwabe, *Hist. of Roman Lit.* (Eng. trans.), pp. 72, 77–79; and the concise account by H. Thédenat in Daremberg and Saglio, *Dictionnaire des antiquités.*

COMMENTRY, a town of central France, in the department of Allier, about 7 miles E.S.E. of Montluçon. Pop. (1936) 6,640. Commentry gives its name to a coalfield over 5,000 acres in extent, and has important foundries and forges.

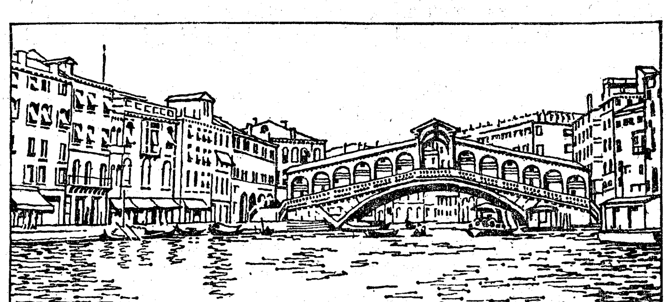
COMMERCE. In the widest sense the term commerce covers the exchange of commodities and all the arrangements necessary for effecting such exchange; but in general usage it is more or less strictly confined to exchanges conducted on a large scale, particularly between distant places. The desire to make an exchange of goods will arise when one area possesses by nature something which another does not, or when it has acquired by skill a relative advantage in the making of particular articles. The extent to which commerce will develop in such circumstances will depend on a number of factors. If the means of transport are primitive the volume of long-distance trade will necessarily be small and the goods which enter into it must be able to bear high costs. If the trade route is dangerous and the trader has no prospect that his enterprise will receive proper protection the heavy risks may seriously discourage him. If methods have not been elaborated for computing, recording and paying debts he has no firm basis for his operations. If the goods have to pass political boundaries and the countries concerned burden it with tolls or taxes the trade will tend to be restricted. The history of the evolution of commerce, therefore, mainly consists of an account of how the tendency towards making exchanges has been limited by defective means of transport, by the perils of the route, by the lack of appropriate mechanism for carrying on trade, and by regulations adopted in the interests of particular States.

Commerce in the Ancient World.—Long-distance trading presented great difficulties in the ancient world. It seems first to have developed along desert routes which had the advantage that comparatively large groups could travel together in caravans and defend themselves against marauders. Oases could be established as ports of call and *entrepôts.* In this way trade sprang up between the civilizations of the Tigris-Euphrates valley and of Egypt. A very large caravan would be required to convey a hundred tons and its progress would be slow. It follows that the goods which entered this trade had to have a high value in proportion to their bulk. They would include such things as oriental spices, drugs and dyes as well as fine textile fabrics and a variety of metal ornaments. But necessaries (for which there was a large and constant demand) would obviously not appear. This caravan trade retained its essential characteristics for centuries. In the course of time the caravan trade became subordinate to sea routes. The first people to make this development of the overland commerce were the Phoenicians. From their bases on the Syrian coast they carried goods by sea to Cyprus and Rhodes and step by step found their way to the western Mediterranean and beyond. The original cities of Tyre and Sidon and the colonies they founded, of which Carthage became the chief, were true commercial centres. Articles wrought in metal, glass ware and textiles were exchanged for tin, copper and silver in the West. The Phoenicians were pioneers in the craft of ship construction, and the wealth which they amassed demonstrated the fact that a long-distance sea trade could be very profitable. Their merchants appear to have made their exchanges on the basis of goods for goods; it remained for their rivals and successors, the Greeks, to spread the use of coined money. Athens, in particular, introduced and maintained an excellent silver currency which won general acceptance because it was not allowed to depreciate. She exported olive oil, figs, honey, pottery and small quantities of metal and textile goods. Her trade with the Black sea is an early example of dependence for essential food supplies on regular communication by sea. The fortified harbour at the Peiraeeus also attracted a considerable volume of *entrepôt* trade, it being used by the merchants of Asia Minor and Syria in their dealings with the rest of Greece and countries to the West. Greek commercial enterprise was offered new opportunities when the conquests of Alexander opened the way into the heart of Asia. The consequent stimulus to long-distance trade was reflected in the growth of Antioch and Alexandria as great commercial cities.

Commerce of the Roman Empire.—In the earlier phases of its history Rome took little interest in commerce. In its origins an agricultural community, it long clung to its traditions. But the series of events which led to the destruction of Carthage (146 B.C.) and the assertion of Roman supremacy over Greece necessarily opened up the possibilities of commercial development. When Augustus put an end to civil dissensions and inaugurated a period of peace these possibilities were fully explored. The main current of trade continued in the direction determined by the Greeks. To Antioch came the chief caravan routes from the East. The commodities thus secured were shipped from its port, Seleucia, to all parts of the Mediterranean. They were the typical articles of this trade—spices, drugs, silks, etc.—and catered for the demands of the wealthier classes. The commerce of Alexandria, however, was of a twofold nature. Oriental luxury goods from Arabia and India reached Egypt by way of the Red sea. Augustus took steps to protect this trade by forcing the Arabs and Ethiopians to desist from piracy and he also had the navigable canals repaired. A sea-captain, named Hippalus, is said to have observed the periodicity of the monsoons about the middle of the 1st century of our era, thus making a direct voyage to India possible and eliminating the need of calling at Arabian ports. There is, indeed, much testimony to the extent of this commerce in the first two centuries. Pliny complains that the demand for Eastern luxuries was so great that it had caused a drain of silver from the West to pay for them. This is partly confirmed by the fact that large quantities of coins of the early Roman emperors have been found in southern India. But there was another side to the trade of Alexandria. The importation of corn from Egypt was essential for the sustenance of the growing population of Rome. Some 20 million bushels were imported annually, part of it being produced on the emperor's domains in Egypt, but most being exacted as tribute from the province. Elaborate precautions were taken to safeguard the supply. Severe penalties were promulgated under Augustus against anyone who delayed the sailing of a corn-ship. The port at Ostia, where the corn was unloaded, was improved by Claudius. Trajan instituted regular sailings and provided granaries for storage. State supervision was necessary not only because the trade was vital to the existence of Rome but because of its very nature. There was no true exchange of goods between Rome and Egypt. Even at its zenith Rome was singularly unproductive; it never had the means of paying for its imports. Little is known of the organization of commerce, as, for instance, of the respective functions of merchants and shippers; but it is obvious that the corn trade was not one in which private enterprise could find a place. The trader was no doubt discouraged in other ways. Ships which were not part of a convoy were in danger of being attacked by pirates. Weather conditions in the Mediterranean made winter sailing perilous. With favourable winds the voyage between Alexandria and Rome could be accomplished in eight or nine days. When winds were contrary recourse had to be had to coasting from point to point and weeks could easily be consumed. A vivid account of such a voyage is given in the 27th chapter of *Acts*, the "ship of Alexandria" and her cargo of wheat being lost. It is not surprising, therefore, that the activities of the private merchant continued to centre in the provinces of the eastern Mediterranean. Some of them found means of extending their trade to the West as the Roman empire promoted the growth of cities where a demand for luxury goods arose. But that commerce had its roots in the East is proved by the fact that in most cases the merchant discovered in the West turns out to be a Greek, a Syrian or a Jew.

The Byzantine Empire.—When the Roman empire in the West collapsed under the successive blows of the barbarian invasions the volume of this trade was greatly reduced. Commerce was virtually confined to the eastern Mediterranean where Constantinople enjoyed pre-eminence as the capital of the east Roman or Byzantine empire. Antioch had been sacked by the Persians in 540 and was captured by the Saracens in 637. The rising tide of Mohammedanism swept over Egypt, and Alexandria itself capitulated in 641. Constantinople, however, did not fall into the hands of a Mohammedan conqueror until the 15th century. She attracted to herself the commerce between Asia and Europe. From the fall of Rome in the 5th century to the age of the Crusades she was the great *entrepôt* of long-distance trade. Unlike Rome, Constantinople and the other cities of the Byzantine empire established a reputation for their manufactures. High quality textile goods, leather work, armour, engraved and enamelled metal articles of exquisite workmanship, carved ivories, mosaics and porcelain were among the exports. Corn, wax, furs, amber, salt fish, unwrought metals and raw wool were secured in exchange from the less advanced peoples whom she did so much to civilize. Merchants had the advantage of good money—the bezant, a gold piece which was generally acceptable. The principles of banking and the use of credit notes were known. Loans could be raised at a moderate rate of interest. Shipping was assisted by the development of insurance. It is true that from the reign of Justinian (528–565) there was a tendency to adopt a commercial policy in the fiscal interests of the empire. There were heavy duties on the import and export of certain commodities, and taxes were levied on purchases and sales. Justinian also introduced the principle of monopoly in favour of the silk industry which he took pains to set up in order that the empire might be independent of the supplies from the East which were controlled by Persia. Against these restrictions must be placed the influence of the great fairs of Constantinople and Thessalonica at which the merchants who resorted to them from all countries enjoyed great freedom of trade. Concessions were also made to alien merchants by granting them special quarters. The most favoured of them, such as the Venetians and the Genoese, had extensive privileges; others were subject to restrictions as to the time they were allowed to stay within the empire and their business had to be conducted under supervision.

The Italian Trading Towns.—The heirs of Constantinople were the Italian trading towns. They had developed under the aegis of the Byzantine empire and they profited from its decline. Venice in particular rose to splendour in the middle ages. Situated amid the lagoons at the head of the Adriatic sea, it was at first a place of refuge in the troubled days of the barbarian invasions. A position could hardly have been better chosen to serve as an *entrepôt* through which the trade of the Levant could pass into central Europe as conditions there became more settled. The merchants of Germany had access to it across the Brenner pass, and goods could also be conveyed along the valley of the Po and by way of the St. Gotthard pass to the growing towns of the Rhineland and the Low Countries beyond. Through Istria and along the Save the countries of the Danube basin could be reached. The Venetians themselves, however, had a predilection in favour of sea routes. It was by sea that they imported oriental commodities. To make the sea route to the eastern Mediterranean secure they aimed at gaining control of the coast-line and the islands. Advantage was taken of the crusades to pursue this policy. Concessions were exacted in return for shipping services. When the leaders of the fourth crusade, for instance, negotiated for their trans-shipment to Egypt—the first proposed objective of the expedition—Venice demanded a payment of 85,000 marks and a share in the conquests. Since they could not satisfy these claims the leaders of the crusade were induced to do Venice a service by capturing for her Zara, a position she coveted on the Adriatic. Although the Venetians were not responsible for the subsequent diversion of this crusade to the capture of Constantinople itself in 1204, they took advantage of the turn of events and claimed large territorial grants. This persistence in strengthening her hold in the Levant indicates the character of her trade. Year by year she was attempting to find new outlets in the West for the goods carried by caravans from the East and the products of Byzantine workshops. As she was pre-eminently a sea-power it was natural that she should consider a sea route to the West.



BY COURTESY OF G.W.H. BRITT

THE RIALTO BRIDGE, IN VENICE, THE WORK OF ANTONIO, OR NOVANNI CONTINO, 1588–91

From the early part of the 14th century a fleet of galleys was despatched to the countries of the western Mediterranean, and it made its way by easy stages through the Strait of Gibraltar as far as the Low Countries. The voyage, which was usually annual, was publicly organized and controlled. The goods, however, were carried on the account of individual merchants to whom opportunity of securing space on the ships was offered by auction. Since Bruges was then the chief mart of north-west Europe most of the cargoes were directed there; but a ship might detach itself from the fleet to call at Southampton, Sandwich or London. By this means such commodities as pepper, cloves, indigo, ginger, etc., were carried to the West at a lower cost than that of the overland route. As a return cargo the galleys took wool, hides and metals which were worked up in Italy for export to the East. Florence, for instance, was the centre of a flourishing cloth industry organized on a capitalist basis, and Lucca had an important silk industry. As the Italian towns were purely commercial some kind of exchange of goods was necessary and consequently the expansion of trade promoted industrial activity. It was also facilitated by the improved mechanism of commerce effected by the Italians in the methods of account-keeping and the organization of credit. Bankers, particularly those of Florence, had connections throughout western Europe. The commercial activities of Venice were rivalled, though not equalled, by those of Genoa and Pisa. Genoa strove not unsuccessfully for a share in the Levantine trade and contended with Pisa for the trade of North Africa and Spain.

The Hanseatic League.—The fact that the Venetians found it worth while to make a direct sea voyage to the Low Countries shows that good markets for long-distance trade had grown up there by the 14th century. These had developed slowly from the 9th century onwards as new kingdoms had arisen out of the ruins of the Roman empire. Merchants began to enjoy some measure of protection. Charles the Great, for instance, assured Offa of Mercia in 796 that any of his subjects lawfully pursuing their business in his dominions would be safeguarded against oppression. The Northmen found their way by river routes from the Baltic to the Black sea and obtained supplies of oriental goods. Progress was slow at first. By the 11th century, however, German towns had taken the initiative and the merchants of Cologne were particularly active. The towns of north Germany also entered into agreements with one another to co-operate in suppressing robbery on the roads and piracy at sea. Out of such understandings the powerful Hanseatic League ultimately emerged. It was a confederation of towns, mostly though not exclusively in Germany, formed to consult their common commercial interests. The League was no less than a great commercial State; it had its regular assemblies, its courts and its treasury, and it entered into treaty relations with foreign States. The main purpose was to gain concessions in its favour from the rulers of other countries. Such privileges it strictly confined to its members. In countries where long-distance commerce had not developed the League negotiated for factories or settlements which were at once residences and warehouses. They were concrete expressions of the treaty privileges gained by the League and the means of supervising the activities of its own members. There was a factory at Bergen from which the trade with Iceland could be carried on, and another at Novgorod where goods could be exchanged for Russian products. In London the League had its settlement called the Steelyard, and it long enjoyed more favourable terms than any other merchants in the payment of customs duties. Still more important was the position which it occupied in Bruges where the merchants of northern Europe and the Mediterranean came into direct contact. It was also the chief market for English wool and Flemish cloth. The Hanseatic merchants, therefore, were chiefly engaged in exchanging the products of the northern countries—furs, salt fish, flax, timber and tar—for wool, leather, cloth and the commodities in which the Italians specialized. They confined their attention to merchandise and did not undertake money-lending. Under the leadership of Lübeck and Hamburg the League established a great prestige which was of first importance in the commercial development of northern Europe.

Characteristics of Mediaeval Commerce.—The total volume of long-distance trade in the middle ages was comparatively small. With respect to the necessaries of life most areas were self-sufficing. The goods which entered into international trade were still mainly articles of luxury for the wealthier classes. Oriental products reached western Europe chiefly through the agency of Venice and Genoa. They were paid for to an increasing extent by the export of high quality woollens. Cloth was the first European product which was carried long distances in considerable quantities. It became worth while for special classes of merchants to devote all their attention to its sale. For the most part, however, merchants dealt in a variety of goods and a wholesale market in any commodity was exceptional. Particular value, indeed, was attached to the right of retail trading. Local merchant gilds tried to monopolize it by forcing outsiders to sell in bulk. The members of the Hanseatic League were extremely jealous of the privilege of retailing where they had secured it. Obviously the retail market was more certain and profitable. The travelling merchant covered a range of articles, and even when he became resident and his business was carried on through agents, it retained its general nature.

Mediaeval commerce was restricted in many directions. Transport remained expensive both by land and sea; by land only small quantities could be carried by pack-horse or some such method and frequent tolls were exacted, and by sea it was customary to arrange common sailings for the sake of convoy and this meant that the relative cheapness of carriage had to be set against the slowness with which the capital invested was turned over. Local organizations of merchants often succeeded in imposing serious restraints on foreigners. The custom of *hosting* was common, usually requiring that aliens should have the period of their sojourn in a country limited to 40 days and that they should stay with a native merchant to whom the details of their business should be revealed. Commerce also frequently suffered from regulations imposed in the fiscal interest of States. The chief goods on which customs were paid had to pass through prescribed staple ports, and the situation and number of such staples were subject to constant change, usually for political reasons. The export of money was often forbidden because special importance was placed on the accumulation of the precious metals within the country. Sometimes alien merchants suffered from popular outcry against the nature of their trade, it being alleged that they were importing useless or harmful luxuries and exporting necessaries. The catalogue of discouragements, whether natural or artificial, seems formidable. It should be remembered, however, that local and Governmental restrictions were often relaxed. Reference has already been made to the privileges enjoyed by organizations of alien merchants such as the Hanseatic League. The fairs (*see* FAIR) also gave opportunity for temporary freedom of trade and were resorted to by merchants engaged in long-distance commerce. Among the most notable fairs in western Europe were those of Champagne, which were held at Provins, Troyes and other centres, and extended over the greater part of the year. Merchants attending them were guaranteed safe journeys and protection in their lawful enterprise. In the conduct of the fairs a common code of mercantile law was evolved to meet the problem of settling disputes between merchants of different countries without delay. The mechanism of trade was improved. Money-changing had to be arranged because of the great variety of coins which were current. From money-changing, money-lending was an easy step. The inconvenience of paying debts at a distance by incurring the risk of sending money, when it was lawful to do so, or by despatching goods which the debtor was willing to accept, was removed by the growing use of the principle of the bill of exchange.

From the Mediterranean to the Atlantic.—The conquests of the Ottoman Turks in the 15th century threatened to close the routes by which oriental goods had reached the Levant. Constantinople fell into their hands in 1453, and although Venice succeeded in her negotiations for the retention of her trading privileges for a time, the Christian powers could not but regard the Turkish advance into Serbia, Wallachia, Bosnia and Greece with apprehension. Venice herself was involved in a series of wars with the Turks in the 16th century and suffered heavily from the exhaustion of her resources and the loss of territory. Prolonged disturbance in the Mediterranean reacted adversely on the long-established and lucrative trade with the East. The question naturally arose whether the commodities could be obtained by some other route. The pioneer work of Prince Henry of Portugal was rewarded by the rounding of the Cape of Good Hope by Bartholomew Diaz in 1486 and by Vasco da Gama's successful voyage from Lisbon to Calicut in 1498. Meanwhile Christopher Columbus, a Genoese sailor in the service of Castile, sought India by sailing west and discovered a "new world" lying across his path.

These two discoveries were destined to effect a revolution in commerce, but their consequences were not apparent for some time. Portugal and Spain claimed exclusive rights in the exploitation of the new routes. The English were not without hope that they would be able to find a northern passage to the East. This would enable them to avoid conflict with the Portuguese and Spaniards, and also to carry on an intermediate trade in woollens for which there was no demand in the tropics. The best-known attempt to find a north-east passage is that of Chancellor and Willoughby in 1553. Chancellor succeeded in reaching Archangel and on the basis of trading concessions made by the tsar of Russia an English joint-stock company—commonly called the Muscovy or Russia Company—was formed. It included in the area with which it proposed to trade Armenia, Media, Hyrcania, Persia and the Caspian sea; in other words, it intended to get into contact with the trade routes of central Asia. That this was possible was demonstrated by the celebrated traveller, Anthony Jenkinson, who in 1557–59 went from Archangel to Moscow, along the Volga to the Caspian sea and then found his way to Bokhara, where he saw great numbers of Indians and Chinese buying and selling. This would seem an impracticable route from England to the East, and yet the fact remains that the Russia Company made good profits from its "Persian Voyages" in the years 1566–81. As to a north-west passage the persistent endeavours of the English to find one are illustrated by the careers of Martin Frobisher, John Davis, Henry Hudson and William Baffin. But the tendency of the Eastern trade to return to its old channels was still strong. An agreement was arrived at with the sultan of Turkey and an English company was formed in 1581 to carry on direct trade with the eastern Mediterranean. It was fully incorporated as the Governors and Company of Merchants of the Levant in 1592. For some years the company did fairly well, particularly by importing currants, but towards the end of the century it met with difficulties.

The Sea Route to India.—Meanwhile Portugal and Spain had been endeavouring to profit from their discoveries. The Portuguese aimed at controlling for their own advantage the existing Indian trade-routes to Africa, the Red sea, the Persian gulf, the Cambay ports and the Spice islands. The centre of their power was Goa, but they had important settlements at Ormuz, Calicut and Cochin. In 1580 the crowns of Portugal and Spain were united in the person of Philip II. This meant that the Portuguese possessions were at the mercy of the enemies of Spain. The position of the Spaniards in the New World had already been challenged by English sea-captains. John Hawkins had tried to gain a footing in the West Indies by supplying the Spaniards there with African negroes to do the field work for them. This breach of her monopoly was strongly resented. Spain had concentrated her main attention on the silver mines of Mexico and Peru. The treasure thus obtained by forced labour was expended in Europe in buying commodities from other countries and in the conduct of wars. It did not strengthen her commercial position; in fact the yield of the plate fleet was often mortgaged to her creditors before it arrived. The one general result of her policy, indeed, was a fall in the purchasing power of money with all the social consequences of a price revolution. Francis Drake in his famous circumnavigation of the world in the years 1577–80 showed at how many points Spain could be attacked by an intrepid adventurer. He returned with a cargo of gold, silver, silk, pearls and precious stones. These were the spoils of a daring exploit and provided no foundation for trade. It was still to be sought in the East.

In the last decade of the 16th century the English and Dutch turned their attention to the Cape passage to India. Sir James Lancaster in the expedition of 1591–94 reached the Indian ocean but then met with a series of disasters. The Dutch voyage of 1595, commanded by Houtman, who had served on Portuguese ships in the East, succeeded in getting a valuable cargo of spices from Bantam. Encouraged by this example, and provoked to action by the high prices the Dutch exacted for spices, the Levant merchants in London took steps to form a new company. A charter was granted to the "Governor and Company of Merchants of London trading to the East Indies" on Dec. 31, 1600. For the first seven years the voyages of the company were directed to the Spice islands. The trade was lucrative, but it presented one serious difficulty—the ships could not take out commodities which the natives wanted. From its inception the company had been given the right to export silver, provided it did not exceed £30,000 in value in any one voyage; but this privilege exposed it to the charge that it was undermining the strength of the country. In the prevailing state of opinion the company could not but be sensitive to this attack. When their factors at Bantam informed them that there was a good market for Indian calicoes there, they naturally explored the possibility of sending English goods to the Cambay ports, where they could be exchanged for calicoes, which were acceptable in exchange for spices in Java. So the company sought and ultimately obtained the right to establish a factory or trading-settlement at Surat. There they found that indigo could be bought at a price which yielded high profits in Europe, and it long remained one of the chief articles of direct trade between England and India. A footing was also gained in Persia where silk was obtained for export to Europe. The English company, in fact, gradually established itself on the mainland, the growing hostility of the Dutch driving it from the Spice islands. In the later years of the 17th century the English woollen industry was complaining that the import of Indian textiles was ruining its trade; and later the use of certain Indian piece-goods was prohibited in Great Britain. They were imported and offered by auction for re-export and mostly shipped to West Africa. This example shows that the costs of carriage were so reduced by the development of the direct sea route to India that fabrics cheap enough to clothe negro slaves could enter into the trade.

Rivalry of England and Holland.—English commerce had been largely in the hands of aliens, chiefly Italians and Germans, during the middle ages. But two groups of native merchants in the course of time won recognition as distinct companies—the Merchants of the Staple who exported wool and the Merchant Adventurers who sought markets for English cloth. With the growth of the woollen industry the latter became the more important of the two. Their origins are obscure, but by the 16th century they enjoyed the monopoly in the export of cloth by English subjects to the Low Countries and Germany. They came into conflict with the merchants of the Hanseatic League, and in 1578 the Germans finally lost the favourable position they had so long held in England. The Merchant Adventurers themselves had their chief seat abroad at Antwerp, which in the 16th century had succeeded to the position previously occupied by Bruges; but the political disturbances in the Low Countries drove them to seek a centre in the north and they eventually settled in Hamburg. The Hanseatic League monopoly in the Baltic was further challenged in 1579 by the formation of the Eastland Company which secured concessions in Elbing at the mouth of the Vistula. This activity in forming trading companies—reference has already been made to the Russia Company, the Levant Company and the East India Company—might seem to indicate a policy of promoting English commerce. That was not necessarily the result. The companies were given exclusive rights as far as English subjects were concerned in the areas assigned to them and they were tempted to exploit this privilege for their own ends. There is good ground for contending that the expansion of trade was due to the interlopers who defied the rights of the companies and tried to break their monopoly. At any rate the 17th century witnessed many attacks on the company system because it was alleged to restrict commerce; and the case against it seemed the stronger since Dutch competition was in so many instances successful in depriving the companies of trade in their special areas. The "endeavours of the industrious Dutch" are the constant theme of English economic writings in the 17th century.

The wealth of Holland rested primarily on the degree of organization she applied to the herring fishery, for it gave her experienced sailors and a commodity for which there was a great demand in the European markets. The fishing season was so arranged that a great fleet was kept constantly at sea and its wants supplied by other ships which brought in the herrings ready salted and packed in barrels. Situated at the mouth of great riverways, the Dutch were able to dispose of this fish on profitable terms. Amsterdam, it was said, was built on herring bones. Fishing led to an improvement in shipping and the building up of the proud position of being the chief maritime carrier in the world. Her towns were intimately connected by waterways and each specialized in some direction. Ships were built appropriate for the different kinds of cargoes and their parts were standardized. With a high net tonnage, and managed by a comparatively small crew, specialized ships following a regular course in quick succession could easily offer freight rates with which other countries could not compete. Writing in 1665 Sir Josiah Child puts down a list of trades which the English had lost—the Russian, the Baltic, the Spanish, that of the Spice islands and the Far East, even that of Scotland and Ireland—all had fallen to the Dutch. They had, according to him, the advantages of better education, better workmanship, better commercial laws, better ship-designing, and above all a better banking system with a lower rate of interest. The English Navigation Act of 1651 was designed to damage the Dutch carrying trade by requiring that, as a general rule, goods should not be imported except in English ships or ships of the country where they originated. Contemporaries supposed that this policy did irreparable harm to the Dutch, but their opinion is not supported by the evidence. The Dutch carrying trade survived with little diminution for many years; its relative decline in the 18th century was due to other causes.

The Mercantile System.—"The ordinary means to increase our wealth and treasure," declared Thomas Mun in the middle of the 17th century, "is by foreign trade, wherein we must ever observe this rule—to sell more to strangers yearly than we consume of theirs in value." This meant that a government should see that the value of the commodities exported was greater than that of those imported; the difference, it was supposed, would have to be paid in treasure, *i.e.*, coin or bullion. The means adopted to secure a favourable balance of trade in this sense constituted the mercantile system. The trade with foreign countries in general and each country in particular was examined to discover whether the general and particular balances were or were not favourable. If a balance was considered to be unfavourable, steps had to be taken to correct it. In France Louis XIV.'s minister, Colbert, set himself to promote French commerce on these principles; he accordingly tried to restrict trade with England and Holland. English mercantilists, on the other hand, regarded trade with France as disadvantageous and it was subjected to the prohibitive tariff of 1678 until Pitt initiated a more liberal policy in the commercial treaty of 1786. It was also found that the importation of naval stores—tar, pitch, resin and timber—from the Baltic meant that England had a permanently unfavourable balance of trade with Sweden and Russia; consequently an attempt was made to stimulate a new source of supply by offering bounties on the production of these commodities in the American colonies. In fact colonization seemed to offer to the countries of western Europe a way of escape from the supposed disadvantages of unfavourable balances of trade. The colonies might either produce the commodities which had otherwise to be imported from a foreign country, such as naval stores, or send to the mother country some staple goods, such as tobacco or sugar, which could be re-exported to foreign countries and thus give it a firmer position in their markets. It was for this reason that the English Navigation Act of 1660 "enumerated" certain articles which had to be sent in the first instance to England, a list which included sugar, tobacco, indigo and ginger. The mother country was to be the *entrepôt* for these goods. It followed that the highest value was put upon the colonies which produced them, *i.e.*, the West Indies, Virginia and Maryland. The New England colonies were looked upon with suspicion because they produced commodities similar to those of the mother country. There is no doubt, of course, that England would have made high profits had she been able to monopolize the new staples which were now entering into long-distance trade. For a time she supplied the European markets with sugar, but in the 18th century Dutch and French producers were able to undersell her. It was to prevent the New England colonies from trading with the foreign West Indies and thus assisting in their development that the Molasses Act of 1733 was passed. For 30 years the act was almost a dead-letter, and then the declared intention of the mother country to enforce it contributed to the beginnings of revolutionary agitation in the colonies. The history of tobacco is different. It was overproduced in the British colonies and prices fell; but since so much credit had been advanced to the planters their position of heavy indebtedness was also an element in estrangement from the mother country. The aims of mercantilism had been defeated by the course of events. The revolt of the American colonies in 1776 made a serious breach in the system, and the publication of Adam Smith's *Wealth of Nations* in the same year supplied the classical refutation of its fallacies.

The Industrial Age.—The fact that so much importance was attached to the trade in sugar and tobacco—and, it should be added, the East India Company's monopoly in tea—is an indication of the change which had come over long-distance trade. Commerce was now supplying the necessaries of the many rather than the luxuries of the few. Since these necessaries were only to be obtained in exchange for other goods, the increasing demand promoted industries in the trading countries. This was particularly the case in Great Britain where commercial expansion led to an industrial revolution. A country which had attempted to use colonial staples in order to become "a nation of shopkeepers" found herself converted into "the workshop of the world." Her position as a great ocean carrier, the financial system which had been built up, the freedom of movement for persons and goods within her boundaries and the natural resources in coal and iron all contributed to this conversion. Perhaps one of the most significant results was the change in the direction of the flow of textiles. Until the end of the 18th century the trade with India had been looked upon with some disfavour because it involved considerable imports of calicoes and muslins and a comparatively small export of English woollens. The introduction of machinery in the Lancashire cotton industry completely altered the position. Raw cotton was now imported in large quantities from America and machine-made piece goods were sent to India where they were sold at such prices that the native products could not compete with them. The application of steam-power to transport enormously enlarged the scope of commerce. Railways opened up the interior of the continents and so brought to the ports commodities which would not otherwise have entered into long-distance trade, or in many cases indeed would not have come into existence. The steamship reduced the length of voyages and construction in iron—and later in steel—greatly increased its carrying capacity; services were also more regular than in the old sailing days. When the Suez canal was opened in 1869 it provided a much shorter route to the East particularly suited to the steamship.

All these changes naturally reacted on commercial policy. Great Britain between 1820 and 1860 abandoned the restrictive system which had survived from the 18th century. To sell her manufactures in the markets of the world she opened her ports to the raw materials and food stuffs which other countries could supply. She was also able to put her financial resources at the disposal of those who undertook the building of railways and other projects abroad and thereby helped to multiply the goods which entered into commerce. Railways and low ocean freights made it possible for wheat grown in the Mississippi valley to be sold in Great Britain at prices which drove British farmers to reduce arable cultivation. A rapidly growing population depended to an ever greater degree on the import of food from overseas.

World Economy.—In the later decades of the 19th century the process of industrialization made rapid progress in other countries, particularly in the United States of America and Germany. They possessed deposits of coal and iron—the essential prerequisites in the first phase of industrialism—and became great manufacturing centres. A country cannot develop such resources on a large scale and remain independent of other countries; for the ideals of self-sufficiency and industrial development are incompatible. The reasons are obvious enough. An industrialized country is an urbanized country with a growing population; the industries require raw materials and wide markets for manufactured goods and the population needs food supplies which must be sought elsewhere. So there emerged a system which was an uneasy combination of rivalry and interdependence. For while the industrial countries competed with one another in supplying non-industrial countries with manufactured articles and in trying to gain access to the tropical products, such as rubber, which were beginning to assume importance, they also found the widest scope for the exchange of goods in the trade between themselves, because highly organized communities naturally offer the best markets for a great variety of commodities. Before the World War, for instance, Great Britain sold more to Germany than to any country except India, and she bought more from Germany than from any country except the United States.

These commercial ties seemed to some to preclude the possibility of war between the Great Powers. In this they proved to be wrong. Still war revealed the fact of the real interdependence of nations. It showed that great industrial communities cannot inflict damage on one another without suffering themselves in the process and indeed endangering the whole economic structure on the preservation of which the standard of life of their dense populations ultimately depends. A world economy must necessarily mean that it is only a degree less disastrous to win a war than to lose it. The conquered can only be made to bear a proportion of the war costs if the conquerors assist them to re-establish their industries, which is merely to say that the only way to heal the disruption caused by war is to bind the nations together again. The fundamental fact in the modern world is the revolution in the means of transport and communication. Before the industrial age the movement of men and goods was difficult and therefore exceptional; it has become easy and usual. And while modern inventions have greatly speeded up transport it has practically annihilated distance with respect to the sending of information. The sale of goods in large quantities can be effected at great distances. Where grading is possible they can be sold by description even before they have come into existence; for speculators engage to deliver goods at a given price at a future date in the expectation that they will be able to buy at a lower price when the time comes to deliver. In these and other respects the mechanism of modern commerce tends to establish a world market in certain staple commodities.

The Post-War Period.—The post-war period at first presented almost insuperable obstacles to the resumption of normal commercial relations. Financial devices adopted in the course of the war produced a derangement of currencies which made international trade extremely difficult. Some nations, alarmed at the possibility that their markets might be flooded by goods from countries where the depreciation of the currency constituted a bounty on export, tried to safeguard themselves by means of restrictions on trade. Such regulations and the absence of commercial understandings gave a general instability to what trade was available. There was also the real poverty of the populations in the chief countries, which meant a falling off in purchasing power. The lack of a surplus for capital investment in the undeveloped parts of the world reacted on the demand for manufactured goods and also on the supply of food and raw materials. But the instability of the exchanges and the fall in purchasing power were short period consequences of war. The real question was whether in the long run normal trade relations would be resumed.

The war and the terms of the treaties which concluded it promoted a movement which hampered foreign trade. During the war native industries had been stimulated and the plea for self-sufficiency strengthened; the countries which won recognition of their national aspirations, therefore, proceeded to erect tariff barriers along their frontiers. As a result of the peace treaties the number of independent customs administrations was nearly doubled. The prohibitions and restrictions imposed by these States together with the constant changes of tariff rates had serious consequences, particularly in central Europe. A return to a general policy of freer international commerce was recognized by the International Economic Conference, which met at Geneva in May 1927, to be a condition precedent to the restoration of prosperity. The advantages which accrue from the lowering of trade barriers hardly require to be demonstrated in view of the history of commerce. For if it proves anything it is that restrictive regulations have been harmful to those who have adopted them when they have not been entirely futile. But there is always the temptation to try to direct the course of events. The war certainly hastened inevitable changes. Eastern countries, for instance, are supplying their own needs in machine-made textiles to an increasing extent. The exports of British cotton piece-goods to India declined 57% between 1913 and 1923, a decline due in unequal proportions to a fall in consumption, increased local production and more severe foreign competition. It is also clear that coal is no longer the only practical means of producing power and that this fact must embarrass the countries which have excess productive capacity. Changes such as these make the future uncertain and often lead to the adoption of short-sighted policies.

A few simple principles stand. There is a mutual advantage in the exchange of commodities between different areas. Modern means of transport and communication make such exchange easy where no hindrances are imposed. To industrial communities such exchange is vital. A country in the position of Great Britain, for instance, can only secure food and raw materials if it can find markets for its manufactures. Should markets be lacking it will be impossible to maintain the present population with the standard of living to which it has become accustomed. The loss of some markets must be compensated for by the discovery of others and a falling off in the demand for the heavier commodities, such as coal, or the coarser goods, such as cheap cotton piece-goods, must be met by the concentration on the more highly manufactured articles. Whether such compensations can be found will depend on many factors, chiefly on increased efficiency of production. It was the practice of commerce that led to the industrial development of the Great Powers and it is hardly conceivable that its volume will be reduced, though its nature and direction will be changed in the course of the 20th century.

COMMERCE, DEPARTMENT OF: *see* GOVERNMENT DEPARTMENTS.

COMMERCIAL COURT, in England, a court presided over by a single judge of the king's bench division, for the trial, as expeditiously as may be, of commercial cases. By the Rules of the Supreme Court, Order xviii. *a* (made in Nov. 1893), a plaintiff was allowed under certain circumstances to dispense with pleadings altogether.

Out of this order there grew the commercial court. It is not a distinct court or division or branch of the High Court, and is not regulated by any special rules of court made by the rule committee. It originated in a notice issued by the judges of the queen's bench division, in Feb. 1895, the provisions contained in which represent only "a practice agreed on by the judges, who have the right to deal by convention among themselves with this mode of disposing of the business in their courts" (per Lord Esher in *Barry v. Peruvian Corporation*, 1896, 1 Q.B. p. 209).

The scheme is only applicable to cases in which there is some single issue of law or fact, or the case depends on the construction of some contract or other instrument or section of an act of parliament, and such issue or question is either agreed upon by the parties or at once ascertainable by the judge.

COMMERCIAL EDUCATION, being a recent development of the educational system, is, in most countries, still in a state of transition, no adequate general plan having yet been adopted. The need for this type of education, however, has gradually become recognized, and in Great Britain and the United States considerable progress is being made.

The Education Act of 1918 led to the formation of Continuation schools and classes under the London County Council and other educational authorities in Great Britain, and an association was formed for the advancement of education in industry and commerce. In the United States the Federal Board for Vocational Education has also done active work in this direction. (*See* CONTINUATION SCHOOLS.)

I. GREAT BRITAIN

The Institute.—The beginnings of public commercial education in Britain may largely be ascribed to the activities of the mechanics' institutes in the early and middle periods of the 19th century, in which evening classes in both book-keeping and languages gradually grew up. These were succeeded by technical institutes, such as the Birmingham and Midland Institute and the Manchester High School of Commerce. In fact, up to 1890, and even later, the north of England and the Midlands were, as regards commercial education, in advance of London and the rest of the country. In 1890 the school boards gained the right to undertake evening work. This ultimately led to the country being covered with a network of evening schools. The work at first was of a rather elementary nature, consisting of book-keeping, shorthand, typewriting, English and often French. The Technical Education Act gave a considerable impetus to the spread of commercial education in polytechnics and similar institutions.

Still the movement had to face a good deal of opposition, or at least inertia, mainly from the widespread belief, which has not yet entirely disappeared and which is based on a half-truth, that commerce is best learned in the shop and the counting-house. Again, there was a good deal of muddle-headed thinking on the subject. Mr. Sidney Webb pointed out in a London conference held at the Society of Arts in 1897 that the term commerce covered a multitude of things—a vast number of distinct callings, from accountancy and banking to typewriting. It therefore involved an education of very varying degree, from elementary to university.

Universities.—Mr. Sidney Webb was largely responsible for the creation in 1895 of the London School of Economics and Political Science as an institute for higher commercial work. Beginning largely as a college for evening work, it subsequently developed a flourishing day side, and became a school of London university. Further developments in the course of higher education were the creation of faculties of commerce in the University of Birmingham (1900) and the re-constituted University of Manchester (1904), while London in 1917 established a bachelorship and mastership of commerce. A commercial degree can also be obtained at Newcastle (University of Durham), and at Liverpool a B.A. is awarded for proficiency in certain commercial subjects.

Economics figure as a prominent subject in the syllabus of other universities, but are taught mainly on theoretical lines, and no degree in commerce is obtainable. Probably the most complete choice of subjects for commercial study is offered by the London School of Economics and Political Science, amounting to nearly 270 courses given by some 80 lecturers and assistants. More than half of its departments are concerned wholly or partially with commerce. It prepares for the degrees of Bachelor of Commerce and Master of Commerce, and provides for research work.

Schools of Commerce.—Below the universities come the various day schools of commerce, often forming a section or department of a technical institute. The age of entry is generally 16, and some prepare for the B.Com. Such are for instance, the City of London College, The Regent Street Polytechnic Higher School of Commerce, the West Ham Technical Institute, with its course in commerce (three years), and the Manchester Municipal High School of Commerce. There are also junior commercial schools, where the age of entry is usually 13 and the course is two years (occasionally three).

Secondary Schools.—Certain secondary schools, like Hackney Downs and Holloway (London), prepare their students for degrees in commerce, while at least one of the public schools (Bradfield) has a definite commercial section. A large number of girls' secondary schools also do commercial work, which in many cases is confined to pupils who have passed the first school examination. In others it is begun by pupils of 15 who desire to specialize in commerce. Typewriting, shorthand and book-keeping, with commercial French, history and geography, are the staple subjects.

Higher Elementary Schools.—Up to 1908 the curricula of the higher elementary schools were based on lines giving a general education. In that year, the London schools of this type were reorganized with a dual bias, commercial and technical, and renamed central—a school might have one or both sections. The London central schools largely became the model for other central schools for the rest of the country. In the voluntary day continuation school the teaching, which at the outset was general, became, in London at least, largely commercial.

Evening Work.—Some evening work in the London School of Economics and elsewhere is of university standard. Below this ranks the work of the evening schools, many of which, especially in the country, are situated in technical institutes, notable examples being the Manchester and Birmingham Municipal Schools of Commerce, the Hull Central School of Commerce, the Bradford Commercial College, the City of London College and the 24 London evening institutes.

The range of work is considerable, and, apart from typewriting, shorthand and book-keeping, includes preparation for examinations in accountancy of all kinds, banking, insurance (life, fire, marine), railway administration, civil service (post-office, inland revenue, customs and excise), courses for solicitors' or stockbrokers' clerks, for secretaries or grocers' assistants. This involves classes in economics, including economic history and geography, and the economics of shipping, railways, etc.; the theory and practice of commerce, banking, currency, foreign exchanges, statistics, the machinery of business, secretarial practice, knowledge of commodities, law of all kinds—general, conveyancing, banking, company, commercial, mercantile, marine, joint stock, income tax, etc.

The teaching of languages comprises French, German, Spanish, Italian and other less known languages, and Esperanto by the course system, all students under 18 who have not had a good secondary or central school education are obliged to take a course in which a language often forms a part. Students enter the institutes at sixteen. Below these are the junior institutes, usually entered at 14, where all pupils are obliged to take a course.

Private Initiative.—There also exist a number of schools attached to big business houses, as well as many private institutions, which prepare mainly for the lower and intermediate walks of commerce and the civil service.

Examinations.—In addition to the examinations mentioned above, and some higher commercial certificates, a large number of students in the evening institutes and elsewhere take the examination of the Society of Arts, the Chamber of Commerce and other societies. The Society of Arts held its first practical examination in 1856, and among the subjects were French and book-keeping. The candidates, mainly drawn from mechanics' institutes, numbered 56. In 1927 the number of papers worked was over 88,000. The London Chamber of Commerce, which began in 1890 with 65 candidates and 17 passes (all junior), had, in 1926, more than 25,000 worked papers. (C. BR.)

II. UNITED STATES

The first commercial courses offered in the United States early in the 19th century were for the purpose of training book-keepers. Since 1894 commercial courses have included, besides book-keeping, the subjects of typewriting and shorthand. Retail selling was added about ten years later.

Early commercial training was given almost entirely in private commercial schools which recruited their students chiefly from the graduating classes of public elementary schools. Public pressure for free commercial education, and business pressure for trained office workers possessing more than elementary schooling, put commercial courses in the curricula of urban high schools. In the beginning, the high school courses were mere copies of those offered in the private schools, and were taught, in the main, by teachers drafted from these institutions. In time, however, both teachers and courses were greatly improved. The better high schools now offer both short and long courses in the three following groups of work—(1) secretarial and recording, (2) accounting and (3) selling.

It is interesting to note that in the competition against the public high schools, the private commercial schools are steadily losing ground as the following statistics taken from a 1926 bulletin of the United States Bureau of Education will show.

Year	No. of private schools	Enrolment	Year	No. of high schools	Enrolment
1920	903	336,032	1916.	2,844	243,185
1925	739	188,363	1924.	3,742	430,975

The introduction of commercial courses into high schools did not insure continued adjustment to the changing needs of a business world in which commercial practices were gradually becoming highly specialized. A Congressional commission in 1916 reported "the quality of commercial education might be improved" and the Smith-Hughes act of 1917 placed definitely upon the newly created Federal Board for Vocational Education the responsibility for making surveys to determine the actual commercial education needs of the country. In its survey of commercial occupations in which workers 14 to 18 years of age are employed, the Federal board classified and analysed the following junior commercial occupations—(1) general clerk, (2) shipping clerk, (3) receiving clerk, (4) stock clerk, (5) file clerk, (6) mail clerk, (7) typist, (8) billing clerk, (9) duplicating and addressograph machine operator, (10) calculating machine operator, (11) office boy, (12) collector, (13) assistant book-keeper, (14) entry clerk, (15) ledger clerk, (16) cost clerk, (17) book-keeping machine operator, (18) time-keeper, (19) statement clerk, (20) stenographer, (21) dictating machine operator, (22) junior sales person, (23) messenger, (24) bundle wrapper, (25) cashier and (26) examiner. Following the presentation of the Federal findings, commercial continuation, high and evening schools greatly altered their curricula to meet more adequately the needs of junior workers who, in more cases than not, need training in other commercial courses than book-keeping, typewriting and stenography. The Federal Board has also been very active in assisting national associations of retail grocers, dry goods merchants, laundry owners and others in developing curricula suitable for the training schools of the special commercial interests.

On the university level there is an unusually active development of schools of commerce and business administration. Besides specialized courses, these schools offer general opportunities in economics, business law, finance, marketing and merchandising, and business organization and administration. The most recent addition to the curriculum to receive great attention is business ethics.

In their research investigations, these university schools are focusing their efforts upon the most perplexing problem business is facing—the economical distribution of goods. In the larger centres, also, these schools are affecting co-operative arrangements with business interests. Notable among these is the Meat Packers' institute affiliated with the University of Chicago.

(W. F. R.)

Schools of Business.—The organization of professional schools of business in the United States is part of that broader educational trend which has given us schools of medicine, law, dentistry, agriculture, engineering and journalism. The first school of commerce in the United States which could properly be regarded as of collegiate type was the Wharton school at the University of Pennsylvania, founded in 1881. During more than the first two decades of its existence it could boast little more than the conventional academic course interspersed with economics, political science and sufficient mercantile law and accountancy to meet the stipulation of the school's founder that it afford "training suitable for those who intend to engage in business or to undertake the management of property." No other school was organized until 1898, when the University of California and the University of Chicago entered the lists. In 1900 the University of Wisconsin, Dartmouth college and New York university presented organized courses. The University of Michigan followed in 1901. Beginning with 1908 growth accelerated, and by the end of 1925 no university was without some courses stressing education for business. Many of the colleges of the country, large and small, have imitated this procedure on a minor scale.

Schools of business have often been classified according to conditions set for student admission. In a number of instances, of which the Wharton school is typical, a student may be admitted at the end of his high school career to a course of study which covers four academic years and affords a mixture of general academic and more specific business instruction. In other instances, of which the school at Columbia is a fair example, two pre-business college years must be completed in general academic subjects before a student may pass on to two or more special years of business study, and thence, if he so choose, to more advanced study of graduate character. At Dartmouth and Michigan, three years of college work are required for admission to a two-year business course leading to a master's degree; and at Harvard and Leland Stanford the schools of business require college graduation for admission to a course leading to a master's degree. Most of the urban institutions have developed continuation courses, often highly specialized, for students not interested in an academic degree.

Owing to varying maturity of students resulting from divergent entrance requirements, and other more local reasons, school objectives as well as curricula show considerable diversity. In many instances the aim has been loosely expressed as "training for business," and the resulting curriculum is a loose collection of business courses adapted to immediate practical needs. But among the older and better organized schools there is gradually emerging a conception of objective which stresses preparation for ultimate managerial responsibility. The aim is to afford business knowledge which is transferable and typical of many fields of business enterprise, and gives its possessor freedom and power rather than narrowly focussed skill leading to fixity of occupational status. Resulting curricula, therefore, are tending less to depict business routine, and more to stress fundamentals, at least as a basis for possible subsequent specialization. A background of geographic knowledge and technology, acquaintance with language, accounting and statistics, familiarity with business structure and function, and its place in the broader fabric of society, have all come to be regarded as essentials of instruction. Beyond this there is a growing array of opportunities for study and research in special fields such as production, marketing, finance, transportation and insurance, with increasing emphasis in the larger urban institutions on specialized and technical phases of current practice and experimentation. Methods of instruction for the most part follow the usual college types; but in a few instances distinctive methods have been evolved. At Cincinnati practice in active business is co-ordinated with theory at school on a supervised co-operative basis; and at Harvard a case method of instruction is being perfected, somewhat along law school lines, to give realistic quality to class work and afford a synthetic view of business administrative devices and judgments which by other methods can be treated only hypothetically and as segregated phases of practice. But all of these problems of curriculum and of teaching method are still in a highly fluid state. Business research in a variety of forms is pursued in a number of schools, and in the stronger ones their research activities are guided by regularly organized bureaux. The American Association of Collegiate Schools of Business through its information service promotes co-ordination and avoidance of duplication in research projects. The association likewise affords a forum for discussion of general school problems. Two periodicals, *The Harvard Business Review* and *The Journal of Business* (Chicago), besides irregularly issued publications, furnish scientific discussion of educational and business problems. (R. C. McC.)

COMMERCIAL FEDERATION: *see* CUSTOMS UNION.

COMMERCIAL LAW, a term used rather indefinitely to include those rules and principles which govern commercial transactions and customs. It includes within its compass such titles as principal and agent; carriage by land and sea; merchant shipping; guarantee; insurance; bills of exchange; partnership; limited companies; bankruptcy, etc.

COMMERCIAL PAPER, a term popularly applied to all kinds of short-term negotiable instruments which call for the payment of money and which may be used for borrowing. Strictly, it should be used only for such paper as arises from commercial, as distinguished from investment, speculative, personal, real estate or public transactions. It includes such instruments as short-term notes, drafts, bills of exchange, acceptances, etc.

In the more narrow financial sense, commercial paper signifies only those unsecured promissory notes issued by business borrowers (industrial or mercantile corporations or partnerships) and sold through note brokers to banks, insurance companies and other large investors. Only loans of considerable size are represented by commercial paper, $25,000 being about the absolute minimum, as small issues would not pay the commercial paper house for the cost of the investigating and selling. Such notes usually range in denominations of from $5,000 to $10,000 each, but often, to accommodate the smaller banks, some are issued in denominations of $2,500. Commercial paper notes are signed by the borrower, made payable to himself or order and then endorsed in blank so that they can be transferred easily to whatever customer that note-broker may find. Guarantees or endorsements sometimes appear on such notes, but this is very rare, and makes the notes unpopular with both the commercial paper houses and the banks, for to them it indicates that the credit of the issuing firm was not sufficiently sound to carry the notes alone.

The commercial paper houses which sell the notes do not (although there are exceptions) endorse or guarantee the paper they sell, but stake their futures as brokers upon the continued offering of sound material only. Before accepting an issue of notes the commercial paper house makes a most rigid and exhaustive examination to assure itself of their soundness, and in the event of the borrower's default, frequently assumes the loss itself in order to protect its reputation with its clients. These notes vary in time from one month to one year, the majority of them being for about a four months' period. Business houses which utilize the commercial paper method of borrowing avoid as far as possible frequent short term loans, as they have to pay $\frac{1}{4}\%$ commission to the paper house for each successive issue. Both the length of the issue and the rate of interest paid, however, are necessarily largely governed by the financial condition and needs of the issuing company and by current demands of the banks and other prospective purchasers.

There are several reasons which may influence businesses to sell their paper on the open market rather than borrow directly from banks. Some of them are: (1) They may sell paper on the open market when the available funds of the local bank are insufficient to take care of the desired loan. (2) They may often be able to sell commercial paper at a lower interest rate than is obtainable at the local banks. (3) They may reserve a regular line of credit at local banks to be used, if advisable, upon other occasions. Care must be taken, however, not to pit the open market as a competitor against the bank for the firm's business, otherwise the bank's line of credit may be found to be withdrawn when wanted. (4) A larger line of credit is usually obtainable through the open market than through dealing exclusively with local banks. (5) A wide geographic distribution of a firm's paper, providing the firm makes all payments promptly and regularly, gives the firm a wide reputation as an issuer of "prime paper," and banks in every part of the country are willing to take it up. This makes future borrowing comparatively easy. (6) The open market may be used to obtain funds to settle up bank loans and thus maintain local bank credit. (7) In a loan obtained through the sale of commercial paper no part of the proceeds is tied up, as is the case with bank loans, where a deposit of about 20% of its line of credit is required.

There are also several reasons why banks are glad to purchase commercial paper. Among them are: (1) Banks may thus utilize funds that are not in immediate demand for local loans. (2) They may sometimes procure a higher interest rate on commercial paper than is current on local loans. (3) They may buy only such notes as have maturities fitting in exactly with the bank's expected needs for cash. (4) The bank is under no obligation, moral or otherwise, to renew such notes, and thus avoids embarrassment which sometimes arises over renewal demands on local loans. It is well assured that commercial paper will be paid at maturity without question or quibble. (5) The bank's money is in obligations scattered over a wide territory, which geographical diversification gives assurance that only a small portion may be affected diversely by unfavourable local causes. (6) The bank obtains the advantage of the broker's careful investigation and experienced judgment in the selection of the paper. (7) The bank may rediscount commercial paper through the Federal Reserve banks to provide liquid assets, in case of necessity. (J. H. B.)

British Usage.—The term "commercial paper" is not used in English banking circles. The term implies the obtaining of credit by means of a promissory note issued to a "note-broker," or alternatively, direct to a bank, and the essence of such a document is that it is merely a promise to pay a certain sum at a certain date.

The usual way of obtaining credit in England is either by an advance from a banker, which may or may not be secured, and which may be for a definite sum and run for a definite period, or simply be a running overdraft; or else by means of a bill of exchange (*see* BILL OF EXCHANGE). The bill is the nearest approach in England to an American note, but even so, there are several vital points of difference. The chief is that while a note is but a promise by a single individual, a bill is an order to pay given by one individual to a second. Thus, a note need only bind one person, while a bill must bind at least two. A bill, too, can be secured. Thus, if it is endorsed D/P, the goods against which it is drawn are only delivered to the purchaser after he has paid the bill.

In general, the bill is used extensively in international trade, where the case of the note would be impracticable. Take the case of a shipment of goods from Hamburg to New York. The seller may draw his bill upon a bank in London, which has arranged to accept on behalf of the New York buyer. The seller may then discount it at his Hamburg bank who, in turn, endorse it and send it to London for acceptance and for sale in the London market. Thus the bill carries the "names" of the seller himself, of his Hamburg bank, and of the accepting London bank, and the holder has two banks and a private individual to fall back upon; whereas if the buyer simply gave a note, all the holder of the note would have would be the name of an individual on the other side of the Atlantic. (N. E. C.)

COMMERCIAL TREATIES. A commercial treaty is a contract between states relative to trade. It is a bilateral act whereby definite arrangements are entered into by each contracting party towards the other—not mere concessions. As regards technical distinctions, an "agreement," an "exchange of notes," or a "convention" properly applies to one specific subject; whereas a "treaty" usually comprises several matters, whether commercial or political.

In ancient times foreign intercourse, trade and navigation were in many instances regulated by international arrangements. The text is extant of treaties of commerce and navigation concluded between Carthage and Rome in 509 and 348 B.C. Aristotle mentions that nations were connected by commercial treaties; and other classical writers advert to these engagements. Under the Roman empire the matters thus dealt with became regulated by law, or by usages sometimes styled laws. When the territories of the empire were contracted, and the imperial authority was weakened, some kind of international agreements again became necessary. At Constantinople in the 10th century treaties cited by Gibbon protected "the person, effects and privileges of the Russian merchant"; and, in western Europe, intercourse, trade and navigation were carried on, at first tacitly by usage derived from Roman times, or under verbal permission given to merchants by the ruler to whose court they resorted. Afterwards, security in these transactions was afforded by means of formal documents, such as royal letters, charters, laws and other instruments possessing the force of government measures. Instances affecting English commercial relations are the letter of Charlemagne in 796, the Brabant Charter of 1305, and the Russian ukase of 1569. Mediaeval treaties of truce or peace often contained a clause permitting in general terms the renewal of personal and commercial communication as it subsisted before the war. This custom is still followed. But these mediaeval arrangements were precarious: they were often of temporary duration, and were usually only effective during the lifetime of the contracting sovereigns.

The Modern System Begins.—Passing over trade agreements affecting the Eastern empire, the modern commercial treaty system came into existence in the 12th century. Genoa, Pisa and Venice were then well-organized communities, and were in keen rivalry. Whenever their position in a foreign country was strong, a trading centre was established, and few or no specific engagements were made on their part. But in serious competition or difficulty another course was adopted: a formal agreement was concluded for the better security of their commerce and navigation. The arrangements of 1140 between Venice and Sicily; the Genoese conventions of 1149 with Valencia, of 1161 with Morocco, and of 1181 with the Balearic Islands, the Pisan conventions of 1173 with Sultan Saladin, and of 1184 with the Balearic Islands, were the earliest Western commercial treaties. Such definite arrangements, although still of a personal character, were soon perceived to be preferable to general provisions in a treaty of truce or peace. They afforded also greater security than privileges enjoyed under usage; or under grants of various kinds, whether local or royal. The policy thus inaugurated was adopted gradually throughout Europe. The first treaties relative to the trade of the Netherlands were between Brabant and Holland in 1203, Holland and Utrecht in 1204, and Brabant and Cologne in 1251. Early northern commercial treaties are those between Riga and Smolensk in 1229, and between Lübeck and Sweden in 1269. The first commercial relations between the Hanse Towns and foreign countries were arrangements made by guilds of merchants, not by public authorities as a governing body. For a long period the treaty system did not entirely supersede conditions of intercourse between nations dependent on permission.

The earliest English commercial treaty is that with Norway in 1217. It provides *ut mercatores et homines qui sunt de potestate vestra liberè et sine impedimento terram nostram adire possint, et homines et mercatores nostri similiter vestram* (that merchants and men who are of your power may freely and without impediment visit our territory, and our men and merchants similarly visit yours). These stipulations are in due treaty form. The next early English treaties are:—with Flanders, 1274 and 1314; Portugal, 1308, 1352 and 1386; Baltic Cities, 1319 and 1388; Biscay and Castile, 1351; Burgundy, 1417 and 1496; France, 1471, 1497 and 1510; Florence, 1490. The commercial treaty policy in England was carried out systematically under Henry IV. and Henry VII. It was continued under James I. to extend to Scotland English trading privileges. The results attained in the 17th century were—regularity in treaty arrangements; permanent instead of personal nature; the conversion of permissive into perfect rights; questions as to contraband and neutral trade stated in definite terms. Treaties were at first limited to exclusive and distinct engagements between the contracting states; each treaty differing more or less in its terms from other similar compacts. Afterwards by extending to a third nation privileges granted to particular countries, the *most favoured nation article* began to be framed, as a unilateral engagement by a particular state. The Turkish capitulations afford the earliest instances; and the treaty of 1641 between the Netherlands and Portugal contains the first European formula. Cromwell continued the commercial treaty policy partly in order to obtain a formal recognition of the commonwealth from foreign powers. His treaty of 1654 with Sweden contains the first reciprocal "most favoured nation clause":—Article IV. provides that the people, subjects and inhabitants of either confederate "shall have and possess in the countries, lands, dominions and kingdoms of the other as full and ample privileges, and as many exemptions, immunities and liberties, as any foreigner doth or shall possess in the dominions and kingdoms of the said confederate." The government of the Restoration replaced and enlarged the Protectorate arrangements by fresh agreements. The general policy of the commonwealth was maintained, with further provisions on behalf of colonial trade. In the new treaty of 1661 with Sweden the privileges secured were those which "any foreigner whatsoever doth or shall enjoy in the said dominions and kingdoms on both sides."

In contemporary treaties France obtained from Spain (1659) that French subjects should enjoy the same liberties as had been granted to the English; and England obtained from Denmark (1661) that the English should not pay more or greater customs than the people of the United Provinces and other foreigners, the Swedes only excepted. The colonial and navigation policy of the 17th century, and the proceedings of Louis XIV., provoked animosities and retaliatory tariffs. During the War of the Spanish Succession the Methuen Treaty of 1703 was concluded. Portugal removed prohibitions against the importation of British woollens; Great Britain engaged that Portuguese wines should pay one-third less duty than the rate levied on French wines.

At the peace of Utrecht in 1713 political and commercial treaties were concluded. England agreed to remove prohibitions on the importation of French goods, and to grant most favoured nation treatment in relation to goods and merchandise of the like nature from any other country in Europe; the French general tariff of Sept. 18, 1664, was again to be put in force for English trade. The English provision was at variance with the Methuen Treaty. A violent controversy arose as to the relative importance in 1713 of Anglo-Portuguese or Anglo-French trade. In the end the House of Commons, by a majority of 9, rejected the bill to give effect to the commercial treaty of 1713; and trade with France remained on an unsatisfactory footing until 1786. The other commercial treaties of Utrecht were very complete in their provisions, equal to those of the present time; and contained most favoured nation articles—England secured in 1715 reduction of duties on woollens imported into the Austrian Netherlands; and trading privileges in Spanish America. Moderate import duties for woollens were obtained in Russia by the commercial treaty of 1766. In the meanwhile the Bourbon family compact of Aug. 15, 1761, assured national treatment for the subjects of France, Spain and the Two Sicilies, and for their trade in the European territories of the other two states; and most favoured nation treatment as regards any special terms granted to any foreign country. The first commercial treaties concluded by the United States with European countries contained most favoured nation clauses: this policy has been continued by the United States, but the wording of the clause has often varied.

In 1786 France began to effect tariff reform by means of commercial treaties. The first was with Great Britain, and it terminated the long continued tariff warfare. But the wars of the French Revolution swept away these reforms, and brought about a renewal of hostile tariffs. Prohibition and differential duties were renewed, and prevailed on the Continent until the sixth decade of the 19th century. In 1860 a government existed in France sufficiently strong and liberal to revert to the policy of 1786. The bases of the Anglo-French treaty of 1860, beyond its most favoured nation provisions, were in France a general transition from prohibition or high customs duties to a moderate tariff; in the United Kingdom abandonment of all protective imposts, and reduction of duties maintained for fiscal purposes to the lowest rates compatible with these exigencies. Other European countries were obliged to obtain for their trade the benefit of the conventional tariff thus established in France, as an alternative to the high rates inscribed in the general tariff. A series of commercial treaties was accordingly concluded by different European states between 1861 and 1866, which effected further reductions of customs duties in the several countries that came within this treaty system. In 1871 the Republican government sought to terminate the treaties of the empire. The British negotiators nevertheless obtained the relinquishment of the attempt to levy protective duties under the guise of compensation for imposts on raw materials; the duration of the treaty of 1860 was prolonged; and stipulations better worded than those before in force were agreed to for shipping and most favoured nation treatment. In 1882, however, France terminated her existing European tariff treaties. Belgium and some other countries concluded fresh treaties, less liberal than those of the system of 1860, yet much better than anterior arrangements. Great Britain did not formally accept these higher duties; the treaty of Feb. 28, 1882, with France, which secured most favoured nation treatment in other matters, provided that customs duties should be "henceforth regulated by the internal legislation of each of the two states." In 1892 France also fell out of international tariff arrangements; and adopted the system of double columns of customs duties—one, of lower rates, to be applied to the goods of all nations receiving most favoured treatment; and the other, of higher rates, for countries not on this footing. Germany then took up the treaty tariff policy; and between 1891 and 1894 concluded several commercial treaties.

During the succeeding 20 years the world's tariffs and concomitant treaties were remodelled again and again, and at the outbreak of the World War, nearly all the nations were linked together by a close network of commercial treaties, by means of which it was attempted to reconcile three very different objects, (1) the gathering of customs revenue, (2) the protection of home industries, and (3) the furtherance of export trade. Each such treaty represented a compromise in the pursuance of these objects, but each, nevertheless, formed a link of real commercial importance.

Scope.—The scope of commercial treaties is well expressed by Calvo in his work on international law. They provide for the importation, exportation, transit, trans-shipment and bonding of merchandise; customs tariffs; navigation charges; quarantine; the admission of vessels to roadsteads, ports and docks; coasting trade; the admission of consuls and their rights; fisheries; they determine the local position of the subjects of each state in the other country in regard to residence, property, payment of taxes or exemptions, and military service; nationality; and a most favoured nation clause. They usually contain a termination, and sometimes a colonial article. Some of the matters enumerated by Calvo—consular privileges, fisheries and nationality—are now frequently dealt with by separate conventions. Contraband and neutral trade are not included as frequently as they were in the 18th century.

The preceding statement shows that commercial treaties afford to foreigners, personally, legal rights and relief from technical disabilities; they afford security to trade and navigation, and regulate other matters comprised in their provisions. In Europe in 1914 the general principles established by a series of treaties (1860–66) held good, viz., the substitution of uniform rates of customs duties for prohibitions or differential rates. The disadvantages urged are that these treaties involve government interference and bargaining, whereas each state should act independently as its interests require; that they are opposed to free trade, and restrict the fiscal freedom of the legislature. It may be observed that these objections imply some confusion of ideas. All contracts may be designated bargains, and some of the details of commercial treaties in Calvo's enumeration enter directly into the functions of government; moreover, countries cannot remain isolated. If two countries agree by simultaneous action to adopt fixed rates of duty, this agreement is favourable to commerce, and it is not apparent how it is contrary even to free trade principles. Moreover, security in business transactions, a very important consideration, is provided.

COMMERCIAL TREATIES AFTER THE WAR

The War made a serious breach in the commercial treaty system. It is true it did not alter the basic principles of the policy of concluding commercial treaties, but it brought financial and protectionist interests so strongly into the foreground that the interest in international trade was extraordinarily restricted and is only now beginning to receive greater recognition. Two forms are characteristic for all modern commercial treaties: tariff rates and the most favoured nation clause. By tariff rates are meant the concessions in the rates of the customs tariffs on both sides. Treaties which embrace both forms are called tariff treaties and are preferred by states which carry on a very active commerce with one another. By far the greatest number of all commercial treaties are restricted to the most favoured nation (M.F.N.) clause; they are called most favoured nation treaties, for, although the first type also include M.F.N. treatment, this is subordinated to the tariff rates which constitute their chief feature. Treaties of a different type, merely comprising tariff rates without M.F.N. treatment, were of rare occurrence and were mostly a survival of an earlier period.

Most Favoured Nation Clause.—M.F.N. treatment secures to the treaty state equality of position with those foreign countries which receive most favourable treatment. In the form in which it has developed since the year 1860, it secures for this state not merely all the privileges which any other state has received in the past and still enjoys, but also those which it will receive in future, and moreover immediately and without additional compensation.

There is, it is true, a still more favourable treatment than the foreign parity given by the M.F.N. clause, viz., inland parity or national treatment, which places the persons and goods of the country concerned on an equality, not with those of other foreign countries, but with those of the nationals of the country itself; but its sphere of application is a different and at the same time a more limited one. By its nature it only applies to such economic measures as are not confined to foreign goods and persons, such as import duties, admission of consuls, etc., but may affect both domestic and foreign goods and persons, so that discrimination in their treatment would constitute a new and arbitrary protection for the home country; *e.g.*, taxes on consumption, admission to trade and settlement, conditions for the use of railways and roads, etc. In oriental countries in which foreigners received special privileges, it sometimes occurred that the foreign parity was more favourable than the inland parity.

Reciprocity, by virtue of which a favour is only accorded to the treaty state in return for an equivalent compensation, is less favourable than M.F.N. treatment or foreign parity. This principle was to be found in many commercial treaties down to the middle of the 19th century and still exists in later commercial treaties, in cases where it is not merely a matter of passive permission, but of an active intervention on the part of the state; *e.g.*, the admission of joint-stock companies, privileges for commercial travellers, the granting of benefits of workers' insurance, etc.

There are several varieties of M.F.N. treatment. The unconditional is to-day the most common, but the conditional is also to be found, by virtue of which the treaty state has a right to a privilege granted to another country if it was given without compensation, but can only secure it for an equivalent compensation if this privilege has been acquired by the other country as a result of a concession on its part. This latter form is distinguished from reciprocity by the fact that it contains an obligation to grant equality of position when the necessary condition is fulfilled, which is not the case with reciprocity. Unconditional M.F.N. treatment has, it is true, the disadvantages (1) that it diminishes the value of every concession, because the area to which this applies is extended, (2) that it hinders a concession to one treaty state, because this would subsequently benefit automatically a stronger competitor, (3) that by adapting the concession to the special conditions of the treaty state, its extension to the other most favoured countries can in practice be excluded. It has, however, the great merit that it guarantees to the treaty state equal competitive conditions in the territory of the other for the whole period of the treaty and greatly facilitates the conclusion of commercial treaties.

Conditional M.F.N. treatment involves fresh negotiations with the other states on the conclusion of each tariff treaty, and may give rise to technical and political difficulties which may endanger the whole treaty structure. The post-War period has brought about an interesting and characteristic change; while the United States, in contrast to the European countries, maintained before the War conditional M.F.N. treatment which, by its nature, is relatively unfavourable to the treaty method, they have gone over in the later commercial treaties, *e.g.*, the treaty with Germany of Dec. 8, 1923, to unconditional M.F.N. treatment. This change is attributable to an alteration in their commercial interests. Formerly they supplied mainly raw materials (cotton, copper, etc.), which the European states needed urgently for industries, while they constituted an important market for European manufactures and therefore were in a strong position when treaties were negotiated. Now, however, the export interests of their industries have come into greater prominence and demand a modification of their foreign commercial relations. On the other hand, France, which before the War had not favoured the treaty method, is now contemplating, in accordance with the law of July 20, 1919, the conclusion of commercial treaties in which reciprocal tariff concessions are granted, and has thus in theory returned to the principle of reciprocity. This policy has, it is true, been substantially modified in practice, for France has not merely allowed the former M.F.N. treaties to continue in force, but has also adopted M.F.N. treatment in newly concluded commercial treaties, though subject to considerable restrictions.

M.F.N. treatment as a rule binds both contracting parties to reciprocal treatment, but this is not a necessary condition, for in the treaties with countries in the East it only applies unilaterally in favour of the European states. The victorious states also chose the unilateral form for the Peace Treaties of 1919, but only for a period of five years; the Council of the League of Nations has made no use of the power granted to it to extend the application of this clause. In many commercial treaties of the former enemy states, the limitation was already set aside at an earlier date.

M.F.N. treatment can, however, be restricted not only in its form, but in its contents. In its widest scope it covers all matters of trade and shipping, but in all cases it applies to the customs tariff and customs procedure. In the post-War period some states have restricted it to certain customs items or parts of the customs tariff. On the other hand, the commercial treaty between England and Germany concluded on Dec. 2, 1924, contains reciprocal, unconditional, unlimited M.F.N. treatment.

Tariff Systems.—Tariff treaties depend largely on the tariff system which is at the basis of the tariffs of the treaty states. We can distinguish the single-line tariff, which has only one tax for each article for all countries, from the double tariff, which consists of two columns of tariff rates of which the one with the lower rates is applicable to the most favoured countries, and the other with the higher rates to remaining countries. Depending on the origin of the lower column, the double tariff can be a general-conventional tariff in which only the higher general tariff is fixed by an autonomous law of the country concerned, while the conventional tariff is composed of the concessions or binding rates granted to other countries by commercial treaties. By a binding rate is meant the transfer of a tariff rate from the general tariff to the conventional tariff at the same figure, in order to secure its application for the whole period of the treaty, since an autonomous tariff can at any time be modified by the country concerned, by a new law. The double tariff can, however, also be a maximum-minimum tariff, in which the column with the lower rate is also fixed by autonomous legislation and therefore provides the limit to which tariff concessions can be granted to foreign countries.

The single-line tariff which Great Britain and some countries of northern Europe have applied, necessarily involves M.F.N. treatment, because it leaves no room for tariff concessions; but there is the possibility, of which formerly Belgium has taken advantage, of granting tariff concessions by commercial treaties which are then taken over into the single-line tariff and thereby extended to all countries, whether or not they have granted M.F.N. treatment by treaty. In the general-conventional tariff which is predominant in Germany and other Central European states, the chief emphasis lies in tariff treaties with M.F.N. treatment. The maximum-minimum tariff is less favourable to the treaty method. This, although of Spanish origin, can to-day be described as the French tariff system, because the unilateral and therefore relatively high minimum rates offer small inducement to the conclusion of commercial treaties, and their autonomous regulation affords no security against subsequent increases. In its most extreme form it might result in the same article being subject to divergent tariff rates according to the country of origin, which would naturally exclude any M.F.N. treatment. Even if France herself has never gone so far as this, her commercial treaties in the post-War period exhibit great specialization. In these treaties she grants some tax rates of the minimum tariff, then some rebates from the tariff rates of the maximum tariff and applies elsewhere the maximum tariff.

Post-War Changes.—The pre-War commercial treaties corresponded to the normal market conditions in which production outran demand so that it was the concern of the seller to find a market for his goods and not of the purchaser to obtain the goods he required. The state only sought to facilitate the path of trade in foreign countries; whether and how far advantage was taken of this was the concern of the merchant. The scarcity of goods brought about by the War, however, upset the normal market conditions; instead of the purchaser, the seller had the stronger position, and it was not the man who wanted the goods who dictated conditions, but the man who controlled their supply. Commercial treaties of the old type were temporarily pushed into the background by two new types; the compensation treaties and the treaties based on quotas, which are distinguished from the ordinary forms by the fact that the contracting states pledge themselves, not merely to permit movement of private trade, but to a definite undertaking.

In the compensation treaties the state declares that it will supply specified quantities of certain goods, in return for which it receives others of which it is urgently in need. Here the obligation to deliver is in the foreground, since it is mainly a matter of essential goods, such as wheat, coal, etc. Occasionally, as for example in the case of France in relation to Switzerland, there was also an obligation to accept delivery, when the other party was at pains to secure at least part of a market for its high-grade luxury products (embroideries) which it had lost as a result of the War. A condition of these treaties was the suppression of private trade and the setting up of state *Centrales* for the most important goods, because the state administration can only deliver goods which are under its own control.

The treaties with quotas which arose later are distinguished from the above by the fact that the treaty states do not pledge themselves to the delivery of goods against goods, but merely agree to the issue of export licences for specified quotas of goods, for which it was also necessary that an import licence should be granted by the receiving state, but whose actual delivery, where the goods were not still subject to state control, remained in the hands of private trade. Such treaties were often not published at all but only communicated to the government departments and the undertakings concerned.

After the War, normal market conditions gradually returned, though less owing to a rise in production than to a general fall in purchasing power. The consequence of this equalization of supply and demand on a lower level was that the struggle for foreign markets gave place to a struggle for the retention of the home market. Protection came so strongly to the fore that even England had to sacrifice part of its traditional free-trade policy. The protectionist tendency was appreciably strengthened by the currency depreciation in many countries, which results in an export bounty for the products of the country concerned. The countries with high exchanges protected themselves against such exchange dumping by raising their import duties or by special additional duties (*e.g.*, Spain, Czechoslovakia). The countries with weak exchanges in turn were forced to prohibit imports of luxury goods, and to hinder payments to foreign countries by controlling exchange transactions, in order to prepare for stabilization by improving the balance of payment. Hence it resulted that the protectionist system was even accentuated by a system of prohibitions such as people had believed to have finally disappeared with mercantilist ideas by the middle of the 19th century.

It is true that gradually the need for normal commercial treaties with M.F.N. treatment and tariff rates has been receiving great recognition, but the after-effects of the conditions of political and commercial war have by no means vanished. The commercial treaties concluded before the War were determined by the belligerent Powers contrary to former custom, when their operation used merely to be suspended for the period of the War. Negotiations entered into since then have been confronted with such great conflicts of interest and uncertainty of conditions, that often agreements could only be made for a year, terminable at three months' notice, whilst formerly they used to hold good for ten years and more. M.F.N. treatment amongst the European states has often been only conditionally granted, and restricted to certain categories of goods. Further, events in Russia have caused a severe dislocation of the old-established trade relations, for she demanded the recognition of her state monopoly of the export trade and of the abnormal political institutions of the Soviet régime.

On the other hand, owing to the economic crisis and the political unrest of Europe, endeavours have been made to join certain states into a customs union by abolishing the customs duties between them. Thus abortive proposals were made that Austria, whose continued existence appeared hopeless, should be united to Germany or should join with other neighbouring states into a Danubian Federation. Schemes for economic union have also been discussed in the Balkans and between the Baltic states. But such preferential relations arouse political objections, because the union of economic interests may also bring about political ties, and are also impeded by the fact that the states receiving M.F.N. treatment are not willing to be excluded from the advantages of preferential relations. Up to the present these ideas have nowhere been realized. (*See* also TREATIES.)

BIBLIOGRAPHY.—Josef Gruntzel, *Handelspolitik* (3rd ed., Vienna, 1921), and *Economic Protectionism* (1916); T. E. Gregory, *Tariffs* (1921). (C. M. K.; J. G.)

COMMERCY, a town of north-eastern France, capital of an arrondissement in the department of Meuse, on the left bank of the Meuse, 26 mi. E. of Bar-le-Duc. Pop. (1936) 7,748. It dates from the 9th century, when its lords were dependent on the bishop of Metz. In 1544 it was besieged by Charles V. For some time the lordship was in the hands of François Paul de Gondi, cardinal de Retz, who lived in the town for a number of years, and there composed his memoirs. From him it was purchased by Charles IV, duke of Lorraine. In 1744 the castle became the residence of Stanislas, king of Poland, as whose guest Voltaire visited the town in 1747. The château is now used as cavalry barracks. The industries include iron-working and the manufacture of boots and hosiery.

COMMERS, the German term for the students' social gatherings held on occasions such as the breaking-up of term and the anniversary of the university's founding (Lat. *commercium*). A Commers consists of speeches and songs and the drinking of beer. Strict rules as to drinking exist, and the chairman after each speech calls for what is called a salamander.

COMMISSAR, or **COMMISSARY,** an official in the Union of Socialist Soviet Republics entrusted with the guidance of a separate branch of the administration, as the People's Commissary for Foreign Affairs, for War and Marine, etc.

COMMISSARIAT, the department of an army charged with the provision of supplies, both food and forage, for the troops. The supply of military stores such as ammunition is not included in the duties of a commissariat. In almost every army the duties of transport and supply are performed by the same corps of departmental troops.

COMMISSARY, generally, a representative, *e.g.,* the emperor's representative who presided in his absence over the imperial diet; and especially, an ecclesiastical official who exercises in special circumstances the jurisdiction of a bishop (*q.v.*); in the Church of England this jurisdiction is exercised in a consistory court (*q.v.*), except in Canterbury, where the court of the diocesan as opposed to the metropolitan jurisdiction of the archbishop is called a commissary court, and the judge is the commissary general of the city and diocese of Canterbury. When a see is vacant the jurisdiction is exercised by a "special commissary" of the metropolitan. Commissary is also a general military term for an official charged with the duties of supply, transport and finance of an army. In the 17th and 18th centuries the *commissaire des guerres,* or *Kriegskommissär* was an important official in continental armies, by whose agency the troops, in their relation to the civil inhabitants, were placed upon semi-political control. In French military law, *commissaires du gouvernement* represent the ministry of war on military tribunals, and more or less correspond to the British judge-advocate (*see* COURT-MARTIAL).

COMMISSION, the act of committing or entrusting any charge or duty to a person, and the charge or trust thus committed, and so particularly an authority, or the document embodying such authority, given to some person to act in a particular capacity. The term is thus applied to the written authority to command troops, which the sovereign or president, as commander-in-chief of the armed forces, grants to officers, or to the similar authority issued to justices of the peace. For the various commissions of assize *see* ASSIZE OR ASSISE. The word is also used of the order issued to a naval officer to take the command of a ship of war, and when manned, armed and fully equipped for active service she is said to be "put in commission."

In the law of evidence (*q.v.*) the presence of witnesses may, for certain necessary causes, be dispensed with by the order of the court, and the evidence be taken by a commissioner. Such evidence in England is said to be "on commission" (*see* R.S.C. Order XXXVII.). In the United States such evidence is taken by "deposition." Where the witness is out of the jurisdiction of the court, and his place of residence is a foreign country where objection is taken to the execution of a commission, or is a British colony or India, "letters of request" for the examination of the witness are issued, addressed to the head of the tribunal in the foreign country, or to the secretary of State for the colonies or for India.

Where the functions of an office are transferred from an individual to a body of persons, the body exercising these delegated functions is generally known as a commission and the members as commissioners; thus the office of lord high admiral of Great Britain is administered by a permanent board, the lords of the admiralty. Such a delegation may be also temporary, as where the authority under the great seal to give the royal assent to legislation is issued to lords commissioners. Similarly bodies of persons or single individuals may be specially charged with carrying out particular duties; these may be permanent, such as the Charity Commission or the Ecclesiastical and Church Estates Commission, or may be temporary, such as international commissions of inquiry (*see* ARBITRATION; DOGGER BANK), or such as the various commissions of inquiry, royal, statutory or departmental, of which an account is given below.

In the United States there are many commissions in both the Federal and State Governments. The U.S. Interstate Commerce, Federal Trade and Civil Service commissions are examples. Many States have public utilities and civil service commissions. Municipalities also have commissions in many instances.

Internationally, commissions often are appointed to settle claims between different nations on behalf of their subjects, and sometimes to define boundaries, and also for other purposes.

A commission may be granted by one person to another to act as his agent, and particularly in business; thus the term is applied to that method of business in which goods are entrusted to an agent for sale, the remuneration being a percentage on the sales. This percentage is known as the "commission," and hence the word is extended to all remuneration which is based on a percentage of the value of the work done. The right of an agent to remuneration in the form of a "commission" is always founded upon an express or implied contract between himself and his principal. Such a contract may be implied from custom or usage, from the conduct of the principal or from the circumstances of the particular case. Such commissions are only payable on transactions directly resulting from agency and may be payable though the principal acquires no benefit. In order to claim remuneration an agent must be legally qualified to act in the capacity in which he claims remuneration. He cannot recover in respect of unlawful or wagering transactions, or in cases of misconduct or breach of duty.

Commissions of Inquiry, *i.e.,* commissions for the purpose of eliciting information as to the operation of laws, or investigating particular matters, social, educational, etc., are distinguished, according to the terms of their appointment, as royal, statutory and departmental. A royal commission in England is appointed by the Crown, and the commissions usually issue from the office of the executive government which they specially concern. The objects of the inquiry are carefully defined in the warrant constituting the commission, which is termed the "reference." The commissioners give their services gratuitously, but where they involve any great degree of professional skill compensation is allowed for time and labour. The expenses incurred are provided out of money annually voted for the purpose. Unless expressly empowered by Act of parliament, a commission cannot compel the production of documents or the giving of evidence, nor can it administer an oath. A commission may hold its sittings in any part of Great Britain, or may institute and conduct experiments for the purpose of testing the utility of invention, etc. When the inquiry or any particular portion of it is concluded, a report is presented to the Crown through the home department. All the commissioners, if unanimous, sign the report, but those who are unable to agree with the majority can record their dissent, and express their individual opinions, either in paragraphs appended to the report or in separately signed memoranda.

Statutory commissions are created by Acts of parliament, and, with the exception that they are liable to have their proceedings questioned in parliament, have absolute powers within the limits of their prescribed functions and subject to the provisions of the Act defining the same. By the Tribunals of Inquiry (Evidence) Act 1921, where it has been resolved by both houses of parliament that a tribunal be established for enquiring into a definite matter described in the resolution as of urgent public importance and in pursuance thereof a tribunal is appointed either by the king or a secretary of State, it may be provided that the act shall apply, and in such case the tribunal shall have all the powers, rights and privileges that are vested in the high court, or in Scotland the court of session, for enforcing the attendance of witnesses and examining them on oath, compelling the production of documents, and the issue of commissions or requests to examine witnesses abroad. Departmental commissions or committees are appointed either by a Treasury minute or by the authority of a secretary of State, for the purpose of instituting inquiries into matters of official concern or examining into proposed changes in administrative arrangements. They are generally composed of two or more permanent officials of the department concerned in the investigation, along with a subordinate member of the administration. Reports of such committees are usually regarded as confidential documents.

In the United States commissions are established through authority of acts of Congress or the State legislatures. Internationally they are created by treaties or conventions.

See A. Todd, *Parliamentary Government in England,* vol. ii.; Charles A. Beard, *American Government and Politics.*

COMMISSION AGENT: *see* Agents in Business.

COMMISSIONAIRE, the designation of an attendant, messenger or subordinate employee in hotels on the Continent of Europe, whose chief duty is to attend at railway stations, secure customers, take charge of their luggage, carry out the necessary formalities with respect to it and have it sent on to the hotel. They are also employed in Paris as street messengers, light porters, etc.

The Corps of Commissionaires.—In England this is an association of pensioned soldiers of trustworthy character, founded in 1859 by Captain Sir Edward Walter, K.C.B. (1823–1904). Its headquarters are at 419a Strand, London, W.C. It was first started in a very small way, with the intention of providing occupation for none but wounded soldiers. The nucleus of the corps consisted of eight men, each of whom had lost a limb. The demand, however, for neat, uniformed, trusty men, to perform certain light duties, encouraged the founder to extend his idea, and the corps developed into a large self-supporting organization. In 1927 there were over 4,600 members of the corps, nearly 3,000 of whom served in London. There are local divisions of the corps at Belfast, Birmingham, Bristol, Edinburgh, Glasgow, Leeds, Liverpool, Manchester and Newcastle.

COMMISSIONER, in general an officer appointed to carry out some particular work, or to discharge the duty of a particular office; one who is a member of a commission (*q.v.*). He is legally defined as a person authorized by letters patent, act of parliament or other lawful warrant to execute any public office. The Commissioners Clauses Act of 1847 provides that commissioners executing undertakings of a public nature under an act of parliament are immune from personal liability. In this sense the word is applied to members of a permanently constituted department of the administration, as civil service commissioners, commissioners of income tax, commissioners in lunacy, etc. It is also the title given to the heads of or important officials in various governmental departments, as commissioner of customs. In some British possessions in Africa and the Pacific the head of the Government is styled high commissioner. In India a commissioner is the chief administrative official of a division which includes several districts. The office does not exist in Madras, where the same duties are discharged by a board of revenue, but is found in most of the other provinces. The commissioner comes midway between the local government and the district officer. In the regulation provinces the district officer is called a collector (*q.v.*), and in the non-regulation provinces a deputy-commissioner. In the former he must always be a member of the covenanted civil service, but in the latter he may be a military officer.

A chief commissioner is a high Indian official, governing a province inferior in status to a lieutenant-governorship, but in direct subordination to the governor-general in council. Of the 15 provinces of British India, nine are administered by lieutenant-governors and the remaining six by chief commissioners.

A commissioner for oaths in England is a solicitor appointed by the lord chancellor to administer oaths to persons making affidavits for the purpose of any cause or matter. The Commissioner for Oaths Act 1889 (with an amending act 1891), amending and consolidating various other acts, regulates the appointment and powers of such commissioners. Under the Rules of the Supreme Court (R.S.C. O. 37 r. 5) the High Court may order that any witness, whose attendance in court ought for sufficient cause to be dispensed with, be examined on oath by an officer of the court or a commissioner appointed for that purpose. In such cases the evidence is said to be taken "on commission."

COMMISSION INTERNATIONALE DE RAVITAILLEMENT. This commission was established as the result of an agreement concluded at a meeting held on Aug. 13, 1914, between delegates of the French ministries of finance, war and marine and representatives of the British Foreign office, Treasury, Admiralty, War Office and Board of Trade. The functions of the commission were to co-ordinate purchases of munitions, military and naval equipment and food supplies by the two Governments, to prevent competition in the same markets and consequent inflation of prices, and to help the French Government to purchase efficiently and economically.

In due course delegates of the Russian, Belgian, Serbian, Japanese, Italian, Portuguese, Rumanian, Greek, Brazilian and United States Governments were appointed on the commission, and its scope was accordingly extended to cover purchases for all the Allied and Associated Governments.

Organization.—The commission comprised: (a) Representatives of British Government departments, (b) representatives of the Allied and Associated Governments, and (c) a British executive staff.

(a) The British representatives included members of the Foreign office, Admiralty, War Office, Board of Trade, Board of Agriculture, Ministry of Munitions, Ministry of Food and Committee of Imperial Defence. The functions of each of these representatives was to act as the official mouthpiece of the department which he represented in expressing its views as to the effect of an Allied Government demand upon the supply of the materials in which the department was interested and in conveying its advice as to the method by which the demand could best be met. In course of time it was found more convenient for the duties originally undertaken by these delegates to be performed by special "allied sections" of the departments concerned, established to receive and take action on Allied demands received from the British staff.

(b) The representatives of the Allied and Associated Governments comprised upwards of 50 accredited delegates, including military and naval officers, civil officials and commercial experts, together with large technical, financial, shipping and clerical staffs, numbering in all some 1,500 persons.

Function of Delegates.—The primary function of these delegates was to formulate to the British Government the requirements of their own Governments and to ascertain how they could be met from the point of view of supplies, finance and tonnage; to advise as to the priority of manufacture and shipments of the materials which it might be found possible to supply; and to discuss technical details, sign or approve contracts, authorize payments by the British Government on Allied Government account, carry out inspection of materials, and the like.

(c) The British executive staff consisted of civil servants and temporary assistants, including a number of military officers and business men, and numbered in 1918 approximately 550 persons. It was at first under the direction of Mr. U. F. Wintour, C.B., C.M.G., and, on his becoming director of army contracts, his place was taken by Mr. (afterwards Sir) Edmund Wyldbore Smith.

The functions of the British executive staff were:—

(1) To receive and examine the demands formulated by the delegates of the Allied and Associated Governments, and to collate them with information obtainable from diplomatic, military or other sources and obtain further details and specifications which might be required.

(2) To examine and report to the Treasury upon all proposals which involved the expenditure of the British credits granted to the Allies.

(3) To enquire into the available supply of tonnage for the transport of the various materials concerned and the relative order of priority in which it should be utilized, and to keep the ministry of shipping, the marine department of the Board of Trade and any other departments concerned in close touch with the needs of the Allied and Associated Governments.

(4) To present the Allied demands in proper form to the different British supply departments concerned, making sure that every department was consulted, and to see that the demands were given prompt attention and that steps were immediately taken by those departments to place contracts, to supply from British stocks or to advise the Allied delegates with what firms, and also upon what conditions contracts might be placed by the delegates.

(5) To carry out all the official business involved in connection with the formal authorization of the supply of material by British Government departments to the Allies; the arrangement of railway and shipping facilities, the issue of export permits under the authority of the president of the board of trade for materials the export of which was prohibited; the preparation of statistics as to contracts placed, deliveries made, total quantities of materials bought and shipped, and the like.

The total value of the war material supplied to the Allies from the United Kingdom, through the Commission Internationale de Ravitaillement, amounted to approximately £672,000,000 of which some 48% went to France, 20% to Russia and 15% to Italy. The commission had its offices in London and was highly effective during the period of its activity.

COMMITMENT, in common law a warrant in writing of a magistrate, justice, or other official having police jurisdiction, directing the conveyance of a person named or sufficiently described therein to a prison or other legal place of custody, and his detention therein for a time specified, or until the person to be detained has done a certain act specified in the warrant, *e.g.*, paid a fine imposed upon him on conviction. An interval must necessarily elapse between the decision to commit and the making out of the warrant of commitment, during which interval the detention in custody of the person committed is undoubtedly legal. A commitment differs also from a warrant of arrest, in that it is not made until after the person to be detained has actually appeared, or has been summoned, before the court which orders committal, to answer to some charge.

It is ordinarily essential to a valid commitment that it should contain a specific statement of the particular cause of the detention ordered. To this the chief, if not the only exception, is in the case of commitments by order of either house of parliament. Commitments by justices of the peace must be under their hands and seals. Commitments by a court of record if formally drawn up are under the seal of the court.

In the case of superior courts no statutory forms of commitment exist, and the same formalities are not so strictly enforced. Committal of a person present in court for contempt of the court is enforced by his immediate arrest by the tipstaff as soon as committal is ordered, and he may be detained in prison on a memorandum of the clerk or registrar of the court while a formal order is being drawn up. And in the case of persons sentenced at assizes and quarter sessions the only written authority for enforcement is a calendar of the prisoners tried, on which the sentences are entered up, signed by the presiding judge.

Commitments are usually made by courts of criminal jurisdiction in respect of offences against the criminal law, but are also occasionally made as a punishment for disobedience to the orders made in a civil court, *e.g.*, where a judgment debtor having means to pay refuses to satisfy the judgment debt, or in cases where the person committed has been guilty of a direct contempt of the court. (*See* HABEAS CORPUS.)

The term is used in substantially the same sense in the United States Federal and State courts.

COMMITTEE, a person or body of persons to whom something is entrusted (Lat. *committere,* to entrust); also a person or persons to whom the charge of the body ("committee of the person") or of the property and business affairs ("committee of the estate") of a lunatic is committed by the court. (*See* INSANITY IN LAW.) The common meaning is that of a body of persons appointed to deal with business matters. For parliamentary committee, *see* PARLIAMENT.

COMMITTEE FOR INDUSTRIAL ORGANIZATION: *see* CONGRESS OF INDUSTRIAL ORGANIZATIONS.

COMMODE, originally, a tall head-dress with a fan-shaped frame covered with lace or silk. It was introduced by Mlle. de Fontanges, the red-haired mistress of Louis XIV. The term is now more commonly applied to a piece of furniture that is closely related to the chest of drawers, the chest, the bureau, and the sideboard. Because of this wide application of its use, the commode has been the object of various modifications. It is of French origin, having come into notice about the latter part of the 17th century, when it was known as a commode table. Some had lids, and opened up in a way similar to that of a chest; others had drawers, which gave opportunity for more ornamentation, with metal handles and escutcheons. The commode was at first confined to very fashionable drawing-rooms, but Chippendale contemplated its use in other places, especially the bedroom. This type is usually made with drawers and set upon legs, resembling in many ways a wash-stand. Another bedroom commode that came into use about the beginning of the 18th century was very similar to the chest, and still another was not unlike a travelling trunk, each being only about 2ft. high, 2ft. long, and 1½ft. deep. These bedroom commodes are rare, however, and the larger, drawing-room types should be considered first because of their wider use and greater quantity. Besides the variety of styles, sizes, and uses of such commodes, all kinds of finishes were applied: mahogany, lacquer, marquetry, and paint. Carving is perhaps the most outstanding feature; in fact, the preponderance of carving and ornamentation is often the only thing that distinguishes them from the sideboard and other pieces of furniture similar in use. (*See* also BUREAU; CHEST; SIDEBOARD.)

COMMODIANUS, a Christian Latin poet, who flourished about A.D. 250. Commodianus is supposed to have been an African. As he himself tells us, he was converted to Christianity when advanced in years, and felt called upon to instruct the ignorant in the truth. He was the author of two extant Latin poems, *Instructiones* and *Carmen apologeticum*. The *Instructiones* consist of 80 poems, each of which is an acrostic (with the exception of 60, where the initial letters are in alphabetical order). The initials of the 80, read backwards, give Commodianus Mendicus Christi. The first part is addressed to the heathens and Jews, and ridicules the divinities of classical mythology; the second contains reflections on Antichrist, the end of the world, the Resurrection, and advice to Christians, penitents and the clergy. In the *Apologeticum* all mankind are exhorted to repent, in view of the approaching end of the world. To the classical scholar the metre alone is of interest. The rules of quantity are sacrificed to accent. The first four lines of the *Instructiones* may be quoted by way of illustration:

> Praefatio nostra viam erranti demonstrat,
> Respectumque bonum, cum venerit saeculi meta,
> Aeternum fieri, quod discredunt inscia corda:
> Ego similiter erravi tempore multo.

These *versus politici* (as they are called) show that the change was already passing over Latin which resulted in the formation of the Romance languages. The use of cases and genders, the construction of verbs and prepositions, and the verbal forms exhibit striking irregularities.

BIBLIOGRAPHY.—*Editio princeps,* by J. B. Pitra in the *Spicilegium Solesmense* (1852) from a ms. in the Middlehill Collection now at Cheltenham, supposed to have been brought from Bobbio. The best edition of the text is by B. Dombart (1887); *see* also M. Manitius, *Geschichte der christlich-lateinischen Poesie* (1891), with bibliography; G. Boissier, "Commodien," in the *Mélanges Renier* (1887); L. Vernier, "La Versification latine populaire en Afrique," in *Revue de philologie,* xv. (1891); C. E. Freppel, *Commodien, Arnobe, Lactance* (1893), and H. Brewer, *Kommodian von Gaza* (Paderborn, 1906). Teuffel-Schwabe, *Hist. of Roman Literature* (Eng. trans., 384), should also be consulted.

COMMODITY, in economics, a portion of wealth, a thing which being desired as possessing the power to satisfy human wants, is limited in supply and has therefore value in exchange. Every commodity which satisfies a want is said to possess "utility"; conversely, everything possessing utility is a commodity. The economic expression "utility" does not mean usefulness, and has no moral significance. The economic touchstone is the satisfaction of human want, from whatever cause arising. Thus, an alcoholic beverage may or may not be useful, but it is wanted and in demand and is therefore in the economic sense a commodity. In the same way, the autograph manuscript of a book already printed may be a commodity. (*See* ECONOMICS.)

COMMODUS, LUCIUS AELIUS AURELIUS (161–192), also called Marcus Antoninus, emperor of Rome, son of Marcus Aurelius and Faustina, was born at Lanuvium on Aug. 31, 161. At the age of 15 he was associated by his father in the government. On the death of Aurelius, whom he had accompanied in the war against the Quadi and Marcomanni, he hastily concluded peace and hurried back to Rome (180). In 183 he was attacked by an assassin at the instigation of his sister Lucilla and many senators, and from this time be became tyrannical. Many distinguished Romans were put to death as implicated in the conspiracy, and others were executed for no reason at all. The treasury was exhausted by lavish expenditure on gladiatorial and wild beast combats and on the soldiery, and the property of the wealthy was confiscated. Plots against his life naturally began to spring up. That of his favourite Perennis, praefect of the praetorian guard, was discovered in time. The next danger was from the people, who were infuriated by the dearth of corn. The mob repelled the praetorian guard, but the execution of the hated minister Cleander quieted the tumult. The attempt also of the daring highwayman Maternus to seize the empire was betrayed; but at last Eclectus the chamberlain, Laetus the praefect of the praetorians, and the emperor's mistress Marcia, finding their names on the list of those doomed to death, had the emperor murdered on Dec. 31, 192. During his reign the frontier of Dacia was successfully defended against the Scythians and Sarmatians, and a tract of territory reconquered in north Britain. In 1874 a statue of Commodus was dug up at Rome, in which he is represented as Hercules—a lion's skin on his head, a club in his right and the apples of the Hesperides in his left hand.

Zürcher, "Commodus" (1868, in Büdinger's *Untersuchungen zur römischen Kaisergeschichte,* a criticism of Herodian's account); Pauly-Wissowa, *Real-encyklopädie,* ii. 2,464 ff. (von Rohden); Heer, "Der historische Wert des Vita Commodi" (*Philologus,* Supplementband, ix.).

COMMON FIELD SYSTEM: *see* CULTIVATION; LAND TENURE, PRIMITIVE.

COMMON GOOD, in Scotland, the name of ancient corporate property owned by the royal burghs and held by them for the communal benefit of their citizens. These properties consist for the most part of land and buildings. The communal funds derived from the Common Good are spent upon objects to which expenditure out of rates cannot be applied. Thus, the Royal Observatory at Edinburgh, an institution of much distinction, is maintained out of the Common Good.

COMMON LAW means the law common to the whole realm, as distinct from the law peculiar to certain classes of persons such as, in the middle ages, the "Law Merchant." This is the sense in which the term comes into general use in the reign of Edward I. The term, which has often been used in many senses, is best defined by contrast. It is contrasted with statute law, as law not promulgated by the sovereign body; with equity, as a kind of "supplemental law," which, in Maitland's words, is in the nature of "a gloss" upon the common law, corrective of it and auxiliary to it; and again with local customary law, as the general law for the whole realm, tolerating variations in certain districts and under certain conditions. It is also sometimes contrasted with civil, or canon, or international law, which are foreign systems recognized in certain special courts only and within limits defined by the common law. When so contrasted with foreign systems of law or with statute law, it is used to include equity itself, and since the "fusion" of common law in equity, which was finally consummated by the Judicature Act of 1873, common law and equity are administered in the High Court "concurrently" and indeed conjointly. As the universal law of the realm it has often been described as the national inheritance or "birthright" of Englishmen which English settlers carry with them when they occupy or colonize a new country. It was defined by Lord Wensleydale in *Mirehouse* v. *Mennell* 8 Bing. 515, as "a system which consisted in applying to new combinations of circumstances those rules which we derive from legal principles and judicial precedents." Its sources are therefore to be found in the law reports of cases actually decided, and it was said with perfect truth by Burke that "to put an end to reports is to put an end to the law of England."

Blackstone divides the civil law of England into *lex scripta* or statute law, and *lex non scripta* or common law. The latter, he says, consists of (1) general customs, which are the common law strictly so called, (2) particular customs prevailing in certain districts, and (3) laws used in particular courts. The first is the law by which "proceedings and determinations in the king's ordinary courts of justice are guided and directed." That the eldest son alone was heir to his ancestor, that a deed is of no validity unless sealed and delivered, that wills shall be construed more favourably and deeds more strictly, are examples of common law doctrines, "not set down in any written statute or ordinance, but depending on immemorial usage for their support." The validity of these usages is to be determined by the judges—"the depositaries of the law, the living oracles who must decide in all cases of doubt, and who are bound by an oath to decide according to the law of the land." Their judgments are preserved as records, and "it is an established rule to abide by former precedents where the same points come again in litigation." Thus Blackstone, a decision of the supreme court of appeal, namely the House of Lords, is consequently final, and the question at issue can never be raised and re-argued again. "Nothing," as Lord Halsbury remarked, "but an act of parliament can set right that which is alleged to be wrong in a judgment of this House." (*London Street Tramways*

v. *L.C.C.,* 1898, A.C. 375.)

Deference to Precedents.—The extraordinary deference paid to precedents is the source of the most striking peculiarities of the English common law. It was the rigid adherence of the common law courts to established precedent which caused the rise of an independent tribunal administering justice on more equitable principles—the tribunal of the chancellor, the court of chancery. The old common law courts—king's bench, common pleas and exchequer—were always, as compared with the court of chancery, distinguished by a certain rigidity of ideas and their whole system of practiced pleading was highly technical. At the same time the common law judges showed extraordinary ingenuity in extending the scope of the "original" writs, with which a common law action began, to meet the changing circumstances of society. The common law by the free use of fictions swallowed the law merchant and digested the greater part of Admiralty law.

Two great defects of form long disfigured the English law. One was the separation of common law and equity. The Judicature Act of 1873 remedied this by merging the jurisdiction of all the courts in one supreme court, and causing equitable principles to prevail over those of the common law where they "conflict." As a matter of fact there had been little conflict between the two systems of law since the 17th century. As Maitland has happily put it, "equity had come not to destroy but to fulfil." Equity was not a self-sufficient system whereas the common law was. Another defect is the overwhelming mass of precedents in which the law is embedded. This can only be removed by some well-conceived scheme of the nature of a code or digest. To some extent this difficulty has been overcome by such acts as the Bills of Exchange Act 1882, the Sales of Goods Act 1893 and the Law of Property Act of 1925. The last act was no mere codification, but revolutionary in the very doctrine of the law. The former acts were, however, little more than a reproduction in statute form of doctrines already established by the courts, and in spite of the modern growth of legislation, mainly social and administrative, what Dicey wrote many years ago is still true, namely that "nine-tenths of the law of contract and nearly the whole of the law of torts are not to be discovered in any volumes of the statutes."

In the early 16th century most countries in Europe underwent the influence of what was known as the "Reception," *i.e.,* the reception of Roman Law which, with the revival of the study of jurisprudence, was "received" into various European countries and displaced their old customary or "common law," or as it was sometimes expressively called "folk-law." England alone escaped this invasion by an alien system of law, and Maitland ascribed her immunity to the fact that "Mediaeval England had schools of law," in other words Inns of Court which preserved the traditions of the common law. "What is distinctive of mediaeval England," he wrote, "is not parliament, for we may everywhere see in Europe assemblies of estates, nor trial by jury, for this was but slowly suppressed in France; but the Inns of Court, and the Year Books (*i.e.,* the mediaeval law reports) that were read therein, and we shall hardly find their like elsewhere." And to any reception of Roman law the Inns of Court offered a stout and successful resistance. The constitutional importance of their victory was enormous, for the absolutist doctrines of Roman law found little or no place in the common law of England, and it was no accident that the greatest champions of the liberties of the subject against the despotic claims of the Stuart kings were the common lawyers, headed by the redoubtable Coke. Indeed most of our constitutional law, more particularily that which relates to the liberty of the subject, to the liability of servants of the Crown to answer for their wrongful acts, and other such fundamental principles, is to be found in the common law and nowhere else.

Judicial Legislation.—Coke held that the common law was the very incarnation of human wisdom and that not only was it superior to the king, in that the king "hath no prerogative but that which the common law allows him," but also that Parliament itself could not change it—a doctrine the second proposition of which, however, was already becoming obsolete with the growth of the modern principle of the sovereignty of parliament. In earlier times, unquestionably, the judges regarded the common law as supreme and unchangeable by any authority other than themselves—a view in which earlier parliaments were only too ready to acquiesce, as innumerable statutes, limiting the arbitrary jurisdiction of the king's council and asserting the right of the subject to claim the jurisdiction of the common law courts with trial by jury, abundantly testify. Magna Carta, which was regarded as simply a declaration of the common law and was granted long before parliament came into existence, represented to the mind of Coke "such a sovereign that he hath no fellow"; in other words it was a kind of fundamental law which parliament itself could not alter. And in the middle ages it was the judges rather than parliament who legislated in the matter of civil rights and criminal liabilities, sometimes avowedly (*e.g.,* Beresford C. J. in the reign of Edward II. [1310], who said "by this decision . . . we shall *make a law* throughout the land"), sometimes by the use of those transparent fictions by which the original action of trespass was extended to cover the whole field of contract and tort. The development of the criminal law was entirely judicial, the most notable example in this respect being the judicial doctrine of "constructive treason." To-day judges disavow the office of "judicial legislation" and, in theory, observe Bacon's monition that their office is *jus dicere* not *jus dare,* in other words to declare the law and not to make it. But in practice the judges undoubtedly legislate, if only by the extension of old rules to new sets of circumstances, or even by laying down a new rule where there is no precedent. The invention of the doctrine of "common employment" in the case of *Priestly* v. *Fowler* (1837) 3 M. and W. 1. is an example of the latter; the extension of petition of right to a claim to recover unliquidated damages for breach of contract by the Crown, in *Thomas* v. *the Queen* (1874) 44 L.J.Q.B. 9., may be legitimately regarded as an example of the former. Equity itself was originally a form of judicial legislation and nothing else, supplementing the defects or correcting the injustices, morally speaking, of the common law. The minds of English judges are certainly still receptive to common usage—*cf.* the words of Vaughan Williams L.J. in *Harrowing Steamship Co.* v. *Thomas and Sons* (*The Times,* March 15, 1913): "The courts have modified the natural construction to make decisions accord with commercial practice and convenience which I have heard described as commercial equity." So too the common law will take note of commercial usage in expanding the legal definition of negotiable instruments.

There is also the possibility of the invocation by judges of what is known as the principle of "public policy"—once defined as "the prevailing opinion of wise men as to what is for the public good"—whereby the judges have innovated freely, as, for example, by declaring certain kind of contracts unenforceable as contrary to the public interest, of which the most familiar example is contracts in restraint of trade. The rule of policy is avowedly a rule susceptible of constant change to suit the changing conditions of society. It would therefore be quite a mistake to regard the fact that our common law is based upon precedent as meaning that it is rigid, inflexible and incapable of expansion. And although a statute can, of course, abolish any rule of common law, it can only do so by express words or necessary intendment. In the absence of such a manifest intention, the common law remains, and is the "key to unlock" the meaning of the statute which will always be construed by the light of it.

In its freedom from the infection of foreign influences, the common law is as much a national possession as the English language itself. It is instinct with the English genius for practice as opposed to theory and of no other system of law can it be said so truly, in the language of Mr. Justice O. W. Holmes that "the life of the law is not logic but experience." The Pilgrim Fathers took it with them to America, even as they took the English speech, with the result that it is the foundation of the law of the United States and nowhere has it been more admirably studied.

COMMON LODGING-HOUSE, a house or part of a house in which persons of the poorer classes are harboured or lodged for hire for a single night or for less than a week at a time (*Daley* v. *Lees,* 1926, 1 K.B. 40), and in which there is community of accommodation for either eating or sleeping (*London C.C.* v. *Hankins,* 1914, 1 K.B. 490). This definition is very generally accepted as embracing those houses which, under the Public Health and other Acts, must be registered and inspected. The provisions of the Public Health Act, 1875, which extends to the country generally, excluding the metropolis, are that every urban and rural district council must keep registers showing the names and residences of the keepers of all common lodging-houses in their districts, the situation of every such house, and the number of lodgers authorized by them to be received therein. The whole of the house must be open at all times to the inspection of any officer of a council. The county of London (except the City) is under the Common Lodging Houses Acts 1851 and 1853. The administration of these Acts was in the hands of the chief commissioner of police from 1851 to 1894, when it was transferred to the London County Council. The county council has authority to make regulations as to common lodging-houses, subject to confirmation by the minister of health to whom the powers of the Local Government Board were transferred on July 1, 1919 (Ministry of Health Act, 1919, ss. 3 and 5). As to Scotland, *see* the Public Health (Scotland) Act, 1897, ss. 89–100. The term common lodging-house is not in use in the United States, although cheap rooming houses frequently are called "lodging-houses." Such lodging-houses are not licensed as are hotels.

COMMON ORDER, BOOK OF, sometimes called *The Order of Geneva* or *Knox's Liturgy,* a directory for public worship in the Reformed Church in Scotland. In 1557 the Scottish Protestant lords in council enjoined the use of the English Common Prayer, *i.e.,* the Second Book of Edward VI. Meanwhile, at Frankfort, among British Protestant refugees, a controversy was going on between the upholders of the English liturgy and the French Reformed Order of Worship, respectively. By way of compromise John Knox and other ministers drew up a new liturgy based upon earlier Continental Reformed services, which was not deemed satisfactory, but which on his removal to Geneva in 1556 he published for the use of the English congregations in that city. The Geneva book made its way to Scotland, and was used here and there by Reformed congregations. Knox's return in 1559 strengthened its position, and in 1562 the General Assembly enjoined its use as the "Book of Our Common Order" in "the administration of the Sacraments and solemnization of marriages and burials of the dead." In 1564 a new and enlarged edition was printed in Edinburgh, and the Assembly ordered that "every Minister, exhorter and reader" should have a copy and use the Order contained therein not only for marriage and the sacraments but also "in Prayer," thus ousting the hitherto permissible use of the Second Book of Edward VI. at ordinary service.

The rubrics of the Scottish portion of the book are somewhat stricter, and, indeed, one or two of the Geneva rubrics were made more absolute in the Scottish emendations; but no doubt the Book of Common Order is best described as a discretionary liturgy. The Westminster Directory which superseded the Book of Common Order, like it, enjoined interment "without any ceremony," such being stigmatized as "no way beneficial to the dead and many ways hurtful to the living." Civil honours may, however, be rendered.

Between 1606 and 1618 various attempts were made under English and Episcopal influence, by assemblies afterwards declared unlawful, to set aside the Book of Common Order. The efforts of James I., Charles I. and Archbishop Laud proved fruitless; in 1637 the reading of Laud's draft of a new form of service based on the English prayer book led to riots in Edinburgh and to general discontent in the country. The General Assembly of Glasgow in 1638 abjured Laud's book and took its stand again by the Book of Common Order, an act repeated by the assembly of 1639, which also demurred against innovations proposed by the English separatists, who objected altogether to liturgical forms, even to the Lord's Prayer. The following years witnessed a counter attempt to introduce the Scottish liturgy into England, especially for those who in the southern kingdom were inclined to Presbyterianism. This effort culminated in the Westminster Assembly of divines (1643), at which six commissioners from the Church of Scotland were present, and joined in the task of drawing up a Common Confession, Catechism and Directory for the three kingdoms. The General Assembly of 1645 after careful study approved the new order. An act of Assembly on Feb. 3, and an act of parliament on Feb. 6 ordered its use in every church, and henceforth, though there was no act setting aside the Book of Common Order, the Westminster Directory was of primary authority. The act of parliament recognizing the Directory was annulled at the Restoration and the book has never since been acknowledged by a civil authority in Scotland. But General Assemblies have frequently recommended its use, and worship in Presbyterian churches is largely conducted on the lines of the Westminster Assembly's Directory.

Contemporary Scottish worship, during the period (1564–1645) when the Book of Common Order was in use, is described by W. Cowper, Bishop of Galloway, in his *Seven Days' Conference Between a Catholic Christian and a Catholic Roman* (1615), and A. Henderson in *The Government and Order of the Church of Scotland* (1641).

COMMONPLACE, a passage or argument appropriate to several cases; a "common-place book" is a collection of such passages or quotations arranged for reference under general heads. To such a book the name *adversaria* was given, which is an adaptation of the Latin *adversaria scripta,* notes written on one side, the side opposite (adversus) of a paper or book. From its original meaning the word came to be used for a platitude or truism, being equivalent to trivial or ordinary. It was first spelled as two words, then with a hyphen, and so is still—in the sense of a "common-place book."

COMMON PLEAS, COURT OF, was the first of the three common law courts to emerge as a distinct judicial body from the *Curia Regis.* Owing to the increase of pleas between subject and subject (*communia placita*) before the *Curia Regis,* Henry II. appointed five justices to sit permanently in that court —*in banco residentes*—to hear such causes, and if any could not be determined by them it should be reserved for the hearing of the king himself and his wise men, i.e., *coram rege* in his council. But as yet there was no clear division. The justices sat now in one division of the *Curia Regis,* now in another. Both before and after John's reign the court of common pleas, although generally stationary at Westminster, followed the king from place to place as part of the *Curia Regis.* This constituted one of the grievances of the barons, and accordingly by Art. 17 of Magna Carta it was provided that it should not do so but should be held in some certain place. This eventually became a particular spot in Westminster Hall. During Henry III.'s minority there could not be a court held *coram rege,* and so one court tried all causes; but upon his majority in 1224 the division again appeared, and from that date the court of common pleas and the court held *coram rege*—which later became the court of King's bench (*q.v.*) —had separate rolls. In 1272 the court of common pleas had its own chief justice, and the separation might be said to be complete. By the Judicature Act, 1873, the jurisdiction of the court was transferred to the king's bench division of the high court of justice.

See Holdsworth, *Hist. Eng. Law,* vol. i. (H. H. L. B.)

COMMONS, the term for the lands held in commonalty, a relic of the system on which the lands of England were for the most part cultivated during the middle ages. The country was divided into vills, or townships—often, though not necessarily, or always, coterminous with the parish. In each stood a cluster of houses, a village, in which dwelt the men of the township, and around the village lay the arable fields and other lands, which they worked as one common farm. Save for a few small enclosures near the village—for gardens, orchards or paddocks for young stock—the whole township was free from permanent fencing. The arable lands lay in large tracts divided into compartments or fields, usually three in number, to receive in constant rotation the triennial succession of wheat (or rye), spring crops (such as barley, oats, beans or peas) and fallow. Low-lying lands were used as meadows, and there were sometimes pastures fed according to fixed rules. The poorest land of the township was left waste—to supply feed for the cattle of the community, fuel, wood for repairs and any other commodity of a renewable or practically inexhaustible character. This waste land is the *common* of our own days, and this system of farming is known as the *common-field* or *open-field* system.

So far back as accurate information extends the arable land is found to be parcelled out, each householder owning strips in each field. These strips are always long and narrow, and lie in sets parallel with one another. The plough for cultivating the fields was maintained at the common expense of the village, and the draught oxen were furnished by the householders. From the time when the crop was carried till the next sowing, the field lay open to the cattle of the whole vill, which also had the free run of the fallow field throughout the year. But when two of the three fields were under crops, and the meadows laid up for hay, it is obvious that the cattle of the township required some other resort for pasturage. This was supplied by the waste or common. Upon it the householder turned out the oxen and horses which he contributed to the plough, and the cows and sheep, which were useful in manuring the common fields,—in the words of an old law case: "horses and oxen to plough the land, and cows and sheep to compester it." Thus the use of the common by each householder was naturally measured by the stock which he kept for the service of the common fields; and when, at a later period, questions arose as to the extent of the rights on the common, the necessary practice furnished the rule, that the commoner could turn out as many head of cattle as he could keep by means of the lands which were parcelled out to him, —the rule of levancy and couchancy, which has come down to the present day. (*See* below: *Rights of Common.*)

In the earliest post-conquest times the vill or township is found to be associated with an overlord. (*See* MANOR.) At whatever date the overlord first appeared, there can be hardly any doubt that the village lands, whether arable, meadow or waste, were substantially the property of the villagers and the use regulated among themselves. The idea that the common was the "lord's waste," and that he had the power to do what he liked with it, subject to specific and limited qualifying rights in others, was, there is little doubt, the creation of the Norman lawyers.

Statutes of Merton and Westminster the Second.—One of the earliest assertions of the lord's proprietary interest in waste lands is contained in the Statute of Merton, a statute which, it is well to notice, was passed in one of the first assemblies of the barons of England, before the commons of the realm were summoned to parliament. This statute, which became law in the year 1235, provided "that the great men of England (which had enfeoffed knights and their freeholders of small tenements in their great manors)" might "make their profit of their lands, wastes, woods and pastures," if they left sufficient pasture for the service of the tenements they had granted. Some 50 years later, another statute, that of Westminster the Second, supplemented the Statute of Merton by enabling the lord of the soil to enclose common lands, not only against his own tenants, but against "neighbours" claiming pasture there. These two pieces of legislation undoubtedly mark the growth of the doctrine which converted the overlord's territorial sway into property of the modern kind, and a corresponding loosening of the hold of the rural townships on the wastes of their neighbourhood. To what extent the two acts were used, it is very difficult to say. By the Tudor period enclosures had made greater progress in some counties than in others. T. Tusser, in his eulogium on enclosed farming, cites Suffolk and Essex as enclosed counties by way of contrast to Norfolk, Cambridgeshire and Leicestershire, where the "open" or "champion" (champain) system prevailed. The Statutes of Merton and Westminster may have had something to do with the progress of enclosed farming; but it is probable that their chief operation lay in furnishing the lord of the manor with a farm on the new system, side by side with the common fields, or with a deer park.

The first event which really endangered the village system was the coming of the Black Death. This scourge is said to have swept away half the population of the country after the middle of the 14th century. The disappearance, by no means uncommon, of a whole family gave the overlord of the vill the opportunity of appropriating, by way of escheat, the holding of the household in the common fields. The land-holding population of the townships and the persons interested in the commons were thus sensibly diminished.

During the Wars of the Roses the small cultivator is thought to have again made headway. But his diminished numbers, and the larger interest which the lords had acquired in the lands of each vill, no doubt facilitated the determined attack on the common-field system which marked the reigns of Henry VIII. and Edward VI.

This attack, which had for its chief object the conversion of arable land into pasture for the sake of sheep-breeding, was the outcome of many causes. It was no longer of importance to a territorial magnate to possess a large body of followers pledged to his interests by their connection with the land. On the other hand, wool commanded a high price, and the growth of towns and of foreign commerce supplied abundant markets. At the same time the confiscation of the monastic possessions introduced a race of new overlords who were not bound to their territories by any family traditions, and also tended to spread the view that the strong hand was its own justification. Of this viewpoint there is abundant evidence both from the complaints of writers such as Latimer and Sir Thomas More, and from the statutes and royal commissions of the day, that large enclosures were made at this time, and that the process was effected with much injustice and accompanied by great hardship. "Where," says Bishop Latimer in one of his courageous and vigorous denunciations of "enclosers and rent raisers," "there have been many householders and inhabitants, there is now but a shepherd and his dog." In the full tide of this movement, and despite Latimer's appeals, the Statutes of Merton and Westminster the Second were confirmed and re-enacted. Both common fields and commons no doubt disappeared in many places; and the country saw the first notable instalment of enclosure.

Rights of Common.—The distinguishing feature in law of common land is that it is land the soil of which belongs to one person, and from which certain other persons take certain profits—for example, the bite of the grass by the mouth of cattle, or gorse, bushes or heather for fuel or litter. The right to take such a profit is a right of common; the right to feed cattle on common land is a right of common of pasture; while the right of cutting bushes, gorse or heather (more rarely of lopping trees) is known as a right of common of *estovers* (*estouviers*) or *botes* (respectively from the Norman-French *estouffer,* and the Saxon *botan,* to furnish). Another right of common is that of *turbary,* or the right to cut turf or peat for fuel. There are also rights of taking sand, gravel or loam for the repair and maintenance of land. The persons who enjoy any of these rights are called commoners.

From the sketch of the common-field system of agriculture which has been given, we shall readily infer that a large proportion of the commons of the country, and of the peculiarities of the law relating to commons, are traceable to that system. Thus, common rights are mostly attached to, or enjoyed with, certain lands or houses. A right of common of pasture usually consists of the right to turn out as many cattle as the farm or other private land of the commoner can support in winter; for, as we have seen, the enjoyment of the common, in the village system, belonged to the householders of the village, and was necessarily measured by their holdings in the common fields. The cattle thus commonable are said to be *levant* and *couchant, i.e.,* uprising and down-lying on the land. But it has now been decided that they need not in fact be so kept. At the present day a commoner may turn out any cattle belonging to him, wherever they are kept, provided they do not exceed in number the head of cattle which can be supported by the stored summer produce of the land in respect of which the right is claimed, together with any winter herbage it produces. The animals which a commoner may usually turn out are those which were employed in the village system—horses, oxen, cows and sheep. These animals are termed commonable animals. A right of pasture attached to land in the way we have described is said to be *appendant* or *appurtenant* to such land. Common of pasture appendant to land can only be claimed for commonable cattle; and it is held to have been originally attached only to arable land, though in claiming the right no proof that the land was originally arable is necessary.

The characteristic of connection with house or land also marks other rights of common. Thus a right of taking gorse or bushes or of lopping wood for fuel, called *fire-bote,* is limited to the taking of such fuel as may be necessary for the hearths of a particular house, and no more may be taken than is thus required. The same condition applies to common of *turbary,* which in its more usual form authorizes the commoner to cut the heather, which grows thickly upon poor soils, with the roots and adhering earth, to a depth of about 9in. So, also, a right of digging sand, gravel, clay or loam is usually appurtenant to land, and must be exercised with reference to the repair of the roads, or the improvement of the soil, of the particular property to which the right is attached.

To the manorial lord the law assigned the ownership of the soil of the common of the vill; and the common has for many centuries been styled the waste of the manor. The trees and bushes on the common belong to the lord, subject to any rights of lopping or cutting which the commoners may possess. The ground, sand and subsoil are his, and even the grass, though the commoners have the right to take it by the mouths of their cattle. To the overlord, also, was assigned a seignory over all the other lands of the vill; and the vill came to be termed his manor. At the present day it is the manorial system which must be invoked in most cases as the foundation of the curiously conflicting rights which coexist on a common. (*See* COPYHOLD, MANOR.)

Manorial Commons.—Within the bounds of a manor, speaking generally, there were three classes of persons possessing an interest in the land, viz.:—(*a*) Persons holding land freely of the manor, or freehold tenants. (*b*) Persons holding land of the manor by copy of court roll, or copyhold tenants. (*c*) Persons holding from the lord of the manor, by lease or agreement, or from year to year, land which was originally demesne, or which was once freehold or copyhold and has come into the lord's hands by escheat or forfeiture.

Amongst the first two classes were found the majority of the commoners on the wastes or commons of the manor. To every freehold tenant belonged a right of common of pasture on the commons, such right being "appendant" to the land which he holds freely of the manor. This right differed from most other rights of common in the characteristic that actual exercise of the right need not be proved. "Common appendant," said the Elizabethan judges, "is of common right, and commences by operation of law and in favour of tillage." It seems almost necessarily to follow that the freehold tenants of the manor were the representatives of the householders of the vill. Copyholders' rights were generally of the same character. They did not, however, exist as of common right, without proof of usage, but by the custom of the manor, but by the Real Property Act (1922) every copyhold is now enfranchised and converted into freehold, and all the manorial incidents connected with that form of tenure disappear. Rights of common enjoyed by the tenants are specifically preserved.

Rights of Common Not Connected with Manorial System.—So far we have considered common rights as they have arisen out of the manorial system, and out of the still older system of village communities. There may, however, be rights of common quite unconnected with the manorial system. Such rights may be proved either by producing a specific grant from the owner of the manor or by long usage. It is seldom that an actual grant is produced, although it would seem likely that such grants were not uncommon at one time. But a claim founded on actual user is by no means unusual and there are special rules applicable to each kind of claim.

A remarkable instance of such a common attached to the survival of an archaic community may be seen at Malmesbury in Wiltshire. Of this an account by Maitland is to be found in his *Collected Essays,* vol. ii., p. 328. Here a tract of 500 acres, named King's Heath, alleged to have been originally granted by King Athelstan to the town for service in battle against the Danes, was, in 1821, set out by a private act among the members of the old corporation, who till 1885 also governed the town, according to which every person in the borough is entitled to possess one allotment and every capital burgess a plot of from 8 to 15 acres.

There are still to be found, here and there, a group of arable common fields, and occasionally a piece of grass land with many of the characteristics of a common, which turns out to be a common field or meadow. The Hackney Marshes and the other so-called commons of Hackney are really common fields or common meadows, and along the valley of the Lea a constant succession of such meadows is met with. They are still owned in parcels marked by metes; the owners have the right to grow a crop of hay between Lady day and Lammas day; and from Lammas to March the lands are subject to the depasturage of stock.

Some of the largest tracts of waste land to be found in England are the waste or commonable lands of royal forests or chases. The thickets and pastures of Epping forest, now happily preserved for London under the guardianship of the city corporation, and the noble woods and far-stretching heaths of the New Forest, will be called to mind. Cannock Chase, unhappily enclosed according to law, though for the most part still lying waste, Dartmoor, and Ashdown forest in Sussex, are other instances; and the list might be greatly lengthened. It is enough in this connection to say that the common rights in a forest were usually enjoyed by the owners and occupiers of land within its bounds (the class may differ in exact definition, but is substantially equivalent to this) without reference to manorial considerations. Epping forest was saved by the proof of this right.

Enclosure.—We have seen that in the case of each kind of common there is a division of interest. The soil belongs to one person; other persons are entitled to take certain products of the soil. This division of interest preserves the common as an open space. The commoners cannot enclose, because the land does not belong to them. The owner of the soil cannot enclose, because enclosure is inconsistent with the enjoyment of the commoners' rights. At a very early date it was held that the right of a commoner proceeded out of every part of the common, so that the owner of the soil could not set aside part for the commoner and enclose the rest. The Statutes of Merton and Westminster the Second were passed to get over this difficulty. But under these statutes the burden of proving that sufficient pasture was left was thrown upon the owner of the soil; such proof can very seldom be given. Moreover, the statutes have never enabled an enclosure to be made against commoners entitled to *estovers* or *turbary.* It seems clear that the statutes had become obsolete in the time of Edward VI., or they would not have been re-enacted. And we know that the zealous advocates of enclosure in the 18th century considered them worthless for their purposes.

When, therefore, the common-field system began to fall out of gear, and the increase of population brought about a demand for an increased production of corn, it was felt to be necessary to resort to parliament for power to effect enclosure. The legislation which ensued was based on two principles. One was that all persons interested in the open land to be dealt with should receive a proportionate equivalent in enclosed land; the other, that enclosure should not be prevented by the opposition, or the inability to act, of a small minority. Assuming that enclosure was desirable, no more equitable course could have been adopted, though in details particular acts may have been objectionable. The first act was passed in 1709; but the precedent was followed but slowly, and not till the middle of the 18th century did the annual number of acts attain double figures. The high-water mark was reached in the period from 1765 to 1785, when on an average 47 acts were passed every year. From some cause, possibly the very considerable expense attending upon the obtaining of an act, the numbers then began slightly to fall off. The first General Enclosure Act was passed in 1801. This act would at the present day be called an Enclosure Clauses Act. It contained a number of provisions applicable to enclosures, which could be incorporated by reference, in a private bill. Under the stimulus thus applied enclosure proceeded apace. In the year 1801 no fewer than 119 acts were passed, and the total area enclosed probably exceeded 300,000 acres. Three enclosures in the Lincolnshire fens account for over 53,000 acres. As before, the movement after a time spent its force, the annual average of acts falling to about 12 in the decade 1830–40. Another parliamentary committee then sat to consider how enclosure might be promoted; and the result was the Enclosure Act 1845, which, though much amended by subsequent legislation, still stands on the statute-book. The chief feature of that act was the appointment of a permanent commission to make in each case all the enquiries previously made (no doubt capriciously and imperfectly) by committees of the two Houses. The commission, on being satisfied of the propriety of an enclosure was to draw up a provisional order prescribing the general conditions on which it was to be carried out, and this order was to be submitted to parliament by the Government of the day for confirmation. It is believed that these enclosure orders afford the first example of the provisional order system of legislation, which has attained such large proportions.

Again enclosure moved forward, and between 1845 and 1869 (when it received a sudden check) 600,000 acres passed through the hands of the enclosure commission. Taking the whole period of about a century and a half, when parliamentary enclosure was in favour, we shall probably not be far wrong in concluding that about one acre in every seven in England was enclosed during the period in question. It seems likely that, on the whole, England would have gained, had enclosure stopped in 1845.

Open Space Movement.—As a fact it stopped in 1869. Before the enclosure commission had been in existence 20 years the feeling of the nation towards commons began to change. The rapid growth of towns, and especially of London, and the awakening sense of the importance of protecting the public health, brought about an appreciation of the value of commons as open spaces. Naturally, the metropolis saw the birth of this sentiment. An attempted enclosure in 1864 of the commons at Epsom and Wimbledon aroused strong opposition; and a select committee of the House of Commons was appointed to consider how the London commons could best be preserved. Fortunately a small knot of men, who afterwards formed the Commons Preservation Society, took the question up. Chief amongst them were George Shaw-Lefevre, afterwards Lord Eversley, chairman of that society since its foundation, Henry Fawcett and Sir Charles Dilke. On the committee's report of the Commons Preservation Society the Metropolitan Commons Act 1866 was passed, which prohibited any further parliamentary enclosures within the metropolitan police area, and provided means by which a common could be put under local management. The lords of the manors in which the London commons lay felt that their opportunity of making a rich harvest out of land, valuable for building, though otherwise worthless, was slipping away; and a battle royal ensued. Enclosures were commenced, and the Statute of Merton prayed in aid. The public retorted by legal proceedings taken in the names of commoners. These proceedings—which culminated in the mammoth suit as to Epping forest, with the corporation of London as plaintiffs and 14 lords of manors as defendants—were uniformly successful; and the London commons were saved. By degrees the manorial lords, seeing that they could not hope to do better, parted with their interest for a small sum to some local authority; and a large area of the common land, not only in the county of London, but in the suburbs, is now in the hands of the representatives of the ratepayers, and is definitely appropriated to the recreation of the public.

The movement to preserve commons as open spaces soon spread to the rural districts. Under the Enclosure Act of 1845 provision was made for the allotment of a part of the land to be enclosed for field gardens for the labouring poor, and for recreation. But those who were interested in effecting an enclosure often convinced the enclosure commissioners that for some reason such allotments would be useless. To such an extent did the reservation of such allotments become discredited that, in 1869, the commission proposed to parliament the enclosure of 13,000 acres, with the reservation of only one acre for recreation, and none at all for field gardens. This proposal attracted the attention of Henry Fawcett, who, with his characteristic intrepidity, opposed the annual enclosure bill (which had come to be considered a mere form) and moved for a committee on the whole subject. The ultimate result was the passing, seven years later, of the Commons Act 1876. This measure, introduced by a Conservative Government, laid down the principle that an enclosure should not be allowed unless distinctly shown to be for the benefit, not merely of private persons, but of the neighbourhood generally and the public. It imposed many checks upon the process, and following the course already adopted in the case of metropolitan commons, offered an alternative method of making commons more useful to the nation, viz., their management and regulation as open spaces. The effect of this legislation and of the changed attitude of the House of Commons towards enclosure has been almost to stop that process, except in the case of common fields or extensive mountain wastes. It can be quite truly said that every struggle to protect commons from unlawful enclosure originated in the desire that the threatened area should be preserved as an open space in the public interest for use and enjoyment. But the public interest as such, although the motive of the action of the Commons Preservation Society was not an interest which the court of law would at that time recognize, being considered too vague and indefinite, and the long struggle in parliament, of which the successive acts of parliament, already mentioned, mark the different stages, was really a struggle to obtain such recognition, far more than for the protection of the commoners themselves. But public opinion during the past 50 years has entirely veered round, and gradually insisted that commons, with due regard to all existing rights, should be preserved as open spaces and protected as such. Owing further to the influence of the Commons Preservation Society, aided by the growth of public opinion, in the year 1893 Lord Thring carried through parliament the Commons Law Amendment Act, which provided that in future no enclosure under the Statute of Merton should be valid, unless made with the consent of the Board of Agriculture, which was to consider the expediency of the enclosure from a public point of view.

Regulation.—We have alluded to the regulation of commons as open spaces. The primary object of this process is to bring a common under the jurisdiction of some constituted authority, which may make by-laws, enforceable in a summary way before the magistrates of the district. Outside the metropolitan police district a provisional order for regulation may be made under the Commons Act 1876, with the consent of the owner of the soil and of persons representing two-thirds in value of all the interests in the common. And under an act passed in 1899 the council of any urban or rural district may, with the approval of the Board of Agriculture and without recourse to parliament, make a scheme for the management of any common within its district, provided no notice of dissent is served on the board by the lord of the manor or by persons representing one-third in value of such interests in the common as are affected by the scheme. There is yet another way of protecting a common. A parish council may, by agreement, acquire an interest in it, and may make by-laws for its regulation under the Local Government Act 1894. The acts of 1894 and 1899 undoubtedly proceed on right lines. For, with the growth of efficient local government, commons naturally fall to be protected and improved by the authority of the district.

The acreage of the remaining common land in England at the beginning of the 20th century was roughly estimated at somewhere between 1,500,000 and 2,000,000 acres. It is most capriciously distributed. In the Midlands there is very little to be found, while in a county of poor soil, like Surrey, nearly every parish has its common, and there are large tracts of heath and moor. In the metropolitan police district nearly 12,000ac. of common land have been put under local management.

The evidence of the change of policy referred to above is shown by the manner in which during the last 20 years the public interest in common lands has been protected in many acts of parliament relating to other subjects. Thus the Town Planning Acts prohibit the taking of common land under a town-planning scheme, unless an equal area be given in exchange to the satisfaction of the Ministers of Agriculture and Public Health. Similar restrictions appear in other Housing Acts, including the act of 1925; and also in the Development and Roads Improvements Act 1909, in the case of new roads in urban areas. So too the Small Holdings Acts of 1908–26 save all existing commons from appropriation or compulsory purchase under those acts, unless local enquiries are first held under the Commons Act of 1876 and the consent of parliament to any such scheme is obtained. Various large areas of common land acquired under water schemes, especially in the Lake district, have been made, subject to public right of access. The Law of Property Act of 1925, ss. 102 and 103, for the first time gives to the public a statutory right of access for air and exercise on every common or piece of manorial waste and to any rural common to which the section may hereafter be applied and provides that no enclosure or appropriation of land on and after Jan. 1, 1926, shall hereafter be lawful without the consent of the Minister of Agriculture, who may not consent to any enclosure unless satisfied that the interests of the public, as distinguished from those of the owners of the soil, will be benefited. These clauses have been aptly described as the "coping-stones" of the edifice which it has taken the Commons Preservation Society 60 years to build.

COMMON SENSE nowadays usually signifies the intelligence of normal people as distinguished from the views more or less peculiar to those who belong to special schools of thought. The contrast intended is sometimes that between the views of average people as against the views of peculiar or exceptional people, and sometimes that between the attitude of those who have just a general education and the attitude or outlook of those who have specialized in some way or other. The term, or rather its Greek equivalent (*κοινὴ αἴσθησις*) was first introduced by Aristotle, who seems to have been prompted by a variety of considerations. The five senses of popular psychology are each of them a special sense —visual only, or auditory only, or tactual only, and so on. As the organs for each of them are distinct and separate it seems remarkable that the visible, auditory, tactual and other sense qualities of an object should be localized in one and the same object. Hence the postulation of a "common" sense in addition to the "special" senses in order to account for the synthesis in question. Again, there are some things apprehended in sense perception which are not peculiar to any one of the special senses but are common to two or more of them—such are, for instance, motion, rest, number, size, shape. It seemed, therefore, reasonable to Aristotle to assume a common sense for the apprehension of such "common sensibles" as they were called. Once more, the different special sense-impressions are frequently compared and commonly differentiated. This likewise seemed to be the function of a common sense capable of comparing the reports of the several special senses. It is not quite certain whether Aristotle regarded the special senses as special functions of the common sense which included them all and more, or whether he regarded common sense as something separate from each of them but co-operating with them. In any case, he was led by the aforementioned and other considerations to formulate the existence of a common sense which he also credited with the function of memory, imagination and even of awareness of the fact that we are having sense-experiences. It is this last function, probably, that prompted some later writers to substitute an "inner" sense for Aristotle's "common" sense. Having regard to the kind of functions which Aristotle attributed to "common sense" it is not strange that the term should eventually have come to acquire the meaning of something like the general intelligence of the ordinary person.

COMMON SENSE PHILOSOPHY, or "the philosophy of common sense," is the usual designation of the Scottish philosophy or the Philosophy of the Scottish school consisting of Thomas Reid (1710–1796), Adam Ferguson (1723–1816), Dugald Stewart (1753–1828) and others. This trend of thought was a reaction or revolt against the scepticism of Hume and the subjective idealism of Berkeley, both of which were regarded as the consequences of a false start, namely an excessive stress on ideas, and as reductions to absurdity of the premises from which they started. For the false start Descartes and Locke were held to be chiefly responsible inasmuch as they gave to ideas an importance that inevitably made everything else succumb to them. "Ideas (says Reid) seem to have something in their nature unfriendly to other existences . . . they have by degrees supplanted their constituents, and undermined the existence of everything but themselves. First, they discarded all secondary qualities of bodies; and it was found out by their means that fire is not hot, nor snow cold, nor honey sweet; and, in a word, that heat and cold, sound, colour, taste and smell, are nothing but ideas or impressions. Bishop Berkeley advanced them a step higher, and found out, by just reasoning from the same principles, that extension, solidity, space, figure and body, are ideas, and that there is nothing in nature but ideas and spirits. But the triumph of ideas was completed by the *Treatise on Human Nature,* which discards spirits also, and leaves ideas and impressions as the sole existences in the universe" (*Works,* i. p. 109). In the actual perception of the normal unsophisticated man, sensations are not mere ideas or subjective impressions but carry with them the belief in corresponding qualities as belonging to external objects. Such beliefs, Reid insists, "belong to the common sense and reason of mankind," and in matters of common sense "the learned and the unlearned, the philosopher and the day-labourer, are upon a level." Kant was too much under the influence of idealism to respect the philosophy of common sense, which is the natural enemy of idealism, and so we find him speaking contemptuously of common sense as "one of the subtlest inventions of modern times, by which the emptiest talker may coolly confront the profoundest thinker, and hold out against him" (*Prolegomena,* Introduction). That, however, did not kill the philosophy of common sense. Not only was it adopted as the official philosophy of France from 1816 till 1870, but in one form or another it has survived to this day, and contemporary thinkers still oppose certain subjective and idealistic tendencies by an appeal to common sense.

See J. McCosh, *The Scottish Philosophy* (1875) and the articles on the philosophers named. (A. Wo.)

COMMONWEALTH, a term generally synonymous with commonweal, *i.e.,* public welfare, but more particularly signifying a form of government in which the general public have a direct voice. "The Commonwealth" is used in a special sense to denote the period in English history embracing the Protectorate of Oliver Cromwell, between the execution of Charles I. in 1649 and the Restoration in 1660. Commonwealth is also the official designation in America of the States of Massachusetts, Pennsylvania, Virginia and Kentucky. The Commonwealth of Australia is the title of the federation of Australian colonies carried out in 1900. The associated self-governing communities of the British empire are also described as the British Commonwealth of Nations.

COMMONWEALTH EDISON COMPANY, supplying substantially all of the electric light and power service in Chicago, is the successor by consolidation and merger to a number of electric utility companies the first of which (the Chicago Edison Company) was incorporated in 1887. It now controls, through direct stock ownership, important electric and gas utilities which supply service to 563 communities in 11,000 sq.mi. of territory in northern Illinois.

In 1892, the generating capacity of the Chicago Edison Company was 3,180 kilowatts. At the 1939 year-end, the generating capacity of Commonwealth Edison Company and subsidiaries was nearly 2,000,000 kilowatts. They were then serving over 1,365,000 electric customers and 279,000 gas customers. The system electric maximum demand for the winter of 1939–40 was approximately 1,542,000 kilowatts. The property, plant, and equipment of the company and subsidiaries (consolidated) at Dec. 31, 1939, was $681,122,806; total assets, $841,424,013; capital stock (including minority interests), $262,014,833; and funded debt, $377,270,900 which includes $82,332,900 of debentures, convertible into stock.

COMMUNE, in its most general sense, a group of persons acting together for purposes of self-government, especially in towns. (*See* Borough, and *Mediaeval,* below.) "Commune" (Med. Lat. *communia,* Lat. *communis,* common), is now the term generally applied to the smallest administrative division in many European countries.

"The Commune" is the name given to the Béla Kun régime in Hungary (*see* Hungary: *History*) and more generally to the Parisian insurrection of March 18 to May 29, 1871. Short-lived communes appeared at the same time in Marseilles, St. Étienne, Lyons and Narbonne. During the Franco-Prussian War the complete separation between Paris and the provinces had led to a total division of political sentiment; the peasant districts, disliking the prolongation of the war by the republic, returned a majority of monarchist deputies to the new assembly which was elected on Feb. 8, while Paris, which had ardently desired a continuance of the war, returned extreme Republicans. Adolphe Thiers (*q.v.*) who was selected as premier concurred with the assembly in believing that the disarmament and crushing of the armed National Guard of Paris was a necessary preliminary to the restoration of order. On the night of March 17–18 by his orders General Vinoy made an attempt to seize the cannon of the National Guard parked in Montmartre. This miscarried in the early morning owing to Vinoy's regular soldiers revolting and joining the Guard. In the ensuing tumult two generals were killed and the Government with the exception of Jules Ferry precipitately fled from Paris. The elective "Central Committee" of the Guard was thus unexpectedly left as the only effective authority: it negotiated elaborately with the local mayors (as the remaining legal authorities) and secured their consent to holding on March 26 an election for a commune, which resulted in a heavy "Red Republican" and Socialist majority. Despite the memories of 1793 called up by this name, it was intended by a majority of the members to mark only the assumption by Paris of the municipal powers previously denied her, and on this basis negotiations were privately opened with Thiers. He, however, adhered to his original policy and on April 2 bombarded Paris. A communard sortie next day was repulsed and thenceforward war was unceasing.

The policy of the Commune was only partly Socialist: the most advanced department in this respect being Leo Frankel's department of labour. Other departments were disorganized by the absence of Blanqui (a prisoner in Thiers' hands) whose followers comprised the majority and were accustomed to work only under his immediate direction. The Commune, which afterwards was regarded as the first "workers' republic," had hardly begun to carry out its semi-Socialist programme, largely adapted from the International, when the military situation became untenable.

Disorganization and unequal odds had led to the loss of Forts Issy and Vanves and the breaching of the wall at Porte Maillot and Auteuil. Thiers' troops entered by the latter on May 22 and occupied the west end, shooting a number of prisoners. Certain of the members of the Commune fled; others, after ordering the shooting of 67 hostages in their hands, conducted an embittered resistance which only ended with the capture of Fort Vincennes on May 29. The victors executed most of their prisoners out of hand: 20,000 Parisians without distinction of sex or age are generally supposed thus to have perished, though some writers put the figure as high as 36,000. The survivors were mostly deported to New Caledonia. The scene of the greatest slaughter, a wall in Père Lachaise cemetery, is the site of an annual international Socialist celebration.

MEDIAEVAL

A short account is here given of the rise and development of towns in central and western Europe since the downfall of the Roman empire. All these arose under similar conditions, economic, legal and political, irrespective of local peculiarities. Kindred economic conditions prevailed in all the former provinces of the Western empire, while new law concepts were everywhere introduced by the Germanic invaders. It seems advisable to begin with an account of the German towns, for their development was least affected by foreign interference, and it may also be said that their constitutional and economic history has been more thoroughly investigated than any other.

Germany.—The German towns should be considered from three points of view, as jurisdictional units, as self-administrative units and as economic units. One of the chief distinguishing features of early as opposed to modern town-life is that each town formed a jurisdictional district distinct from the country around. Another trait, more in accordance with modern conditions, is that local self-government was more fully developed in the towns than without. And, thirdly, each town in economic matters followed a policy as independent as possible of that of any other towns or of the country in general. The problem is, how this state of things arose.

The German towns may be divided into two main classes: those that arose on the ruins of former Roman cities in the Rhine and Danube countries, and those that were newly founded at a later date in the interior. Foremost in importance among the former stand the episcopal cities. Most of them had never been entirely destroyed during the Germanic invasion. Roman civic institutions perished; but probably parts of the population survived, and small Christian congregations with their bishops in most cases seem to have weathered all storms. Much of the city walls presumably remained standing, and within them German communities soon settled.

In the 10th century it became the policy of the German emperors to hand over to the bishops full jurisdictional and administrative powers within their cities. The bishop henceforward directly or indirectly appointed all officers for the town's government. The chief of these was usually the *advocatus* or *Vogt,* some neighbouring noble who served as the proctor of the church in all secular affairs. It was his business to preside three times a year over the chief law-court, the so-called *echte* or *ungebotene Ding,* under the cognizance of which fell all cases relating to real property, personal freedom, bloodshed and robbery. For the rest of the legal business and as president of the ordinary court he appointed a *Schultheiss, centenarius* or *causidicus.* Other officers were the *Burggraf* or *praefectus* for military matters including the preservation of the town's defences, walls, moat, bridges and streets, to whom also appertained some jurisdiction over the craft-gilds in matters relating to their crafts; further the customs-officer or *teleonarius* and the mint-master or *monetae magister.* It was not, however, the fact of their being placed under the bishop that constituted these towns as separate jurisdictional units. The chief feature rather is the existence within their walls of a special law, distinct in important points from that of the country at large. The towns enjoyed a special peace, as it was called, *i.e.,* breaches of the peace were more severely punished if committed in a town than elsewhere. Besides, the inhabitants might be sued before the town court only, and to fugitives from the country who had taken refuge in the town belonged a similar privilege. This special legal status probably arose from the towns being considered in the first place as the king's fortresses or burgs (*see* Borough), and, therefore, as participating in the special peace enjoyed by the king's palace. What struck the townless early Germans most about the Roman towns was their mighty walls, which were to them the main feature distinguishing a town from a village; and the fact of the town being a fortified place likewise necessitated the special provisions mentioned for maintaining the peace.

The New Towns.—The new towns in the interior of Germany were founded on land belonging to the founder, some ecclesiastical or lay lord, and frequently adjoining the cathedral close of one of the new sees or the lord's castle, and they were laid out according to a regular plan. The most important feature was the market-square, often surrounded by arcades with stalls for the sale of the principal commodities and with a number of straight streets leading thence to the city gates. As for the fortifications, some time naturally passed before they were completed. Furthermore, the governmental machinery would be less complex than in the older towns. The legal peculiarities distinguishing town and country, on the other hand, may be said to have been conferred on the new towns in a more clearly defined form from the beginning.

An important difference lay in the mode of settlement. There is evidence that in the former Roman towns the German new-comers settled much as in a village, *i.e.*, each full member of the community had a certain portion of arable land allotted to him and a share in the common. Their pursuits would at first be mainly agricultural. The new towns, on the other hand, general economic conditions having meanwhile begun to undergo a marked change, were founded with the intention of establishing centres of trade. Periodical markets, weekly or annual, had preceded them, and already enjoyed the special protection of the king's ban, acts of violence against traders visiting them or on their way towards them being subject to special punishment. The new towns may be regarded as markets made permanent. The settlers invited were merchants and handicraftsmen. The land now allotted to each member of the community was just large enough for a house and yard, stabling and perhaps a small garden. These building plots were given as free property or, more frequently, at a merely nominal rent with the right of free disposal, the only obligation being that of building a house. All that might be required besides would be a common for the pasture of the burgesses' cattle.

The example thus set was readily followed in the older towns. The necessary land was placed at the disposal of new settlers, either by the members of the older agricultural community, or by the various churches. The immigrants were of widely differing status, many being serfs who came either with or without their lords' permission. The necessity of putting a stop to belated prosecutions on this account in the town court led to the acceptance of the rule that nobody who had lived in a town undisturbed for the term of a year and a day could any longer be claimed by a lord as his serf. But even those who had migrated into a town with their lords' consent could not very well for long continue in serfdom. When, on the other hand, certain bishops attempted to treat all new-comers to their city as serfs, the emperor Henry V. in charters for Spires and Worms proclaimed that in these towns all serf-like conditions should cease. This ruling found expression in the famous saying: *Stadtluft macht frei,* "town-air renders free." As may be imagined, this led to a rapid increase in population, mainly during the 11th and 13th centuries. There would be no difficulty for the immigrants to find a dwelling, or to make a living, since most of them would be versed in one or other of the crafts in practice among villagers.

The most important further step in the history of the towns was the establishment of an organ of self-government, the town-council, with one, two or more burgomasters at its head. As *units of local government* the towns originally stood on the same legal basis as villages, with the responsibility for all common interests below the cognizance of the public courts or of those of their lord. In the towns, however, this right was strengthened at an early date by the *jus negotiale.* At least as early as the beginning of the 11th century, mercantile communities claimed the right, confirmed by the emperors, of settling mercantile disputes according to a law of their own. Furthermore, in the rapidly developing towns, opportunities for the exercise of self-administrative functions constantly increased. The new self-governing body soon began to legislate in matters of local government, imposing fines for the breach of its by-laws. Thus it assumed a jurisdiction, partly concurrent with that of the lord, which it further extended to breaches of the peace. And, finally, it raised funds by means of an excise-duty. In the older and larger towns it soon went beyond what the bishops thought proper to tolerate; conflicts ensued; and in the 13th century several bishops obtained decrees in the imperial court, either to suppress the council altogether, or to make it subject to their nomination, and more particularly to abolish the excise as detrimental to episcopal finances. In the long run, however, these attempts proved of little avail.

The Craft-gilds.—Meanwhile the tendency towards self-government spread even to the lower ranks of town society, resulting in the establishment of craft-gilds. From a very early period there is reason to believe that merchants among themselves formed gilds for social and religious purposes, and for the furtherance of their economic interests. On the other hand, the most important commodities offered for sale in the market had been subject to official examination already in Carolingian times. Bakers', butchers', shoemakers' stalls were grouped together in the market-place to facilitate control, and with the same object in view a master was appointed for each craft as its responsible representative. By and by these crafts or "offices" claimed the right of electing their master and of assisting him in examining the goods, and even of framing by-laws regulating the quality of the wares and the process of their manufacture. The bishops at first resented these attempts at self-management, as they had done in the case of the town council, and imperial legislation in their interests was obtained. But each craft at the same time formed a society for social, beneficial and religious purposes, and, as these were entirely in accordance with the wishes of the clerical authorities, the other powers could not in the long run be withheld, including that of forcing all followers of any craft to join the gild. It is not suggested that in each individual town the rise of the gilds was preceded by an organization of crafts on the part of the lord and his officers; but that voluntary organization could hardly have proceeded on such orderly lines as on the whole it did, unless the framework had in the first instance been laid down by the authorities. The principle of compulsory association would have found still less ready acceptance both on the part of the authorities and on that of the men, had it not previously been in full practice and recognition under the system of official market-control.

External Relations.—From an early date the towns, more particularly the older episcopal cities, took a part in imperial politics. Legally the bishops were in their cities mere representatives of the imperial government. This fact found formal expression mainly in two ways. The *Vogt,* although appointed by the bishop, received the "ban," *i.e.,* the power of having justice executed, which he passed on to the lesser officers, from the king or emperor direct. Secondly, whenever the emperor held a general assembly, or diet, in one of the episcopal cities, and for a week before and after, all jurisdictional and administrative power reverted to him and his immediate officers. The citizens on their part clung to this connection and made use of it whenever their independence was threatened by their bishops, who strongly inclined to consider themselves lords of their cathedral cities, much as if these had been built on church-lands. As early as 1073, therefore, we find the citizens of Worms successfully rising against their bishop in order to provide the emperor Henry IV. with a refuge against the rebellious princes. Those of Cologne made a similar attempt in 1074. But a second class of imperial cities (*Reichsstädte*), much more numerous than the former, consisted of those founded on demesne-land belonging either to the empire or to one of the families who rose to imperial rank. This class was largely reinforced after the extinction of the royal house of Hohenstaufen, when a great number of towns founded by them on their demesne successfully claimed immediate subjection to the crown. During the interregnum, a federation of more than 100 towns was formed, spreading from the Rhine as far as Bremen in the north, Zurich in the south and Regensburg in the east, with the object of helping to preserve the peace. In the following centuries the imperial cities in south Germany, where most of them were situated, repeatedly formed leagues to protect their interests against the power of the princes and the nobles, and destructive wars were waged; but no great political issue found solution, the relative position of the parties after each war remaining much what it had been before. On the part of the towns this was mainly due to lack of leadership and of unity of purpose. At the time of the Reformation the imperial towns, like most of the others, stood forward as champions of the new cause and did valuable service in upholding and defending it. After that, however, their political part was played out, mainly because they proved unable to keep up with modern conditions of warfare. It should be stated that seven among the episcopal cities, viz., Cologne, Mainz, Worms, Spires, Strasbourg, Basle and Regensburg, claimed a privileged position as "Free Cities," but neither is the ground for this claim clearly established, nor its nature well defined. The general obligations of the imperial cities towards the empire were the payment of an annual fixed tax and the furnishing of a number of armed men for imperial wars, and from these the above-named towns claimed some measure of exemption. Some of the imperial cities lost their independence at an early date, as unredeemed pledges to some prince who had advanced money to the emperor. Others seceded as members of the Swiss Confederation. But a considerable number survived until the reorganization of the empire in 1803. At the peace in 1815, however, only four were spared, namely, Frankfurt, Bremen, Hamburg and Lubeck, these being practically the only ones still in a sufficiently flourishing and economically independent position to warrant such preferential treatment. But finally Frankfurt, having chosen the wrong side in the war of 1866, was annexed by Prussia, and only the three seaboard towns retained the style of *Freie und Hansestädte*. But until modern times most of the larger *Landstädte* or mesne-towns for all intents and purposes were as independent under their lords as the imperial cities were under the emperor. They even followed a foreign policy of their own, concluded treaties with foreign powers or made war upon them. Nearly all the *Hanseatic towns* belonged to this category. With others like Bremen, Hamburg and Magdeburg, it was long in the balance to which class they belonged. All towns of any importance, however, were for a considerable time far ahead of the principalities in administration. It was largely this fact that gave them power. When, therefore from about the 15th century the princely territories came to be better organized much of the *raison d'être* for the exceptional position held by the towns disappeared. The towns from an early date made it their policy to suppress the exercise of all handicrafts in the open country. On the other hand, they sought an increase of power by extending rights of citizenship to numerous individual inhabitants of the neighbouring villages. By this and other means, *e.g.,* the purchase of estates by citizens, many towns gradually acquired a considerable territory. These tendencies both princes and lesser nobles naturally tried to thwart, and the mediate towns or *Landstädte* were finally brought to stricter subjection in the greater principalities such as Austria and Brandenburg. Besides, the less favourably situated towns suffered through the concentration of trade in the hands of their more fortunate sisters. But the economic decay and consequent loss of political influence among both imperial and territorial towns must be chiefly ascribed to inner causes.

Commercial Policy.—The period of the rise of cities till well on in the 13th century was naturally a period of expansion and of a considerable amount of freedom of trade. Afterwards, a protectionist spirit gained the upper hand, and each town made it its policy to restrict as far as possible the trade of strangers. In this revolution the rise of the lower strata of the population to power played an important part. The craft-gilds had remained subordinate to the council, but by-and-by they claimed a share in the government of the towns. Originally any inhabitant holding a certain measure of land, freehold or subject to the mere nominal ground-rent abovementioned was a full citizen independently of his calling, the clergy and the lord's retainers and servants of whatever rank, who claimed exemption from scot and lot, to use the English formula, alone excepted. The majority of the artisans, however, were not in this happy position. Moreover, the town council, instead of being freely elected, filled up vacancies by co-optation, with the result that all power became vested in a limited number of rich families. Against this state of things the crafts rebelled, alleging mismanagement, malversation and the withholding of justice. During the 14th and 15th centuries revolutions and counter-revolutions, sometimes accompanied by considerable slaughter, were frequent, and a great variety of more democratic constitutions were tried. Zurich, however, is the only German place where a kind of *tyrannis,* so frequent in Italy, came to be for a while established. On the whole it must be said that in those towns where the democratic party gained the upper hand an unruly policy abroad and a narrow-minded protection at home resulted. An inclination to hasty measures of war and an unwillingness to observe treaties among the democratic towns of Swabia were largely responsible for the disasters of the war of the Swabian League in the 14th century. At home, whereas at first markets had been free and open to any comer, a more and more protective policy set in, traders from other towns being subjected more and more to vexatious restrictions. It was also made increasingly difficult to obtain membership in the craft-gilds, high admission fees and so-called masterpieces being made a condition. Finally, the number of members became fixed, and none but members' sons and sons-in-law, or members' widows' husbands were received. The first result was the formation of a numerous proletariat of life-long assistants and of men and women forcibly excluded from following any honest trade; and the second consequence, the economic ruin of the town to the exclusive advantage of a limited number. From the end of the 15th century population in many towns decreased, and some once important centres of trade sank to the level almost of villages. Those cities, on the other hand, where the mercantile community remained in power, like Nuremberg and the seaboard towns, on the whole followed a more enlightened policy, although even they could not quite keep clear of the ever-growing protective tendencies of the time. Many even of the richer towns, notably Nuremberg, ran into debt irretrievably, owing partly to an exorbitant expenditure on magnificent public buildings and extensive fortifications, calculated to resist modern instruments of destruction, partly to a faulty administration of the public debt.

One of the principal achievements of the towns lay in the field of *legislation.* Their law was founded originally on the general national law, or custom, and on special privilege. New foundations were regularly provided by their lord with a charter embodying the most important points of the special law of the town in question. This miniature code would thenceforth be developed by means of statutes passed by the town council. The codification of the law of Augsburg in 1276 fills a moderate volume in print (ed. by Christian Meyer, Augsburg, 1872). Later foundations were frequently affiliated by their founders to the nearest existing town of importance, though that might belong to a different lord. Afterwards, if a question in law arose which the court of a younger town found itself unable to answer, the court next senior in affiliation was referred to, which in turn would apply to the court above, until at last that of the original mother town was reached, whose decision was final. This system was chiefly developed in the colonial east, where most towns were affiliated directly or indirectly either to Lubeck or to Magdeburg; but it was by no means unknown in Germany proper.

Italy.—To turn to *Italy,* the country for so many centuries in close political connection with Germany, the foremost thing to be noted is that here the towns grew to even greater independence, many of them in the end acknowledging no overlord whatever after the yoke of the German kings had been shaken off. On the other hand, nearly all of them in the long run fell under the sway of some local tyrant-dynasty.

From Roman times the country had remained thickly studded with towns, each being the seat of a bishop. From this arose their most important peculiarity. For it was largely due to an identification of diocese and municipal territories that the nobles of the surrounding country took up their headquarters in the cities, either voluntarily or because forced to do so by the citizens, who made it their policy thus to turn possible opponents into partisans and defenders. In Germany, on the other hand, nobles and knights were carefully shut out so long as the town's independence was at stake, the members of a princely garrison being required to take up their abode in the citadel, separated from the town proper by a wall. In consequence of this, municipal life in Italy was from the first more complex, the main constituent parts of the population being the greater nobles, the lesser nobles (knights) and the people. Furthermore, the bishops being in most cases the representatives of the imperial power, the struggle for freedom from the latter ended in emancipation from all temporal episcopal government as well. Foremost in this struggle stood the cities of Lombardy, most of which all through the barbarian invasions had kept their walls in repair and maintained some importance as economic centres, and whose *popolo* largely consisted of merchants of some standing. As early as the 8th century, the laws of the Lombard King Aistulf distinguished three classes of merchants (*negotiantes*), among whom the *majores et potentes* were required to keep themselves provided with horse, lance, shield and a cuirass. The valley of the Po formed the main artery of trade between western Europe and the East, Milan being besides the point of convergence for all Alpine passes west of the Brenner. Lombard merchants soon spread all over western Europe, a chief source of their ever-increasing wealth being their employment as bankers of the papal see.

The struggle against the bishops, in which a clamour for ecclesiastical reforms and a striving for local self-government were strangely interwoven, had raged for a couple of generations when King Henry V., great patron of municipal freedom as he was, legalized by a series of charters the *status quo* (Cremona, 1114, Mantua, 1116). But under his weak successors the independence of the cities reached such a pitch as to be intolerable to an energetic monarch like Frederick I. Therefore in 1158 a commission was appointed embracing four Roman legists as representatives of the emperor, as well as those of 14 towns, to examine into imperial and municipal rights. The claims of the imperial government were acknowledged, only such rights of self-government being admitted as could be shown to be grounded on imperial charters. But when it came to carrying into effect these Roncaglian decrees, a general rising resulted. Milan was besieged by the emperor and destroyed in 1162 in accordance with the verdict of her rivals. Nevertheless, after a defeat at Legnano in 1176 Frederick was forced to renounce all pretensions to interference with the government of the cities, merely retaining an overlordship that was not much more than formal (peace of Constance in 1183). All through this war the towns had been supported by Pope Alexander III. Similarly under Frederick II. the renewal of the struggle between emperor and pope dovetailed with a fresh outbreak of the war with the cities, who feared lest an imperial triumph over the church would likewise threaten their independence. The emperor's death finally decided the issue in their favour.

Municipal Government.—Municipal freedom in Italy was based on the formation of a commune headed by elected consuls, usually to the number of 12 representing the three orders of *capitani, valvassori* and *popolo*. Frequently, however, the number actually wielding power was much more restricted, and their position altogether may rather be likened to that of their Roman predecessors than to that of their German contemporaries. In all important matters they asked the advice and support of "wise men," as a body called the *credenza*, while the popular assembly (*parlamentum, concio, consilium generale*) was the true sovereign. The consuls with the assistance of *judices* also presided in the law-courts; but besides the consuls of the commune, there were *consules de placitis* specially appointed for jurisdictional purposes. In spite of these multifarious safeguards, family and political factions early destroyed the fabric of liberty. Party government was impossible and resort was often had to the appointment as chief magistrate of a *podestà* from among the nobles or knights of a different part of the country not mixed up with the local feuds. But the end was in most cases the establishment of the despotism of some leading family, such as the Visconti at Milan, the Gonzaga at Mantua, the della Scala in Verona and the Carrara in Padua.

In Tuscany, the historic rôle of the cities, with the exception of Pisa, begins at a later date, largely owing to the overlordship of the powerful margraves of the house of Canossa and their successors, who here represented the emperor. Nevertheless, communes with consuls at their heads were formed in Tuscany much as elsewhere. On the other hand the Tuscan cities managed to prolong the reign of liberty to a much later epoch, no *podestà* ever quite succeeding here in his attempts to establish the rule of his dynasty. Even when in the 15th century the Medici attained to power in Florence the form at least of a republic was still maintained, and not till 1531 did one of them, supported by Charles V., assume the ducal title.

Long before the last stage, the rule of *signori*, was reached, the commune as originally constituted had everywhere undergone radical changes. As early as the 13th century the lower orders in Florence formed an organization under officers of their own, side by side with that of the commune, which was controlled by the great and the rich. Its establishment was followed by numerous constitutional experiments which led to constant disorder and to an occasional reign of terror like that of the Signore Gauthier de Brienne, duke of Athens (1342–43). It was not till after a rising of the lowest order of all, the industrial labourers, had been suppressed in 1378 (*tumulto dei Ciompi*, the wool-combers), that quieter times ensued under the wise leadership, first of the Albizzi and finally of the Medici.

The history of the other Tuscan towns was equally tumultuous, all of them save Lucca, after many fitful changes, finally passing under the sway of Florence, or the grand-duchy of Tuscany, as the State was now called. Pisa, one time the mightiest, had been crushed between its inland neighbour and its maritime rival Genoa (battle of Meloria, 1282).

Venice.—Apart in its constitutional development from all other towns in Italy, and, it might be added, in Europe, stands Venice. Almost alone among Italian cities its origin does not go back to Roman times. It was not till the invasions of Hun and Lombard that fugitives from the Venetian mainland founded a number of small communities under elected tribunes, acknowledging as their sovereign the emperor at Constantinople. Just before or after A.D. 700 the young republic seems to have thrown off the rule of the Byzantine *dux Histriae et Venetiae* and elected a duke (*doge*) of its own, in whom was vested the executive power, the right to convoke the popular assembly (*concio*) and appoint tribunes and justices. Political unity was thus established. In 1032 it was provided that no duke might appoint his successor or procure him to be elected during his own lifetime. Besides this two councils were appointed without whose consent nothing of importance was to be done. After the murder by the people of Duke Vitale Michiel in 1172, the ancient popular meeting was replaced by a great council of from 450 to 480 members elected annually by special appointed electors in equal proportion from each of the six wards. One of the functions of this body was to appoint most of the State officials or their electors. There was also an executive council of six, one member from each ward. Besides these, the duke, who was henceforward chosen for life by a body of 11 electors from among the aristocracy, would invite persons of prominence (the *pregadi*) in order to secure their assent and co-operation whenever a measure of importance was to be placed before the great council. Only under extraordinary circumstances was the *concio* to be summoned. In order to control the executive the *avvogadori di commune* were appointed. After 1310, this body developed into the Council of Ten (*Consiglio dei Dieci*), from which the State inquisition arose in the 16th century. The general tendency of constitutional development in Venice henceforward ran in an exactly opposite direction to that of all other Italian cities, towards a growing restriction of popular rights, until in 1296 the great council was for all future time closed to all but the descendants of a limited number of noble families, whose names were in that year entered in the Golden Book.

The marked steadiness in the evolution of the Venetian constitution is no doubt largely due to the fact that in Venice the nobility was entirely commercial. Elsewhere the presence of large numbers of turbulent country nobles furnished the first germ for the unending dissensions which ruined such promising beginnings. In Venice, on the contrary, its businesslike habits of mind led the ruling class to make what concessions might seem needful, while both the masses and the head of the State were kept in due subjection to the laws. Too much stability, however, finally changed into stagnation, and the constitution proved too rigid to deal effectively with the many problems which confronted the government under the changed conditions of the 16th century.

The cities of southern Italy do not here call for special attention. Several of them developed a certain amount of independence and free institutions, and took an important part in trade with the East, notably so Amalfi. But, after incorporation in the Norman kingdom, all individual history for them came to an end. (For Rome, *see* separate article.)

France.— In no other country is there such a clear grouping of the towns on geographical lines as in *France,* these geographical lines, of course, having in the first instance been drawn by historical causes. Another feature is the extent to which, in the unruly times preceding the civic movement, serfdom had spread among the inhabitants even of the towns throughout the greater part of the country, and the application of feudal ideas to town government. In some other respects the constitution of the cities in the south of France has more in common with that of the Italian communes, and that of the northern French towns with those of Germany, than the constitutions of the various groups of French towns have with each other.

In the group of the *villes consulaires,* comprising all important towns in the south, the executive was, as in Italy, in the hands of a body of *consules,* whose number in most cases rose to 12. They were elected for the term of one year and re-eligible only after an interval, and they were supported by a municipal council which, however, as a rule was far from comprising the whole body of citizens. Another feature which these southern towns had in common with their Italian neighbours was the prominent part played by the native nobility. The relations with the clergy were generally of a more friendly character than in the north, and in some cases the bishop or archbishop even retained a considerable influence in the management of the town's affairs. Dissensions among the citizens, or between the nobles and the bourgeois, frequently ended in the adoption of a *podestat.* In several cities of the Languedoc, each of the two classes composing the population retained its separate laws and customs. The influence of Roman law is shown by the *statuts municipaux* of many southern towns. In the improvement and expansion of these statutes a remarkable activity was displayed by means of an annual *correctio statutorum* carried out by specially appointed *statutores.* In the north, on the other hand, the *carta communiae,* forming as it were the basis of the commune's existence, seems to have been considered almost as something sacred and unchangeable.

The constitutional history of the communes in northern France in a number of points widely differed from that of these *villes consulaires.* Their origin was often the result of a revolution. These revolutions were in the first place directed against the bishops; but the higher clergy and the nobility were here distinctly more hostile to the aspirations of the citizens than in the south. As a result the clergy and the nobles were excluded from all membership of the commune, except that those residing in the town might be required to swear not to conspire against it. The commune was formed by an oath of mutual help. The members were usually described as *jurati* although in some communes that term was reserved for the members of the governing body. None but men of free and legitimate birth, and free from debt and contagious or incurable disease were received. The members of the governing body were styled *jurés pairs* or *échevins.* The last was, however, as in Germany, more properly the title of the jurors in the court of justice, which in many cases remained in the hands of the lord. In some cases the town council developed out of this body; but in the larger cities, like Rouen, several councils worked and all these names were employed side by side. The number of the members of the governing body proper varies from 12 to 100, and its functions were both judicial and administrative. The most striking distinction, however, as against the *villes consulaires* was the elevation of the president of the body to the position of *maire* or *mayeur* (sometimes also called *prévôt, praepositus*). As elsewhere, at first none but the civic aristocracy were admitted to take part in the management of the town's affairs; but from the end of the 13th century a share had to be conceded to representatives of the crafts. Dissatisfaction, however, was not easily allayed; the lower orders applied for the intervention of the king; and that effectively put an end to political freedom. This tendency of calling in State help marks a most striking difference from the policy followed by the German towns, where all classes appear to have been always far too jealous of local independence. The result for the nation was in the one case despotism, equality and order, in the other individual liberty and an inability to move as a whole. At an early stage the king had frequently come to the assistance of the communes in their struggle with their lords, and his confirmation came to be considered necessary for their lawful existence. This proved a powerful lever for the extension of the king's authority. It is strange that in France the towns never had recourse to those inter-urban leagues which played so important a part in Italian and in German history.

The Villes Franches.—These two varieties, the communes and the *villes consulaires,* together form the group of *villes libres.* As opposed to these stand the *villes franches,* also called *villes prévotales* after the chief officer, *villes de bourgeoisie* or *villes soumises.* They make up by far the majority of French towns, comprising all those situated in the centre of the kingdom, and also a large number in the north and the south. They are called *villes franches* on account of their possessing a franchise, a charter limiting the services due by the citizen to their lord; but political status they had little or none. According to the varying extent of the liberties conceded them, there may be distinguished towns governed by an elective body and more or less fully authorized to exercise jurisdiction; towns possessing some sort of municipal organization, but no rights of jurisdiction, except that of simple police; and, thirdly, those governed entirely by seignorial officers. To this last class belonged some of the most important cities in France, wherever the king had power enough to withhold liberties deemed dangerous and unnecessary. On the other hand, towns of the first category often came close to the *villes libres.* A strict line of demarcation, however, remained in the mutual oath which formed the basis of the civic community in both varieties of the latter, and in the fact that the *ville libre* stood to its lord in the relation of vassal and not in that of an immediate possession. But however *complètement assujettie* Paris might be, its organization, naturally, was immensely more complex than that of hundreds of smaller places which, formally, might stand in an identical relationship to their lords. Like other *villes franches,* under the king, Paris was governed by a *prévôt* (provost), but certain functions of self-government for the city were delegated to the company of the *marchands de l'eau,* that is, the gild of merchants whose business lay down the river Seine, to the citizens as such. At their head stood a *prévôt des marchands* and four *échevins de la marchandise.* Other *prud'hommes* were occasionally called in, and from 1296 *prèvôt* and *échevins* appointed 24 councillors to form with themselves a *parloir aux bourgeois.* The crafts of Paris were organized in *métiers,* whose masters were appointed, some by the *prévôt de Paris,* and some by certain great officers of the court. In the tax rolls of A.D. 1292 to 1300 no fewer than 448 names of crafts occur, while the *Livre des métiers* written in 1268 by Étienne de Boileau, then *prévôt de Paris,* enumerates 101 organized bodies of tradesmen or women and artisans. Among the duties of these bodies, as elsewhere, was the *guet* or night-watch, which necessitated a military organization under *quartainiers, cinquantainiers* and *dixainiers.* This gave them a certain power. But both their revolutions, under the *prévôt des marchands,* Étienne Marcel, after the battle of Maupertuis, and again in 1382, were extremely short-lived, and the only tangible result was a stricter subjection to the king and his officers.

Flanders.—An exceptional position among the cities of France is taken by those of Flanders, more particularly the three "Great Towns," Bruges, Ghent and Ypres, whose population was Flemish, *i.e.,* German. They sprang up at the foot of the count's castles and rose in close conjunction with his power. On the accession of a new house they made their power felt as early as 1128. Afterwards the counts of the house of Dampierre fell into financial dependence on the burghers, and therefore allied themselves with the rising artisans, led by the weavers. These, however, proved far more unruly, bloody conflicts ensued, and for a considerable period the three great cities ruled the whole of Flanders with a high hand. Their influence in the foreign relations of the country was likewise great, it being in their interest to keep up friendly relations with England, on whose wool the flourishing state of the staple industry of Flanders depended. It is a remarkable fact that the historical position taken up by these cities, which politically belonged to France, is much more akin to the part played by the German towns, whereas Cambrai, whose population was French, was the only city politically situated in Germany, where a commune came to be established.

In the *Spanish peninsula,* the chief importance of the numerous small towns lay in the part they played as fortresses during the unceasing wars with the Moors. The kings therefore extended special privileges (*fueros*) to the inhabitants, and they were even at an early date admitted to representation in the Cortes. Of greater individual importance than all the rest was Barcelona. Already in 1068 Count Berengarius gave the city a special law (*usatici*) based on its ancient usages, and from the 14th century its commercial code became influential all over southern Europe.

The constitutions of the *Scandinavian* towns were largely modelled on those of Germany, but the towns never attained anything like the same independence. Their dependence on the royal government most strongly comes out in the fact of their being uniformly regulated by royal law in each of the three kingdoms. In Sweden particularly, German merchants by law took an equal share in the government of the towns. In Denmark their influence was also great, and only in Norway did they remain in the position of foreigners in spite of their famous settlement at Bergen. The details, as well as those of the German settlement at Wisby and on the east coast of the Baltic, belong rather to the history of the Hanseatic League (*q.v.*). Denmark appears to be the only one of the three kingdoms where gilds at an early date played a part of importance.

Bibliography.—For Germany it is best to consult Richard Schröder, *Lehrbuch der deutschen Rechtsgeschichte* (5th ed. Leipzig, 1907), ss. 51 and 56, where a bibliography as complete as need be is given, both of the monographs dealing with various aspects of the question, and of works on the history of individual towns. As a sort of complement to Schröder's chapters may be considered, F. Keutgen, *Urkunden zur städtischen Verfassungsgeschichte* (1901), a collection of 437 select charters and other documents, with a very full index. There is an excellent succinct account for general readers by Georg von Below, "Das ältere deutsche Städtewesen und Bürgertum," *Monographien zur Weltgeschichte,* vol. vi. (Bielefeld and Leipzig, 1898, illustrated). As for Italy, the most valuable general work for the early times is still Karl Hegel, *Geschichte der Städteverfassung von Italien seit der Zeit der römischen Herrschaft bis zum Ausgang des zwölften Jahrhunderts* (2 vols. Leipzig, 1847), in which it was for the first time fully proved that there is no connection between Roman and modern municipal constitutions. For the period from the 13th century it will perhaps be best to consult W. Assmann, *Geschichte des Mittelalters,* 3rd. ed., by L. Viereck, dritte Abteilung, *Die letzten beiden Jahrhunderts des Mittelalters: Deutschland, die Schweiz, und Italien,* by R. Fischer, R. Scheppig and L. Viereck (Brunswick, 1906). In this volume, pp. 679–943 contain an excellent account of the various Italian States and cities during that period, with a full bibliography for each. For France, there are the works by Achille Luchaire, *Les Communes françaises à l'époque des Capétiens directs* (1890), and Paul Viollet, "Les Communes françaises au moyen age," *Mémoires de l'Académie des Inscriptions et Belles-lettres,* tome xxxvi. (1900). A valuable account for France north of the Loire is that contained in the great work by Karl Hegel, *Städte und Gilden der germanischen Völker im Mittelalter* (2 vols. Leipzig, 1891). Of course, there are also numerous monographs, among which the following may be mentioned: Édouard Bonvalot, *Le Tiers État d'après la charte de Beaumont et ses filiales* (1884); and A. Giry, *Les Établissements de Rouen* (2 vols. 1883–85); also a collection of documents by Gustave Fagniez, *Documents relatifs à l'histoire de l'industrie et du commerce en France* (2 vols. 1898, 1900). Some valuable works on the commercial history of southern Europe should still be mentioned, such as W. Heyd, *Geschichte des Levantehandels im Mittelalter* (2 vols. Stuttgart, 1879; French edition by Furcy Raynaud, 2 vols. 1885 *seq.,* improved by the author), recognized as a standard work; Adolf Schaube, *Handelsgeschichte der romanischen Völker des Mittelmeergebietes bis zum Ende der Kreuzzüge* (Munich and Berlin, 1906); Aloys Schulte, *Geschichte des mittelalterlichen Handels und Verkehrs zwischen Westdeutschland und Italien mit Ausschluss Venedigs* (2 vols. Leipzig, 1900); L. Goldschmidt, *Universalgeschichte des Handelsrechts* (vol. i. Stuttgart, 1891). (F. K.)

COMMUNICATION: *see* Railways: *Signalling;* Signal Communication; Wireless Telegraphy; Telegraph; Telephone; Broadcasting; Television; Semaphore; Fathometer.

COMMUNICATIONS. In military language, the system of communication for supply, reinforcement, evacuation of wounded, etc., by road, rail, navigable waterways and air, between an army and its base (*q.v.*) or bases of operation inclusive.

COMMUNISM, a term often loosely used to denote different systems of social organization aiming at common property of the means of production, or at an equal distribution of wealth and income, or at both. Historically the term was frequently used as identical with socialism, as was done by Karl Marx and Friedrich Engels in their famous *Communist Manifesto* (1848). In earlier times there were many communist movements, most of them formed on a religious basis, generally under the inspiration of a literal interpretation of passages in the Scripture. These early communists founded communities in which, as a rule, articles of production and consumption were held in common property and the reform of society was advocated on ethical grounds. The early or "Utopian" socialists of the 19th century followed, on the whole, a similar course, though they replaced the religious emphasis by a rational and philanthropic motivation. Best known among them are Robert Owen (1771–1858), who founded the community of New Harmony in 1825 in Indiana, and François Fourier (1772–1837), whose disciples organized a number of settlements in the United States after the model of Fourier's original "phalanx." The most famous of these American settlements was Brook Farm, established in 1841 at West Roxbury, Mass. With the writings of Karl Marx, communism and socialism gained a new meaning.

The communalization was confined to the means of production; the basis of the movement was no longer sought in religious or ethical assumptions, but in the social sciences and in a historical and economic analysis of the forces at work in society; the industrial working class was regarded as the bearer of the new order which would no longer be confined to small groups but would become worldwide as the result of an immanent historical process which uses the class war as its vehicle.

In recent times the meaning of the word communism has been narrowed down to denote that interpretation of Marxian doctrine proposed by Lenin when he came to power in Russia as a result of the revolution in Nov. 1917, and on the basis of which he and his followers have tried to transform society in Russia. Communism in that sense is only one of the possible interpretations of Marxian socialism, and leading socialists from the beginning have attacked Lenin's theory and its realization in Russia. While socialism put its faith in an evolutionary development and in democratic means of attaining the liberation of all men from economic servitude, communism regarded revolution and an ensuing dictatorship of the proletariat as a necessary period of transition to the future free and equalitarian society in which everyone would contribute to the common good according to his abilities and would receive according to his needs. Lenin's communistic interpretation of Marxian socialism goes back to the year 1903, when at the second party congress the Russian Social Democratic party split into two factions, one representing the majority and therefore called bolsheviks (which means "majority group") under Lenin, and a minority group (mensheviks) under Martov. Against his opponents who proposed the formation of a mass party after the example of the German Social Democrats, Lenin insisted upon the necessity of founding a party of picked and selected men, entirely devoted to the socialist cause, who would be able to act in revolutionary situations as a closely-knit, disciplined and resolute group, and seize power, though only a minority. Lenin's group opposed any co-operation with bourgeois democratic or moderate socialistic parties; during the war of 1914–18 it assumed an intransigent attitude against any form of "patriotism" and concentrated its efforts on the transformation of the national war into a social war. After the outbreak of the Russian revolution in March 1917, the bolsheviks under the leadership of Lenin (whose real name was Vladimir Ilyich Ulyanov, 1870–1924) were the only group with strict discipline and definite purpose and thus were able to direct the amorphous and leaderless revolutionary discontent of the masses. After having seized power in Nov. 1917, the bolsheviks established their dictatorship as a dictatorship of the proletariat, renamed the party communist party, and defeated (thanks to the leadership and gift of organization of Leon Trotsky) the counterrevolution and kept themselves in power against great initial odds.

According to communist theory, the social revolution—accomplished in the interests of the proletariat and, after the abolition of class society, of all men—must be conducted by the "proletariat's advance guard," the communist party, because the people as a whole and even large parts of the proletariat, educated in the presocialist era in the bourgeois concepts of life, are unable to grasp and to realize the new order immediately. The communists insist upon the activization of the masses and their growing participation in the establishment of the new order. As the instrument of this participation they accepted the workers', soldiers' and peasants' councils (the Russian word for council is *soviet*) which had been formed during the Russian revolution in 1905. In these soviets only the working classes were represented, not the "capitalists" or "exploiters"; the mode of election was so carefully regulated that only deputies belonging to or approved by the party were chosen. But communism, differing in that respect from fascism, regards dictatorship as a transitional institution, and full democracy as the goal. It believes that true democracy cannot be realized in capitalistic society on account of the economic exploitation imposed upon the economically weaker elements of society, and that the generally accepted forms of parliamentary democracy only veil the control of society by capitalists. While fascism believes in the unalterable and beneficial inequality of men and races and appeals to the instincts of man which have their origins in the past, communism believes in the equality of all men and races, and its outlook is based on reason as a common element in all men and as a guide for the construction of the future. To this future the happiness of the present generation and the traditions of the past are ruthlessly sacrificed. Theoretically a classless society of free individuals will emerge as a result of the dictatorship. Marxism regards the state as an organ of class rule, and as the struggle for the emancipation of the proletariat is the last of all possible class conflicts (because after its emancipation there will remain no lower class to be emancipated), the communist state in suppressing the class basis destroys its own basis or, as it has been expressed, the state withers away and a system of complete freedom emerges. What has happened so far in reality, however, is the opposite. The state in Russia under communist dictatorship has not yet begun to wither away, but is the first example of the truly totalitarian state in which no sphere of individual life is allowed to remain outside its all-inclusive grip.

In trying to create a true democracy of free and equal individuals, terror was ruthlessly employed, all humanitarian considerations and individual rights were disregarded, and the assumption of the class character and economic determination of all intellectual and moral life led to a complete relativization of all standards of truth and of ethics.

In its practical application in Russia, communism has passed through several stages. By the end of 1920, after a long struggle against external and internal enemies, the communist power appeared consolidated within Russia. At the same time, it had to abandon the expectations of world revolution which had animated Lenin and his followers in 1917. They had looked upon the Russian revolution as the first stage of a worldwide process; for them socialism or communism were international movements which could only succeed, and were destined to succeed, on a worldwide basis. In 1919 Lenin had founded the Communist or Third International, but it proved unable to make any progress outside Russia, and the several communist parties existing abroad soon became instrumental to the policy of the communist state in Russia. With the practical abandonment of all hopes for an immediate world revolution and with the complete exhaustion of Russia's resources as a result of the war of 1914–18 and its own civil wars, Lenin was forced to replace the policy of "war communism" in March 1921, by the so-called "new economic policy" (NEP). It represented a compromise between nationalized and private economy, an interim providing for the education of the Russian people to that initiative and efficiency which is needed for the functioning of modern industrial civilization. Large-scale industry remained nationalized and foreign trade was a government monopoly; but small-scale industry, domestic trade, and especially agriculture, reverted to private enterprise, and a new class of prosperous peasants (kulaks) and urban middle-men (nepmen) developed, whose wealth, however, gave them neither political rights nor social standing. During the NEP period (1921 to 1928) a struggle for leadership in the communist party (after the death of Lenin) developed between Trotsky, his nearest collaborator in the decisive years of the conquest of power, and Joseph Stalin, who as secretary-general had succeeded in bringing the party machine under his control. In this struggle Stalin was victorious. During the NEP Russia's constitutional structure was also fundamentally changed. Communism, firmly believing in the equality of all races and peoples, abandoned the concept of the Russian Empire in which the Russian element had ruled over many different racial and ethnical groups, some very considerable in size and some tiny, some highly literate and some most primitive. In its place it created in 1924 the Union of Soviet Socialist Republics (USSR), a federation of a number of equal sister-republics within which smaller ethnical groups and all minorities enjoy autonomy and fully equal rights. All precedence of the Russian element or of the Russian language has been abolished; the soviet government made a great effort to create or promote literatures in the vernacular tongues and to make the non-Russian population share in the activities of the party and of the administration.

The period of the NEP was followed in 1928 by a renewed drive for the "realization of socialism" in the soviet union. The aim of the new policy was defined in retrospect by Stalin in his report to the Seventeenth Party congress in Jan. 1934, when he pointed out that the USSR "has become radically transformed; it has discarded the features of backwardness and mediaevalism. From an agrarian country it has become transformed into an industrial country. From a land of small individual agriculture it has become a land of collective, large-scale mechanized agriculture. From an ignorant, illiterate and uncultured country it has become—or rather it is becoming—a literate and cultured country covered with a network of higher, middle and elementary schools operating in the languages of the nationalities of the USSR." This speedy drive toward socialism called for advance planning in all branches of the economic and cultural life of the country; the so-called Five-Year Plan. In a poor and backward country like Russia the excessive tempo of the planning, the lack of managerial and engineering talent and of skilled labour, naturally resulted not only in frequent maladjustments and tremendous waste, but could be financed only by a general reduction of the standard of living. The "advance towards socialism" proceeded on three lines: industrial, agricultural and educational. In the first field the Five-Year Plan was devoted to the better exploitation of natural resources and to the building up of heavy industry; in the second field to the collectivization of individual farms and to the introduction of machinery and more efficient methods of cultivation; in the third field to the fight against illiteracy and traditionalism, and to a change of the ways of life and thought-habits of the population. The first Five-Year Plan dating from Oct. 1, 1928, was declared successfully terminated at the end of 1932, and was then followed by further similar plans.

In its foreign policy the soviet union, after having abandoned the hope of a European revolution, concentrated for some years upon the expectation of stirring up revolutionary movements in the Orient. The communists supported the nationalist movements in the colonial and semi-colonial countries, in Turkey and Persia, in India and China. Their hopes were frustrated by the defeat suffered in China in 1927. After that time the soviet government pursued a policy of making Russia secure against any foreign invasion. With the growth of fascism in Japan and Germany, and with the conclusion of the anti-communist pact by Germany, Italy and Japan, the soviet union, which had joined the League of Nations in 1934, stressed its willingness to co-operate with other nations in a system of collective security. Similarly, the communist parties outside the soviet union, who until then had violently opposed all bourgeois democracies and moderate socialistic parties, and who had seen their main purpose less in a struggle against conservative or reactionary parties than in violent abuse of democratic and social democratic groups, changed their tactics after 1933 and declared themselves ready to co-operate in creating a "popular front" against fascism. For a short time they gained thereby some influence in several countries. Before this they had been unable to gain a strong position anywhere in the western world, even in times of great economic stress. Deeply imbued with the Russian example which, peculiar to the character of a backward and undeveloped country, had very little to offer to progressive and highly developed societies, the communist parties outside Russia remained a sect essentially foreign to the environment in which they proposed to function, and their doctrinaire terminology carried no conviction. Their negative policy helped rising fascism to undermine democracy, and the bogey of communism frightened many members of the upper classes in democratic countries and drove them to a closer co-operation with fascism. The influence of communism was further weakened by the great purges of the party in the years 1937 and 1938, to which many high officials of the political and economic administration, old and trusted leaders of the party, and the most experienced and renowned officers of the armed forces, fell victims. A complete overhauling of the personnel and even of the doctrines of the communist revolution strengthened the personal position of Stalin, and the regime in the soviet union took on more and more the character of his personal dictatorship. In the light of this new development the history of the Russian revolution and all doctrinal manuals were rewritten. Stalin's position became more and more akin to that of the leaders in the fascist dictatorships and a similar Byzantine exaltation was accorded to his person. "Progressive" tendencies regarding marriage and divorce, abortion and high natality, education and family, which had been characteristic of the first period of communism, were abandoned, and replaced by more conservative attitudes. A new stress was laid upon the national past.

During the period of the co-operation of the soviet union with the democratic nations, a new democratic constitution was introduced on Nov. 25, 1936, which stressed the principles of democracy without abandoning the firm grip of the dictatorship upon the country. But in 1939 communism again performed a complete about-face in its international and in its general policy. The communists had until then demanded energetic and armed resistance against every case of fascist aggression anywhere. This policy was completely reversed at the end of Aug. 1939, when the soviet union signed a nonaggression and friendship treaty with national socialist Germany, which was followed in April 1941 by a similar treaty with Japan. During the first 20 months of the war which began in 1939, the soviet union was bent upon keeping aloof from the war itself, but at the same time extended its own territory. By a war against Finland certain minor but strategically important slices of that country were added to the soviet union; without military opposition, the soviet union incorporated the three Baltic republics, Esthonia, Latvia and Lithuania, occupied eastern Poland and attached it to the existing soviet republics of Ukraine and of White Russia, and annexed Bessarabia and northern Bukovina from Rumania. In all these new acquisitions the communist regime and way of life were immediately introduced. Hand in hand went a regime of ever-increasing military preparedness within the soviet union. On May 9, 1940, the soviet army, in order to achieve higher efficiency, abandoned some of the principles of communism. The vast powers of the political commissioners in the army were ended and full authority was restored to the military officers.

Outside the soviet union all communist activities are forbidden in fascist and semi-fascist countries. Some democracies like Switzerland have lately adopted similar measures. Communist parties were of some importance at the end of the '30s in France and in Czechoslovakia, but with the end of the democratic regimes there they have ceased to exist. Internationally their activities were of importance only in Spain and in China. The civil war in Spain, which lasted from July 1936 to March 1939, provided the numerically weak communists with an opportunity to influence in various ways the policy of the Spanish republican government, especially in view of the fact that the soviet union was the only power which supplied the Spanish government, though insufficiently, with war materials to enable it to maintain its authority against the fascist military uprising of General Franco and his followers, who were fully supported by the Italian and German governments. In China communist groups established themselves in the western provinces and fought for agrarian reform and for better educational and sanitary standards. Long hostile to the national government of Generalissimo Chiang Kai-shek, they finally made common cause with him against Japanese invasion. Communism in China seemed more an indigenous agrarian revolutionary movement born of the backward conditions of the country and the exploitation of the masses, than an integral part of the worldwide communist movement which has its centre in Moscow.

COMMUNISM, PRIMITIVE. Many societies which are classified as primitive or as belonging to the lower culture, exhibit features which have given rise to the view that communistic principles regulate their economic system. Thus, among the Lhota Nagas of Assam "land can be held either by the village, a *morung*—men's house—a clan, or an individual. The land close to a village is usually waste land and common property, as are the rights of 'poisoning' in certain pools. Every *morung* owns land which is the property of the *morung* as a whole and not of any individuals in it. It is worked by the boys of the *morung*. . . . A very large proportion of the land in the Lhota country is clan land, which is held in common by all members of that particular clan in the village. . . . Heirlooms such as the ancient *doos* and spears which a Lhota so prizes are held in trust by the senior member of the clan in the village" (J. P. Mills, *Lhota Nagas*, 1922, p. 97). Corporate ownership by clans or *morungs*, and common rights over waste land cannot fairly be called communistic. They indicate—what is already true of the majority of lower culture societies—that the kindred, or biologic, groups of which those societies are composed (*see* TRIBE and CLAN) have economic functions in the sum of social life. It is asserted emphatically by Rivers (*History of Melanesian Society*, 1914, vol.

ii. p. 146 *seq.*) that "it is clear that definite communism of property still flourishes in one form or another throughout Melanesia." He states in support of this that "at Pentecost, not long ago, all property was owned by the *verana* or social group within the moiety, and that this communistic ownership still persists in the case of canoes." He saw in certain features of ceremonial in the Banks Islands survivals of communism, and found at Eddystone "a large degree of community in the ownership of land" which "belongs to a group of persons brought into relationship with one another by kinship." In a later chapter (*ibid.* p. 384 *seq.*) he argued that a communistic people would need money, not for internal economic functions, but only for external transactions, and associated the use of money with the disappearance of communism. In elaborating the theory of culture movements in Polynesia he found that the communism in Polynesia was characteristic of the earlier settlers, who accepted the later immigrants as chiefs—"endowed with Divine attributes" and "able to obtain all they needed for the asking." People enjoying these ample privileges would need no money. The picture is incomplete because it raises the suspicion that the chiefs—licensed plunderers—kept their booty to themselves.

The intimate investigations made by Malinowski in the Trobriands, disclose facts which warrant the conclusion that "there is a strict definition in the rights of everyone, and this makes ownership anything but communistic" (*Crime and Custom,* 1926, p. 19). Clearly, therefore, we must distinguish between control, exploitation, utilization and ownership—and we must be prepared to find that social groupings which sometimes coincide and are identical with, and at other times cut right across, biologic groupings such as the clan, are endowed with economic functions which constitute their unity and give them their value. That primitive ownership, as we now know it, is tempered by rights of others, is hardly a proof of prior communism. Among the Ba-Ila (*Ila-speaking Peoples,* vol. i., p. 339), "My collateral grandfather's property is mine potentially. I may enter my grandfather's brother's village, spear his oxen, or rob his fields with impunity." Elsewhere, in the Torres Straits (*Report,* vol. v., p. 146), "The nephew, even if quite a small boy, could take, lose, spoil or destroy anything belonging to his (maternal) uncle and the uncle would utter no word of reproach or anger." The fact is that "reciprocity, the give and take principle, reigns supreme also within the clan, nay within the nearest group of kinsmen. As we have seen already, the relation between the maternal uncle and his nephews, the relations between brothers, nay the most unselfish relation, that between a man and his sister, are one and all founded in mutuality and the repayment of services." (B. Malinowski, *Crime and Custom,* 1926, p. 47.)

It is suggestive of the difficulties of this topic, some of which are, perhaps, due to awkward uses of a terminology which has specialized connotations, that in his account of the Andaman islanders (1922, p. 41) Prof. Radcliffe-Brown states that "The economic life of the local group, though in effect it approaches to a sort of Communism, is yet based on the notion of private property." Land is sometimes in common, but there is private ownership of trees of economic value. Priority of labour entails ownership, but the custom of constantly exchanging presents, and the strong feeling that no request should be refused, result in the constant circulation of "almost every object" which they possess. Every man is expected to do his share in providing both himself and others with food, and in its distribution regard is had to seniority. E. T. Man (*Andaman Islanders,* 1880, p. 29) records that the *oko-pai-ads,* dreamers of dreams, who are credited with the possession of supernatural powers, often arrange with those who lavish gifts upon them to keep available for them articles not immediately needed, which are thereby bespoken and not available as gifts to others. Therefore, at a low level of culture, individual ownership is recognized but is tempered by the sense of solidarity and mutuality, which places generosity high as a virtue. Here, too, as throughout the lower culture, when viewed closely, personality and individuality are factors in the economic as in all other aspects of social life. The subjective character of the lower culture attitude towards property finds its expression in the sentimental value attached by modern communities to the old and venerable. The economic attitudes of the lower culture comprise respect of heirlooms, but in their normal working exhibit the principle of reciprocity of service—a far different thing from Communism, however defined—just as the social order of lower culture groups is based on the ultimate facts of inequality of men, leaving theories of equality and rights to purblind theorists. (*See* works quoted in text.)

COMMUNIST INTERNATIONAL: *see* INTERNATIONAL, THE.

COMMUNITIES, INDUSTRIAL, group systems of housing employees and their families near isolated factories, provided by the factory owners. Although employers' housing in the United States is as old as industry itself, it was not until the latter part of the 19th century, when economic conditions following the Civil War made it necessary for owners to provide, if not completely control, the living conditions of employees, that industrial communities came into any great prominence. Since that time, when the Pullman and southern mill villages were established, such communities have become common all over the United States, especially in the regions of the Western coal fields, New England textile mills and the Ohio rubber factories. The degree to which the company owns and controls the village activities varies considerably, but often the employees have a voice in the Municipal Government. In the better type of industrial communities streets are laid out, houses constructed, water supply and sewage systems constructed and stores are operated where food, clothing and fuel may be bought at reduced prices. Physicians and visiting nurses are maintained by the factory officials, while education is conducted through clinics, day nurseries and hygiene classes. Often the company helps to support the public schools and to conduct night classes, and it frequently provides gymnasium and recreation facilities. Working further on the theory that good living conditions result in increased production, there is a growing tendency among some of the more progressive factory owners to plant trees, set aside parks and generally to combine the aesthetic with the utilitarian in the make-up of industrial communities.

COMMUNITY CENTRES, a phrase used in the United States to describe rooms or buildings, often public school buildings, in which all residents of a village, small town, or neighbourhood of a city may meet for entertainment, recreation, educational pursuits, cultural, civic, or other activities. Groups of women, agricultural organizations, religious associations, or community societies representative of the major social groups in the community, administer the buildings not owned by governmental agencies.

Community centres have developed largely in the United States since 1910 and are steadily increasing in number. Community solidarity became a matter of public interest during the World War, but in general the complexity of group organization and differentiation in social, civic and industrial life have created a feeling of need for co-ordination and common understanding among the residents of a district. Community centres are the chief result of this desire for neighbourhood unity. Thirty-two States and the District of Columbia have laws providing for community use of school buildings. Community centres are encouraged by State departments of education, university extension departments, farm organizations and at least three national associations. (L. E. Bo.)

COMMUNITY CHEST, a term used largely in the United States to describe a co-operative organization of citizens and social welfare agencies in a community. Its general functions are (1) to raise funds each year, by community-wide appeal, for affiliated voluntary social welfare and health agencies, and to distribute those funds in accord with a mutually agreed-upon budget procedure, and (2) to promote the social welfare and health of the community by co-ordinating existing programs and improving standards of social work, preventing duplication, conducting research, administering common services, and developing better public understanding and support. Closely allied with the community chest is the central planning group, known as the Council of Social Agencies. In 1940 there were 552 community chests or funds. Of these, 534 were in the United States (mainland), eleven in Canada, two in South Africa, one in the Virgin islands, and two in Hawaii. The areas in which community chests are organized include a total population of about fifty millions, nine million of whom annually contribute. All but six cities of 100,000 and over in the United States have community chests. In 1940, 552 chest campaigns raised $86,186,466.

The history of the modern community chest movement is traced from the organization in Cleveland, Ohio, in 1913, of a Federation for Charity and Philanthropy, which not only raised money for its member agencies but introduced the principle of budgeting to determine needs and resources. Denver, Colorado, has had joint financial campaigns for its social agencies since 1887, but Cleveland first used the community chest principle as it is known today. Community Chests and Councils, Inc., national organization of community chests on a voluntary membership basis, was organized in Feb. 1918, as a clearing house for information for the 21 local chests then existing. First called the American Association for Community Organization, and later the Association of Community Chests and Councils, in 1933 it was incorporated and adopted its present name. An advisory committee of local chest and council executives guides the staff in carrying out policies decided upon by a board of directors. The association is financed by dues from its corporate members.

To give nation-wide backing to the money-raising efforts of local community chests and voluntary social work generally, the Community Mobilization of Human Needs was organized in 1932. It is administered by Community Chests and Councils, Inc., for 36 national social agencies which co-operate in an annual "Mobilization." The Mobilization chairman is assisted by a National Citizens' Committee of nearly 150 members. (G. E. V.)

COMMUNITY DRAMA AND COMMUNITY THEATRE: *see* LITTLE THEATRE MOVEMENT.

COMMUNITY FOUNDATION, or **COMMUNITY TRUST, THE,** in the United States is an agency organized for the permanent administration of funds placed in trust for public educational, charitable, scientific, or benevolent purposes. The first of such trusts to be organized was the Cleveland Foundation, brought into existence in Jan. 1914 by the Cleveland Trust Company, of Cleveland, O. (*q.v.*). Its founder was Frederick Harris Goff, then president of the Cleveland Trust Company. The fundamental plan of organization of the Cleveland foundation has been closely followed by nearly all subsequent community foundations. It has four characteristic features: (1) Its funds are not the gift of a single individual or family, but the union of numerous large and small gifts left at different times by various donors and designed to promote the well-being of mankind. (2) These funds are placed in the custody of banks and trust companies charged with the duty of safeguarding and investing them, but having no voice in directing their expenditure. (3) The income of the funds is disbursed by a committee, changing through rotation of appointments, chosen for their knowledge of the educational, charitable and benevolent needs of the time, and selected in major part by public officials. (4) This distribution committee must respect and observe the expressed desire of the founder of a trust as to the particular purpose for which it shall be applied, subject to the condition that if it shall appear that circumstances have so changed since the execution of the will or deed of trust as to render unnecessary, undesirable, impractical or impossible a literal compliance with its terms, a resolution adopted by the committee may operate to free the instrument of gift from any specific restriction or provision. The fundamental characteristics of the community foundation may be summarized as providing for the union of numerous gifts instead of a single large one; arranging for the business control of the investments, and the social control of the expenditures; and the attempt to substitute contemporary wisdom for foresight in the use of the income.

In the years since the Cleveland Foundation was organized there have been established more than 75 such trusts, with about 250 banks and trust companies as their trustees. In some cases there is only one trustee, and in others several. This latter arrangement is known as the multiple trusteeship. In nearly all cases the objectives are broadly stated as being the promotion of the well-being of mankind, and especially that of the inhabitants of the city where the foundation is located.

In 1945 there were 11 community foundations each of which had active principal funds in excess of $1,000,000. The aggregate resources of community trusts in the United States and Canada rose to $67,000,000 at the end of 1944 compared with $57,000,000 at the close of 1943. The community foundations having the largest resources were located in New York, Chicago, Boston, Cleveland, Indianapolis, Winnipeg, Los Angeles, Buffalo, New Haven and Minneapolis. In the case of each of these cities, and also in that of many others, it was known that wills of certain persons were in existence that would bring bequests to the organizations in later years, and in some of the instances in very large sums of money.

In 1925 some 16 different community foundations distributed nearly $450,000 of income. In the year 1938 there were 43 which disbursed about $1,750,000. In 1944 the number that had begun to distribute funds had increased to 76, and the distributions to more than $1,900,000. (L. P. A.)

COMMUNITY KITCHEN. In the United States there has been, since 1910, an increasing tendency on the part of Americans to take their meals outside of their homes, with the growth of the community kitchen and its corollary the community dining room.

Community Kitchens and Dining Rooms.—Many reasons may be assigned for this movement. In the first place it was a natural step in view of the changes in the home itself: the urban home had become smaller, for every square inch of floor area, every cubic inch of space, cost money in rent, and consequently the functions of the home were limited so as to effect a reduction of space. The home kitchen shrank first to the kitchenette, and is now in process of vanishing entirely. Even where the space for an elaborate kitchen is available, the problem of getting suitable servants is so troublesome as to induce many to get along with a minimum of domestic service, and, as the mistress of the house is herself less willing to be a kitchen drudge than formerly, many meals are taken outside the home, particularly those of an elaborate nature. Private hospitality is more and more offered in hired hotel space in preference to the home. Banquets and other special functions are easily handled in public dining rooms, and involve little responsibility on the part of the host and hostess. The emancipation of women is another factor. Many women have succeeded in establishing themselves, professionally or commercially, before marriage. They prefer financial independence to keeping house. The small, compact, efficiently arranged apartment is the result, with meals away from the home.

These factors are intensified by the constantly rising standards of living and by the greatly improved marketing technique which has stimulated a demand for many possessions previously non-existent or rare. Demands upon the family income have advanced, encroaching upon the former budget allotment for rent and servants. Small and servantless homes come as a natural sequence. If even then the income is too meagre, the modern woman has no hesitation in aiding her husband to double it by taking a position herself. Another blow to the home as the chief or sole source of prepared food has been dealt by the automobile and touring habit. It is estimated that in 1910 there were, in the United States, less than 350,000 automobiles; in 1925 over 17,000,000 were registered. Such an increase in the use of a personal means of conveyance with a day's travel radius of, say, 200m. could not but have its effect on the food habits of the nation. "Automobile" business is considered a substantial part of the total business of hotels and restaurants.

The hotel kitchen, like its domestic counterpart, has had its troubles with its personnel, and for similar reasons. Working, however, on a larger scale and increasingly on standardized products, it can make readier use of machines as a substitute for labour. The modern quantity kitchen is thinly staffed but splendidly equipped. Washing-machines for dishes, glassware, and silver, each adapted to the task in hand, enable two men to do the work of ten and to do it better. There is less breakage, the silver bears an enhanced sheen, and the bacteria count is reduced 90%. Dirt and filth, once the bugbears of any but the most expensive dining places, are now, perhaps, more rare in hotels than in the home. There are also the great mixers which, for example, beat up a bushel of mashed potatoes or a gallon of cream with equal facility, the steam-cookers, the potato-peelers and a host of smaller indispensables that save time, labour, and space where food is cooked on a wholesale scale. Electricity has helped in cookery and is now applied to refrigeration. (H. B. M.)

COMMUNITY SINGING is mass singing by groups or crowds, or in a more advanced stage, singing by a community chorus meeting regularly for training and instruction in four part chorus singing. Some of the best renditions of the oratorios and choral works come from these community choruses. For community singing in Great Britain *see* CHORAL SINGING.

The community chorus movement in the United States was launched in Rochester, N.Y., in 1912 by Harry Barnhart, a singer, musician, conductor and a pupil of Maestro Cortezze and Verdi, trained for the concert and operatic stage. For some time before 1912, Mr. Barnhart was filling engagements in vaudeville. A feature of his "act" had been to get the audience to join in the chorus of his songs. Discovering that everybody wanted to sing and could sing under proper encouragement and direction, he determined to develop the idea. While filling an engagement in Rochester, N.Y., he secured permission from the mayor to appear with the municipal band in Convention hall and have the people sing. The audience responded most enthusiastically and there was formed the first community chorus. The idea spread to other surrounding communities. In 1914 many of these choruses came together for a great festival in the Rochester Exposition buildings, forming a trained chorus of some 1,500 singers. They began with unison singing and evolved into well trained choral groups.

Arthur Farwell, U.S. composer and exponent of American Indian lore, became deeply interested in the movement and induced Mr. Barnhart to come to New York once each week to conduct a community chorus. During this time Claude Bragdon, architect and author, then resident in Rochester, saw the possibility of combining light and colour with the outdoor singing. Crowds up to 15,000 gathered in a public park led by the trained community singing group. This became known as "Song and Light." The New York city community chorus grew rapidly with Arthur Farwell as president and W. K. Brice as treasurer. Weekly public sings and rehearsals were held. Soon a great chorus was developed which culminated in giving Handel's "Messiah" in Madison Square Garden and three annual "Song and Light Festivals" in Central Park with 100,000 people singing antiphonally across the lake in the night. At about this time community choruses started in many cities. When the United States entered World War I Gen. Franklin Bell, then in command of the eastern division, commandeered Mr. Barnhart to take charge of singing in the army. Singing was organized in every camp under the direction of competent song leaders. At the close of the war, there was a song leader in every community in the U.S. but the movement did not go forward as it should have because of a lack of competent conductors. There were, however, in 1945, many fine community choruses throughout the country. (H. BT.)

COMMUTATION, a process of exchanging one thing for another, particularly of one method of payment for another, such as payment in money for payment in kind or by service, or of payment of a lump sum for periodical payments. (*See* ANNUITY; COPYHOLD and TITHES.) In law, the substitution of a lesser sentence on a criminal for a greater. In electrical engineering, the reversal of the course of an electric current, by means of a contrivance known as a "commutator" (see ELECTRIC GENERATOR; MOTOR, ELECTRIC). In the U.S. a "commutation ticket" on a railway is the equivalent of an English season-ticket, and the ticket-holder is known as a "commuter."

COMMUTATIVE LAWS. Two laws relating to numbers, one with respect to addition and the other with respect to multiplication. The symbolical forms for these laws are respectively $a+b=b+a$ and $ab=ba$. Thus they are equivalent to the statement that a finite sum or product is unaltered by reordering the terms or factors. The laws, however, do not hold everywhere in mathematics. For example, the commutative law does not necessarily hold for conditionally convergent series such as $1-\frac{1}{2}+\frac{1}{3}-\frac{1}{4}+\ldots$ unless no term in the rearrangement is displaced more than a fixed number of places from its original position. Also there are numbers, such as quaternions, for which the commutative law of multiplication is invalid. The vector product obeys the law $a\times b=-b\times a$ instead of the usual law. (R. W. BD.)

COMMUTATOR, a switch by means of which the current in a circuit is reversed. (*See* also ELECTRIC GENERATOR.)

COMMUTER: *see* COMMUTATION.

COMNENUS, the name of a Byzantine family which occupied the throne of Constantinople 1081–1185 and originally came from Paphlagonia. Its first member in Byzantine history is MANUEL EROTICUS COMNENUS, an able general serving Basil II in the east. The increasing unpopularity of the Macedonian dynasty culminated in a revolt of the nobles and the soldiery of Asia against its feeble representative Michael VI Stratioticus, who abdicated after a brief resistance. Manuel's son Isaac was crowned emperor in St. Sophia on Sept. 2, 1057. For the rulers of this dynasty *see* ALEXIUS I; ALEXIUS II; ISAAC I; JOHN II; MANUEL I, COMNENUS; ROMAN EMPIRE, LATER. With Andronicus I (1183–1185) the rule of the Comneni proper at Constantinople ended. A younger line of the original house, after the establishment of the Latins at Constantinople in 1204, secured possession of a fragment of the empire in Asia Minor, and founded the empire of Trebizond (*q.v.*), which lasted till 1461, when David Comnenus, the last emperor, was deposed by Mahommed II.

COMO (anc. COMUM), a city and episcopal see of Lombardy, Italy, capital of Como province, at the south end of the west branch of the Lake of Como, 32 mi. by rail N.W. of Milan. Pop. (1936) 42,569 (town); 56,304 (commune). Mountains enclose the city. The old town, with rectangular Roman plan, is enclosed by walls with 12th century towers. The marble cathedral on the site of an earlier church has a nave of 1396, the façade belongs to 1457–86, while the exterior of the east end was altered into the Renaissance style, and decorated with sculptures by Tommaso Rodari in 1487–1526. The dome is an unsuitable addition of 1730–70 by Filippo Juvara. In the same line as the façade of the cathedral are the Broletto (in black and white marble), dating from 1215, the seat of the original rulers of the commune, and the massive clock-tower. The Romanesque church of S. Abbondio outside the town (11th century) has two fine campanili at the ends of the aisles close to the apse. The churches of S. Giacomo (1095–1117) and S. Fedele (12th century) are also Romanesque. Como is a tourist resort, and the steamboat traffic on the lake is largely for travellers. The hill station of Brunate (2,350 ft.) above the town to the east is reached by a funicular railway. The Milanese possess many villas here. Como has large silk factories and other industries. (*See* LOMBARDY.) It is connected with Milan by two lines of railway, one via Monza the other via Saronno, and also with Lecco and Varese.

Of the Roman Comum little remains above ground; the southeast gate, flanked by two octagonal towers, was found in 1914, and a portion of the southeast wall may be seen: later fortifications, largely constructed with Roman fragments, had been superimposed on it. *Thermae* have also been discovered. Comum belonged to Gallia Cisalpina; in 196 B.C. M. Claudius Marcellus conquered the Insubres and the Comenses. In 89 B.C., having suffered damage from the Raetians, it was restored by Cn. Pompeius Strabo, and given Latin rights with the rest of Gallia Transpadana; 5,000 colonists were sent by Caesar in 59 B.C., and the place received the name Novum Comum. The place had an important iron industry; and the banks of the lake were, as now, dotted with villas. It was also the starting point for the journey across the lake in connection with the Splügen and Julier passes. (*See* CHIAVENNA.) The elder and younger Pliny were born here, the latter founded baths and a library and gave money for the support of orphan children. There was a *praefectus* *classis Comensis* (a commander of the Como flotilla) under the late empire, and it was regarded as a strong fortress.

During the early barbarian invasions many inhabitants took refuge on the Isola Comacina off Sala, but Como recovered in Lombard times. It became subject to the archbishops of Milan, but gained its freedom towards the end of the 11th century. In 1118 war broke out with Milan; Como was taken and its fortifications dismantled in 1127. From 1154 it gave its allegiance to Barbarossa throughout the war of the Lombard League. After frequent struggles with Milan, it fell under the Visconti in 1335. Thenceforth it shared the fortunes of Milan, becoming in the Napoleonic period the chief town of the department of the Lario. It bore a considerable part in the national risings of 1848–59 against Austrian rule. Pope Innocent XI. and Alessandro Volta were born here.

COMO, LAKE OF, in Lombardy, north Italy, due north of Milan (its ancient name was *Lacus Larius* and it is still sometimes called Lario, though already termed *Lacus Comacinus* in the 4th century). It is formed by the Adda, flowing through the Valtelline to the north end of the lake (here falls into the Mera, *see* CHIAVENNA) and flows out of it at the south-east end. The area is 55⅓sq.m.; it is about 30m. from end to end, ½ to 2½m. in breadth, surface 650ft. above the sea, greatest depth 1,345ft. A railway runs along its eastern shore from Colico to Lecco (24½m.), while on its western shore Menaggio is reached by rail from Porlezza on the Lake of Lugano (8 miles). Colico, at the northern extremity, is by rail 17m. from Chiavenna and 42m. from Tirano, while at its southern end Como is 32m. from Milan, and Lecco the same distance. The lake fills a remarkable depression cut through the limestone ranges that enclose it, and once doubtless extended as far as Chiavenna, the Lake of Mezzola being a witness of its ancient bed. The Bellagio promontory divides the south-east arm, the true exit ending at Lecco, from the enclosed south-west arm ending at Como. The north, *Tivano,* wind blows during the morning, the south, *Breva,* in the afternoon. Violent storms occur suddenly. Virgil and Claudian sang Como's beauty and the two Plinys are associated with the lake. The shores are bordered by splendid villas, while perhaps the most lovely spot on it is Bellagio. Varenna, to the east, and Menaggio, to the west, are nearly opposite each other, while Cadenabbia, to the west, faces Bellagio.

COMORIN, CAPE, a headland in the state of Travancore, forming the extreme southern point of the peninsula of India. It is situated in 8° 4′ 20″ N., 77° 35′ 35″ E., at the end of the Western Ghats. The village of Comorin, with the temple of Kanniyambal, the "virgin goddess," on the coast at the apex of the headland, is a frequented place of pilgrimage.

COMORO ISLANDS, a group of volcanic islands belonging to France, in the Indian Ocean, at the northern entrance of the Mozambique Channel between Madagascar and the African continent. The islands of Mayotte and Comoro have an area of 849 sq.mi.; a total population (1936) of 128,608 inhabitants. These have adopted Islamism but continue, nevertheless, to practise Fetichism. They earn their living mostly from navigation and trade between the islands. Their chiefs, known as sultans, are Arabs. There are besides a large number of islets of coral formation. Particulars of the four principal islands follow:

1. Great Comoro, or Angazia, the largest and most westerly, has a length of about 38 mi., with a width of about 12 mi. Pop. (1936) 66,265. Near its southern extremity it rises into a fine dome-shaped active volcano, Kartola (Karthala), which is over 8,500 ft. high, and is visible for more than 100 mi. Up to about 6,000 ft. it is clothed with dense vegetation. Eruptions are recorded for the years 1830, 1855, 1858 and 1904. In the north the ground rises gradually to a plateau some 2,000 ft. above the sea; from this plateau many regularly shaped truncated cones rise another 2,000 ft. The centre of the island consists of a desert field of lava streams, about 1,600 ft. high. The chief towns are Moroni (pop. [1936] 5,108), Itzanda and Mitsamuli; the first being the seat of the French administrator.

2. Anjouan, or Johanna, next in size, lies E. by S. of Great Comoro. Pop. (1936) 39,010. It is some 30 mi. long by 20 at its greatest breadth. The land rises in a succession of richly wooded heights till it culminates in a central peak, upwards of 5,000 ft. above the sea in 12° 14′ S., 44° 27′ E. The former capital, Mossamondu, on the N.W. coast, is substantially built of stone, surrounded by a wall, and commanded by a dilapidated citadel; it is the residence of the sultan and of the French administrator. There is a small but safe anchorage at Pomony, on the S. side, formerly used as a coal depot by ships of the British navy.

3. Mayotte, pop. (1936) 17,477, about 21 mi. long by 6 or 7 mi. broad, is surrounded by an extensive and dangerous coral reef. The principal heights on its extremely irregular surface are: Mavegani Mountain, which rises in two peaks to a maximum of 2,164 ft., and Uchongin, 2,100 ft. The French headquarters are on the islet of Zaudzi, which lies within the reef in 12° 46′ S., 45° 20′ E. There are substantial government buildings and storehouses. On the mainland opposite Zaudzi is Msapéré, the chief centre of trade.

4. Moheli or Mohilla, pop. (1936) 5,256, lies S. of and between Anjouan and Great Comoro. It is 15 mi. long and 7 or 8 mi. at its maximum breadth. Unlike the other three it has no peaks, but rises gradually to a central ridge about 1,900 ft. in height. Fomboni (pop. about 2,000) in the N.W. and Numa Choa in the S.W. are the chief towns.

Except Great Comoro, which is arid, the islands are very fertile. There are forests of coconut palms, and among the products are rice, maize, sweet potatoes, yams, coffee, cotton, vanilla and various tropical fruits, the pawpaw tree being abundant. The fauna is allied to that of Madagascar rather than to the mainland of Africa; it includes some land birds and a species of lemur peculiar to the islands. Large numbers of cattle and sheep are reared. Turtles are caught in abundance along the coasts, and form an article of export. The climate is in general warm, but not torrid nor unsuitable for Europeans. The dry season lasts from May to the end of October, the rest of the year being rainy. The natives are of mixed Malagasy, Negro and Arab blood. Native life owes to Muslim civilization most of its external characteristics. The inhabitants of Madagascar call them *Antalaora* (people from across the sea). The European inhabitants are mostly French. The external trade of the islands has developed since the annexation of Madagascar to France. Sugar refineries, distilleries of rum, and sawmills are worked in Mayotte by French settlers. Cane sugar and vanilla are the chief exports. The islands are regularly visited by vessels of the Messageries Maritimes fleet, and a coaling station for the French navy has been established. The natives live on vegetables, fish, fruit and meat. They are cultivators, sailors and fishermen. They are more advanced than the Malagasy to whom in the past they have furnished many chiefs.

The islands were first visited by Europeans in the 16th century; they are marked on the map of Diego Ribero made in 1527. At that time, and for long afterwards, the dominant influence in, and the civilization of, the islands was Arab. A Sakalava chief who had been driven from Madagascar by the Hovas took refuge in Mayotte *c.* 1830, and, with the aid of the sultan of Johanna, conquered the island. French naval officers having reported on the strategic value of Mayotte, Admiral de Hell, governor of Réunion, sent an officer there in 1841, and a treaty was negotiated ceding the island to France. Possession was taken in 1843, the sultan of Johanna renouncing his claims in the same year. In 1886 the sultans of the other three islands were placed under French protection. The islands, as regulated by the decree of April 9, 1908, are under the supreme authority of the governor-general of Madagascar. The archipelago as a whole is entitled "Mayotte and dependencies." The local administration is in the hands of an official who himself governs Mayotte from his residence at Zaudzi but is represented in the other islands by administrators. On the council which assists the governor are two nominated native notables. In 1910 the sultan of Great Comoro ceded his sovereign rights to France.

The *Îles Glorieuses,* three islets 160 mi. N.E. of Mayotte, with a population of some 20 persons engaged in the collection of guano and the capture of turtles, were in 1892 annexed to France and placed under the control of the administrator of Mayotte.

See *Notice sur Mayotte et les Comores,* by Emile Vienne, one of the memoirs on the French colonies prepared for the Paris Exhibition of 1900; *Le Sultanat d'Anjouan,* by Jules Repiquet (1901), a systematic account of the geography, ethnology and history of Johanna; *Les colonies françaises* (1900), vol. ii., pp. 179–197, in which the story of the archipelago is set forth by various writers; an account of the islands by A. Voeltzkow in the *Zeitschrift* of the Berlin Geog. Soc. (No. 9, 1906), and *Carte des Îles Comores,* by A. Meunier (1904).

COMPANION, a store-room for provisions on board ship (Fr. *chambre de la compagne*); the framed windows over a hatchway on the deck of a ship; also the hooded entrance-stairs to the captain's cabin.

COMPANY. The smallest administrative unit functioning in an infantry battalion; it is usually commanded by a captain or officer of equivalent rank, though in the British service junior majors also command companies (*see* MAJOR). The number of companies in a battalion varies according to the system favoured by each country, and the sub-division of a company into platoons, sections, etc., is dictated by the distribution, and consequently the tactical value, of the arms which it carries. Up to the outbreak of the World War the company was also the tactical unit of the battalion.

Although the expression now refers to a fixed number of officers and men, in the early days of all armies it, or its equivalent, referred loosely to the number of men a lord or knight brought into the field. About the middle of the 14th century "Free Companies" came into being. These were disbanded soldiers, who, having a greater love for war than peace, banded themselves together and plundered France at their pleasure. The greatest leader of these was John Hawkwood. In order to bring about their suppression, a certain number were taken into the service of France against Spain. As their distinctive mark they adopted the white cross, the old English colour of the Crusades, and one company, "The White Company," has been immortalized in literature by Sir Arthur Conan Doyle.

In the 16th century a company of German *landsknechts* was 400 strong, and about the same period a company in the Spanish army varied from 150 to 300 men, whilst in England 100 was the usual strength. In 1650 Gustavus Adolphus made great reforms in military organization. As regards the infantry he made companies of uniform strength, 106 men, distributed in twenty-one *rots* or files, and six corporalships. A corporalship of pikes consisted of three files, and four files of musketeers. Each company had a reserve of eighteen supernumerary men. Eight companies constituted a regiment. Four companies, or half of such a regiment, were called either a squadron or by the Italian name *battaglia,* from which the modern battalion is derived.

The infantry of the Commonwealth "New Model" army bore a close resemblance to the foregoing in that each regiment had ten companies of 110 men apiece. The colonel, lieutenant-colonel and major each had companies, the remaining commanders being seven captains. The privates were divided into an equal number of pikemen and musketeers. At the Restoration in 1660 the number of men in a company was reduced to 80, and sometimes 50, but the number of companies in a regiment was increased to twelve. At his accession in 1685, James II. added a company of grenadiers to every regiment. Towards the end of the 18th century the "Dundas System" (evolved by Colonel David Dundas) was introduced into the British service, under which each company was divided into 2 platoons and each platoon into 2 sub-divisions, but in 1913 this organization was abolished for the present system.

At the present time (1928) the following is the organization of a company in some armies:—*Great Britain*—4 platoons, each platoon subdivided into 4 sections (2 Lewis gun and 2 rifle); *U.S.A.*—company headquarters and 3 platoons, each platoon consisting of section headquarters and 3 squads; *France*—a headquarters section and 4 fighting sections (*sections de combat*), each corresponding to a British platoon; *Germany*—company headquarters and 3 platoons, each divided into 2 light machine gun groups and one or more rifle groups; *Belgium*—3 platoons each of 4 *groupes de combat; Japan and Poland*—company headquarters and 3 platoons; *Netherlands*—company headquarters and 4 platoons on British model; *Baltic States: Estonia*—3 platoons of 4 sections each; *Latvia*—3 platoons of 2 sections each; *Lithuania*—2 platoons of 3 sections each. Several countries also have "headquarter companies," "machine gun companies," etc., the name of which usually indicates their special purpose.

COMPANY LAW. "Company" is one of a number of words like "union," "guild," "society," "corporation," denoting—each with its special shade of meaning—the association of individuals in pursuit of some common object. The taking of meals together was, as the word signifies (*cum,* with, *panis,* bread,) a characteristic of the early company. Guild had a similar meaning: but this characteristic, though it survives in the Livery company (*see* LIVERY COMPANIES), has in modern times disappeared. The word "company" is now monopolized—in British usage—by two great classes of companies—(1) the joint stock company, constituted under the Companies Acts, 1908 to 1917, namely the Companies (Consolidation) Act, 1908 (which consolidated the various Acts from 1862 to 1908) and certain amending acts, and (2) the "statutory company," constituted under a special Act to carry on some work of public utility, such as a railway, docks, etc., and regulated by the Companies Clauses Acts, 1845 and 1863, and amending Acts. (For United States law *see* p. 151.)

I. JOINT STOCK COMPANIES

The joint stock company may be defined as an association of persons incorporated to promote by joint contributions to a common stock the carrying on of some commercial enterprise. Associations formed not for "the acquisition of gain" are referred to below. The joint stock company has had a long history which can only be briefly sketched here. The name "joint stock company" is—or was—used to distinguish such a company from the "regulated company," which did not trade on a joint stock but was in the nature of a trade guild, the members of which had a monopoly of foreign trade with particular countries or places. (*See* Adam Smith, *Wealth of Nations,* bk. v. ch. i. pt. iii.)

The earliest kind of joint stock company is the chartered. (*See* CHARTERED COMPANIES.) The grant of a Charter is one of the exclusive privileges of the Crown, and the Crown has from time to time exercised it in furtherance of trading enterprise. Examples of such grants are the Merchant Adventurers of England, chartered by Richard II. (1390); the East India Co., chartered by Queen Elizabeth (1600); the Bank of England, chartered by William and Mary (1694); the Hudson's Bay Co.; the Royal African Co.; the notorious South Sea Co.; and in later times the New Zealand Co., the North Borneo Co., and the Royal Niger Co. Chartered companies had, however, several disadvantages. A charter was not easily obtainable and was costly. The members could not be made personally liable for the debts of the company: and once created—though only for defined objects—such a company was invested with entire independence and could not be kept to the conditions imposed by the grant, which was against public policy. A new form of commercial association was wanted, free from these defects, and it was found in the common law company—the lineal ancestor of the modern trading company. The common law company was not an incorporated association, but a great partnership with transferable shares. Companies of this kind multiplied rapidly towards the close of the 17th and beginning of the 18th centuries, but they were regarded with strong disfavour by the law, for reasons not very intelligible to modern notions, the chief being that such companies purported to act as corporate bodies, raised transferable stock, used Charters for purposes not warranted by the grant, and were—or were supposed to be—dangerous and mischievous, tending (in the words of the preamble of the Bubble Act) to "the common grievance, prejudice and inconvenience of His Majesty's subjects or great numbers of them in trade, commerce or other lawful affairs." They were too often—and this no doubt was the real ground of the prejudice against them—utilized by unprincipled persons to promote fantastic and often fraudulent schemes. Matthew Green, in his poem "The Spleen," notes how

> "Wrecks appear each day,
> And yet fresh fools are cast away."

The result was that by an Act of 1719, commonly called the

Bubble Act, such companies were declared to be common nuisances and indictable as such. But the Act, though not formally repealed till 1825, proved quite ineffectual to check the growth of joint stock enterprise, and the legislature, finding that such companies had to be tolerated, adopted the wiser course of regulating what it could not repress. One great inconvenience of these common law trading companies arose from their being unincorporated. They were formed of large fluctuating bodies of individuals, and a person dealing with them did not know with whom he was contracting or whom he was to sue. This evil the legislature sought to rectify by empowering the Crown to grant to companies by letters patent without incorporation the privilege of suing and being sued by a public officer. Ten years afterwards—in 1844—a more important line of policy was adopted, and all companies, with some exceptions, were enabled to obtain a certificate of incorporation without applying for a Charter or special Act. The Act of 1862 carried this policy one step farther by prohibiting all associations of more than 20 persons from carrying on business without registering under the Act. The real vitality of joint stock enterprise lies in the co-operative principle, and the natural growth and expansion of this fruitful principle was checked until the middle of the 19th century by the notorious risks attaching to unlimited liability. Failures like those of Overend and Gurney, and of the Glasgow Bank, caused widespread misery and alarm. It was not until limited liability had been introduced that the real potency of the principle of industrial co-operation became apparent. The practical difficulty was how to bring home to persons dealing with the company notice that the liability of the shareholders was limited. This was solved by requiring the company to add to its name the word "Limited," paint it up on its premises, and use it on all documents. While limited companies have been multiplying, the unlimited company has become practically an extinct species. The growth of limited companies is, indeed, one of the most striking phenomena of our day. Their number may be estimated at about 99,000. Their paid-up capital amounts to the stupendous sum of £4,636,000,000 and what is even more significant is that the number of shareholders has grown in a much greater ratio than the colossal growth of the aggregate capital. The profits and risks of nearly every kind of business have been spread over fresh thousands of individuals, and those with moderate incomes are more and more participating in that accumulation of wealth from business which formerly built up the fortunes of individual traders, bankers, or single families.

It is with the limited company then—the company limited by shares—as the normal type and incomparably the most important, that this article mainly deals.

COMPANIES LIMITED BY SHARES

The Companies (Consolidation) Act, 1908 (replacing the Companies Act, 1862) was intended to constitute a comprehensive code of law applicable to joint stock companies for the whole of the United Kingdom. Recognizing the mischief of trading concerns being carried on by large and fluctuating bodies the Act begins by declaring that no company, association or partnership, consisting of more than 20 persons, or ten in the case of banking, shall be formed for the purpose of carrying on any business which has for its object the acquisition of gain by the company, association or partnership or the members thereof, unless it is registered as a company under the Act, or is formed in pursuance of some other Act of parliament or of letters patent, or is a company engaged in working mines within and subject to the jurisdiction of the Stannaries. Broadly speaking, the meaning of the Act is that all commercial undertakings, as distinguished from literary or charitable associations, shall be registered. "Business" has a more extensive signification than "trade." Having thus cleared the ground the Act goes on to provide in what manner a company may be formed under the Act. The machinery is simple, and is described as follows:—

Any seven or more persons, or where the company will be a private company (*see* infra) any two or more persons, associated for any lawful purpose may, by subscribing their names to a memorandum of association and otherwise complying with the requirements of this Act in respect of registration, form an incorporated company with or without limited liability. It is not necessary that the subscribers should be traders, nor will the fact that six of the subscribers are mere dummies, clerks or nominees of the seventh affect the validity of the company.

Memorandum of Association.—The document to be subscribed—the Memorandum of Association—corresponds, in the case of companies formed under the Companies Acts, to the Charter or deed of settlement in the case of other companies. Its form is given in a schedule to the Act, and varies slightly according as the company is limited by shares or guarantee, or is unlimited. It is required to state, in the case of a company limited by shares:

(1) the name of the proposed company, with the addition of the word "limited" as the last word in such name;
(2) the part of the United Kingdom, whether England, Scotland or Ireland, in which the registered office of the company is to be situate;
(3) the objects of the company;
(4) that the liability of the members is limited; and
(5) the amount of share capital with which the company proposes to be registered, divided into shares of a fixed amount.

No subscriber of the memorandum may take less than one share, and each subscriber must write opposite his name the number of shares he takes.

These five matters the legislature has deemed of such intrinsic importance that it has required them to be set out in the company's Memorandum of Association. They are the essential conditions of incorporation, and as such they must not only be stated, but the policy of the legislature has made them with certain exceptions unalterable.

The most important of these conditions is the third, and its importance consists in this, that the objects defined in the memorandum circumscribe the sphere of the company's activities. This principle, which is one of public policy and convenience, and is known as the "*ultra vires* doctrine," carries with it important consequences, because every act done or contract made by a company *ultra vires, i.e.,* in excess of its powers, is absolutely null and void. The policy, too, is a sound one. Shareholders contribute their money on the faith that it is to be employed in prosecuting certain objects, and it would be a violation of good faith if the company, *i.e.,* the majority of shareholders, were to be allowed to divert it to something quite different. So strict is the rule that not even the consent of every individual shareholder can give validity to an *ultra vires* act.

Articles of Association.—The articles of association are the regulations for internal management of the company—the terms of the partnership agreed upon by the shareholders among themselves. A model or specimen set of articles known as Table A was given by the Companies Act, 1862, and is appended in a revised form to the Consolidation Act.

The articles usually contain a complete code for the government of the company, dealing with the company's shares, the issue of certificates, the company's lien on its shares, the making of calls, the transfer, transmission and forfeiture of shares, their conversion into stock, the issue of share warrants, alteration of capital, general meetings and the voting thereat, directors and their qualification, powers, duties, election and proceedings, managing directors, dividends and reserve fund, capitalization of profits by the issue of bonus shares, accounts, audit and notices. They can be altered by special resolution.

Registration.—When a company is to be registered the memorandum of association, generally accompanied by articles, is taken to the registrar of companies at Somerset House, together with (1) a list of persons who have consented to be directors of the company (fee stamp 5s.); (2) a statutory declaration by a solicitor engaged in the formation of the company, or by a person named in the articles as a director or secretary of the company, that the requirements of the Act in respect of registration have been complied with (fee stamp 5s.); and (3) a statement as to the nominal share capital (stamped with an *ad valorem* duty of £1 per £100). If these documents are in order, the registrar registers the company and issues a certificate of incorporation. On registration, the memorandum and articles of association become public documents, and any person may inspect them on payment of a fee of 1s. This has important consequences, because every person dealing with the company is presumed to be acquainted with its constitution, and to have read its memorandum and articles. The memorandum and articles also bind the company and its members to the same extent as if each member had signed and sealed them.

The stamps and fees payable on registering a company with a capital of £1,000 are about £7; £10,000 about £34; £100,000 about £280.

Capital.—The capital, which is required to be stated in the memorandum, and which represents the amount which the company is empowered to issue, is what is known as the nominal capital. This must be distinguished from the subscribed capital, which is the aggregate amount agreed to be paid by those who have taken shares in the company. A "minimum subscription" may be fixed by the articles. If it is, the directors cannot go to allotment on less; if it is not, the whole of the capital offered for subscription must be subscribed. A company may increase its capital, consolidate it into shares of larger amount, and subdivide it into shares of smaller amounts; it may also, with the sanction of the court, reorganize its capital; and the objects can be altered, in certain respects, by special resolution confirmed by the court.

The rights attached to preference shares are sometimes set out in the memorandum, but if this is done, they cannot be altered without the sanction of the court, unless a power of alteration is reserved in the memorandum. The usual practice is, accordingly, either to set out the rights in the articles, when they can be altered by special resolution, or else to set them out in the memorandum, reserving a power of alteration. If this power were to be abused so as to amount to a fraud by the ordinary shareholders on a minority of preference shareholders, the court would interfere by injunction. If the preference rights are set out in the memorandum without power of alteration, they can be altered as part of a scheme of arrangement, involving a resolution passed by a majority in number representing three-fourths in value of the preference shareholders present at the meeting, and the sanction of the court. Preference shares with rights set out in the memorandum can also be consolidated with other shares as part of a reorganization by special resolution, sanctioned by resolution of the preference shareholders, passed by an absolute majority in number and three-fourths in amount of the preference shareholders, whether present or not present at the meeting, confirmed by order of the court. But a limited company cannot reduce its capital, either by direct or indirect means, without the sanction of the court. The inviolability of the capital is a condition of incorporation—the price of the privilege of trading with limited liability and by no subterfuge will a company be allowed to evade this cardinal rule of policy, either by paying dividends out of capital, or buying its own shares, or returning money to shareholders. But the prohibition against reduction means that the capital must not be reduced by the voluntary act of the company, not that a company's capital must be kept intact. It is embarked in the company's business, and it must run the risks of such business. If part of it is lost, there is no obligation to replace it and to cease paying dividends until such lost capital is repaid. The company may in such a case write off the lost capital and go on trading with the reduced amount. But for this purpose the sanction of the court must be obtained.

Shares.—A share is an aliquot part of a company's nominal capital. It may be of any amount. The tendency of late years has been to keep the denomination low (£1, 10s. or even 1s.) and so to appeal to a wider public. Shares are of various kinds—ordinary, preference, deferred, founders' and management. Into what classes of shares the original capital of the company shall be divided, what shall be the amount of each class, and their respective rights, privileges and priorities, are matters for the consideration of the promoters of the company.

Preference Shares.—A company may issue preference shares even if there is no mention of them in the memorandum of association; the preference given may be as to dividends only, or as to dividends and capital. The dividend, again, may be payable out of the year's profits only, or it may be cumulative, that is, a deficiency in one year is to be made good out of the profits of subsequent years. Prima facie, a preferential dividend is cumulative. Preference shareholders have the right to inspect balance sheets.

Founders' Shares—which originated with private companies—are shares which usually take the whole or a portion of the profits after payment of a dividend of 7 or 10% to the ordinary shareholders. They are much less in favour than they used to be.

Stock and Share Warrants.—Paid up shares may be converted into stock, and share warrants to bearer may be issued. A share warrant entitles the bearer to the shares or stock specified in it, and such shares or stock are transferable by delivery of the warrant. The warrant is a negotiable instrument.

Promoters.—The machinery of company formation is generally set in motion by a person known in business, but not in law, as a "promoter," *i.e.*, one "who undertakes to form a company with reference to a given project and to set it going, and who takes the necessary steps to accomplish that purpose." Whether what a person has done towards this end constitutes him a promoter or not, is a question of fact; but once an affirmative conclusion is reached, equity clothes such promoter with a fiduciary relation towards the company which he has been instrumental in creating. This doctrine is now well established, and its good sense is apparent when once the position of the promoter towards the company is understood. Promoters "have in their hands the creation and moulding of the company. They have the power of defining how and when and in what shape and under what supervision it shall start into existence and begin to act as a trading corporation." Such a control over the destinies of the company involves correlative obligations towards it, and one of these obligations is that the promoter must not take advantage of the company's helplessness. A promoter may sell his property to the company, but he must first see that the company is furnished with an independent board of directors to protect its interests and he must make full and fair disclosure of his interest in order that the company may determine whether it will or will not authorize its trustee or agent (for such the promoter in equity is) to make a profit out of the sale. It is not a sufficient disclosure in such a case for the promoter merely to refer in the prospectus to a contract which, if read by the shareholders, would inform them of his interest. They are under no obligation to inquire. It is for the promoter to bring home notice, not constructive but actual, to the shareholders.

When a company is promoted for acquiring property—to work a mine or patent, for instance, or carry on a going business—the usual course is for the promoter to frame a draft agreement for the sale of the property to the company or to a trustee on its behalf. The memorandum and articles of the intended company are then prepared, and an article is inserted authorizing or requiring the directors to adopt the draft agreement for sale. In pursuance of this authority the directors at the first meeting after incorporation take the draft agreement into consideration; and if they approve, adopt it. Where they do so in the exercise of an honest and independent judgment, no exception can be taken to the transaction; but where the directors are nominees of the promoter, perhaps qualified by him and acting in his interest, the situation is open to grave abuse. Indeed the fastening of an onerous or improvident contract on a company at its start, by interested promoters acting in collusion with the directors, has been the principal cause of the scandals associated with company promotion. *See* also Company Promoting.

Prospectus.—Concurrently with the adoption of the contract for the acquisition of the property which is the company's *raison d'être,* the directors have to consider how they will best get the company's capital subscribed. Sometimes this is done by issuing a prospectus inviting the public to subscribe for shares; sometimes the directors prefer to place the capital through the medium of brokers, financial agents and other intermediaries. A company which is not a private company but does not go to the public on a prospectus must file a statement in lieu of prospectus.

A prospectus is an invitation to the public to take shares on the faith of the statements therein contained, and is thus the basis of the agreement to take the shares; there therefore rests on those who are responsible for its issue an obligation to act with the most perfect good faith, and this obligation has been repeatedly emphasized by judges of the highest eminence. (*See* the observations of Kindersley, V.C., in *New Brunswick Railway Co.* v. *Muggeridge,* 1860, 1 Dr. & Sm. 383, also those of Lord Herschell in *Derry* v. *Peek,* 1889, 14 A.C. 376.) Directors must be perfectly candid with the public; they must not only state what they do state with strict and scrupulous accuracy, but they must not omit any fact which, if disclosed, would falsify the statements made. This is the general obligation of directors when issuing a prospectus; but on this general obligation the legislature has engrafted special requirements. The Companies Act, 1867, required the dates and names of the parties to any contract entered into by the company or its promoters or directors before the issue of the prospectus, to be disclosed in the prospectus; otherwise the prospectus was to be deemed fraudulent. This enactment was repealed by the Companies Act, 1900, but only in favour of more stringent provisions incorporated in the Consolidation Act of 1908. Now, not only is every prospectus to be signed and filed with the registrar of companies before it is issued, but it must set forth a long and elaborate series of particulars about the company—the contents of the memorandum of association, the number of founders, management or deferred shares, the share qualification of the directors and the provisions in the articles as to their remuneration, the minimum subscription on which they may proceed to allotment, the shares and debentures issued otherwise than for cash, the names and addresses of the vendors and the amount payable to them, the amount paid for underwriting, the amount of preliminary expenses, of promotion money (if any), the dates of and parties to material contracts, the interest (if any) of every director in the promotion or in property to be acquired by the company, and the voting rights conferred by the several classes of shares. Neglect of this statutory duty of disclosure will expose directors to personal liability. For false or fraudulent statements—as distinguished from non-disclosure—in a prospectus directors are liable in an action of deceit or under the Consolidation Act, s. 84, replacing the Directors Liability Act, 1890. This Act was passed to meet the decision of the House of Lords in *Derry* v. *Peek* (14 A.C. 337), that a director could not be made liable in an action of deceit for an untrue statement in a prospectus, unless the plaintiff could prove that the director had made the untrue statement fraudulently. The section enacts in substance that when once a prospectus is proved to contain a material statement of fact which is untrue, the persons responsible for the prospectus are to be liable to pay compensation to anyone who has subscribed on the faith of the prospectus, unless they can prove that they had reasonable ground to believe, and did in fact believe, the statement to be true. Actions under this section have been rare, but their rarity may be due to directors having become more careful in their statements. Directors who circulate a prospectus containing statements which they know to be false, with intent to induce any persons to become shareholders, may be prosecuted.

Allotment of Shares.—Before the Companies Act, 1900, it was a matter for directors' discretion on what subscription they should go to allotment; this they often made scandalously inadequate, but now the Consolidation Act, replacing the Act of 1900, provides that no allotment of share capital offered to the public for subscription is to be made unless the amount fixed by the articles and named in the prospectus as "the minimum subscription" upon which the directors may proceed to allotment has been subscribed and the application moneys—which must not be less than 5% of the nominal amount of the share—paid to and received by the company. If no minimum is fixed, the whole amount of the share capital offered for subscription must have been subscribed before the directors can go to allotment. A company which is not a private company but does not go to the public is subject to similar restrictions, the statement in lieu of prospectus being substituted for the prospectus. The "minimum subscription" is to be reckoned exclusively of any amount payable otherwise than in cash. If these conditions are not complied with within 40 days, the application moneys must be returned. Any "waiver clause" or contract to waive compliance with the section is to be void. An allotment of shares made in contravention of these provisions is voidable at the option of the applicant for shares within one month after the first or statutory meeting of the company.

Even when a company has got what under the name of the "minimum subscription" the directors deem enough capital for its enterprise, it cannot commence business or make any binding contract or exercise any borrowing powers until it has obtained a certificate entitling it to commence business. To obtain this the company must have allotted shares to the amount of not less than the minimum subscription, every director must have paid up his shares in the same proportion as the other members of the company, and a statutory declaration, made by the secretary of the company or one of the directors, must have been filed with the registrar of companies, that these conditions have been complied with.

Directors.—These conditions fulfilled, the company gets its certificate and starts on its business career, carrying on its business through the agency of its directors, to whom, as we have seen above, considerable responsibilities attach.

The first directors are often appointed by the articles; their consent to act must be filed with the registrar of companies. Directors other than the first are elected at the annual general meeting, a certain proportion—usually one-third—retiring under the articles by rotation each year, their places being filled by election. A share qualification is nearly always required, on the well-recognized principle that a stake in the undertaking is the best guarantee of fidelity to the company's interests. A director once appointed cannot be removed during his term of office by the shareholders, unless there is a special provision for that purpose in the articles; but a company may remove a director if the articles—as is usually the case—authorize removal. The authority and powers of directors are prima facie those necessary for carrying on the ordinary business of the company, but the more important of such powers are usually defined in the articles. For instance, it is commonly prescribed how and when the directors may make calls, to what amount they may borrow, how they may invest the company's funds, in what circumstances they may forfeit shares, or veto transfers, in what manner they shall conduct their proceedings, and what shall constitute a quorum of the board; whenever, indeed, specific directions are desirable they may properly be given by the articles. But, superadded to and supplementing these specific powers, there is usually inserted in the articles a general power of management; the powers, whether general or specific, thus conferred upon directors are in the nature of a trust, and the directors must exercise them with a single eye to the benefit of the company. For instance, in allotting shares they must consult the interests of the company, not favour their friends. So in forfeiting shares they must not use the power collusively for the purpose of relieving the shareholder from liability. To do so is an abuse of the power and a fraud on the other shareholders.

Directors not Trustees.—It would give a very erroneous idea of the position and functions of directors to speak of them —as is sometimes done—as trustees, except in a modified sense. They are "commercial men managing a trading concern for the benefit of themselves and the other shareholders." They have to carry on the company's business, to extend and consolidate it, and to do this they must have a free hand and a large discretion to deal with the exigencies of the commercial situation. This large discretion the law allows them, so long as they keep within the limits set by the company's memorandum and articles. They are not to be held liable for mere errors of judgment, still less for being defrauded; all that the law requires of them is that they should be faithful to their duties as agents—"diligent and honest," to use the words of Sir George Jessel, formerly master of the rolls. A director is not bound to attend all meetings of the board. He must not sign cheques without informing himself of the purpose for which they are given. On the same principle, directors must not delegate their duties to others unless expressly authorized to do so, as where the articles empower the board to appoint a committee, or individual directors to appoint substitutes. Directors may, it is true, employ skilled persons, such as engineers, solicitors, valuers or accountants, to assist them, but they must still exercise their judgment as business men on the materials before them. Then in the matter of honesty, a director must not accept a present in cash or shares or in any other form whatever from the company's vendor, nor must he make any profit in the matter of his agency without the knowledge and consent of his principal, the company. He must not, in other words, put himself in a position in which his duty to the company and his own interest conflict or even may conflict. This rule often comes into play in the case of contracts between a company and a director. There is nothing in itself invalid in such a contract, but the onus is on the director, if he would keep such a contract, to show that the company assented to his making a profit out of the contract, and for that purpose he must show that he made full and fair disclosure to the company of the nature and extent of his interest under the contract. It is for this reason that when a company's vendor is also a director he does not join the board until his co-directors have exercised an independent judgment on the propriety of the purchase.

Misfeasance.—A director must also bear in mind—what is a fundamental principle of company management—that the funds of the company are entrusted to the directors for the objects of the company as defined by the company's memorandum of association and authorized by the general law, and that they must not be diverted from those objects or applied to purposes which are outside the objects of the company (*ultra vires*), or outside the powers of management given to the directors. This does not abridge the large discretion allowed to directors in carrying on the business of the company. The funds embarked in a trading company are intended to be employed for the acquisition of gain, and risk, greater or less according to circumstances, is necessarily incidental to such employment; but it is quite another matter when directors pay dividends out of capital, or return capital to the shareholders, or spend money of the company in "rigging" the market, or in buying the company's shares, or paying commission for underwriting the shares of the company, except to the extent authorized by the articles and Companies Acts. Directors who in these or any other ways misapply the funds of the company are guilty of "misfeasance" (breach of trust), and all who join in the misapplication are jointly and severally liable to replace the sums so misapplied. The remedy of the company for misfeasance, if the company is a going concern, is by action against the delinquent directors; but where a company is being wound up, the legislature has provided a summary mode of proceeding, by which the liquidator, or any creditor or contributory of the company, may take out what is known as a misfeasance summons, to compel the delinquent director or officer to repay the misapplied moneys or make compensation. The court is, however, given a discretionary power to relieve a director from liability if he has acted honestly and reasonably and ought fairly to be excused.

In managing the company's affairs directors must meet together and act as a body, for the company is entitled to their collective wisdom in council assembled. Board meetings are held at such intervals as the directors think expedient. Notice of the meeting must be given to all directors who are within reach, but the notice need not specify the particular business to be transacted. The articles usually fix, or give the directors power to fix, what number shall constitute a quorum for a board meeting. They also empower the directors to elect a chairman of the board. The directors exercise their powers by a resolution of the board, which is recorded in the directors' minute-book. The articles usually provide for the payment of a certain sum to each director for his services during the year. When this is the case, it is an authority to the directors to pay themselves the amount of such remuneration. The remuneration, unless otherwise expressly provided, covers all expenses incidental to the directors' duties. A director, for instance, cannot claim to be paid in addition to his fixed remuneration his travelling expenses for attending board meetings.

Directors are liable criminally for falsification of the company's books, and for this or any other criminal offence the court in winding up may direct a prosecution; but the court will not as a rule interfere with the discretion of directors honestly exercised in the management of the company's affairs. The directors have prima facie the confidence of the shareholders, and it is not for the court to say that such confidence is misplaced. If shareholders are dissatisfied with the management, the remedy is in their own hands—they can call a meeting and elect a new board.

Companies registered since the 22nd November 1916 must in all trade catalogues, trade circulars, showcards and business letters sent to any part of His Majesty's dominions mention the present Christian names or initials, the present surnames, any former Christian names and surnames, and the nationality, if not British, and, if the nationality is not the nationality of origin, the nationality of origin of all the directors. The annual summary sent to the registrar of companies by all companies whenever registered must contain somewhat similar particulars.

When a company is wound up, the directors' powers of management come to an end. Their agency is superseded in favour of that of the liquidator.

Meetings.—Although the Companies Acts treat the directors of a company as the persons in whom the management of its affairs is vested, they also contemplate the ultimate controlling power as residing in the shareholders. A controlling power of this kind can only assert itself through general meetings; and that it may have proper opportunities of doing so, every company is required to hold a general meeting, called the statutory meeting, within three months from the date at which it is entitled to commence business. This meeting acquired new significance under the Companies Act of 1900 and marks an important stage in the history of a company. Seven days before it takes place the directors are required to send to the members a certified report informing them of the general state of the company's affairs—the number of shares allotted, cash received for them, an abstract of receipts and payments, the amount of preliminary expenses, the particulars of any contract to be submitted to the meeting, etc. Furnished with this report the members come to the meeting in a position to discuss and exercise an intelligent judgment upon the state and prospects of the company. Besides the statutory meeting a company must hold one general meeting at least in every calendar year, and not more than fifteen months after the holding of the last preceding general meeting. This annual general meeting is usually called the ordinary general meeting. Other meetings are extraordinary general meetings. Notices convening a meeting must inform the shareholders of the particular business to be transacted; otherwise any resolutions passed at the meeting will be invalid. Voting is regulated by the articles. Generally a vote is given to a shareholder for every share held by him, but sometimes a scale is adopted, for instance, one vote for every share up to ten, with an additional vote for every five shares beyond the first ten up to one hundred, and an additional vote for every ten shares beyond the first hundred. In default of any regulations, every member has one vote only. Sometimes preference shareholders are given no vote at all, or are only allowed to vote in certain events, *e.g.*, if their dividends are unpaid, or on certain matters, *e.g.*, winding up, reduction of capital or matters directly affecting their rights. The articles usually contain provisions regulating the demand for a poll; this may be demanded on an extraordinary or special resolution by three persons, unless the articles require a demand by a greater number of persons, but they cannot require a demand by more than five.

Agreement for Shares.—A contract to take shares is like any other contract. It is constituted by offer and acceptance, communicated to the offerer. The offer in the case of shares is usually in the form of an application in writing to the company, made in response to a prospectus, requesting the company to allot the applicant a certain number of shares in the undertaking on the terms of the prospectus, and agreeing to accept the shares, or any smaller number, which may be allotted to the applicant. An allottee is entitled to rescind his contract where the allotment is irregular, *e.g.*, where the minimum subscription has not been obtained. When an application is accepted the shares are allotted, and a letter of allotment posted to the applicant. Allotment is the usual, but not the only, evidence of acceptance. As soon as the letter of allotment is posted the contract is complete, even though the letter never reaches the applicant. An application for shares can be withdrawn at any time before acceptance. As soon as the contract is complete, it is the duty of the company to enter the shareholder's name in the register of members, and to issue to him a certificate under the seal of the company, evidencing his title to the shares.

Register of Members.—The register of members plays an important part in the scheme of the company system. The principle of limited liability having been once adopted, justice required not only that such limitation of liability should be brought home by every possible means to persons dealing with the company, but also that such persons should know as far as possible what was the limited capital which was the sole fund available to satisfy their claims—what amount had been called up, what remained uncalled, who were the persons to pay and in what amounts. These data might materially assist a person dealing with the company in determining whether he would give it credit or not; in any case they are matters which the public has a right to know. The legislature, recognizing this, has exacted as a condition of the privilege of trading with limited liability that the company shall keep a register and make returns to the registrar of companies containing those particulars, which shall be accessible to the public. In order that the register may be accurate, and correspond with the true liability of membership for the time being, the court is empowered to rectify it in a summary way by ordering the name of a person to be entered on or removed therefrom. This power can be exercised, whether the dispute as to membership is one between the company and an alleged member, or between one alleged member and another, but the machinery of the section is not meant to be used to try claims to rescind agreements to take shares. The proper proceeding in such cases is by action.

Payment for Shares.—The same policy of guarding against an abuse of limited liability requires that shares in the case of a limited company shall be paid for in full. The legislature has allowed such companies to trade with limited liability, but the price of the privilege is that the limited capital to which alone the creditors can look shall at least be a reality. It is therefore *ultra vires* for a limited company to issue its shares at a discount; but there is nothing in the Companies Acts which requires that the shares of a limited company, though they must be paid up in full, must be paid up in cash. They may be paid "in meal or in malt," and it is accordingly common for shares to be allotted in payment for property purchased or for services. The company must, however, file with the registrar of companies a return stating, in the case of shares allotted in whole or in part for a consideration other than cash, the number of the shares so allotted, and the nature of the consideration for which they have been allotted.

Though every share carries with it the liability to pay the full amount in cash or its equivalent, the liability is only to pay when and if the directors call for it. A call must fix the time and place for payment.

Rescission of Agreement.—When a person takes shares from a company on the faith of a prospectus containing any false or fraudulent representations of fact material to the contract, he is entitled to rescind the contract. The company cannot keep a contract obtained by the misrepresentation or fraud of its agents; the misrepresentation, for purposes of rescission, need not be fraudulent, it is sufficient that it is false in fact: fraud or recklessness of assertion will give the shareholder a further remedy by action of deceit, or under sect. 84 of the Consolidation Act; but, to entitle a shareholder to rescind, he must show that he took the shares on the faith or partly on the faith of the false representation; if not, it was innocuous. A shareholder claiming to rescind must do so promptly. It is too late to commence proceedings after a winding-up has begun.

Transfer of Shares.—The shares or other interest of any member in a company are personal estate and may be transferred in the manner provided by the articles. One of the chief objects when joint stock companies were established was that the shares should be capable of being easily transferred; but, though every shareholder has a prima facie right to transfer his shares, this right is subject to the regulations of the company, and it may and usually does by its articles require that a transfer of partly paid shares shall receive the approval of the board of directors before being registered,—the object being to secure the company against having an insolvent shareholder substituted for a solvent one. This power of the directors to refuse a transfer must not, however, be exercised arbitrarily or capriciously. If it were, it would amount to a confiscation of the shares. Directors, for instance, cannot veto a transfer because they disapprove of the purpose for which it is being made (*e.g.*, to multiply votes), if there is no objection to the transferee.

Blank Transfers.—It is a common and convenient practice to deposit share or stock certificates with bankers and others to secure an advance. When this is done the share or stock certificate is usually accompanied by a blank transfer—that is, a transfer executed by the shareholder borrower, but with a blank left for the name of the transferee. The handing over by the borrower of such blank transfer signed by him is an implied authority to the banker, if the loan is not paid, to fill in the blank with his name and get himself registered as the owner.

Dividends.—A company can only pay dividends out of profits—which have been defined as the "earnings of a concern after deducting the expenses of earning them." To pay dividends out of capital is not only *ultra vires* but illegal, as constituting a return of capital to shareholders. Before paying dividends, directors must take reasonable care to secure the preparation of proper balance-sheets and estimates, and must exercise their judgment as business men on the balance-sheets and estimates submitted to them. If they fail to do this, and pay dividends out of capital, they will incur serious liabilities. The onus is on them to show that the dividends have been paid out of profits. The court, as a rule, does not interfere with the discretion of directors in the matter of paying dividends, unless they are doing something *ultra vires*.

Borrowing.—One of the many advantages incident to incorporation under the Companies Acts is found in the facilities which such incorporation affords for borrowing on debentures or debenture stock. Borrowing was not specifically dealt with by the Companies Acts prior to 1900, but that it was contemplated by the legislature is evident from the provision in § 43 of the act of 1862 for a company keeping a register of mortgages and charges. The policy of the legislature in this, as in other matters connected with trading companies, was apparently to leave the company to determine whether borrowing should or should not form one of its objects.

A company is debarred from borrowing unless it is expressly or impliedly authorized to do so by its memorandum of association. In the case of a *trading* company borrowing is impliedly authorized as a necessary incident of carrying on the company's business, but a non-trading company, for instance a company formed to promote art, science, religion or charity, has no implied borrowing power. A company established for the conveyance of passengers and luggage by omnibuses, a company formed to buy and run vessels between England and Australia, and a company whose objects included discounting approved commercial bills, have all been held to be trading companies with an incidental power of borrowing as such to a reasonable amount. A building society, on the other hand, has no inherent power of borrowing (though a limited statutory power was conferred on such societies by the Building Societies Act, 1874). Public companies formed to carry out some undertaking of public utility, such as docks, water works, gas works, etc., have only limited powers of borrowing. It has been found, however, that an implied power of borrowing, even when it attaches, is too inconvenient to be relied on in practice, and an express power is always now inserted in the memorandum. This power is in most general terms. It is left to the articles to define the amount to be borrowed, the nature of the security, and the conditions, if any, such as the sanction of a general meeting, on which the power is to be exercised. A company cannot exercise any borrowing power until it has become entitled to commence business. (*See* supra.) A person who is proposing to lend money to a company must be careful to see (1) that the memorandum authorizes borrowing, and (2) that the borrowing limit in the articles is not being exceeded, for if it should turn out that the borrowing was in excess of the company's powers and *ultra vires,* the company cannot be bound, and the borrower's only remedy is against the directors for breach of warranty of authority, or to be surrogated to the rights of any creditors who may have been paid out of the borrowed moneys.

A company proposing to borrow usually issues a prospectus, similar to the ordinary share prospectus, stating the amount of the issue, the dates for payment, the particulars of the property comprised in the security, the terms as to redemption, and so on, and inviting the public to subscribe. Underwriting is also resorted to, as in the case of shares, to ensure that the issue is taken up. There is no objection to a company issuing debentures or debenture stock at a discount, as there is to its issuing its shares at a discount. The directors must borrow on the best terms the company's credit will enable it to obtain. A prospectus inviting subscriptions for debentures or debenture stock must be filed and contain the same particulars as a prospectus offering shares, and it comes within s. 84 of the Consolidation Act. Further, persons who are parties to it have the onus cast upon them, should the prospectus contain any misstatements, of showing that, at the time they issued the prospectus, they had reasonable grounds to believe, and did in fact believe, that the statements in question were true; otherwise they will be liable to pay compensation to any person injured by the misstatements.

Debentures.—Etymologically, "debenture" is merely the Latin word *debentur,* the first word in a document in common use by the Crown in early times admitting indebtedness to its servants or soldiers. This was the germ of a security which has now, with the expansion of joint stock company enterprise, grown into an instrument of considerable complexity.

Debentures may be classified in various ways. From the point of view of the security they are either (1) debentures (simply); (2) mortgage debentures; (3) debenture bonds. In (1) the security is a floating charge: in (2) there is also a floating charge, but the property forming the principal part of the security is specifically mortgaged by the company to trustees under a trust deed for the benefit of the debenture-holders: in (3) there is no security proper, only the covenant for payment by the company. For purposes of title and transfer, debentures are either "registered" or "to bearer." For purposes of payment they are either "terminable" or "perpetual."

The Floating Debenture.—The form of debenture chiefly in use is that secured by a floating charge. By it the company covenants to pay to the holder thereof the sum secured by the debenture on a specified day, or at such earlier date as the principal moneys become due under the provisions of the security, and in the meantime to pay interest on the principal moneys until payment, or until the security becomes enforceable under the conditions; and the company further charges its undertaking and all its property, with the payment of the amount secured by the debenture; uncalled capital, if included, must be expressly mentioned, because the word "property" by itself will not cover it. This is the body of the instrument; on its back is endorsed a series of conditions, constituting the terms on which the debenture is issued. Thus the debenture-holders are to rank *pari passu* with one another against the security; the debenture is to be transferable free from equities between the company and the holder; the charge is to be a floating charge, and the debenture-holders' moneys are to become immediately repayable and the charges enforceable in certain events: for instance, if the interest is in arrear for (say) two or three months, or in the event of winding-up. Other events indicative of insolvency are sometimes added in which payment is to be accelerated. The conditions also provide for the mode and form of transfer of the debenture, the death or bankruptcy of the holder, the place of payment, etc. The most characteristic feature of the security—the floating charge—grew naturally out of a charge on a company's undertaking as a going concern. Such a charge could only be made practicable by leaving the company free to deal with and dispose of its property in the ordinary course of its business—to sell, mortgage, lease and exchange it as if no charge existed; and this is how the security works. The debenture-holders give the directors an implied licence to deal with and dispose of the property comprised in the security until the happening of any of the events upon which the debenture-holders' money becomes, under the debenture conditions, immediately repayable. Pending this the charge is dormant. The licence extends, however, only to dealings in *the ordinary course of business.* Payment by a company of its just debts is always in the ordinary course of business, but satisfaction by execution levied *in invitum* is not. The lender has a security covering the whole assets for the time being, and can intervene at any moment by obtaining a receiver, if his security is imperilled, even though none of the events in which the principal moneys are made payable have happened. If any of them has happened, for instance default in payment of interest, or a resolution to wind up, the payment of the principal moneys is accelerated, and a debenture-holder can at once commence an action to obtain payment and to realize his security.

Often a proviso is inserted in the conditions endorsed on the debenture, that the company is not to create any mortgage or charge ranking in priority to or *pari passu* with that contained in the debentures. A floating charge created by a company within three months of winding up is invalid, except to the amount of the cash paid and interest at 5%, unless the company is shown to have been solvent at the time.

Trust Deeds.—When the amount borrowed is large, the company commonly executes a trust deed by way of further security. The object of such a trust deed is twofold: (1) it creates a legal mortgage of specific property in favour of the trustees of the deed (the charge contained in the debentures is only an equitable security), and it further charges all the remaining assets by way of floating charge, with appropriate provisions for enabling the trustees, in certain events similar to those expressed in the debenture conditions, to enforce the security, and for that purpose to enter into possession and carry on the business, or to sell it and distribute the proceeds; (2) it organizes the debenture-holders and constitutes trustees who can watch over the interests of the debenture-holders and take steps for their protection, if necessary. In particular it provides machinery for the calling of meetings of debenture-holders, and empowers a majority of (say) three-fourths in value at such meeting to bind the rest to any compromise or arrangement with the company which such majority may deem beneficial. This may save recourse to a scheme or arrangement sanctioned by the court.

Debentures Registered and to Bearer.—Debentures are, for purposes of title and transfer, of two kinds—(1) registered debentures, and (2) debentures to bearer. Registered debentures are transferable only in the books of the company. Debentures to bearer are negotiable instruments and pass by delivery. Coupons for interest are attached. Sometimes debentures to bearer are made exchangeable for registered debentures and vice versa.

Debenture Stock.—Debenture stock bears the same relation to debentures that stock does to shares. "Debenture stock," as Lord Lindley states (*Companies,* 5th ed., 195), "is merely borrowed capital consolidated into one mass for the sake of convenience. Instead of each lender having a separate bond or mortgage, he has a certificate entitling him to a certain sum, being a portion of one large loan." This sum is not uniform, as in the case of debentures, but variable, and is usually made transferable in sums of any amount not involving a fraction of £1. One debenture-stockholder, for instance, may hold £20 of the stock, another £20,000. Debenture stock created by companies under the Companies Acts, unlike that created by statutory companies governed by the Companies Clauses Acts, is created by a contract between the company and the trustees of a debenture-stock trust deed, which is analogous in its provisions to the trust deed above described used to secure debentures. By such deed the company covenants with the trustees, as representing the debenture-stockholders, to pay the amount of the stock, and creates a legal mortgage of specific property, and charges its other assets by way of floating charge, in favour of the trustees, with all requisite powers and provisions for enabling them to enforce the security on default in payment of interest or on the happening of certain specified events evidencing insolvency. The company further covenants to enter the names of the stockholders in a register, and to issue certificates for the amount of their respective holdings. These certificates have, like debentures, the conditions of the security endorsed on their back.

Redemption.—A company generally reserves a right of redeeming the security before the date fixed for repayment; and accordingly a power for that purpose is commonly inserted in the conditions and trust deed, if there is one. But as debenture or debenture-stockholders, who have got a satisfactory security, do not wish to be paid off, the right of redemption is often qualified so as not to arise till (say) five years after issue, and a premium is made payable by way of bonus. Sometimes the number of debentures or the amount of stock to be redeemed each year is limited. The selection is made by drawings held in the presence of the directors, or, if there is a trust deed, of the trustees. A sinking fund is often provided for, and this is especially suitable where the security is of a wasting character such as leaseholds, mining property or a patent. Such a fund is formed by the company setting apart a certain sum each year out of the profits of the company after payment of interest on the debentures. Redeemed debentures and debenture stock may in certain cases be reissued.

Registration of Mortgages and Charges.—A company is bound to keep a register of mortgages and charges, which is open to the inspection of creditors and members of the company. Mortgages and charges of certain specified classes must also be registered within twenty-one days from their creation with the registrar of companies. Otherwise they are void—so far as they are securities—against the liquidator and any creditor of the company, but the holders retain the rights of unsecured creditors. An extension of the time for registering may be granted by the court.

Debenture Scrip.—Debentures and debenture stock are usually made payable by instalments, for example 10% on application, 10% on allotment and the remainder at intervals of a few months. Until these payments are complete the securities are not issued, but to enable the subscriber to deal with his security pending completion the company issues to him an interim scrip certificate acknowledging his title and exchangeable on payment of the remaining instalments for debentures or debenture stock certificates.

Remedies.—When debenture-holders' security becomes enforceable there are a variety of remedies open to them. These fall into two classes—(1) remedies available without the aid of the court; (2) remedies available only with the aid of the court.

1. If there is a trust deed, the trustees may appoint a receiver of the property comprised in the security, and they may also sell under the powers contained in the deed, or under the Law of Property Act, 1925. Sometimes, where there is no trust deed, similar powers—to appoint a receiver and to sell—are inserted in the conditions endorsed on the debentures.

2. The remedies with the aid of the court are—(*a*) an action by one or more debenture-holders on behalf of all for a receiver and to realize the security; (*b*) an originating summons for sale or other relief; (*c*) an action for foreclosure where the security is deficient (all the debenture-holders must be parties to this proceeding); (*d*) a winding-up petition. Of these modes of proceeding, the first is by far the most common and convenient. Immediately on the issue of the writ in the action the plaintiff applies for the appointment of a receiver to protect the security, or if the security comprises a going business, a receiver *and manager*. In due course the action comes on for judgment, when the court directs accounts and inquiries as to what is due to the holders of the debentures and what property is comprised in the security, and gives leave to apply for a sale. If the company has gone into liquidation, leave must be obtained to commence or continue the action, but such leave in the case of debenture-holders is *ex debito justitiae.* The administration of a company's assets in such actions by debenture-holders (debenture-holders' liquidations, as they are called) has encroached very much on the ordinary administration of winding up, and great hardship is often inflicted by the floating security on the company's unsecured creditors, who find that everything belonging to the company, uncalled capital included, has been pledged to the debenture-holders. No doubt such creditors might have inspected the company's register of mortgages and charges, but it is not always practicable to do this.

Auditors.—By the Consolidation Act strict provisions are made for the appointment and remuneration of auditors by a company, and their rights and duties are defined.

Private Companies.—The "private company" may be likened to an incorporated partnership. To be a private company the articles must restrict the right to transfer shares, limit the number of members, and prohibit any invitation to the public to subscribe for shares, debentures or debenture stock of the company. A private company need not consist of more than two members, and enjoys many advantages as regards commencement of business, freedom from the obligation to issue a statement in lieu of prospectus and to make certain returns to the registrar of companies and other matters.

Individual traders and trading firms have become alive to the advantages offered by incorporation; for it gives them the protection of limited liability, prevents dislocation of a business by the death, bankruptcy or lunacy of any of its members, enables a trader to distribute among the members of his family interests in his business on his decease through the medium of shares and facilitates borrowing on debentures or debenture stock; and with a view to secure these advantages thousands of traders have converted their businesses into limited companies. To so large an extent has this been done that private companies now form about 90% of the companies registered.

Although a private company does not appeal to the public to subscribe its capital, in the main features of its constitution it differs little from a public one. It is only in one or two particulars that special provisions are requisite. It is generally desired for instance: (1) to keep all the shares among the members—the partners or the family—and not to let them get into outside hands; and (2) to give the principal shareholders, the original partners, a paramount control over the management. For this purpose it is usual to provide specially in the articles that no share shall be transferred to a stranger so long as any member is willing to purchase it at a fair value; that a member desirous of transferring his shares shall give notice to the company which shall offer the shares to the other members; that if within a certain period the company finds a purchaser, the shares shall be transferred to him, and that in case of dispute the value shall be settled by arbitration or shall be such a sum as the auditor certifies to be the fair value. So in regard to the management it is common to provide that the owners of the business shall be entitled to hold office as directors for a term of years or for life, provided they continue to hold a certain number of shares; or an owner is empowered to authorize his executors or trustees, whilst holding a certain number of shares, to appoint directors. Directors holding office on these special terms are often given very extensive powers and are described as "governing" or "permanent" or "life" directors. This union of interest and management in the same persons gives a private company an unquestionable advantage over a public company.

The so-called "one-man company" is merely a variety of the private company. The fact that a company is formed by one man, with the aid of six dummy subscribers, is not in itself (as was at one time supposed) a fraud on the policy of the Companies Acts, but it is occasionally used for the purpose of committing a fraud, as where an insolvent trader turns himself into a limited company in order to evade bankruptcy; and it is to an abuse of this kind that the term "one-man company" owes its opprobrious signification.

COMPANIES LIMITED BY GUARANTEE

The second class of limited companies are those limited by guarantee, as distinguished from those limited by shares. In the company limited by guarantee each member agrees, in the event of a winding-up, to contribute a certain amount to the assets—£5, £1 or 10s.—whatever may be the amount of the guarantee. The peculiarity of this form of company is that the interests of the members are not expressed in any terms of nominal money value like the shares of other companies, a form of constitution designed to give a superior elasticity to the company. The property of the company simply belongs to the company in certain fractional amounts. This makes it convenient for clubs, syndicates and other associations which do not require the interest of members to be expressed in terms of cash.

COMPANIES NOT FOR GAIN

An association formed to promote commerce, art, science, religion, charity or any other useful object may, with the licence of the Board of Trade, register under the Companies Acts with limited liability, but without the addition to its name of the word "Limited," upon proving to the board that it is the intention of the association to apply its profits or income in promoting its objects, and not in payment of dividends to its members. This licence is revocable. In lieu of the word "Company," the association usually adopts as part of its name some such title as association, chamber, club, college, institute or society. The power given by this section has proved very useful, and many kinds of associations have availed themselves of it, such as medical institutes, law societies, nursing homes, chambers of commerce, clubs, schools and learned societies. The guarantee form (see *supra*) is well adapted for associations of this kind, supported as they usually are, by annual subscriptions. No such association can hold more than two acres of land without the licence of the Board of Trade.

COST-BOOK MINING COMPANIES

These are in substance mining partnerships. They derive their name from the fact of the partnership agreement, the expenses and receipts of the mine, the names of the shareholders, and any transfers of shares being entered in a "cost-book." The affairs of the company are managed by an agent known as a "purser," who from time to time makes calls on the members for the expenses of working. A cost-book company is not bound to register under the Companies Acts but may do so.

Winding-up.—A company once incorporated under the Companies Acts cannot be put an end to except through the machinery of a winding-up, though the name of a company which is commercially defunct may be struck off the register of companies by the registrar. Winding-up is of three kinds: (1) voluntary, (2) by the court and (3) subject to the supervision of the court. Of these voluntary winding-up is by far the most common. Of the companies that come to an end 90% are so wound up; and this is in accordance with the policy of the legislature, that shareholders should manage their own affairs—winding-up being one of such affairs.

Voluntary.—A voluntary winding-up is carried out by the shareholders passing a special resolution requiring the company to be wound up voluntarily or an extraordinary resolution to the effect that it cannot by reason of its liabilities continue its business, and that it is advisable to wind up. The resolution is generally accompanied by the appointment of a liquidator. In a voluntary winding-up there is a power for the liquidator or any contributory or creditor to apply to the court to determine any question arising in the winding-up, or to exercise any powers which the court might exercise if the company were being wound up by the court. The liquidator must summon a meeting of creditors to determine whether an application shall be made to the court for the appointment of a new liquidator or a committee of inspection. When the affairs of the company are fully wound up, the liquidator calls a meeting, lays his accounts before the shareholders, makes a return to the registrar and the company is dissolved by operation of law three months after the registration of the return.

By the Court.—Irrespective of voluntary winding-up, the legislature has defined certain events in which a company may be wound up by the court. These events are: (i.) when the company has by special resolution resolved that the company be wound up by the court; (ii.) when default is made in filing the statutory report or holding the statutory meeting; (iii.) when the company does not commence its business within a year or suspends it for a year; (iv.) when the members are reduced, in the case of a private company, below two, or, in the case of any other company, below seven; (v.) when the company is unable to pay its debts, and (vi.) when the court is of opinion that it is just and equitable that the company should be wound up. A petition for the purpose may be presented either by a creditor, a contributory, or the company itself. Where the petition is presented by a creditor who cannot obtain payment of his debt, a winding-up order is *ex debito justitiae* as against the company or shareholders, but not as against the wishes of a majority of creditors. A winding-up order is not to be refused because the company's assets are over mortgaged.

On a winding-up order being made the official receiver, as liquidator, *pro tem.*, requires a statement of the affairs of the company verified by the directors, and on it reports to the court as to the causes of the company's failure and whether further inquiry is desirable. If he further reports that, in his opinion, fraud has been committed in the promotion or formation of the company by a particular person, the court may order such person to be publicly examined.

A liquidator's duty is to protect, collect, realize and distribute the company's assets in due course of administration; and for this purpose he advertises for creditors, makes calls on contributories, sues debtors, takes misfeasance proceedings, if necessary, against directors or promoters, and carries on the company's business—supposing the goodwill to be an asset of value—with a view to selling it as a going concern. He may be assisted by a committee of inspection, composed of creditors and contributories. When the affairs of the company have been completely wound up the court makes an order that it be dissolved, and it is dissolved accordingly, but the court has power to declare the dissolution void.

Under Supervision.—The court may make an order that a voluntary winding-up shall continue but subject to the supervision of the court. Such an order has the advantage of operating as a stay of any actions or executions pending against the company. Except in these respects, the winding-up remains a voluntary one. The court does not actively intervene unless set in motion.

Reconstruction.—A large number of companies now wind up only to reconstruct. The reasons for a reconstruction are generally either to raise fresh capital, or to get rid of onerous preference shares. Reconstructions are carried out in one of three ways: (1) by sale and transfer of the company's undertaking and assets to a new company, under s. 192 of the Consolidation Act, or (2) by sale and transfer under a power to sell contained in the company's memorandum of association, or (3) by a scheme of arrangement, sanctioned by the court, under s. 120. Usually debenture-holders take debentures in the new company.

Wrongs by a Company.—A company, though a mere legal abstraction, without mind or will, may be made liable in damages for malicious prosecution, nuisance, fraud, negligence, trespass and other wrongs. The sense of the thing is that the "company" is a *nomen collectivum* for the members. It is they who have put the directors there to carry on their business and they must be answerable, collectively, for what is done negligently, fraudulently or maliciously by their agents. A company may be convicted of many kinds of crime.

Later Legislation.—By the Companies Bill now (1928) before Parliament it is proposed to empower companies to issue redeemable preference shares, to tighten up the law as to prospectuses and offers of shares or debentures for sale, to recast the law as to minimum subscription, under certain conditions to allow the issue of shares at a discount, to give creditors more power in a voluntary winding-up, to create various offences on the lines of the law of bankruptcy, to prevent the hawking of shares from house to house, and to amend the Companies Acts in many other ways. The present Acts and the new Act, when passed, are to be consolidated in a new Consolidation Act.

II. STATUTORY COMPANIES

There is another large class of companies, which for shortness may be called statutory companies, constituted by special Act of Parliament for the purpose of carrying on undertakings of public utility, such as railways, canals, harbours, docks, waterworks, gasworks, bridges, ferries or tramways. The objects of such companies nearly always involve an interference with the rights of private persons, often necessitate the commission of a public nuisance, and require therefore the sanction of the legislature. For this purpose a special Act has to be obtained. A private bill to authorize the undertaking is introduced in Parliament, considered in committee, and either passed or rejected. These private bill committees are tribunals acknowledging certain rules of policy, taking evidence from witnesses and hearing arguments from professional advocates. In many of these special Acts, dealing as they do with a similar subject matter, similar provisions are required, and to avoid repetition and secure uniformity the legislature has passed certain general Acts—codes of law for particular subject matters frequently recurring—which can be incorporated by reference in any special Act with the necessary modifications. Thus the Companies Clauses Acts, 1845 to 1889, supply the general powers and provisions which are commonly inserted in the constitution of such companies, regulating the distribution of capital, the transfer of shares, payment of calls, borrowing and general meetings. The Lands Clauses Consolidation Act, 1845, supplies the machinery for the compulsory taking of land incident to most undertakings of a public character. The Railways Clauses Acts, 1845 and 1863 (as amended by the Mines [Working Facilities and Support] Act, 1923), the Waterworks Clauses Acts, 1847 and 1863, the Gasworks Clauses Act, 1847 and the Electric Lighting (Clauses) Act, 1899, are other codes of law designed for incorporation in special Acts creating companies for the construction of railways or the supply of water, gas or electric light.

The provisions of the Companies Clauses Acts as to shares and stock are, with a few exceptions, analogous to those of the Companies Acts. The capital is divided into shares of a certain number and amount. A share register is kept and certificates are issued to shareholders; power is given to convert paid-up shares into stock; preference shares may be created, but carry dividends only out of the profits of each year; shares and stock may be issued at a discount, but if the old ordinary shares are at a premium, any new shares must be offered first to the old shareholders.

The borrowing powers of these companies, the form of their debenture or debenture stock, and the rights of the holders depend on the conjoint operation of the companies' own special Act and the Companies Clauses Acts. The provisions of these Acts as to borrowing, being express, exclude any implied power of borrowing. The policy of the legislature is to give proper facilities for borrowing, and at the same time to take care that undertakings of public utility which have received legislative sanction shall not be broken up or destroyed, as they would be if the mortgagees or debenture-holders were allowed the ordinary rights of mortgagees for realizing their security by seizure and sale. Hence the legislature has given them only "the fruit of the tree." The debenture or debenture-stock-holders may take the earnings of the company's undertaking by obtaining the appointment of a receiver, but that is all they can do. They cannot sell the undertaking or disorganize it by levying execution, so long as the company is a going concern; but this protecting principle of public policy will not be a bar to a debenture-holder, in his character of creditor, presenting a petition to wind up the company, if it is no longer able to fulfil its statutory objects. Certain statutory companies may now under the Stat. Companies (Redeemable Stock) Act, 1915, issue redeemable debenture stock, and also redeemable preference stock.

Railway Companies.—These have special legislation which will be found in the Railway Companies Powers Act, 1864, the Railways Construction Facilities Act, 1864, and the Railway Securities Act, 1866, and numerous other acts. The more important railways have been amalgamated under the Railways Act, 1921. (*See* GREAT BRITAIN: *Communications.*)

III. BRITISH COMPANIES ABROAD

The status of British companies trading abroad, so far as Germany, France, Belgium, Greece, Italy and Spain are concerned, is expressly recognized in a series of conventions entered into between those countries and Great Britain.

In France.—The value of the convention with France has been much impaired by the interpretation put upon the words of it by the court of cassation in *La Construction Lim.* According to this case the nationality of a company depends not on its place of origin but on where it has its centre of affairs, its principal establishment. The result is that a company registered in Britain under the Companies Acts may be transmuted by a French court into a French company in direct violation of the convention.

In Germany.—The convention with Germany, which is in similar terms to that with France, has also been narrowed by judicial construction. The "power of exercising all their rights" given by the convention to British companies has been construed to mean that a British company will be recognized as a corporate body in Germany, but it does not follow from the terms of the convention that any British company may as a matter of course establish a branch and carry on business within the German republic. It must still get permission to trade and to hold land, register itself in the communal register and pay stamp duties.

Foreign companies may found an affiliated company or have a branch establishment in Italy, provided they publish their memorandum and articles and the names of their directors.

Foreign Companies Generally.—Where no convention exists the status of an immigrant corporation depends upon international comity, which allows foreign corporations, as it does foreign persons, to sue, to make contracts and hold real estate, in the same way as domestic corporations or citizens; provided the stranger corporation does not offend against the policy of the state in which it seeks to trade.

There is a growing practice for states to impose by express legislation conditions on foreign corporations coming to do business within their territory. These conditions are mainly directed to securing that the immigrant corporation shall make known its constitution and shall be amenable to the jurisdiction of the courts of the country where it trades. Thus, by the law of Western Australia—to take a typical instance,—a foreign company is not to commence or carry on business until it empowers some person to act as its attorney to sue and be sued and has an office or place of business within the State, to be approved of by the registrar, where all legal proceedings may be served. New Zealand, Manitoba and many other States have adopted similar precautions; and by the Companies (Consolidation) Act, 1908, s. 274, a foreign company having a place of business within the United Kingdom is required to file with the registrar of companies a copy of its Charter or memorandum and articles, a list of directors, and the names and addresses of one or more persons authorized to accept service of process. Special conditions of a more stringent nature are often imposed in the case of particular classes of companies of a quasi-public character, such as banking companies, building societies or insurance companies. Regulations of this kind are perfectly legitimate and necessary. They are in truth only an application of the law of vagrancy to corporations, and have their analogy in the restrictions now generally imposed by states on the immigration of aliens.

IV. COMPANY LAW OUTSIDE THE UNITED KINGDOM

Australia and New Zealand.—Company law in Australia and New Zealand follows very closely the lines of legislation in the United Kingdom. In New South Wales the law is consolidated by the Companies Act, 1899, amended 1900, 1906, 1907, 1918; in Victoria by an Act of 1915, amended 1920, 1926; in South Australia by an Act of 1892, amended 1893, 1924 and 1926 (two Acts); in Tasmania by an Act of 1920, amended 1922, 1923, 1927; in Western Australia by an Act of 1893, amended 1897, 1898, 1899, 1902, 1922. In Queensland the law is contained in the Companies Act, 1863, amended 1889, 1891, 1892, 1893, 1894, 1896, 1909, 1913. In New Zealand the law is consolidated by an Act of 1908, amended 1910, 1919, 1920, 1921, 1921–22 (temporary), 1924.

Canada.—Companies in Canada can be incorporated either under the Dominion Companies Act (Revised Statutes of Canada, 1927, c. 27) or under the Companies Acts of one or other of the nine Provinces. The Acts of the Provinces of Nova Scotia, Saskatchewan, Alberta and British Columbia in the main follow the English law, incorporation being effected by the registration of a memorandum of association, usually accompanied by articles of association. The Dominion Act and the Acts of the Provinces of Ontario, Quebec, Manitoba, Prince Edward Island and New Brunswick on the other hand provide for incorporation by letters patent granting a Charter. The various Acts and amending Acts are too numerous to refer to here in detail.

Applicants for letters patent for a Dominion company must file an application showing the purposes of incorporation, the place of business, the amount of the capital stock, the number of shares and the amount of each, the names of the applicants, the amount of stock taken by each and the amount and mode of payment. Other provisions may also be embodied. A company cannot commence business until 10% of its authorized capital has been subscribed and paid for. The word "limited" as part of the company's name is to be conspicuously exhibited and used in all documents. The directors are not to be less than three, and must be holders of stock. Borrowing powers may be taken by resolution of a two-thirds majority at a special meeting of the stockholders.

AUTHORITY—Mitchell on Canadian Commercial Corporations.

(H. T. E.)

France.—There are two kinds of limited liability companies in France—the *société en commandite* and the *société anonyme*. The *société en commandite* corresponds in some respects to the British private company or limited partnership, but with this difference, that in the *société en commandite* the managing partner is under unlimited liability to creditors; the sleeping-partner's liability is limited to the amount of his capital. The French equivalent of the English ordinary joint stock company is the *société anonyme*. The minimum number of subscribers necessary to form such a company is seven. The *société anonyme* is not legally constituted unless the whole capital is subscribed and one-fourth of each share paid up. Assets, not in money, brought into a company are subject to verification of value by a general meeting. The minimum nominal value of shares, where the company's capital is less than 200,000 fr., is 25 fr.; where the capital is more than 200,000 fr., 100 fr. The *société* is governed by articles which appoint the directors, and there is one general meeting held every year. A *société anonyme* may issue preference shares. The doctrine that a corporation never dies has no place in French law. A *société anonyme* may come to an end.

Since 1925 a new form of association has been brought into existence under the name of *société à responsabilité limitée*. Its main differences from the *société anonyme* are as follows:—(1) The number of partners or shareholders is not limited and there may be only two partners or shareholders; (2) the capital of the company must be at least 25,000 fr. and it cannot be reduced to less than that amount; (3) the company can only be finally incorporated when all the shares have been allotted and have been fully paid up; (4) the shares are not transferable to persons other than shareholders except with the consent of the majority of the shareholders representing between themselves at least three-quarters of the company's capital; (5) the company must have a fixed nationality which cannot be changed except with the consent of all the shareholders.

Germany.—In Germany the class of companies most nearly corresponding to English companies limited by shares are "share companies" (*Aktiengesellschaften*) and "commandite companies" with a share capital (*Kommanditgesellschaften auf Aktien*). Since 1892 a new form of association has come into existence known by the name of partnership with limited liability (*Gesellschaften mit beschrankter Haftung*), which has largely superseded the commandite company.

In forming this paid-up company certain preliminary steps have to be taken before registration:—(1) The articles must be agreed on; (2) a managing board and a board of supervision must be appointed; (3) the whole of the share capital must be allotted and 25%, at least, must be paid up in coin or legal tender notes; (4) reports on the formation of the company must be made by certain persons; and (5) certain documents must be filed in the registry.

In all cases where shares are issued for any consideration, not being payment in full in cash, or in which contracts for the purchase of property have been entered into, the promoters must sign a declaration in which they must state on what grounds the prices agreed to be given for such property appear to be justified. In the great majority of cases shares are issued in certificates to bearer. The amount of such a share to bearer must as a general rule be not less than the equivalent of £50, but registered shares of £10 may be issued. Balance sheets have to published periodically.

Partnerships with limited liability may be formed by two or more members. The articles of partnership must be signed by all the members, and must contain particulars as to the amount of the capital and of the individual shares. If the liability on any shares is not to be satisfied in cash, this also must be stated. The capital of a limited partnership must amount to £1,000. Shares must be registered. Insolvent companies in Germany are subject to the bankruptcy law in the same manner as natural persons.

For further information *see* a memorandum on German companies printed in the appendix to the *Report of Lord Davey's Committee on the Amendment of Company Law*, pp. 13–26.

Italy.—Commercial companies in Italy are of three kinds:—(1) General partnerships, in which the members are liable for all debts incurred; (2) companies in *accomandita*, in which some members are liable to an unlimited extent and others within certain limits; (3) joint stock companies, in which the liability is limited to the capital of the company and no member is liable beyond the amount of his holding. None of these companies needs authority from the Government for its constitution; all that is needed is a written agreement brought before the public in the ways indicated in the code. In joint stock companies the trustees (directors) must give security. They are appointed by a general meeting for a period not exceeding four years. The company is not constituted until the whole of its capital is subscribed, and until three-tenths of the capital at least has been actually paid up. When a company's capital is diminished by one-third, the trustees must call the members together and consult as to what is to be done. An ordinary meeting is held at least once every year. Shares may not be made payable "to bearer" until fully paid up. A company may issue debentures if this is agreed to by a certain majority. One-twentieth, at least, of the dividends of the company must be added to the reserve fund, until this has become equal to one-fifth of the company's capital. Three or five assessors—members or non-members—keep watch over the way in which the company is carried on. (X.)

THE UNITED STATES

The word "company," which has of recent years acquired a definite meaning in England, retains in the United States all of its original vagueness, being used indiscriminately to designate all sorts of associations of men from a group of volunteer firemen to the Pennsylvania railroad. The modern business organizations which are called in England the joint-stock company and the statutory company, respectively, are in America known as the "corporation," or, when one wishes to differentiate the two, as the "business corporation" and the "public service corporation."

ORDINARY BUSINESS CORPORATIONS

The development of business corporations in the United States has in general been substantially similar to that of joint stock companies in England, but there are a number of important divergencies between the business practices and law of the two countries. The legal differences are in part the consequence of a difference in business practices, in part due to different views of public policy and in part to the peculiarities of the American federal system of government.

State and Federal Corporations.—It is a well settled principle of American law that power to create corporations is vested in the legislature alone, and the word legislature in this connection means, in general, the legislature of some one of the States. The U.S. Congress has implied power to create many kinds of corporations, but it has rarely done so except in the case of national banks. Persons desiring to incorporate for other than banking purposes must therefore look to some State legislature for assistance.

General Corporation Laws.—During the early years of the 19th century, this assistance was given sparingly, the incorporation of every enterprise requiring a special legislative act. During the last 100 years, however, more liberal views have prevailed, and in all the States to-day there are general laws enabling persons desiring to incorporate to do so by performing certain specified acts. In the case of ordinary business corporations, the principal statutory requirements are the payment of certain fees and the signing and filing of a document, called "articles of incorporation" or some similar name, which sets forth the powers which the corporation is to have, and certain other matters, such as the total amount of the authorized capital and whether preferred as well as common stock is to be issued.

Promotion and Organization.—Although the statutes thus determine the legal framework of the enterprise, the actual organization of a business corporation usually involves many things to which the statutes make no reference. Most corporations are formed to develop some particular property or to take over some existing business. Important preliminary agreements are ordinarily entered into by the promoters of the enterprise prior to incorporation. Although these agreements are not in legal theory binding upon the subsequently formed corporation, in practice one of the first acts of the corporation upon its formation is the adoption of them.

Moreover, although incorporation laws frequently provide for the making of a minimum number of subscriptions in some statutory form, they generally permit additional subscriptions to be made either prior or subsequent to incorporation by informal contracts subject only to certain statutory regulations with regard to payment. Furthermore, although it is well settled that a corporation has power to finance itself through the issue of bonds, as well as by subscriptions to stock, the issue of bonds is not as a general rule based upon any provision in the statute but upon the implied power of borrowing money which is possessed by all business corporations.

In addition to the acts which are necessary to incorporation, the statutes generally contemplate the doing of additional acts before the corporation shall be in a position to do business. Thus, most incorporation acts provide that the incorporators shall, before engaging in business, meet together for the purpose of adopting by-laws and electing directors.

Doing Business in Several States.—The laws of the several States differ considerably both as to the manner in which incorporation may be obtained and as to the powers which corporations may have. In view of these differences, the question how far it is possible to become incorporated in a State whose laws are peculiarly favourable to the sort of organization which the promoters of the enterprise desire and to retain the benefits of such incorporation while carrying on business in another State is one of great importance. The courts have held that a corporation formed in one State may engage in business in another State unless expressly forbidden to do so and that, under such circumstances, its internal organization continues to be governed by the laws of the State in which it was created. Nevertheless, except in so far as the corporation's business is interstate commerce, the second State may, by statute, deny it the right to do business therein or may, as the price of permitting it to do so, impose severe restrictions upon it.

In practice, corporations of one State are, with few exceptions, permitted to do business in other States, subject to certain regulations. In some cases these regulations are sufficiently burdensome to make it desirable for the owners of an incorporated enterprise to organize a second corporation under the laws of the second State for the purpose of carrying on the business done in that State. Frequently, however, the situation is such that persons desiring to do business mainly or even wholly in one State deem it for their advantage to incorporate in another.

Stockholders' Liability.—Although the corporation laws of the States differ in a number of important respects, they all possess the common feature of limiting to some extent the liability of the stockholders for the corporate debts, the limit of liability being in most States the amount of the stockholders' subscription. In order to prevent this stockholders' liability from approaching the vanishing point, it was until recently generally provided that all stock issued must have a par value and that the subscribers to the stock should remain liable to the corporation's creditors until they or their transferees had paid either in cash, property or services, a sum equal to this par value. The practical consequences of these laws have been regarded by most persons concerned with the financing of corporations as undesirable and their criticisms have in recent years led to the enactment of laws permitting the issue of stock without par value.

Blue Sky Laws.—No-par stock is a device to insure greater flexibility in capitalization and to relieve stockholders from what may in some cases be regarded as an unfair burden of liability. Permission to use such a device certainly does not diminish the need of surrounding the issue of corporate stock with safeguards designed to protect the investor against being misled by fraudulent or over-optimistic promoters and stock salesmen. In order, if possible, to discourage the activities of such persons, the majority of the States have in recent years enacted so-called "blue sky" laws which make it a criminal offence to sell stock without a licence from a public official, who is under a duty of refusing to grant a licence if he believes the plan of incorporation to be illegal, fraudulent or unfair. Certain classes of securities, such as those listed on a stock exchange, are generally exempted from the requirements of these statutes.

De Facto Corporations.—The enactment of such laws may tend to reduce somewhat the tendency to carelessness with respect to compliance with incorporation laws, which has been a source of considerable difficulty in American corporation law. As a result of such carelessness it not infrequently happens that persons engage in business under what they believe to be a corporate form of organization without being legally incorporated. The courts have treated organizations of this type as having a *de facto* corporate existence, a view of the situation which has no parallel in the law of England.

Corporate Powers and Ultra Vires Acts.—The powers which corporations possess depend in the main upon the provisions in their articles, though there are certain powers which are implied from the mere fact of incorporation, and other powers which are denied to all corporations regardless of what their articles may provide. One important power which is freely granted in some States while rigidly refused in others is the power to hold stock in other companies, a power which enables one corporation to control another through ownership of a majority of its stock. It not infrequently happens that the managing officers of corporations attempt to do in the corporate name acts which the corporation is not authorized to do. In contrast to the English view that such *ultra vires* acts are wholly void, American courts have in general held that they will, in many cases, confer rights and impose liability upon the corporation.

Directors.—The legal principles which govern the activities of an American corporation once it becomes a going concern are, however, in the main, substantially similar to those which govern an English joint-stock company. Both are managed by officers under the supervision of boards of directors, who possess autocratic powers but are liable to their corporations for losses due to *ultra vires* acts or to gross negligence, and are accountable for any profits derived from taking an unfair advantage of their position.

Stockholders' Rights.—The stockholders in American corporations, like those in English companies, have no share in the management of the enterprise but have the right of meeting together, generally at annual intervals, to elect directors, amend the articles of incorporation or the by-laws, and approve or disapprove certain voidable acts of the directors. As a general rule the principle governing such stockholders' action is one of majority control, although devices for obtaining what may amount to minority control, such as the disfranchisement of certain classes of stock or the organization of voting trusts, are permissible in some States.

In addition to the voting rights which he generally possesses, a stockholder's more important rights include the right to share in any dividend paid to the class of stockholders to which he belongs, the right to subscribe to any new stock issued, to share in the assets on dissolution, to transfer his stock and to sue to redress wrongs done to the corporation where the directors fraudulently or unreasonably refuse to act.

Dissolution.—The laws of most States contain elaborate provisions for the dissolution of corporations and the distribution of their assets among stockholders and creditors. In the case of insolvent corporations, however, what practically amounts to a dissolution of the corporation is frequently obtained without resort to these statutes, either by the institution of bankruptcy proceedings against the corporation or by a receivership. Such proceedings often result in a reorganization rather than an abandonment of the enterprise.

OTHER CORPORATIONS

Special Types of Corporations.—In addition to the statutes governing ordinary business corporations, there are in most States separate enactments relating to stock corporations engaged in special kinds of business, such as banking and public service. Banks may be organized under either Federal or State laws, which in general do not differ greatly from those relating to the organization of ordinary business corporations, except with respect to a few matters such as that of stockholder's liability. The activities of banking corporations are, however, subject to a much greater degree of supervision by the State than is the case with respect to ordinary business corporations.

So, too, in the case of public service corporations, the differences between the laws relating to them and those relating to corporations engaged in ordinary business are less with respect to the manner of organization of such corporations than with respect to the amount of regulation to which they are subjected. The regulation of such enterprises is a very important part of the business law of to-day, but since such regulation depends rather upon the nature of the business than on its incorporation, it is not dealt with here.

In addition to these various classes of stock corporations, the laws of the States also provide for the organization of various non-stock corporations, including organizations engaged in business on the mutual or co-operative basis, and non-business corporations, such as charitable, educational, religious, social and fraternal bodies.

UNINCORPORATED ASSOCIATIONS

The unincorporated association is a common form of organization for other than business purposes, and is also occasionally used for the carrying on of business. When used for the latter purpose it is in effect a large partnership with transferable shares and has the serious disadvantage that it results in personal liability on the part of the shareholders. Such liability may, however, be avoided in many States by giving control of the enterprise and legal title to its assets to trustees. This latter form of organization at one time possessed certain advantages over the corporation, but recent statutes have largely done away with these advantages. (E. M. D.)

See S. D. Thompson, *Commentaries on the Law of Private Corporations* (6 vols.); Beach on *Corporations,* and the *American Encyclopaedia of Law.*

COMPANY-PROMOTING. Company-promotion is a recognized branch of financial industry, called into being by the readiness of capitalists, large and small, to take a share or shares in any kind of enterprise, from a government loan down to a mining venture in some obscure part of the earth. Some companies, notably many evolved at the time of the South Sea craze that ended in the bursting of the Bubble, had no more solid foundation than the imagination of the people who promoted them; people who traded upon the eagerness of the greedy, and the innocence of the ignorant, in drawing-up the prospectus of some fantastic scheme that might lure money from the public's pocket and direct it into the hands, farther than which it did not travel, of the fraudulent company promoter. The Limited Liabilities act, 1862, and its supplementary enactments, went far to lay down greatly needed law upon the subject of new companies, and, by slow degrees, company promotion won a place for itself amongst responsible branches of finance. Company-promoting is no longer a synonym for dishonesty and legalized chicanery. It is recognized as an essential cog in the wheel of financial machinery.

Promotion of a Company.—The founder of a successful store, desirous of turning his interest into cash, approaches a company promoter and says how much he wants for the undertaking. Valuations are made, reports drawn up, profit-statements or estimates set out, the proportions settled of what the seller, founder of the business, will accept in cash and shares, preference, ordinary, deferred shares—perhaps debenture stock—of his own property. He asks certain terms: the company-promoter, experienced judge in such matters, suggests variations. By degrees, and by compromise, agreement is reached. Underwriting arrangements, with trust companies and others, are then made. The promotion of the company has thus arrived at that stage where the public can be approached with a prospectus of the undertaking, and investors are thereupon invited to subscribe the money for the purchase of the business, provision of working capital, etc. The company-promoter may buy the whole business outright and re-offer it to the public, making a profit for himself on the transaction. The small-print part of a prospectus, which not everybody takes the trouble to study, often contains information that will enable a prospective subscriber to judge whether an excessive sum has been paid to the intermediaries between the seller of the business and the public who are invited to buy it through application for its shares. There may be a number of businesses which, bought singly by the company-promoter, lend themselves to amalgamation and to issue of their shares in a new, big concern to the public.

Promoters and Promoting.—Company-promoting fulfils a necessary part of the development of the principles governed by the Limited Liabilities Acts. It can be, and is, carried on by an individual, or a firm, or a limited company. It is a business in which the ordinary risks vary a good deal, according to the fluctuating factors of the money market; of political events, domestic and foreign; of natural disturbances. The company-promoter may find prospects of a very successful new issue are marred, on a sudden, by a revolution, an earthquake, the illness or death of a foreign ruler. Company-promoting takes into account these hazards, the unknown as well as the known, and charges its clients accordingly. There is no set scale of profit or commission. There is no set rule as to who may or may not be the promoter. Sometimes a railway or other company, with powers in hand to issue more stock, will give an order to stock exchange firms to sell, at a fixed minimum price, a particular security of its own until a certain amount has been disposed of, and the railway or company has thereby obtained the money it requires. In such a case, the services of a professional company-promoter are dispensed with, while, to instance a foreign government or municipal loan, the borrower frequently sells the whole amount to a single firm, or to three or four firms, who pay one price, and issue the loan to the public at some higher figure. The borrower is thereby secured of getting his money. The issuing firms, out of the profit they make, may pay underwriting, advertising and other expenses. The popularity of the limited liability principle, and of its application to all sorts and conditions of business, have made company-promotion a lucrative branch of business, and have accordingly drawn to its ranks an increasing number of persons though, as has been said above, it is a business by no means without its risks

Share "Introductions."—Before the World War, the usual manner for the company-promoter to approach the investor was through the medium of a prospectus, advertised in the newspapers and circulated, with a certain degree of discrimination, through the post. Since the War, there has sprung up a widespread development of the practice of doing without a prospectus, and, in lieu, of "introducing" shares to the stock exchange markets. The owner of a business which he, the owner, wishes to turn into cash, will take the necessary legal steps to incorporate that business into a public company, the shares of which he will sell outright to a buyer who advertises certain particulars, including various contracts in relation to the company, in newspapers, as being for public information only, and not as an invitation to subscribe for the shares. This is preliminary to the Stock Exchange committee being asked to give their sanction—without which nothing can be done to make a stock exchange market—for dealing in the shares. Public interest is aroused by the advertisement; possibly there may be a few other advance paragraphs that whet curiosity; the buyers of the shares can usually count with confidence upon finding other buyers who will pay a higher price if they, the prospective buyers, have the assurance that the newcomer is a sound concern. By the time that permission to deal is given by the Stock Exchange committee, the people who hold all the shares, and who therefore are the only people able to sell, find themselves armed with a long list of buyers ready-made for the opening of the market: buyers who quite commonly do not know the price at which the shares will be sold to them, but who do know that it will be a reasonable figure, as compared with the lower price that the first buyers had given for the shares. This system of company-promotion had a mild vogue before the War, but it achieved prominence by reason of the difficulties encountered during the War in the way of raising money for fresh enterprises through the medium of the prospectus. Since then the practice, despite obvious disadvantages that have evoked criticism from the thoughtful and the austere, has gained increasing popularity amongst those who have stocks and shares for sale, and who claim for this method that it is more economical than that of issuing and circulating a full prospectus.

Promotion by Offer of Sale.—The main disadvantage, and principal point for criticism, is the fact that less information may appear in an offer for sale than is contained in a prospectus. Reference to the newspapers will show, on many days in a month, the marked differences between the two kinds of invitation offered to the public to subscribe money for the stock, bonds or shares in a new company, in some new loan, or other form of borrowing. The prospectus sets out a good deal of comprehensive detail. It gives (generally in small print) the amount of money or shares payable to the original sellers, and the amount that the intermediary, the promoter, is asking from the public, the difference being, of course, the promoter's profit. The offer for sale, which is a different thing from the introduction of shares to a market, frequently takes the shape of a letter, written by someone connected with the concern—the chairman of a company, or perhaps its managing director—which letter details the same kind of information as a prospectus would give, but from which there will be omitted, in all probability, the intermediate profits that are being made by promoters or others.

Stock Exchange Requirements.—In all cases, the Stock Exchange committee, before granting permission to deal in the new issue, require the assurance that the directors collectively and individually are responsible for the information advertised. The announcements made for "public information only" are generally followed by the shares being introduced to the stock exchange market in the manner described above. The issue must be advertised in two leading London morning papers, and must give all material conditions relating to the formation of a company, as precedent to permission being obtained from the Stock Exchange committee for transactions to take place in the shares. As the object of the people who have bought the shares is to sell the latter again at a profit, it is obvious that the Stock Exchange committee's permission to deal is essential; otherwise, there will be no such free market as shall enable the sale to be easily effected. The sellers, in command of the majority of the issue, can ask what price they please. The buyers, with little to guide them except details required to be advertised, are divided between the fear on the one hand, of paying too high a price, and, on the other hand, of being left out of some good opportunity because it is advertised in a way that certainly saves money. The ordinary prospectus affords the investor a more considerable body of detail, as a general rule, than do the offers of sale or the particulars advertised as being "for public information only." (W. L.)

UNITED STATES

The rôle of the promoter is to take the new idea of the inventive mind and make it feasible for commercial exploitation. Until comparatively recently, he was the only link who brought the dreamer and the practical man together. The promoter's stock in trade is imagination, backed by enthusiasm. He must be able to open the windows of his mind to admit oblique rays of light, to which the common run of mentalities are not yet sensitive. As a figure who makes business more dynamic, more receptive to the inevitable consequences of flux, the promoter serves a useful economic function.

Of late, the financing of new ideas has not rested exclusively with promoters. Established companies have to an ever-increasing extent since the World War recognized the importance of research. Going concerns have in their laboratories consciously sought to extend the frontiers of applied science. The General Electric Company, for example, spends more on research each year than Harvard university. The Bell laboratories of the American Telephone and Telegraph Company appropriate huge sums annually to keep abreast of the newer thought in the field of communications. That relative newcomer, the Radio Corporation of America, is another leader in research. In the field of industrial chemistry, E. I. du Pont de Nemours and Company, of Wilmington, Del., is active in combining science with business. In the purely industrial field, the General Motors Corporation devotes vast energies to engineering research. Accordingly, economic progress is less haphazard than it used to be before the war. New ideas are no longer borne primarily in the minds of casual, outside inventors. To an increasing extent, new methods and new processes are found as a result of deliberate planning. New inventions spring to an increasing extent from a deliberate search in the laboratories for novel means of accomplishing new objectives.

An outstanding characteristic of the management of the best conducted American companies is an open mind. Accordingly, the individual with a new idea no longer finds his only avenue to success through combination with a promoter. Frequently, his best market is with an established company. But changes of viewpoint come gradually. Conservatism in business, though relatively less insistent, still lingers. Some pioneers must still set up new business agencies to exploit their novel conceptions. In the United States, the conditions for starting new companies vary in the 48 States. In general, a vast amount of freedom is given to promoters. Some commonwealths, like Delaware, specialize in granting companies a free hand, and accordingly even companies intending to operate mainly in other States prefer a Delaware charter. Tax exemption features in Florida have encouraged company organization in that State. Ninety per cent of American business is carried on by corporations operating under State charters. Although the nature of the restrictions vary, new companies get a large area of freedom. However, in the last decade, two score States have adopted so-called blue sky laws, which set up standards to safeguard the interests of security buyers. Under the blue sky laws, the vendors of securities must satisfy a State commission of their own integrity and also as to the authenticity of statements made concerning the new company, which is being financed. Of late, there has been a drift away from this paternalistic type of regulation in favour of the fraud law, which has been adopted in New York, New Jersey and Maryland. Under this type of legislation, the law enforcement officers do not deal with all new security issues, but specialize in those which seem tainted with fraud. The blue sky and fraud laws are State enactments, rather than Federal laws. The Federal Government operates to protect investors from fraud largely through the statutes to prevent the use of the mails for fraudulent purposes. The argument used in favour of the newer type of fraud law, as opposed to the blue sky type, is that it is less burdensome to legitimate business. Moreover, it is commonly stated that the blue sky law gives the investor a false sense of security, in that he feels that the State has certified as to the good character of a particular new offering. As a matter of fact, the State only intends to imply an absence of fraud, but to the untrained mind there is an implication that governmental authority stands behind the investment.

In dealing with new promotions, governmental authority is supplemented by the organized effort of honest business to protect its good name. "Better Business Bureaux" have been organized in 44 American cities, and their work in fraud fighting in the financial and merchandise field is co-ordinated through the National Better Business Bureau, whose headquarters are in New York city. Recently, Better Business Bureaux have been organized in Montreal and Toronto. These bureaux are voluntary organizations, supported by subscriptions of individuals, corporations and organized security exchanges. The New York Stock Exchange virtually underwrote the initial expenses of the New York Better Business Bureau, which is the largest and most effective link in the nationwide system. The better business movement originated from a realization that fraudulent practices increased the sales resistance which legitimate business faced. With the rise of the small investor during the war loans, the public became easy prey for crooked promoters. Andrew W. Mellon, secretary of the Treasury, once estimated that the American public squandered a billion dollars a year in fraudulent investments. Unless new ideas are sponsored by established companies, financing becomes difficult. The better grade investment houses are chary of novelties promoted by newcomers without a record of business success behind them. Accordingly, many inventors have been driven into the hands of security charlatans who operate in the shadow of the financial district. Recognizing the economic need of financing promising new ideas, a group of New York capitalists banded together and agreed to put up their own capital to finance new projects during the experimental stage, after which securities would be offered directly to the investment public. Out of thousands of ideas submitted, an extraordinarily small percentage was deemed feasible. Inventors are frequently deluded with the importance of their creation, and are inclined to overvalue it.

Ordinarily the promoter limits himself to finding business opportunities, and to organizing to take advantage of them. Such preliminary work includes the mobilizing of capital, physical property and management. If the individual is a professional promoter, he steps out when the company has been launched, and turns to something else. Charles R. Flint, organizer of the American Chicle Company, was not inclined to continue to manage companies after organizing them. Sometimes, as in the case of O. P. and M. J. Van Sweringen, of Cleveland, real estate and railroad operators, the genius of promoters is combined with a capacity for management. When a promoter deals with established investment bankers, the procedure resembles the English practice. Bankers make their commitments dependent on surveys by engineering concerns and audits by certified public accountants. The work of promoters in recent years has included not only the sponsoring of new ventures, but also the merging of old. In the field of gas and electricity, mergers have been almost universal. Huge holding companies have absorbed increasing numbers of operating companies scattered in various districts at home and abroad. Promoters and brokers have played an active part in persuading the old owners to sell out to the new. The development has been paralleled in industry, where the newest development has been the creation of what Paul M. Mazur, of Lehman Brothers, bankers, has described as the circular trust, which consists of a combination of companies in allied lines, like the cereal, coffee, salad dressing and imitation coffee units banded together by the Postum Company. The alleged advantage of such trusts, which are neither of the old fashioned vertical or horizontal type, is that they become more important factors in dealing with their customers, particularly the powerful chain stores. Moreover, there are supposed to be economies in the saving of executive salaries, in financing, in co-ordinated handling of advertising and in combination of sales and service forces. Frequently, new units are acquired through an exchange of stock. The deal is made attractive to the group selling out because it gets a liquid security for an illiquid one. The public, moreover, is willing to capitalize the earnings behind the liquid security far more liberally. In the railroad field, under the Transportation Act of 1920, railroad mergers are encouraged, and the restraining hand of the anti-trust laws is partially lifted. Progress in the direction of railroad weddings has been slow, partially because of vagaries in the law, but important initial steps have already been taken. These new groupings call for promotion skill of the highest order.

In the case of new companies, the promoter is frequently compensated in stock, and his remuneration depends on the success of the venture. Company-promotion has been facilitated in the United States in recent years by a new public appreciation of the value of common stocks as long term investments. The bulk of industrial financing has not consisted of the launching of brand new companies, but of the turning of hitherto close corporations, like the great department stores, into companies in which outside investors participate. In some transactions, like the sale of Dodge Brothers, to the banking house of Dillon, Read and Company, the former owners completely relinquished their stake in the company. In other deals, like the financing of great department stores, the bankers will buy for the public only a minority interest, and will insist on a continuance of the same management.

Ordinarily new untested securities are not promptly admitted to trading on the New York Stock Exchange, but are first required to go through a seasoning process on the New York Curb Market. Many new issues are unlisted and are dealt in only over the counter. New issues are most economically distributed through the established banks and investment banking houses, with a regular clientele. Newspaper and magazine advertising backs up the efforts of legitimate stock and bond salesmen. The process of financing through less well established finance houses that send out "high-pressure" salesmen to call upon strangers, has repeatedly been demonstrated to be costly and unsatisfactory. Established companies, like the public utilities enterprises, have been able in specific deals to eliminate the middle man—the banker—by selling securities directly to patrons of the companies. Many of the large public utility, industrial and railroad companies have been selling stock directly to employees. (M. S. R.)

COMPANY UNIONS. A labour organization in the U.S.A. in which the employer exerts an influence which interferes with collective bargaining is a "company union." Most frequently it is a union whose membership and officers are restricted wholly to the employees of the special establishment, and differs thus in form from the trade union which enrols in a unified body workers of the same or similar occupations in a large number of plants. Company unions grew with special rapidity during 1919–26 and after the enactment of the National Industrial Recovery Act of 1933, which guaranteed labour's "right to organize."

Since 1935 the National Labor Relations Act has outlawed employer practices which would result in company unions. Principles involved are: (1) whether organization is employer dominated at its inception; (2) the nature and efficacy of collective bargaining by the organization; (3) contrast in the employer's treatment of rival organizations; (4) whether the constitution and by-laws of the organization reveal extensive control by the employer or his agents; (5) whether employer-controlled organizations and public officials in the community have been utilized to secure control over the labour organization. In the establishment of these principles the board followed the assumption that the formation and administration of labour organizations were the concern of the employee and not of the employer.

Since 1937, when the National Labor Relations Act was declared constitutional, company unions have been on an "experimental" retreat. Employers have been attempting to adapt them for legitimacy under the law. Among the techniques of adaptation are reorganization of old company unions, or forming new ones, into "independent" unions; readaptation of company unions by the introduction of dues-paying, written agreements, holding meetings outside of company property, and by incorporation. However, certain basic features, like the discouragement of "outside" unions and membership in only the plant, or plants, of the single company, are still retained. (*See* CLOSED SHOP.) (S. PE.)

COMPARATIVE ANATOMY is a term that is usually applied to the study of the structure of diverse animals, intended to bring out their differences and resemblances. It arose as a separate science in the 16th century, although the most important generalization which has resulted from it was tacitly assumed by those earlier anatomists who, unable to dissect human bodies, made observations on pigs and other domestic animals, applying their results to man. A comparative study of anatomy actively pursued during the 18th and early part of the 19th centuries, led zoologists to the discovery that all animals might be placed in a few great groups, distinguished from one another by fundamental dissimilarities in structure. Of these groups, that which attracted the greatest attention was the group Vertebrata. It was soon realized that all mammals resembled one another in the fundamental structure of their skeletons, that the differences that were discernible could plausibly be regarded as explicable by the loss or alteration of parts, *e.g.*, that the hand of a horse differed from that of man by the complete loss of two outermost digits, and such reduction of the second and fourth that the third alone remained functional. Observations of this type led to the theory of "architypes" invented by Oken, and accepted and much extended by R. Owen.

Comparative anatomy formed the foundation on which the theory of evolution was and is based. Until the community of structure which exists between animals often widely different in appearance, had been discovered, no reasons whatsoever existed for doubt of their separate creation.

Comparative anatomy forms the basis of all work on the classification of animals. The larger groups are established on a basis of knowledge of the complete structure of the animals included in them, and the differences which are used to separate the smaller groups, genera, and species, although they can very often be observed in surface view, are really anatomical in their nature.

The study of comparative anatomy led to the development of the conceptions underlying the terms homology and analogy, and an attempt further to discriminate between these two caused comparative anatomists to begin the study of embryology in order to determine the homologies of structures from their mode of origin. Such combined anatomical and embryological studies have made comparative anatomy, especially as regards the vertebrates, an active branch of zoology, whose aim is to elucidate the evolutionary changes undergone by the various groups of vertebrates and by their organs and organ-systems. Among invertebrates, comparative anatomy is of less importance because of the lack of resemblance between major invertebrate groups. (D. M. S. W.; X.)

COMPARATIVE ETHICS. The comparative study of ethics is concerned with the rules, principles and ideals guiding or inspiring human behaviour, technical rules for sufficiently obvious reasons excluded. Its field is thus nearly coincident with that of philosophical ethics. But while philosophy is at bottom interested in the ultimate validity of moral conceptions, comparative ethics is primarily concerned with the fact that, valid or invalid, they exist, that they play their part in the life of the individual and society and have their affiliations with other factors in human development. It is as much interested in their differences as in their points of agreement, in the conceptions which the student may think absurd or outrageous as in those which he approves as sound, in the customs of the simplest peoples as in those of the most advanced civilizations. Whether the question of validity can in the end be excluded from this study has been a matter of controversy. Some would think that in the last resort it is required as the underlying standard of comparison. Others maintain that there is no such standard and that comparative ethics can very well get on without it. Some seem even to imagine that comparison itself gives the standard, since it shows what ideas prevail and success is the only measure of worth. But such optimism cannot be maintained. The lower ideal may make the stronger appeal to prevailing sentiments, and if prevalence is itself the test we get varying standards with varying times. If it is contended that what prevails anywhere must be best for that time and place, this is contrary to fact, since it is often clear enough to the observer or historian that accepted standards work injuriously, even ruinously. More careful writers agree that comparative treatment does not of itself yield a standard of rationality, but are not agreed on the question whether such a standard is (*a*) attainable, (*b*) required for the purposes of comparative ethics. On the first question it is assumed in this article that such a standard is attainable, and is implied when we use terms like "higher" or "lower" "progress" or "deterioration" in morals. But in strictness its elucidation is the problem of philosophic ethics and will not be attempted here. Nevertheless comparative study both points the way to the philosopher and, in exhibiting the operation of moral ideas in social life, provides a broad basis of experience as the test of his theory.

In any case we should not exaggerate differences. Those who affirm and those who deny a "truth" in the ethical order may follow the same path for a long distance, if not to the end. The same data are before both parties, the same record of customs, laws, religious requirements and moral codes, and they may be compared as historical facts without deciding on their relative values. We may work out a series of historic changes or compare the variations of moral outlook characteristic of one culture with those of another. We may enquire into the causes of such variation and investigate the influence of economic and other factors, all without resort to a philosophical valuation. We may even (and this is important) select any given order of moral ideas as a standard of reference and show the deviations of other accepted orders therefrom without assuming its superior validity. A very simple code is of value for such a purpose, because it enables us to mark the kind of deviations which arise with the greater complexity of life. The code of our own day is also useful (so long as we do not covertly and uncritically assume that it is the highest), because, good or bad, it is the product of the civilization which is latest in point of time and beyond question the most developed in certain forms of human achievement. Combining the two points of reference we can enquire how far ethical codes are correlated with the advance of general culture, a question which, wherever philosophic truth lies, is of great intrinsic importance. This does not affect the right of those who hold to some system as the ideal and the truth to make it the basis of another series of comparisons, and how far the two schemes of comparison would coincide or diverge is a question which for them is of high interest.

The Special Problems of Comparative Ethics.—Thus, whatever our attitude to the final problems of philosophic ethics, we seem to have something to learn from the comparative method. Let us try to state our objective in general terms. We are confronted with divergencies relatively slight as between individuals of the same society, but often very material when we compare one society with another, one class with another, one epoch or one culture with another. Comparative ethics may be said to have taken its rise from the recognition of these differences, and to consist essentially in the endeavour to interpret them. The first question which it raises may be put in this way: (1) Is there behind the specific differences some generic principle common to human societies; (2) if so, are we to think of the differences simply as phases in the development of the common principle or are they due in whole or in part to other factors in social life, economic for example, or religious or intellectual? Some of these appear from the outset to be much more closely bound up with the ethical than others, and it is (3) for comparative investigation to examine the different modes and degrees of correlation and so determine the place of the ethical factor in the cultural history of mankind. In so doing it will have (4) to consider whether a real ethical development is discoverable, and if so how it is related to other developments in society. To the question how far this last point necessitates a philosophic analysis we will not add anything to what has been said above. It is on any view clear that comparative investigation is essential to any theory of development.

Moral Elements Common to All Known Societies.—(1) On the first question comparative investigation has reached some definite results. It shows that as far as our records go the acceptance of some code of conduct is co-extensive with humanity. It has often been questioned whether every society has its religion, but if a very wide induction has any validity it is certain that every society has its code. If exceptions are to be found at all they are not in what appear as the most "primitive" societies but in cases of decadence, where the long-established code of one culture is broken and not replaced by the irruption of another. Everywhere in stable society there is a code which bids men do this and not do that. The codes differ a good deal and the reasons rendered for them are sometimes obscure or to modern minds absurd. Among the simplest peoples the moral and the customary, the legal, the magical, the religious, are barely, if at all, distinguished, but there are customs or laws, oral or written, prescribing or forbidding definite classes of action, upheld by the impartial onlooker and the general judgment of society, which visits a breach with reprobation if not with specific penalty. These are the essential elements of a working moral code and have to be recognized as such, even if some parts of the code are condemned as defective or, as judged by some other standards, immoral.

This is not all. If we run the gamut of culture from the highest to the lowest, we shall find that the codes cover the principal relations of social life. They deal with person and property and specifically with sex, imposing restraints on behaviour which from our point of view may be just or unjust, but which are certainly working rules. These rules rest on, and in turn support, a certain community of life, extending beyond the simple family of parents and young children, where natural feeling might be a sufficient guide. It is true that the moral purview is often seriously limited and that behind it and sometimes even within it economic or political forces or perversities of religious or magical ideas may work havoc with human relations, but such failings do not prevent the code from being effective in its own way and on its own conditions. In particular, it is highly effective among the simplest peoples that we know. We do not within the field of comparative ethics find a people without a working code, and if we are dealing with an evolution, it is within this field not an evolution of morals out of something else but an evolution within morals of clearer, more comprehensive or more powerful principles, which are better fitted to cope with the problems multiplied and intensified by the complex and many-sided developments of human activity.

The Moral as an Aspect of the Rational Development.—This generalization must not be taken for more than it is worth. It does not apply beyond the field of our observation. We know nothing of the social organization or ethics of really primitive men, *a fortiori* nothing of the intermediate forms of life which must have intervened, if we accept the evolution hypothesis, between man and beast. We confine ourselves rigidly to the statement that comparative ethics knows of no pre-moral stage. But if we go beyond comparative ethics to the behaviour of the higher animals and combine the study of institutions with that of psychology we shall discover a perfectly feasible line of advance. On the one hand the simplest societies that we know consist of small groups of families related by the combined links of descent and intermarriage. On the other hand the higher animals give evidence of strong parental attachment and in many cases of herd sympathies as well. Fundamentally their instincts are as much race-preservative as self-preservative in function. If man evolved from an animal, the central psychological change which came about was that, as cause and effect of language and social intercourse, he acquired the rational power of relating the instincts and emotions of the moment to general and permanent needs, could see the past and future in the present, and so transmute the impulses of sex and parenthood into a permanent family tie and the pack instincts into a code of mutual loyalty and co-operation. Morality is essentially the rationalization[1] of primary impulse-feelings, and we find the codes of the simplest peoples to be just such as would be achieved by the rationalization of simple impulse-feelings by a simple intelligence. We do not witness the birth, still less the prenatal history of morals, but what we find is what we should expect as the product of the known causes in operation.[2] In becoming rational, man became moral.

Intimate Relation of Moral and Religious Development.—(2) and (3) So far the generic principle. What of the variations? The social code, always embodying a certain morality, is deeply influenced by religious, economic, political and even environmental factors. As to religion, the attitude that men assume to the agencies controlling human life, its relation to morals, is so close as at times to approach identity. The divine is at certain phases almost an incarnation of the moral law. In other phases the relation is not so close. In some of the lower cultures the spirits recognized are non-moral. In higher phases again morality is often critical of religion, and claims for itself the ultimate sovereignty in the world of conduct. All through there is a possible ground of difference in that morality is essentially concerned with the ordering of human life, religion with the ordering of the universe in which human life is included, and though in the remoteness of final truth the part must harmonize with the whole, in the partial truth that men attain this harmony is yet imperfectly understood and historically the two orders have certainly not always been in sympathy. Men's notions of religion, as above defined, depend not on their moral standing alone but on any or all of their intellectual attainments. For beliefs about the governance of the world seriously affect the view of what is necessary to personal and social well-being, and therewith the moral order. Intellectual advance makes in the end for truth, but may import fresh errors on its way. A tribal god, for example, represents a certain advance in definiteness of conception and even a moral advance in the direction of social unity, yet he may be a Moloch. Human sacrifice is not found in the simplest societies, but rests on conceptions representing a certain advance. It must be subjoined that a scientific conception of the universe may become, as in our own time, a basis of resistance to the developed social conscience, and serve as a justification for unrestricted selfishness. In sum, neither religion nor philosophy is identical with morals and may be in conflict with them.

Influence of Economic and Political Developments.—The political and economic situations of a people again are intimately related to its social code. We may believe that there is a moral principle in the individual, but we cannot fail to realize that the applications of a principle, the working shape that it assumes, are taken by the average man from the society in which he finds himself, and taken without criticism. He distinguishes right and wrong, but what is right he learns, as he grows up, from his teachers and companions. The right for him is what he comes to expect and what he knows will be expected of him. That means that it will be defined by the relations of men in the society to which he belongs and these relations are determined by a complex of political and, more pervasively, of economic relations, and in both of these the physical environment, taken in conjunction with the available skill in dealing with it, is a serious factor. These influences condition the relations of men, shape and reshape them, and the customary system of any period, though it may resist changes, is in the main overborne by the constant pressure of needs. The actual institutions of a society are the results of an adjustment of human relations to the needs of life, and a solution, good or bad, of the problem of living

[1]The word is used in its legitimate sense, in which it means the explicit, consistent, generalized expression of an antecedent impulse, not in the spurious sense now popular in which it means the sophistical justification of an impulse by something plausible but extraneous.

[2]The rise of fundamentally new impulse-feelings is not excluded at any stage, but we should not postulate them so long as we can explain the phenomena by combinations or modifications of elements already known. If any quite new instinct or quasi-instinct arose in the early evolution of man, it was probably of the nature of some restraint on the sex impulse and especially connected with aversion to intercourse between the nearest kin. The controversies that arise on this point cannot be entered into here.

together under given conditions. In higher stages of culture men begin to pose this problem consciously and seek to remedy faults in the existing scheme of solution, or to resist changes making for its deterioration. But in the main social change proceeds on its unreflective course, and in so doing governs rather than obeys the moral conscience. In fact, both political and economic developments involve differentiations and divisions, often gravely affecting the code of moral obligations.

General Character of Ethical Development.—(4) In the end, however, the moral principle reasserts itself by an enlargement of the common good and a fuller insistence on primary rights and duties. Superficially the order which emerges out of a conflict may resemble that which has never been assailed, but in spirit it is quite otherwise. The conflict here in question is not one in which we expect to find a decisive victory for good and all, for the development of human life on all sides goes forward, and every fresh step brings new occasions of discord. To balance such opposites, to select the good in each, to purge the contradictions, refine the crudities and mould the divergencies into a wider harmony, is the standing problem of social ethics, and its solution, with the clarification of moral ideas, the widening of sympathies and the fuller appreciation of human purpose which it involves, is what is meant by ethical development.

Ethics of the Simplest Cultural Stages Known.—Any attempt to sketch this development, even in the roughest outline, encounters great difficulties. The available material, though voluminous, is patchy. Of the civilized peoples we have partial (on the side which interests us, very partial) histories, and their beginnings are lost in antiquity. For the lower cultural stages the only evidence of any great value is derived from the study of contemporary or quite recent peoples. Here materials for history run very short and end in abysses of conjecture. Essentially we are not tracing continuous development, but comparing cultures, reached often on divergent lines, subjected to ubiquitous cross-currents of culture-contact, whereby the products of higher and lower stages come to jostle one another in the same people. Even the most untouched primitives have their long history behind them, a history which has brought some of them to the pinnacle of their own special arts and has given ample time for the adjustment of their institutions to their mode of life. Difficulties and complications of this kind must be borne in mind when we start, as, after all, we must, with peoples as we find them in their various cultures as they stand. We begin then with the lowest grades known, where food is gained from day to day by gathering vegetable products and hunting, or, more rarely, fishing, a state in which we find a large number of peoples now slowly or swiftly passing to extinction under the influence of civilization. There is the great group of Australian aboriginals, and there is a number of scattered peoples in the Malay Peninsula and Archipelago with a few representatives among the most primitive of the Indian hill tribes, in the Andaman and Philippine Islands, in the Central African Forest (Pygmies), in the Kalahari desert (remnants of the Bushmen) and in South America (Botocudos and Fuegians). If we omit the Australian aboriginals, the remainder, in spite of their very wide diffusion, present such remarkable similarities that they have been thought to be the scattered remnants of a race once spread over the whole world. But the suggestion cannot be sustained. If there were an original unity the world over it was a unity not of race—unless in a sense too vague to be of any value—but of culture. Our concern, however, is with their actual culture which presents variations indeed, but variations within a striking identity. They live in little groups of anything from a couple of dozen to five or six score of men, women and children (larger numbers probably represent in the main temporary combinations), generally with a leading man whose powers are what he makes of them, and they hunt and gather in a territory of known boundaries, which is either peculiar to each little group or perhaps common to a number of friendly groups. Unauthorized trespass on this territory is resented, often to the death, and that is the cause of feud with the white man who was unable to grasp that the land was group property. The family is by preponderant practice but rarely by rigid rule monogamous, and the wife has a position which varies but is often one approaching equality and in general better than that which obtains among the cultivating or pastoral peoples. Marriage is stable after the birth of children and sometimes it would seem virtually indissoluble (Vedda, perhaps Andamanese), but conjugal fidelity is not always rated high (Ituri Pygmies). Parental and filial love are strongly marked and the old and weak are cared for unless in times of distress (Bushmen). By practice if not by rule the little groups freely intermarry and courtship is free, subject to varying degrees of parental influence. There is private property in such things as weapons, tools and the hut, and the wife has her own. There is even a queer form of private ownership of trees, wild honey and the like which turns up in oddly coincident forms in very remote regions. Whether this points to identity of origin is doubtful, but an odd thing about it is that it amounts to very little, for not only is the land common to the group, but its produce, the food, is almost always shared and no member of the group who is present goes without.

Peace and Order.—With regard to peace and order we must discriminate. The Semang are peaceable, and in one of their tribes, the Djahai, both murder and theft are said to be unknown. The Punans of Borneo are said not to fight one another unless egged on by stronger tribes. The wild Kubu have never known war. On the other hand, feuds between groups were common among the Andamanese, and blood revenge is said by a good authority to be the basis of the Bushman's code. The Central African Pygmies are renowned fighters under negro leaders, but among those untouched by outer influences feuds between groups seem to be unknown, and the occasions for private vengeance very rare. Some Fuegians fought over trespass, and so, may be, did the extinct Tasmanians. The Philippine Negritos, now very peaceable, seem from the Spanish records not only to have fought doughtily against the encroaching Indians and Spaniards, but also on occasion among one another. The Kubus and Punans, innocent of organized war, know private revenge. In general while crime is rare there is no means of redress outside the group except vengeance, and even within the group the evidences of impartial criminal authority are, for the "wild" tribes, very slight. Adultery and trespass were the two main causes of quarrel. To round off the picture we must point out that the little groups were innocent of slavery, cannibalism (one exception), human sacrifice, prostitution, polyandry (with rare exceptions), large scale polygamy, infanticide (with a few exceptions, *e.g.*, the Bushmen and perhaps the Fuegians) and degradation of women—in fact of the vices which we have been taught to associate with savagery and which are in fact realized among peoples of more advanced material culture. The picture is one of human society with the barest minimum of organization, accumulation and differentiation, and if it only presented the rudiments of cleanliness as well as godliness it would be far from unpleasing.

At the lowest it is quite clear that the moral order at this stage is free from the grave defects which soon become apparent as we follow the political and economic advance. To what is this due? Recent missionary investigators lay great stress on the religious factor wherein they find the elements of ethical monotheism, or something nearly amounting thereto. To examine this opinion would be to embark on endless controversy. All that can be said here is that the best evidence is derived from the Semang. Here, and perhaps among the Fuegians and African Pygmies, we find the fear of a power associated with thunder who kills people. Generally he kills for certain offences, mostly of a morally indifferent sort, but including, among some Semang tribes, adultery (and seemingly practices which might give rise to incest), and in one case murder. If this is a beginning of ethical monotheism it is certainly rudimentary enough, but if it should turn out to be in fact a part of the original Semang tradition we must admit a root of ethical monotheism not previously ascertained.

The Australian Aboriginals.—The other great group of gatherers and hunters, the Australian aboriginals, present a less amiable picture. In important respects the social structure is similar to that described, but there is a complex of marriage prohibitions which has never been satisfactorily explained, but at any rate serves to keep different groups connected by ties of affinity. The position of women is in general less favourable and polygamy is more common. It would seem, however, that the alleged group marriage is rather a logical construction of the investigator than an actual institution. Infanticide is known and so is cannibalism. The idea of blood vengeance underlies the whole juridical system because deaths are imputed to witchcraft and, though peaceful relations are in general maintained between neighbours, it is by an elaborate institution of regulated combats and ordeals in which every effort is made to avoid serious bloodshed. The fear of the feud, however, is always in the background and the reality is far from being unknown. Bloodshed is certainly on a very small scale, but it is to be remembered that we are dealing with groups which can afford to lose very few members. There was no general state of war, but neither was there a state of secure justice and peace.

Advancing Culture and Social Differentiation.—As we ascend from the gatherers to the higher hunters (a few of whom, more properly fishermen, are of relatively advanced culture) and to the lowest and thence to the more advanced agriculturists, or alternatively to the lower and higher pastoral cultures, the organization of society grows. The tribe, originally a barely definable unity, acquires a government and perhaps incorporates other tribes and becomes a little state. Within it the family enlarges into the kindred group which gives organized protection to its members but, as a consequence, often threatens to dissolve society in blood feuds. However, these are brought into some order by the mechanism of composition for crimes, and, as we move towards the upper end of the scale, we more frequently find a government assuming responsibility for the protection of its subjects and controlling or even suppressing vengeance. On the other hand, fighting takes a more organized shape and, by the side of feuds or in place of them, we get real wars which require at first an occasional, but later on a standing, military organization and in which the treatment of the vanquished is often severe. The captive women become inferior wives or concubines, reinforcing the tendency to polygamy; the men may be "adopted" or killed, but with the development of agriculture they become useful as slaves and raids are even organized to obtain them. Cannibalism is not rare, though less common than has been popularly supposed, and human sacrifice is prompted by magicoanimistic conceptions of the effect of blood upon fertility. The chief's power is increased and by his side appears a nobility or upper caste to whom in many cases the ownership of land is restricted. Apart from the institution of slavery we more and more frequently meet with a differentiation of ranks and the contrast of wealth and poverty sets in. Religion, mainly animistic, although admitting of some greater gods, has little to say to morals, and the taboos which protect property and the automatic retribution of the broken oath or the beggar's curse have more of magic in them than of religion. Politically society is organized more efficiently and on a larger scale, but at a cost which, when we compare the resulting order with that of the simplest peoples, seems excessive. On the whole we must admit a moral decadence if we take the series of cultures as successive in time. The truth seems to be that among the gatherers and hunters the lack of all differentiation, the utter absence of ambition, of desire to accumulate and to improve the position of the people, removes the most potent causes of strife and prevents the emergence of anything in the nature of oppression. The wholesale cannibalism and human sacrifice of relatively high cultures could not arise unless there were a helpless population with whom the stronger could deal at his will. Polygamy from first to last seems in the main a matter of wealth and social position. It is not easily tolerated among equals, particularly where women are so few that, if one man has two wives, another must have none. In brief, the early moral code can deal not amiss with uniformity and lack of effort. It is quite unable to cope with the inequalities, the ambitions and fears which are the product of energy of movement.

The Early Civilizations.—In turning from the uncivilized world, best known to us from contemporary or recent evidence, to the peoples who have a recorded history, we have to hark back some 5,000 years or more in time. The character of our evidence changes. We have written codes of law, sacred books, ethical and philosophical treatises. We have large stretches of continuous history in distinct countries and can trace development or deterioration in time and read the narrative of the impacts of culture upon culture. What we call civilization carries the organization of life, of which we have seen the beginnings in barbarism, to a higher pitch. Industry, including improved agriculture, makes the position of man in relation to nature relatively secure, renders the systematic cultivation of arts and sciences a possibility for the more prosperous classes and admits the growth of population and the formation of dense aggregates at trading, political, religious or military centres. States are organized at first, it would seem, on the relatively small scale of the Egyptian Nome, the Sumerian city state, and, perhaps, the early Indian tribal republics, and their tendencies to internecine warfare are apt to end in larger consolidations under the more successful centres which, in their turn, establish vast but insecure empires over peoples of different race and culture. But throughout the earlier part of this history, indeed through the greater part of Oriental history, the stability of civilization seems due rather to the persistence of the archaic organizations of the patriarchal family, the clan and the village, than to the kingdoms or great empires superimposed upon others. The village husbandman goes on with his work—"agricola incurvo terram dimovit aratro"—brings up his children and grandchildren and follows the cult of his ancestors and household gods while empires rise and fall around him, knowing the central power in the person of the tax-gatherer or the corruptible magistrate to whose court, even if wronged, he obstinately prefers the decision of the family council or the village elders. It is not our business to deal with cultural or political history, and, even if we were to confine ourselves to those laws and institutions which are of special interest to ethics, we should find too many differences of detail and too many points of doubt and obscurity to justify summary treatment. So far as the earlier Oriental history is concerned we must confine our attention to a few salient points.

(1) The union of peoples with divergent customs required a codification of law, which is now no longer the spontaneous product, universally accepted, of a homogeneous group, but relies on kingly powers for enforcement. The earliest code that has come down to us is that of Hammurabi, dating from about the close of the third millennium before Christ. Ethically it contains much that is barbaric in the way of retaliation and vicarious punishment, but it contemplates organized courts of justice with rules of procedure and provision for documentary evidence. It protects the debt-slave and limits his servitude to three years, regulates divorce and recognizes a concubine by the side of the fully legitimate wife (more than one such wife being admissible, it would seem, only in some exceptional circumstances). Unfortunately we have no such code of Egyptian law, and we have no evidence of self-help or retaliation as recognized customs, but find organized justice in being in the earliest dynasties. The position of women is known to have been good in many ways, both in Egypt and Babylonia (in the former country in particular it surprised the Greek travellers), but it would seem that the Egyptian bride had to protect herself against the introduction of other wives by a clause in the marriage contract, and the contracts we have are of a late period. Slavery existed both in Egypt and in Babylonia, but it would seem that the majority of the cultivators were personally free, though subject to arbitrary treatment by king, feudal noble and tax-gatherer. Slaves were obtained in large numbers for great works by successful wars or simple slave raids. Prisoners were also sacrificed in Egypt, though neither under the Pharaohs nor under any of the rulers of Sumer and Akkad do we meet with the exaggerations of wholesale barbarity which were the boast of the Assyrian kings.

Early Ethical Documents.—(2) Ethically interesting documents come down to us from both Egypt and Babylonia—from the latter a series of incantation tablets, giving long lists of sins which might involve men in the meshes of demons or witches. The "sins" are partly ceremonial but many belong to the class of offences condemned by commonplace morals, the most interesting ethical feature being that their consequences could be avoided by such magical means as burning them away. With these tablets we may compare the two famous "negative confessions" in the *Book of the Dead,* a list which again is commonplace when not utterly obscure, the interest lying once more in the fact that a formal repudiation, an address to the god specially cognizant of each sin, and a claim of power based on knowledge of the right names of the deities concerned, are the requisites of safety in the trial to which the deceased is subjected. It is here, however, that, primitive as the procedure of the court may be, we have far the earliest systematic exposition of a trial of the dead, and as to the substance of the proper life, it is worth noting that the repudiations end with a claim of merit. "I have given bread to the hungry, and water to the thirsty, and apparel to the naked, and a boat to the shipwrecked mariner." With this assertion of beneficence we must compare the repeated boasts of feeding the hungry, considerate treatment of widows and so forth, on tombs of the Old and Middle Kingdoms.

(3) We have also from Egypt the first moral treatises, such as the precepts of Ptah-Hotep dating from the Middle Kingdom. Their mild platitudes recommend a certain moderation in life, submission to authority and restraint in dealing with inferiors, but on the whole constitute an extremely dull prologue to the later wisdom literature of the Hebrews. There is, however, a real fire in "The Peasant's Complaint" (also Middle Kingdom) which is a sustained invective against the law's delays and the magistrate's neglect.

(4) In the cult of Osiris and the judgment of the dead, Egyptian religion seems to be feeling its way to some relation to ethics. During the 2nd millennium B.C. its own structure began to be criticised. The multiplication of gods had gone too far and the well known attempt at solar monolatry by Akhenaton represented one form of reaction. It does not however appear that the new monolatry had any special interest in ethics and the attempt to establish it was defeated once and for all. The other line of criticism was more subtle and successful, consisting in a mystical identification of the many gods as names, forms or manifestations of one and the same spiritual principle. This tendency is frequently present in religious writings of the new kingdom and may be taken as the best expression of religious thought in Egypt. Whether it was the starting point of the ethico-religious development in Asia from the Jordan to the Hoangho from about the 8th or 9th century onwards there is no evidence to decide.

Ethico-religious Thought in India.—In any case it would appear probable that there were connecting links between movements which took their rise during this period in India, China, Iran and Palestine and finally in Ionia. It is true that they are spread over some centuries, but 200 or 300 years are but a small fraction of the long history of civilization. It is equally true that there is little surface resemblance between the mysticism of the Upanishads, the hard outlines of Zoroastrian dualism, the practicality of Confucius, the ethical monotheism of the prophets and the philosophy of the Greeks. But there is a deeper and far more impressive identity in the stir of thought, and thought about ultimate questions and their bearing on the life of man, which is apparent in them all. Things were said and written in this period which are still of interest; questions were raised which are still unanswered; foundations were laid on which we are still building. It is the real birth-time of thought and it cannot be by mere coincidence that the germination took place at no distant periods in very distant places. Possibly the real beginnings were in India, but in the obscurity of all questions of date it is impossible to speak with certainty. Recent criticism refuses any very high antiquity to the "Vedic Age" and seems to bring the compilation of the Upanishads to within 200 years of the birth of Buddha. Some beginnings of speculation are, however, to be found in the Vedas themselves and are the more striking because they express for the first recorded time man's sense of utter helplessness in the presence of the problem of origins. "Death was not there, nor immortality; there was no distinction of day and night. That One breathed, calmly, self-supported, there was nothing different from or above it . . . from what this creation arose and whether anyone made it or not—he who in the highest heaven is its ruler, he verily knows, or even he does not know." Contrasting such language with that of an ordinary Vedic hymn to Indra we feel that we have passed into a different world—a world in which men are beginning to think and experience for the first time what it is to seek a solution and find none.

The hymn quoted is no unfitting prelude to the constructive efforts put together in the Upanishads where the central conception is that the Reality at the base of all experience is spiritual—smaller than the kernel of a canary seed, but greater than the earth and the sky, greater than all these worlds. This spirit is "the self within my heart," who, though myself, is yet so hard for me to find that I must go through austerities, make sacrifices and, above all, study the law and the truth in order to arrive at that inner knowledge. Ethically the important feature is the conception of life upon two planes, the lower one of the workaday world and the higher reserved for the ascetic and recluse and revealing his union with the spiritual principle of all reality. The system is (in its most orthodox expression) metaphysically monistic and ethically dualistic, and the conflict or adjustment of these divergencies may be said to have dominated all later Indian thought and to have deeply influenced the thought of the West. One line of development may be briefly indicated as of ethical importance. The monistic principle pressed far enough reduced the whole world of ordinary life to an illusion and along with it all plurality, including the distinction of self and self. In reaction from this the Sankhya system, without leaving its anchorage in Vedic orthodoxy, asserted the reality and the permanence, *i.e.,* the immortality, of the personal self. This doctrine could take concrete shape by allying itself with aboriginal non-Vedic notions of transmigration. The self lived before this birth and would live after death in one or other of the transitory forms which did not affect its eternal being. Nevertheless the manner of its life in each incarnation left its effect, the Karma, which determined the subsequent incarnations in such sort that ultimately, though it would seem with no regularity of succession, one paid for one's sins by a lower and was paid for one's virtues by a higher incarnation. This doctrine could be used to justify the slowly germinating distinctions of caste which arose from the union of a multiplicity of tribes, many of low culture, under the conquering Aryan and became by degrees the dominating fact in the Hindu social system. Practically and legally the caste system maintained and fostered divisions and distinctions incompatible with moral unity, but in theory it gave concrete expression to the original principle that life in the highest and lowest is fundamentally one. He who is now a Brahman and godlike, if not actually a god, may have been and may yet be again a pariah, and for that matter an insect. When this conception is pressed as in Jainism all life becomes sacred. The doctrine of Ahimsa, or harmlessness to all that lives, takes the centre of the ethical stage and in milder forms is to influence all subsequent ethics in India.

Buddhism.—But metaphysical discussion rotating endlessly round the same insoluble questions is sure to germinate not only new dogmas but simple scepticism as to ultimate truth. Men who are not content with negative results then fall back on the experience of life and its actualities of happiness and misery. This was the track leading to the Buddhistic system in which in its original form the permanence or substantiality of things was declared to be beyond the reach of our knowledge. All that we know is transitory. Not even our self or our soul is substantial. But life is suffering, and we can in our experience trace the root of suffering, which is desire. Moreover we can extirpate desire not by the violent reaction to extreme austerity but just by abandoning every selfish impulse, which we can learn to do by cultivating restraint of conduct and the higher thought which expresses itself in love and compassion for all that lives. What then of future existence and the doctrine of transmigration? This was too deeply ingrained to be set aside, but an accommodation was reached by regarding Karma not as itself a quasi-substance ingrained upon a substantial soul, but as a mode of causality whereby the doings of one life are carried over into another. The manner of this transference was left wholly unexplained, but one thing was insisted on, that the working of Karma was maintained entirely by desire. Cut this root and the Karma would die. Its Nirvana or total extinction was open to anyone who would tread the noble eightfold path of the Buddha to the end, which would involve cutting himself off from household cares and living not with austerities but with restraint, as a mendicant monk.

Religion in this form is little more or less than ethics. It propounds a life to be led and a salvation to be won therein. This life is that of a higher plane, only attainable by resolutely abandoning the ordinary level of human interests, and it offers no reward except the surcease of unrestful passions and accompanying remorse. It is not obedience to religion, it is religion itself; not a consequence of dogma, but an interpretation of experience; very negative in regard to practical aims, it yet has its positive side in the universalism which would recognize no real distinction of Brahman and non-Brahman, and which fitted it for its place as the oldest of the world religions. But the delicate poise between practicality and mysticism could not be maintained. Buddhism had its day when Magadha united the bulk of the peninsula in one empire and King Asoka set up the pillars intended to educate his people in the mild rules of his faith; but stronger and ruder forces broke upon it, driving it from the land of its birth, and from within transforming it into a theistic system with the founder as a god and reincarnation restored as the centre of belief. In this evolution we cannot attempt to follow it here.

Taoism.—A more prosaic but more practical ethics had its origin in China almost contemporaneously with the teaching of Buddha. Confucius defined his position in the first place in opposition to animistic conceptions and secondarily in opposition to the mysticism of the Tao. Taoism had its roots rather in magic than religion and has tended always to return to the pit from which it was digged. Its traditional founder, Laotse, formerly described as an older contemporary of Confucius and criticized by name in the Confucian records, is now thought of as half legendary and of quite uncertain date. We cannot therefore speak with any certainty of the affiliations between the remarkable Quietism developed in the Taoist schools and the doctrines of universalism, restraint of self and harmlessness that we have seen in India. "The sage governs by ridding the heart of its desires" is the very essence of Buddhism. "The soft and the weak overcome the hard and the strong" goes a little farther. On the other hand the parallel is close between "I would return good for good. I would also return good for evil," which we read in *The Simple Way,* and "Let a man overcome anger by kindness, evil by good," which is a verse from a Buddhist Sutta. It is a pity that such phrases should have degenerated into platitudes, for as a fact they express an exceedingly subtle law of moral causation which needs the cool scientific explanation and definition which it has never received. At best in quite modern times the underlying truth has been approached from different sides in the appreciation of the value of error to truth, of the stability of unions founded on freedom, and of the backstroke of success in war upon the victor.

The Chinese Classics.—Laotse, however, pushed his ideas to an extreme from which the practical sense of Confucius revolted. A Conservative Radical, he stood for the integral Chinese social tradition, in particular for the solidarity of the Patriarchal family, without the supernatural support of the spirit world. The social order was good in itself and the moral life which served it honestly was good in itself and needed no reward. Moral innovations are not sought, so what Confucius has to tell us sounds a little too obvious, but the Golden Rule was no platitude when he first enunciated it, and his later disciples, particularly Mencius, had a good deal of serious criticism to make on the working of political institutions and did much to develop the national dislike of militarism. In any case the autonomy of ethics, its emancipation from theology and from political authority, the conception of a good social order as an end in itself and of its service as inherently the best life for the individual, are as much Chinese as Greek in their origin, and have had a wider and more continuous influence in China than in the West.

Ethical Teaching of the Prophets.—When we turn from the Far East to the Western World we find it true, when all indirect and secondary influences have been allowed for, that the main sources of European ethics and religion are Hebrew or Greek. During the period that we have been considering, the Hebrew prophets set up a national deity for exclusive worship in opposition to the native polytheism. With this monolatry they came to associate something more important, a humane social code for all Hebrews which they actually succeeded in incarnating in a new code of law, and they finally extended the authority of their God, now conceived as a spiritual being to be worshipped in spirit and truth, from the land of Palestine to the surface of the earth and from the surface of the earth to Heaven and Sheol. We have vague outlines of a supreme god among the simpler peoples. We have seen such a god punishing certain acts, including some in which morality is concerned. We have had no such clear-cut personality controlling a systematized moral law, nor do we find anything approaching it in the cult of Atum, while the Indian philosophy sought spiritual unity in an immanent principle rather than a transcendent personality. In the light of these comparisons the work of the prophets, which is too well known to need detailed illustration, stands out as one of the original contributions of the world and the religious source alike of Christianity and Mohammedanism.

The Development of Ethics in Greece.—On the ethical side however this influence is fairly matched by that of the Greek thinkers who first turned the light of systematic analysis on the passions of men and the rules that bind them. The far-reaching scepticism of knowledge, religion, morals and law which developed in the 5th century was met by a great effort of reconstruction in which a thoroughgoing attempt was made to place the obligations of man as a thinking and social being on the basis of a reasoned system of values. The attempt might suggest too intellectual a view of morals, but especially in the hands of Aristotle other elements in the formation of character obtain full recognition, and the function of reason is seen to lie not in the dictatorial imposition of abstract principles but in the harmonization of the fundamental needs of personal and social life. Man must be in harmony with himself, and the inner harmony, as Plato was the first to show, would express itself in the social harmony of which it might be regarded as both cause and effect. Without a well ordered state man could not obtain the education or the environment in which he could make the most of himself, and without the co-operation of the best men the state could not be well ordered. On the lower levels of human nature there are conflicts of interest between society and the individual, but there is a deeper and more real self whose interests include those of society. Thus the rationality of the moral life lies in its necessity to the harmonious fulfilment of human nature in personal and social relations. Here lies the true rationality of Ethics. Yet there runs throughout this school the sense of a final discrepancy at the highest stage of development. For the ideal of the thinker is to think, and thought is above and in many directions removed from practice. The Guardian having attained philosophy only returns to the care of human affairs from a sense of burdensome obligations. The Aristotelian sage will as far as possible put off his mortality, and the ultimate value to him of practical wisdom and statesmanship is that it sets the speculative reason free. The social life with its duties after all appears rather as a means to ends above society, than as itself the fullest expression of the rational good—and there is a premonition here of the withdrawal of the Stoic from a social order which is no longer free to the inner shell of his own virtue, or even of the saint from a corrupted world to the cell in which he can meditate on heavenly things. But the earlier thinkers, including Aristotle, rested their work on the tradition of free city states in which the good citizen was one who could both rule and be ruled with a view to life at its best. Plato, the revolutionary aristocrat, saw clearly enough that the social harmony which he desired was fatally split by internal divisions. The state of actuality was not one state but two, fatally divided by what we now call class conflict, what was for the Greek the ever threatening shadow of faction which at any time might overwhelm patriotism and open the gates to the enemy. Plato's ideal solution was to sweep away private property and the family life, at least for the ruling class, as the foci of obstruction to the perfect unity in which he saw salvation. As a practical reformer he set out more moderate proposals, but his method was still essentially Utopian, starting with the supposition of a new city to be erected and a free hand for the philosophic statesman in the framing of its institutions. Aristotle, the Conservative moderate, is opposed to the destruction of institutions of long standing which seem to meet deep-seated human needs and fears the excess of unity as a distortion of the real meaning of happiness. He is the founder of comparative politics, but for a moral rationalist he is too ready to find specious reasons for the established fact—slavery for instance—instead of resolutely submitting the traditions of society to the test of reason; and he could so far ignore the changes that were going on before his eyes as to treat the decaying city state as the last word of political development.

The Stoics.—The need for a broader basis was in fact most clearly conceived by some of those writers contemptuously dismissed as "incomplete Socratics." The cosmopolitanism of the Cynics bore fruit in the generation which followed the establishment and witnessed the wars of the military monarchies, in the Stoic school, whose teaching has had a wider influence on law and government than that of the much greater philosophers who preceded them. For Stoicism the true community was neither the city state nor any actual political organization to which a man is subject, but nothing short of the entire cosmic system ordered by the universal reason, as his own life is or should be ordered by his private reason, whereby he shares in the universal. How, if all things are so governed, evil and error arise is no easier for the Stoic to explain than for others who place perfect wisdom and goodness in the seat of final authority. But however explained it was the fact, and man has to steer a course disturbed by his own passions in a world often awry from the same cause. He has however two fixed points to guide him. The first and foremost is that he must keep himself erect. This he can do by following the inner light of his own rationality and as long as he does so it is fundamentally well with him, though he perish on the rack. But this implies consistent disregard of outward circumstances, and among outward circumstances he must include other persons —even his father, wife or child. To say that neither their misfortunes nor their death nor their disgrace can affect the inner citadel of his being so long as he has done his best for them would be to reduce the Stoic Wise Man to a cold-hearted prig, but logical consequences often produce caricatures, and the sensible Stoic would confine himself to maintaining that whatever you have to bear you save yourself from the worst by bearing it well—*non quid feras interest, sed quemadmodum feras.* But how does this heightened claim of personality square with social obligations? This brings us to the second point, the law of nature, proceeding from the cosmic reason which the private reason will recognize. This law is above positive law, which may depart from it. Thus by the law of nature all men are equal, while the laws of the State may countenance slavery. The duty of the Stoic as lawyer or ruler is to bring the law of the State into harmony with the law of nature, and the influence of the Stoic jurisprudence on the imperial legislation in this regard bore fruit not unworthy of Stoic pretensions. We saw the first-fruits of ethical religion in Deuteronomy. Here we find those of an ethical theory which has become a religion, but was soon to be overshadowed by a religion of a different order.

Ethics in the Mediaeval Church.—Much of Greek philosophy, ethical as well as metaphysical, was embodied in the fabric of Christian doctrine, but the core is, as in Buddhism, a life rather than a theory of the universe. This life resembles that of original Buddhism in its selfless unworldliness, but adds to it a fuller sense of personality and a more optimistic outlook. Its ideal is not confined to the extinction of selfishness, but includes the unimpeded fellowship with God and man for which the way is thus prepared. It is not a code, still less a theology. One would have said that it must be killed by organization but for the historic fact that it has endured to re-inspire successive impulses of revival. However, Christianity like Buddhism was from the first propagandist and like all successful propaganda had to make its terms with the world, becoming thereby an elaborate theology and a widespread organization, which soon lost its democratic elements and became a vast hierarchy. Finally converting the State it had to find means of reconciling its ethics with law, government and social life—an adjustment more easily made plausible in form than genuine in spirit. However, there came into being a system undertaking the supreme direction of life on all sides, personal and political, educational and moral, economic, literary, artistic and even sportive, seeking moreover by arduous missionary effort to extend its sway over all mankind. The system was essentially authoritarian; in fact it conceived human nature as steeped in original sin, from which it was to be redeemed only by the blood of Christ acting through the sacraments of the Church. The moral law is not educed from so corrupt a nature by the analysis of its true needs and the rational investigation of the means to their fullest and most harmonious expression. It is imposed on our reluctant being as the divine command interpreted by the divinely appointed authority. Whatever place charity may hold in theory it is faith, unquestioning acceptance and implicit obedience, which will in the fabric of such an ethics constitute the keystone, and, if all men are the sons of God, and brothers accordingly, the line between those within and without the fold will be as deeply marked as in any primitive moral order. To the outsider the supreme duty is to convert him, and to this end strong measures will be justified. Still stronger ones will be in order to save the backslider or punish the perverter of the faithful. Among the faithful it is the sins of the flesh that are the most feared, for their attack is subtle and dangerous even to the godly. The flesh wars against the spirit and its gratification is only saved from polluting us by the Sacrament of Marriage, available only in strict indissoluble monogamy and only so for laymen. The experience of the joys of marriage and parenthood is incompatible with spiritual functions. The degree in which the control of sex takes the centre of the moral stage is in fact a distinguishing mark of the theological as compared with other systems, and seems at bottom to be a part of that repression of the natural man which is the essence of a supernatural law. It is for the same reason that pride is the chief of the deadly sins and that the moral appeal is not to a proper self-respect but to a humble and contrite heart. Indeed, contrition borders upon a virtue. This rigid code none can keep at every point, but for the gravest lapse there is room for repentance in penance done with sincerity of contrition. Such forgiveness meets a genuine human need, but its systematic organization not only brings relief to the stricken heart after the event but can hardly avoid suggesting to the tempted man that if he yields he will be at worst incurring a debt which he can pay off. In fine, the functions of the confessor seem to take upon themselves what is elsewhere left to the stirrings of the individual conscience, and the regularization of confession allows no moral privacy. Finally, worldly well-being for the community as for the individual falls into a very secondary place. It is not necessary to salvation that man should conquer nature or control the conditions of racial development. Neither can any of the truths of science matter greatly, since the one essential truth is known. To expound and defend it is the one great intellectual duty and to have the intelligence necessary to follow the exposition is the measure of the education required for the layman. For the rest it may be better that he should abstain from things which except in the hands of the appointed experts may be dangerous to the faith.

Protestantism and Ethics.—On the ethical side the Reformation acted in the first instance as an astringent. In its opposition to Sacramentalism it brought the ethical to the front and placed each man's salvation ultimately in his own personal relation to God. Its interpretation of Christian duty could be hard and austere. In its insistence on the Mosaic Law as a genuine revelation of God it might overlook the admitted superiority of the New Dispensation. But it was faithful to its lights and unambiguous in its demands on its followers. That it was directly responsible for the withdrawal of moral control from economics has been recently and conclusively shown to be a false charge; but its strength was in the industrial and commercial classes and it gave a certain religious sanction to the industrial virtues. A deeper influence on individuality emerged as it developed, for even against its will it was forced to appeal to the individual conscience, and in the end to set it as a judge above all traditional authority. The exercise of private judgment became not only a right but a duty and, as the social implications of the principle became apparent, was seen to lie at the centre not only of personal religion but of social progress. The central position of liberty which is the characteristic contribution of modern ethics had its birth in the religious struggles of dogmas which long waged war without quarter.

But there was more to come. The literalness of Biblical interpretation led to more than one revival of the Christian life. The doctrine of non-resistance revived in more than one quarter and found persistent and influential expression in Quakerism, which gave the lead to modern ethics in opposition to war, slavery, a barbarously cruel penal system and the irrational subjugation of women. The wider appeal of Methodism and Evangelicalism not only reformed manners but, cultivating the arts of the platform and the press, made an appeal to elementary Christianity the touchstone of political issues and for the first time established an organized body of moral conviction as a driving force in public affairs on a great scale. The moral influence of Christianity was probably never so great as in the 19th century, which was the time of the most serious intellectual attack on its foundations.

Modern Ethical Theory.—For in the meantime a rationalizing movement was gathering strength. The revival of science, which dates back to the contact with the Arabic schools in the 13th and even the 12th and 11th centuries, achieved its first spectacular success with Galileo, and between his time and that of Newton a great "physical synthesis" was established, which set scientific method on the footing from which it could advance upon the series of discoveries that have given its distinctive character to the modern world. Philosophers might ally themselves with theologians in criticizing the mechanistic assumptions on which science relied, but too often they found that the definite results obtained by these methods survived attack and, what was even more, that where error came about science could repair it without loss of temper or damage to its main fabric. It was not till physical science had achieved the final triumph of the later 19th century that it began to doubt its own assumptions and a reconstruction set in, of which the end is not in sight, but which has gone far enough to shake the apparent simplicity and seemingly axiomatic character of mechanistic principles and to justify those who study the world of mind, of ethics, politics, religion and art in pursuing their course without the uneasy belief that their ultimate results can be nothing but superficial appearance, the underlying causes of which must be ultimately traceable to the mechanical interaction of physical particles.

As a fact the application of rational methods to ethics—that is to say the use of critical analysis in the ascertainment of data, defined principles in their elucidation, and the check of experience upon the results—has gone on from the first great days of science. Of its history we can here mention only certain central conceptions which are closely related to ethical development in general. Its beginning may be regarded as a development of the idea of the law of nature which came down from the Stoics and had been preserved in the foundations of the Canon Law. What ground could be found for morals in the nature of man and society? Hobbes thought that men were by nature enemies and that society was an artifice of restraint which they imposed on themselves through mutual fear. Locke, with more reason and with some knowledge of the life of American Indians without organized government, found a social principle in man and a sense of obligation which would bind where no constraint of law existed. The 18th century could find natural rights which organized society might enforce but did not create, and Adam Smith could argue that the system of natural liberty would give us an economy that was more often hampered than improved by collective regulation. That personality has rights which written law does not create and may violate has become an integral part of modern ethics, but the antithesis of nature and society was not a happy basis for their affirmation. Rights are social obligations viewed from one end as duties are social obligations viewed from the other end, and though they are valid whether required by law or not they cannot be laid down as so many independent absolute truths, but must be taken in relation to one another and to the social well-being to which they contribute. The true right is in fact a condition of social well-being, and it is because this is the fact, whether we know it or not, that it has a validity which is independent of enactment or opinion. On the other hand, as a condition of the very complex whole which makes up the common weal, its definition is a much more arduous matter than appeared when we approached it light-heartedly in isolation, and indeed though we may be confident in the direction we are taking we are still seeking and probably shall long seek better and more inclusive definitions of liberty and equality. These drawbacks in the theory of natural rights were clearly seen by Bentham and were among the causes urging him to put forward his conception of the greatest happiness of the greatest number as the ethical and political end. This standard had in his opinion the great advantage of being determinable by experience. We can find out what makes people happy or miserable, and our morals, laws, institutions and executive government should be shaped thereby. Ethically his doctrine performed the service of convincing people first that there is in morals and law an end to be attained, which is what makes them worth having; secondly that this end is concerned with human happiness and misery—the happiness or misery of every single person affected being brought into the account; thirdly, that we may be mistaken as to the things that make for happiness and must submit our judgment in this as in other matters to the test of experience. For these reasons the Benthamite dictum formed a useful theoretic basis for the democratic changes of the Reform period. Its weakness was that in taking happiness as the sum of pleasures minus pains it deserted the real fact, which is, that it lies in qualitative conditions of personal and social life which can be but very imperfectly rendered in any numerical terms. Even the practical difficulties in working democracy come back to the inadequacy of numerical majorities to measure the effective will in a community.

Ethics and Religion in the Modern World.—A remedy was sought by Green in the conception of a common good which was the harmonious realization of personality in the members of the community. In such realization there is happiness and in the thwarting of it misery and failure, so that Bentham's principle was rather to be supplemented than altogether set aside, but it could be seen that instead of reckoning in indefinite millions of individuals extending through generations we must look for the general causes of social development and deterioration, and that what was right would come finally to be recognized as that which would make for the development of humanity, whether by giving larger freedom of scope for the expression of personality or by facilitating mutual aid and collective achievement. The ethical thus takes its place as the governing condition of human development, and to understand it is to have the key to the future of all that man can do to shape his own destiny. The moral impulses arose through heredity in response to vital needs. They were shaped by experience into standards accepted with little criticism and sometimes distorted by the gnarled forms assumed by different societies in response to their environment. By selection of those which are consistent with human needs and the rejection of the inharmonious we can form a feasible conception of the goal of human effort and arrive at a reasoned analysis of that which we have hitherto pursued without fully knowing it, and therefore without clear conceptions either of our true ends or of the ways and means thereto.

In spite of all differences of method and outlook there was a great deal in common between the rationalistic movement in ethics and the applied ethics of the religious movements described above. In fact some of the most severe critics of the speculative basis of Christianity were concerned to uphold the moral validity of the Christian ethics. On both sides the simplest and most universal sentiments and obligations of humanity were put in the place of authority, and a similar humanitarianism was reflected in the dominant literary influences of the 19th century.

Materialistic Cross-currents.—On the other hand there have been cross-currents of no small importance. Historical materialism, which has gained a wide hold in Europe, treats the entire ethico-religious history of man as a secondary result of the economic life of society. The theory of natural selection has been held to justify might as against right, whether as between individuals or nations. A strongly developed strain in the semi-philosophical literature of the last generation from Nietzsche to many contemporary writers makes the self the centre of something approaching worship and is highly disparaging of anything like altruism. The World War and the subsequent political and industrial upheavals have weakened confidence in the social order and relaxed the inhibitions on violent self-assertion. So while much has been done in practical legislation to give effect to the ideals referred to above, the moral basis of these ideals seems to have lost some of its hold upon men. On the other hand the materialist assumptions that lie behind the reaction are themselves shaken, and scepticism has been turned on scientific as well as theological dogma. The way is opened to wider applications of scientific method and a more liberal interpretation of scientific principles, from which humanistic and in particular ethical studies have all to gain. (L. T. Ho.)

H. Lowie, *Primitive Society* (1921) should be consulted. The first series of Sacred Books of the East—translations, ed. by F. Max Muller—contains rich material for the Oriental civilizations, mainly religious but with much ethical matter. For European civilization ancient and modern see the special bibliographies for each period, or religious body or school of thought.

COMPARATIVE NERVOUS SYSTEM. Feeling, thinking, and acting depend upon the nervous system. In man the sense organs, the central nervous organs, and the muscles form a combination by which we feel, think, and act. It is usual to limit the term nervous system to the first two of these three sets of organs. All three, however, are linked together as a unit in performance.

The sense organs, such as the eye and the ear, receive external stimuli, light and sound, and originate nervous messages or impulses that are sent over the appropriate nerves to the brain. In this central organ these impulses awaken the sensations of sight and of hearing and are switched over outgoing nerves to the appropriate muscles whereby a specified act may be performed. Thus if very strong light is thrown on the eye we experience the sensation of great brightness and certain muscles respond in that the eye winks.

Since sense organs are the means of receiving external changes they are commonly called receptors. They include in addition to the eye and the ear, the organs of taste and of smell, of touch and of pain, of cold and of heat, and of a score or more other senses. The central organs, such as the brain, are not only the seat of the sensations, but, like the central office in a telephone system, they switch the impulses to the proper terminals. Hence they are often called adjustors. The terminals of the various animals may be not only muscles but glands, electric organs, luminous organs, colour organs and the like. They are the effective parts of the combination by which a given animal responds to changes about it. Hence they have been called effectors. By the combined working of receptors, adjustors, and effectors all animal behaviour is carried out. It is by means of these three sets of organs that the worm retreats from danger into its burrow, the ant carries food to its hill, the frog jumps for a fly, the bird builds its nest, and man writes a page. In short these are the organs that underlie all animal behaviour.

Many of the acts of the higher animals are carried out with almost invariable uniformity, *e.g.,* the withdrawal of the foot when it is pricked or the watering of the mouth when food is smelled. Such acts are called reflex, for the sensory impulse seems to be turned back to the exterior by the central organ in almost the mechanical way in which light is reflected from a mirror. Other acts, *e.g.,* the crying of a newborn child or the suckling of a young mammal, are more complicated than reflexes and yet are inborn in that they are not learned and need only an appropriate stimulus to start them going. Such acts are called instinctive and rest upon a structural basis preformed in each individual. Finally there is the large body of daily performance acquired by learning and including those plastic activities that, under the influence of memory and other stored experience, are moulded into the acts of everyday life. These range from such simple performances as walking, running, or flying, to the enormously complex operations in the intellectual life of the higher animals including man. Here belong the capacity for memory, for imagination, for voluntary action with its moral implications, and the like. Here too occur those important modifications, which, essentially pathological, lead to abnormal mental conditions and insanity.

When an attempt is made to arrange normal animal activities under the three classes of reflexes, instincts, and higher acts, it is found that they are not always conveniently so placed. Walking is not only learned, but is in part instinctive if not reflex. The so-called reflexes themselves are often open to profound change. Thus the sneeze of a yokel, an almost purely reflex act, can through the social training of the well-bred be brought under control and even completely extinguished. Hence reflexes, instincts, and habits are really not classes of acts in themselves but rather phases of behaviour that qualify almost all performances. In the vertebrates, from fishes to man, the nervous organization includes a large variety of plastic operations which thus favour active habit formation. In the insects and other like creatures, on the contrary, the nervous organization, though including plasticity, leans strongly toward the instinctive side. Bees like men may learn to find their way about and are helped in this by their fellows, but they build their comb and do a thousand other things instinctively and without training. Much of the life of an insect is thus semi-automatic, and in this respect it is in strong contrast with that of a vertebrate, where freedom of action and learning play predominant parts.

The structure of the various types of nervous systems by which the behaviour of the higher animals is carried out shows great individuality, and yet each such type exhibits a certain uniformity in that it is made up of a combination of nerve-cells or neurones. A neurone commonly consists of a cell-body and one or more lengthy processes or nerve-fibres. Ordinarily the cell-bodies mass together and thus establish what are called nerve-centres whereas the nerve-fibres are assembled in the form of nerve tracts by which one centre is put into connection with another. These relations can be easily seen in the nervous system of such an animal as the earthworm.

The nervous system of this creature consists of a small brain in its head from which a long strand of nervous material passes backward along the under side of its body to the tail. In each of the hundred or more segments in the worm this strand enlarges into a nerve-centre from which nerves pass out to the adjacent parts, muscles and skin. In the skin are lodged a large number of nerve-cell bodies whose outer ends reach the external surface of the worm as fine bristle-like terminals and whose inner ends become attenuated into delicate nerve-fibres that make their way as constituents of a nerve to their terminations in the ventral nerve-centre. Each of these peripheral cells with its attached fibre is a neurone and since these neurones are concerned with the reception of stimuli that impinge upon the skin they are called receptor neurones. In the ventral nerve-centre these neurones come into contact with the cell-bodies of a second set of neurones whose nerve-fibres make their way out from the centre to terminate in the worm's muscles. Neurones of this kind, in consequence of their connection with muscles, are known as effector neurones. When the skin of an earthworm is stimulated and the animal responds by muscular movement, receptor and effector neurones are active in carrying out such a simple nervous operation.

Beside these two classes of neurones there is in the nervous system of the earthworm a third class, the internuncial neurones. These are neurones the whole of whose extent lies within the central organs and which serve as a means of uniting one nerve-centre with another. They extend for the most part up and down the length of the central nervous organ.

In worms generally the three types of neurones already described are about equally abundant, but in the crabs, insects and other higher invertebrates the internuncial neurones increase disproportionately till finally in the vertebrates they make up a very large part of the central nervous organs. In these animals the central organs consist of a brain in the head and a spinal cord extending backward through the body. These nervous parts are located on the dorsal aspect of the animal, not on its ventral face as in insects, crabs, and worms. The cord and brain in the vertebrates include receptor and effector neurones as in the invertebrates but these two classes of elements together do not make up more than a few per cent of the central organs, the great bulk of which is composed of internuncial neurones. In fact some of the most important organs in man and the higher vertebrates, such for instance as the cerebral hemispheres, are composed exclusively of this type of neurone.

In all animals from the worms and insects to the higher forms the brain is a conspicuous and very characteristic part of the central system. It is always located at the anterior end of the creature and is the nervous centre with which the chief sense organs of the body are connected. In man and in other higher animals the brain is thus associated with the organs of taste and of smell, with the ears and the eyes. The development of these important receptors and of the brain has progressed hand in hand in an evolutionary way. This progress has involved the change of several of the head sense organs from what may be called surface-receptors to distance-receptors. The nature of these two kinds of receptors may be illustrated by certain human sense organs. We refer our sensations of touch to the spot on the outer surface of the skin where the foreign body impinges. We believe we taste our food where it is in contact with the surface of our tongue. Receptors that are thus concerned with the surfaces of our bodies are called surface-receptors and represent a very primitive type of such organ. There is good reason to assume that all the receptors of an earthworm or other lowly creature are of this type. But in higher animals there is a second kind of receptor. We see the surrounding landscape through the eye but we do not think of seeing it on the sensitive surface of the eye where the image is really formed but in the distant exterior. In a similar way the sound of the noon bell does not seem to be in the ear but comes from the distant clock tower. With such sense organs as the eye and the ear we project the disturbance that excites us to a distant point and think of it as being far away from us and not in contact with our bodies. Hence such sense organs are appropriately called distance-receptors.

In the evolution of sense organs there are ample grounds to believe that distance-receptors have evolved from the relatively more primitive and simpler surface-receptors. Those sense organs in the skin of the earthworm that are concerned with the reception of odours, of light, and of vibrations are without doubt surface-receptors of the kind from which have evolved the distance-receptors of the higher animals.

In the evolutionary changes whereby surface-receptors have been converted into distance-receptors there has gone on hand in hand in the higher animals a corresponding growth of the brain. Thus in a way the transformations undergone by the sense organs have made possible a corresponding transformation of the brain. In this growth, however, the brain has assumed a rôle of its own and has developed peculiar and characteristic functions that have carried it far beyond what is merely needed for increased sensory action. This growth has placed the brain at the apex of nervous development. For the brain of the higher animals and especially of man is not only a most complicated switching station for nerve impulses, but has become a repository of past experiences, and a centre for all those higher nervous activities that make up mental life, and that we regard as most characteristic of our personal selves. In this way the brain has come to serve as the seat of those remarkable performances of memory, volition, imagination and the like that are looked upon as the distinguishing features of the individual man.

As already shown the ordinary nervous activities of the higher animals depend upon the three-fold organization of sense-organ, central organ, and effector. In animals simpler than crabs and worms this degree of nervous organization is greatly reduced or even lacking. In many lowly creatures, especially in jelly-fishes and sea-anemones, the nervous system is represented chiefly by receptors which are often directly connected with the muscles. These receptors are located in the outer skin of the animal but are seldom specialized enough to be easily distinguishable as such. They connect with the muscle below them either immediately or through a delicate nervous net-work. This net-work spreads over much of the animal's body following the distribution of receptors and muscles. It is nowhere sufficiently concentrated to form a central organ and the system may therefore be described as diffuse. It is an arrangement of receptors and effectors without an adjustor.

Since this diffuse system very generally permeates the bodies of these lower animals their parts show remarkable independence of action. Thus the tentacles of a sea-anemone which surround the mouth of the animal and are very effective in the appropriation of its food, will respond to bits of meat with great efficiency even after they have been cut from the animal. The creeping foot of the sea-anemone will continue to creep after the rest of the animal has been cut away. This autonomy of the parts demonstrates the all-sufficiency of the nerve and muscle contained in each particular portion and shows that a given activity is not dependent upon some distantly located central organ. The leg of a crab, an insect, or a frog, if cut off, shows no such powers. It no longer moves as it formerly did because it lacks nervous connection with a central adjustor. The tentacle of the sea-anemone contains within itself the nerve and muscle necessary for its own type of response.

The receptors of the sea-anemone and other such animals serve as delicate triggers to set their muscles in action. As this seems to be their one function they are more appropriately designated receptors than sense organs for they are apparently not concerned with sensations.

Collectively the receptors and underlying nerve-net of these simple creatures constitute a type of nervous system quite distinct from that seen in the higher forms. Not only does such a nervous system lack centralization but its nerve-net has the remarkable property of transmitting nervous impulses in any direction. Its diffuse character is not only structural but also functional. In the centralized nervous system of one of the higher animals it is possible to send a nervous impulse over a succession of neurones from the receptor to the effector side. When the attempt is made to send the impulse in the reverse direction the transfer fails. In the region where one neurone touches the next there is a valve-like device which will allow the impulse to pass in one direction but not in the reverse. No such impediment occurs in nerve-nets where impulses spread with the utmost freedom, and in any direction. It is interesting to observe that although the nerve-net is a type of nervous organization characteristic of the lower animals, it has been retained in part at least in many higher forms. Thus the vertebrate digestive tube has a nervous organization closely resembling that of a sea-anemone, and many details in the movements of the vertebrate digestive organs are repetitions of those found in animals whose nervous systems are wholly of the nerve-net type.

Simple receptors and nerve-nets such as those described apparently mark the first step in the evolution of true nervous organs, for in animals lower in the scale than sea-anemones, *e.g.*, sponges, no nervous structures at all have been identified nor do the activities of these animals suggest such parts. Sponges grow almost plant-like from a submerged base and show scarcely any movements. By means of a system of minute lashes they draw through their bodies a current of water from the floating contents of which they extract their food. Their chief movements are the opening and closing of inlet and outlet pores for this system of water circulation. These movements are accomplished by very simple muscles which apparently act through direct stimulation and without the intervention of nerves. Such muscles since they act of themselves may be designated independent effectors.

In the protozoans, the simplest of all animals, each individual as a rule is a single cell. Within the bodies of some of these forms fibrous systems have been discovered which connect the central part of the cell with locomotor lashes on the exterior. These systems have been regarded by some as nervous in character but it is by no means certain that such is the case.

Apart from these possible traces of nervous origins in the protozoans, true nervous elements appear first in the trigger-like receptors of the sea-anemones and jelly-fishes. Organs of this type were doubtless the forerunners of the true sense organs of the higher animals. To these in the course of time were added central nervous parts, especially the brain, that organ of paramount importance in the life of the higher animals and especially of man.

Parker, *The Elementary Nervous System* (1919); C. U. A. Kappers and A. B. D. Fortnyn, *Vergleichende Anatomie des Nervensystems* (1920). (G. H. P.)

COMPARATIVE PHYSIOLOGY. Physiology as defined in the medical curriculum of most institutions of higher learning confines its enquiries pre-eminently to man and his nearest allies, focussing attention on those activities of the body which are of special interest to the problems of health and disease and those which can be conveniently studied within a narrow range of animal material. From a practical point of view this preoccupation with clinical objectives has its drawbacks: for medicine has been repeatedly enriched by the more catholic approach which makes no restriction on its materials or problems. This more embracing attitude to the scope of physiological science is referred to by the terms general physiology and comparative physiology. In practice there is no hard and fast distinction between these two terms, though some authors have endeavoured to define one.

Modern comparative physiology represents a *rapprochement* between the teaching of physiology and zoology which is really a return to the practice of an earlier period, when morphology and physiology were not as yet divorced. Many of the zoologists of the earlier half of the 19th century regarded morphology as the handmaid of physiology. To men like Milne-Edwards it is clear that the ultimate problems of the biologist were physiological. With the rising influence of the evolutionary theory the purely architectural approach of the Cuvierian school received a strong impetus. Structural details of little or no significance as aiding an understanding of the properties of living matter came to be cherished for their historical interest as a possible means of throwing light on the ancestry of man and the pageant of life in preceding geological epochs. The 20th century has witnessed a strong reaction against this tendency. This is partly because progress in palaeontology and in the morphology of recent animals has made it clear that the extent of parallel and convergent evolution presents unsurmountable difficulties to the task of constructing a classification of living beings which expresses in all its minutiae their family relationships. It has arisen also through the recognition that the ultimate justification of the evolutionary hypothesis is bound up with the understanding of the machinery of heredity and variation. The awakened interest in experimental problems which has resulted from Mendelian research has exerted its influence over the whole field of zoology, so that morphology is taking second place in current investigation. Morphology, the study of structure as a separate issue, has completed its task. It has placed the principle of geological succession on a firm foundation. It has laid down as far as it is possible, at least for some time to come, those major associations in systematic zoology which can with any legitimate confidence be considered to indicate ancestral relationships. Further than that it cannot progress to any considerable distance except in so far as fresh relics of extinct animals may be unearthed from time to time. Here and there lacunae remain. Certain practical problems in relation to parasitic forms of life justifiably continue to absorb a considerable measure of attention. But there is no likelihood that morphology divorced from physiology will contribute to the building up of another generalization of the magnitude of the evolutionary hypothesis. In short the study of the lower organisms is likely to receive its chief driving force from comparative physiology.

The practical justification for extending the scope of physiological science to the study of the lower animals resides partly in the fact that many phenomena of universal biological significance can be more conveniently studied in species only remotely related to man; partly also because it is sometimes easier to approach the latter with the detachment and objectivity which are essentials of scientific method. Thus, on the one hand, the phenomena of reproduction in its most fundamental aspects and the physical properties of the cell as a physiological unit present almost unsurmountable difficulties in the case of viviparous warm-blooded animals like man and his nearer relatives: but rapid progress can be made in dealing with simpler aquatic forms of life which spawn their reproductive cells into the sea; and such progress suggests methods which may direct fruitful enquiry into the investigation of more difficult material. Again, it is at present impossible to think about human behaviour in purely objective terms; yet considerable progress has been made in the acquisition of predictable knowledge about behaviour in more lowly organisms, and from such enquiries have emerged habits of treatment which are paving the way to a scientific study of behaviour in more complex beings. One might say that the business of the comparative physiologist is to find the right animal for the solution of a particular problem. In no field is the value of the comparative method emphasized in a more striking manner than in the experimental study of inheritance, which, rightly conceived, is an essential compartment of physiological science, though frequently discussed under the separate heading Genetics (*q.v.*). For rapid advance in genetics, it is necessary to deal with organisms that breed prolifically, attain sexual maturity in the least possible time, and present well-defined true-breeding varieties for study. The fruit-fly *Drosophila melanogaster* passes through its life-cycle in a few days, breeding prolifically and has a great number of discrete varieties which breed true to type (*see* CYTOLOGY). It would hardly be an exaggeration to say that more could be found out in a year's research on inheritance in *Drosophila* than in several thousand years of study of human material. Yet many of the generalizations derived from the study of the fruit-fly and other low organisms apply to the problems of inheritance in man himself, though the principles themselves would never have been elucidated if no other forms had been accessible.

Within the limits of space available it is only possible to select a few lines of enquiry in which the comparative method has proved especially illuminating. First and perhaps foremost the physiology of the fertilization and early development of the egg may be mentioned. The reader who is not familiar with the nature of the fertilization process is referred to the article CYTOLOGY. From the physiological standpoint the problem of absorbing interest is the material nature of the stimulus imparted by the sperm to the egg, by which a phase of active cell-division is initiated in the latter, culminating in the production of a new individual. A new epoch dawned in the closing year of the 19th century, when Loeb, perhaps the most distinguished pioneer of the comparative method in physiology, found it possible by means of purely physicochemical stimuli to induce eggs of the sea-urchin to develop in a normal manner without contact with the sperm or male element. By placing the eggs in certain solutions of organic acids and subsequently treating them with concentrated sea-water, the content of which in dissolved material had been raised by adding such substances as sugar or salts, eggs of the sea-urchin can be induced to segment and to grow into larvae, though free of any contamination by sperm. This discovery initiated a large volume of research, the net result of which has been to show that the physical changes produced by these artificial agencies are similar to the internal events that precede active development in normally fertilized eggs: and it has now been possible to produce fertilization by physicochemical means in eggs of species of most groups of cold-blooded animals whose eggs are fertilized externally. Modern work on tissue culture (*q.v.*) encourages the anticipation that this may be achieved in the near future in warm-blooded animals, possibly ultimately in man himself. A fuller exposition of this work would lead into technical issues, but one feature of the development of the sea-urchin's eggs discovered by Loeb is of the utmost interest, namely the immense increase of respiratory activity that accompanies fertilization. Warburg found that the oxidation process was proportional to the iron content of the egg, and that by carefully drying the egg-substance a powder might be prepared that would continue to absorb oxygen and burn up organic compounds, as does the living cell. Not only did he separate the functions of respiration from what would be ordinarily called "living matter," but succeeded in making suspensions of charcoal containing iron capable of facilitating the spontaneous oxidation of organic substances such as occur in animal food, and these physical respiratory models were shown to be affected by various types of reagents which reduce oxygen consumption in the living body in a precisely analogous manner.

In the study of behaviour from the physiological standpoint the progress that has been achieved illustrates in a convincing manner the intellectual discipline to be derived from dealing with animals that can be approached readily without the bias towards the traditional anthropomorphic attitude that is inevitable in dealing with man's nearer relatives. Thus the analysis of behaviour of jelly-fishes and sea-anemones by Romanes, Parker and others, can be discussed without difficulty in terms of the properties of the conducting (nervous) tissues without recourse to terms like memory or will, like or dislike. In the behaviour of the more complex animals notable advance has been made by studying bodily orientation in relation to group stimuli such as light and gravitation. Thanks to the labours of Loeb, Mast and others the old meaningless statement that the moth moves towards the candle because it likes the light, has given place to an understanding of how light stimulating certain parts of the retina discharges nervous impulses to particular groups of muscles whose contraction brings the body into such a position that it must move along the path of the incident rays. The new interpretation makes possible predictions that are actually verifiable, as for instance the fact that, if one eye is blackened, the moth will fly in circles. The application of the comparative method to the study of animal behaviour has been one of the main contributing influences to the development of the modern school of *behaviourist* psychology (*see* PSYCHOLOGY, COMPARATIVE; ANIMAL BEHAVIOUR).

Examples of chemical co-ordination in animal responses are set forth in the article ENDOCRINOLOGY, where the rôle of internal secretion in the developmental processes is also indicated. It can be said that everything of any general significance that is known about the physiology of development has been based on the study of lower forms of life, more especially those which display phases of abrupt development (metamorphosis, *q.v.*), as do sea-urchins, salamanders, etc. (*see* EXPERIMENTAL EMBRYOLOGY). Of recent developments in comparative physiology, one field in which the comparative method has proved invaluable is the physiology of the cell or microscopic units of the animal body (*see* CYTOLOGY: *Experimental Cytology*). The germ cells of marine organisms, worms, starfishes, and the like have provided much of the most favourable material for manipulation in experimentation on isolated cells. The researches of Pantin, Chambers and others on the movements of the Amoeba are worthy of mention in this connection. In the study of nervous co-ordination and muscular activity the most favourable materials have hitherto been found among animals dealt with by the medical physiologist. But considerable attention has been paid of recent years to the mechanism of ciliary activity, bioluminescence, colour change and other forms of response which are specially illustrated by the lower organisms. One field in which significant advance has been made through the researches of Krogh, Barcroft and their co-workers, is in the study of the variety of respiratory pigments which in different groups of the animal kingdom serve, like the haemoglobin or red colouring matter of human blood, as a means of taking up oxygen and transporting it to the tissues.

Though the influence of comparative physiology has largely been manifest in relation to human physiology, it is probable that it has unrealized possibilities of practical application in relation to agriculture, fisheries and other applied sciences. At present the experimental study of breeding is the only branch of comparative physiology which has notably contributed to the solution of commercial problems. Comparative physiology has still to shoulder the task of interpreting the mechanism of animal distribution in terms very different from the teleological assumptions of the evolutionists of the 19th century. (*See* ECOLOGY, ANIMAL; DISTRIBUTION OF ANIMALS.)

COMPARATIVE PSYCHOLOGY. Comparative sciences generally are concerned with the co-ordination of differences in a common subject matter. Comparative psychology attempts this task in the world of Mind. Now in the expressions of mental activity the range of difference is enormous, extending from very low phases of animal life to the highest achievements of civilized culture, and all these differences must be regarded as significant for the student of Mind and its function in the world of life. Are we then to infer that they all belong to the field of comparative psychology? A critic will object that this would be to create an impossible science. The study of culture, for instance, is sociological or historical. It requires quite different methods from those of the study of an ape or a beetle or a decerebrated frog. We must in mere mercy to our student put a limit. Shall we then say that the concern of psychology is with faculty rather than performance? The difficulty here is that in the last resort faculty can only be measured by performance. Thus a popular explanation of the immense divergencies of human culture refers them to what is known as racial psychology, *i.e.,* to supposed inherent differences in the faculties of different races. Psychology can only test this supposition by calling in the aid of sociology to determine how much difference can be effected by the cumulative effect of social inheritance, operating on a common groundwork of capacity. But it cannot wash its hands of the problem. Whether through some extension of innate faculty or through the social causes suggested, the actual achievements of thought are indutiably greater in the civilized than in the uncivilized world, and the function of Mind in the direction of life proportionately enlarged. The significance of mental development would be missed if these chapters in its story were cut out.

Nevertheless, the student, forced to economize his energies, must limit his field. He may hope to become an expert in one method, but not in a dozen, so he chooses one for his speciality. Unfortunately the demands of specialization are progressive. He might choose, say, animal psychology as his field, but there is still an immense difference between the study of chimpanzees and that of starfish, an immense difference between the methods of a physiological laboratory, which may be applied to any animal and to man himself, and those of the systematized observation of the normal animal. Cruelty barred, all methods are legitimate, but it is a familiar fact that he who follows one exclusively will tend to take that one alone as the universal solvent. Now it is precisely the business of the comparative psychologist to accept evidence from all quarters and all methods, and try to piece them together into a coherent whole. We cannot then make any such division as would destroy the unity of the comparative view, but we may recognize that with development methods change; the changes determine the lines of specialization.

Behaviour and Behaviourism.—In all fields the principal data are contained in behaviour. This is easily seen in regard to the higher fields, as soon as we recollect that the use of words and therefore the writing and reading of books, to say nothing of the execution of works of art, are forms of behaviour. In the last analysis the phenomena of our own consciousness are also the behaviour of those complex wholes which are ourselves and this radical Behaviourism is the one and only method of all psychology. It is also the one and only method of physical science, for if Mind is the unity which we conceive to run through certain forms of behaviour, so Matter is the unity which runs through other forms of behaviour. This truth is now fully recognized in physics, which conceives matter as a form of energy. Radical behaviourism applies impartially to "matter" and "mind." The world of our experience is material in so far as it acts in certain generic ways known roughly to commonsense and more elaborately to physical sciences. But we also find many objects, which while behaving in some ways like matter, being *e.g.* visible and tangible, nevertheless reveal differences which are the more striking the more rigidly physics delineates the material world as essentially indifferent in all its changes to the later outcome of such changes. For throughout the world of living things we find behaviour so correlated with circumstances as to contribute to the maintenance of an individual organism and its race, and among many organisms we find the correlation wider, more efficient, and making not only for racial life but for certain qualities of life. The factors at work in this correlation are many, but there is something running through them all which stands in marked contrast with our conception of matter and we call it generically Mind. It is still for psychology to give more precision to that term, as it is for physics to give the precision to the conception of matter. And it is for philosophy to explain how one and the same reality can exhibit these differences of aspect.

What is at present known as Behaviourism would sweep the whole field of direct consciousness out of psychology in the name of the strict requirements of observable fact as a basis of science. We do not know what facts we observe more directly and immediately than that, for example, we are sometimes cold or hot, angry, pleased, grieved or joyous. But, says the behaviourist, all these are physical states. That is a confusion between *e.g.*, a sensation and its stimulus. Science has only two rules about observation. One is that our inductions must be founded on it, and the other is that we must treat all observations impartially.

At the same time, it should be recognized (a) that introspection as a technical method is full of difficulties which increase with refinement; (b) that when we come to beings not altogether like ourselves, and with no language to correct our errors, the imputation of processes like our own is risky, and in extreme cases impossible; (c) that it is possible, though more laborious, to build up and state a comparative psychology without using terms derived from the direct consciousness of mental process, merely by analysing modes of correlation; (d) that when we observe correspondence, say between an animal's response to external things and our own, we must infer in the animal a function corresponding to that of which we are conscious though it may be that what performs the function is not in all respects the same as in us. We are sure that our dog "recognizes" us, but it is equally apparent that he does so in terms of scent, a mode which to us is alien and almost incomprehensible. When describing animal behaviour in terms implying conscious process we must always have this limitation in mind. On this condition we shall use such terms in the sequel.

The Structural Basis of Correlation.—All living things inherit a psycho-physical structure which lays the foundation of a self-sustaining and race-preserving life. One way in all organisms in which the structure acts is by response to a stimulus, and some hold that all behaviour can in the last resort be reduced to responses to stimuli, external or internal. This theory is difficult to disprove because the internal stimuli are beyond the reach of exhaustive observation, but an hypothesis resting on vague possibilities is of no value. There is no apparent reason why a structure should not be formed to act of itself in determinate ways, or why internal changes should not take place which at some point give rise to recognizable forms of behaviour. The real contrast, as experience shows us, lies between the specific response to specific stimulus and the subordination of passing or partial responses to a broad and relatively enduring line of behaviour.

Structures may be purely mechanical and give accurately predictable response to external influences. In the case of a man-made machine, the external influence often resembles a stimulus in that it bears no quantitative or qualitative relation to its results, *e.g.* when a lightly-turned handle sets a powerful engine in motion. The condition is simply that all the mechanical connections must be intact. But the working of the machine is in no way dependent on its successful execution of the result for which it was designed, and any part which is itself intact may work separately from the whole, as when a repairer having taken a machine to pieces works a part by hand and gets the responses normally given to the operation of the other parts. The parts then are in essentials indifferent to one another and work in the same way in or out of the machine. Some organic responses appear to be of this type. They seem to be governed neither by their results nor by the condition of the organism as a whole, but to depend purely on the integrity of communication between the part stimulated (the receptor) and the muscle, gland or other "effector." The contraction of the iris and the blinking of the eyelids on the approach of a body to the face seem to be of this type. These are the true unconditioned reflexes. We get in these cases a vivid impression of a definite mechanism which, once set going, proceeds to its specific conclusion without any of the variations in accordance with circumstances and consequences which suggest the operation of mind. More often however the reflex is not so completely unconditioned. Other parts of the organism may inhibit it. Other stimuli may modify it, and finally it may depend on what we can only call the general condition of the organism. Thus, sucking in young mammals is a reflex response to a body placed within the lips, but the replete infant ceases to suck.

Acquired Response.—Reflexes play a large part in animal life from the protozoön which withdraws its pseudopodium on contact with a blunt needle to a man who is set coughing by a crumb in the windpipe. Generally they are hereditary, and many are perfect from birth while others, like the pecking of newly hatched chicks, need a little time to perfect them. With practice however a new element comes in, the continued influence of the results of action by which the hereditary reflex acquires perfection. But a good deal more may be acquired than this polish of a rough-hewn response. The newly hatched chick will peck at the edible and inedible indiscriminately at first, but very few experiments suffice to quell the response to inedible things like bits of orange peel and concentrate them on grains and the like. Here results operate at a slightly higher remove. At some point in or after the contact with the peel the chick will try to reject the peel and thereafter avoids it. Our natural interpretation is that the taste is nasty, while that of the grain is acceptable. This raises the whole question discussed above of the interpretation of behaviour in terms derived from our consciousness. Following the principle there laid down, we shall say that something in the chick performs just the same function as pleasant or unpleasant feeling in us. Whether, apart from this function, it is the same thing in a chick as in us we cannot say. If we use a term importing feeling, in this case "bad taste," of the chick, it is solely to express this identity of function.

But there is a further point. In ourselves we should say that we avoided certain food because we expected the bad taste. Probably this would not be true of the chick. It is more likely that the unpleasant reaction operates directly on the responding mechanism, and that the chick never has the act and its consequence before it as two distinct objects. The result changes the whole character of the response, but by a process which we may call *inarticulate* as compared with that *articulate* forecast which we can make. All the lower grades of learning depend on these inarticulate correlations. In the case taken, experience of results inhibited response, but it may also engender positive responses, *e.g.*, to "signals" where none previously existed. Pavlov, who has studied such responses elaborately under the title "Conditioned Reflexes," makes the time factor a centre of importance, and this is probably true wherever the correlation is inarticulate. The signal must overlap the access to the food and must precede it. (Some qualifications of this general statement need not be considered here.) All sorts of arbitrary signals can be used and a dog will come to react to them by salivation in from three to 20 trials. Secondly, reflexes may be established by applying a new stimulus not less than 10 seconds before one to which response was already made, and in some cases even a third reflex was established in the same way. Beyond this it was not found possible to go. The acquired reflex, generally a measured salivation, could be easily distinguished by withholding the food, and, if a brief interval of time were allowed between signal and food, the appearance of the reflex would be proportionately delayed. It is evident that this behaviour closely resembles that which in man we call expectancy. How are we to decide by behaviour whether such an element is present or not?

Conation.—The answer must be found in Conation, to which expectancy, so far as affecting action, belongs. Conation can be best understood in its developed form of deliberate purpose. In psychological terms purpose is that which directs action towards an end defined in an idea and guided by judgments of the relation of each act to the end. The objection made that the end is not always clear from the beginning, and is sometimes modified as we approach it, is not relevant. The facts on which it rests indicate, sometimes that the purpose is not fully developed, sometimes that we only come to understand its conditions by trial and error, sometimes that it is inspired by some larger want which we have not ourselves understood. Purpose as such is that which directs action to ideal ends. The distinction between this and the reflex appears clearly in behaviour, for the reflex is the specific type response of a pre-formed structure, whether founded on heredity or acquirement. But in purpose we are free to vary our responses indefinitely as the bearing of the act upon the end may require. Outer objects become important which otherwise stimulate no response whatever. We make adjustments and combinations that have never occurred before and may never occur again; we may vary our actions in the progress of the effort, discarding or correcting one that turns out useless and substituting methods which suit the case. All this, which can be easily amplified, but is of course familiar, may be summed up in the simple formula that in purpose behaviour is subject to continuous direction towards an end. Now this is the direct antithesis of the conception of mechanism, which is founded on the total exclusion of ends, and which would be revolutionized if we were to allow that the relation of a mechanistic change to some ultimate outcome were to be imported as a factor into our calculations.

But there are forms of conation which fall short of true purpose. There are efforts towards an end of which there is no articulate idea. These are expressed in behaviour in more than one way. First, there is persistence in activity with variation of method until a certain result is attained; secondly, the result once attained, the method which has produced it is subsequently preferred, the others being discarded. This form of conation has been verified among protozoa by Jennings' well-known observations of "Stentor." It is the true foundation of the method of trial and error, where either we want something but do not quite know what it is, but only that we are dissatisfied with everything else, or we know what we want but do not know the means to it. This is the position of Professor Thorndike's cats, who want to get out of the cage in which they are shut, but not knowing how to do it, "scrabble" about till they at last happen to pull or push the catch which sets them free. The value of these experiments was to show the seemingly ingenious things which might be done by this method. There is thirdly the adjustment and combination of responses to the indefinitely varying requirements of a situation. Here any single response might be taken as mechanistically predetermined by heredity or habit, but the combination is a unique product that can never be repeated. There must then be a factor dealing with the situation of the moment as required by the bearing on the result, otherwise the result is a success with no cause but "chance."

The question may be asked, why we should deny ideas in such cases. The answer is that ideas are founded upon experience and in particular an articulate experience which in many of these cases is available. This brings us to the problem of instinct.

Instinct.—A bird at mating time begins to build a nest, and even when brought up in captivity builds it true to type. The laying of eggs, brooding over them, feeding and attending to the young till they are fledged, follow in due course. There is a continuous sequence of actions till the result is reached and all is over. In the meantime every detail of behaviour is determined by relation to this result. Yet it is extremely difficult, and in the very comparable case of the solitary wasp quite impossible, to believe in any such elaboration of ideas as would be implied in saying that the bird fully understood what it was about. The whole proceeding then is steadily directed to an end which is not foreseen. This is the general definition of instinct. It cannot be identified with a compound reflex on account of the modifications and unique combinations of type activities that can be found in it. It is conative, but it is a mode of conation, a drive or a need which we must regard as part of the hereditary structure. But if there is no foresight, how are responses adapted to changes of the environment? The bird will in fact modify its behaviour to suit special cases, *e.g.* the location, materials or form of the nest. What modifies this behaviour if not foresight of the end? Sometimes possibly a foresight of shorter range, *e.g.* a dog having once been frustrated by a rabbit doubling at a particular point may anticipate it and cut the curve. Perhaps in less articulate fashion a bird finding a cat about moves its nest-building operations to a safer place. Even the solitary wasp, unable to get a spider into its hole by ordinary methods, has been seen to resort to one device after another till it has succeeded. To this proximate end her actions seem definitely directed. With such cases we may contrast instances of caterpillars persisting in details of cocoon spinning when they are superfluous; or that of the Sitaris beetle grub, which "ought" to attach itself to the hairy undergrowth of the bumble-bee, but will in fact respond to any similar surface in the same way and often perishes for that reason. If we contemplated such instances alone we should think of instinct as after all very like compound reflex; if we contemplated the others alone we should think of it as very like intelligence. The truth seems to be that it moves between an upper and a lower limit —Intelligence, which as it advances gradually takes its place by substituting foresight for hereditary determination of response, and Reflex in which no modification of detail is possible, and the mechanism must be perfect from birth in all particulars or useless. When either of these limits is touched the use of the term instinct seems inappropriate.

Limits of Animal Intelligence.—In instinct, however modified by inarticulate correlation, there is conation but no true purpose; but stages in the execution of an instinct may become purposive if there is articulate correlation, that is if the result is present in idea as something distinct from but connected with the act. This is impossible as long as the sensory life is limited to experience charged with Affect or feeling and thereby modifying reactions. But if we suppose an articulate perception, *e.g.* of visual objects as wholes of parts and of things related to and succeeding one another, whether charged with Affect or not, we have complexes of distinct but related elements. If again we suppose one element of such a complex capable of "reviving" the remainder the "revival" is easily shown to take the form of ideas of things related to the elements given. If, finally, action is directed to one of the elements so revived, it is directed by an ideal reference and is purpose. Thus purpose in an elementary form is an articulate correlation of perceptual and conative reactions. The evidence of such correlation in behaviour is broadly that the acquisition of co-ordinated modes of behaviour is not limited to habituation or trial and error. Much controversy has arisen on the question of whether any animal behaviour furnishes conclusive evidence of this kind for the operation of purpose. The most decisive evidence is that produced by Köhler's observations of chimpanzees. Below the anthropoids, which might be regarded as a transitional class, experimental work on monkeys, and in a less degree on dogs, cats, elephants and other mammalia reputed intelligent, tends, though less decisively, in the same direction.

Universals and Their Correlation.—What has told most strongly against the attribution of purpose to animals is probably the belief that ideas involve language and are of a general character, but (1) whether with or without language we form ideal references to particular things or occurrences which we remember or anticipate. Ideas are not as such general, though everything general is grasped in ideas. (2) In forming anticipatory ideas, we are moving in the direct line of conation, the idea merely giving necessary direction to the conative behaviour. In forming general ideas expressible in language, we go beyond the range of our immediate efforts (though of course we are constantly calling on ideas to help us in them), and compare one case with another. As the general ideas become formed, all objects to which they apply are in a sense grouped irrespectively of juxtaposition in a class, and what we learn by the idea we can apply to any member of the class. Here we get down to the "universal" underlying the less reflective use of observation in guiding anticipation, and at this deeper level an immense expansion of the field of correlation is opened. Further, in getting away from the immediate situation we have a similarly indefinite extension of range into the past and future. We grasp those combinations of inner and outer experiences which are ourselves and other persons and objects. We become aware of self in the true sense of a continuous unity, for which the immediate situation is only a detail. Thus in the result we arrive at a completely new principle of correlation and behaviour wherein any object or occasion may be dealt with in accordance with its affinities of character (its class) or its position in a structural whole, constituted by the life of the individual and of the groups, family and society to which he belongs.

Thought is more than language but it is by expression and communication that its achievements are consolidated and made the basis of further advance. Thus it is the social factor which makes its higher development possible.

Critical Thought.—In the animal world intelligence (the correlation effected by the individual) is confined to detail. The ground plan is laid by heredity in the shape of instinct. With the formation of general ideas it becomes possible to guide life by rules of behaviour which can be taught and eventually criticized, and by general aims, from self-advancement to religious devotion, which may govern all conduct. This does not abolish the underlying hereditary factor, but it does modify and even transform it. The simplest peoples have codes which put considerable restraint on raw impulse. Broadly, what all codes have to do is to accommodate the animality, selfishness and narrowness of the physical structure to the needs of social life and, as in response to the growth of knowledge social life expands, to adapt behaviour to the new requirements. Such codes do not originate in any systematic plan, but in action and reaction as between individuals and groups, which work towards an equilibrium of accepted custom, enduring until disturbed by some change in the social situation. But the order of life leaves men dissatisfied in many ways both intellectually and emotionally, and from a very early stage they begin to look for a compensation or solution, real or imaginary. They build up a wonder world of magic and an inner or after world of spirits, and find in one or both some shadow of the fuller harmony of feeling and experience which they need. All the time, through the cumulative action of tradition they are increasing their real power of dealing with nature and of organizing combined efforts and so learning the need of more definite conceptions and more trustworthy methods. Theories of nature and human life are originated, and though propagating themselves by suggestion and dogma they have eventually to sustain themselves against criticism. Their fortunes constitute the history of ethics, religion, philosophy and conscience, and cannot be outlined here. What must be said is that they force us to the attempt to bring the underlying conditions of life, ever in the background as the ultimate arbiters of success and failure, within the scope of intelligent appreciation, so that we may come to understand what has made us that which we are, and what are the ultimate conditions of that fuller harmony for which we seek. In this task of philosophy in its most comprehensive sense the principles underlying the purposes and methods of the mind become objects of the mind capable of critical exposition, and if such a task can ever be completed the extension of scope and increment of power would be comparable to that which came about through the rise of general ideas. It would be a step as great as that which separates human self-consciousness from animal instinct.

COMPARETTI, DOMENICO (1835–1929), Italian scholar, was born at Rome on the 27th of June 1835. He studied at the university of Rome, took his degree in 1855 in natural science and mathematics, and entered his uncle's pharmacy as assistant. His scanty leisure was, however, given to study. He learned Greek by himself, and gained facility in the modern language by conversing with the Greek students at the university. In spite of all disadvantages, he not only mastered the language, but became one of the chief classical scholars of Italy. In 1857 he published, in the *Rheinisches Museum,* a translation of some recently discovered fragments of Hypereides, with a dissertation on that orator. This was followed by a notice of the annalist Granius Licinianus, and one on the oration of Hypereides on the Lamian War. In 1859 he was appointed professor of Greek at Pisa on the recommendation of the duke of Sermoneta. A few years later he was called to a similar post at Florence, remaining emeritus professor at Pisa also. He subsequently took up his residence in Rome as lecturer on Greek antiquities and greatly interested himself in the Forum excavations. He was a member of the governing bodies of the academies of Milan, Venice, Naples and Turin. The list of his writings is long and varied. Of his works in classical literature, the best known are an edition of the *Euxenippus* of Hypereides, and monographs on Pindar and Sappho. He also edited the great inscription which contains a collection of the municipal laws of Gortyn in Crete, discovered on the site of the ancient city. In the *Kalewala and the Traditional Poetry of the Finns* (English translation by I. M. Anderton, 1898) he discusses the national epic of Finland and its heroic songs, with a view to solving the problem whether an epic could be composed by the interweaving of such national songs. He comes to a negative conclusion, and applies this reasoning to the Homeric problem. He treats this question again in a treatise on the so-called Peisistratean edition of Homer (*La Commissione omerica di Pisistrato,* 1881). His *Researches concerning the Book of Sindibād* have been translated in the *Proceedings* of the Folk-Lore Society. His *Vergil in the Middle Ages* (translated into English by E. F. Benecke, 1895) traces the strange vicissitudes by which the great Augustan poet became successively grammatical fetich, Christian prophet and wizard. Together with Professor Alessandro d'Ancona, Comparetti edited a collection of Italian national songs and stories (9 vols., Turin, 1870–1891), many of which had been collected and written down by himself for the first time. Comparetti died in 1929.

COMPASS, a term of which the evolution of the various meanings is obscure; the general sense is "measure" or "measurement," and the word is used thus in various derived meanings—area, boundary, circuit. It is also more particularly applied to a mathematical instrument ("pair of compasses") for measuring or for describing a circle, and to the mariner's compass.

The common mathematical compasses or dividers are composed of two legs or rods, usually of steel, joined together by a pivot-joint at one end and pointed at the other. When used for drawing circles or arcs, the lower parts of the legs are removable or changeable for a new section carrying pen or pencil. *Beam compasses,* which consist of points sliding on a bar, to which they may be clamped at any desired point, are used for lengths greater than the pivot compasses can expand. The compasses used in engineering drawing are more fully described in the article DRAWING, ENGINEERING. It should be noted, however, that while the instruments used in this work are simple in design careful manipulation must be exercised to obtain good results.

Proportional dividers or compasses have a point at each end of the leg and the pivot between, thus forming a double pair of compasses opposite to each other. To adapt these two sets of compasses for variable proportions, the pivot is made a clamping screw and may be fixed at any point, or contains some similar device. In one type of proportional divider the whole length of the legs is divided into 200 equal parts, which are further subdivided into tenths by means of a vernier. By this means any desired ratio may be readily set off. Such an instrument is applicable to a variety of purposes in connections with lines, planes and solids. For example, the ratio between the diameter and the circumference of a circle is quickly obtained by one setting of the vernier, the circumference being reduced to lineal measure. *Triangular compasses* have three legs so that the vertices of a triangle may be all transformed simultaneously. *See* also TOOL: *Measurement.*

The compass has long been used in land surveying as an instrument for determining directions and, indirectly, angles. Almost all of the old surveys in America have been made with the compass as the angle-measuring instrument, and while this instrument to a great extent has been supplanted by the transit there are still many compasses in use. The compass is frequently used in preliminary mine surveys and for exploratory surveys, and the compass on the transit instrument is always used in all but city surveys as a check. A knowledge of the compass and compass surveying is essential to a clear understanding of old surveys, with which every surveyor is concerned when resurveying old lands measured by compass survey. For these reasons, the compass and compass surveying finds a place in every treatise of surveying and is discussed under the article SURVEYING. The solar compass is an instrument for determining the true meridian by an observation on the sun. It was formerly specified for important government surveys in the United States.

There are two distinct types of mariner's compasses in general use at the present time—the magnetic compass, which depends upon the Earth's magnetic field to obtain its directive force, and the gyro-compass (*q.v.*) which obtains its directive force from the Earth's rotation. (X.)

The Magnetic Compass, with which this article is concerned, is an instrument by means of which the directive force of that great magnet, the Earth, upon a freely-suspended needle, is utilized for a purpose essential to navigation. The needle is so mounted that it only moves freely in the horizontal plane, and therefore the horizontal component of the earth's force alone directs it. The direction assumed by the needle is not generally towards the geographical north but diverges towards the east or west of it, making a horizontal angle with the true meridian, called the magnetic variation or *declination;* amongst mariners this angle is known as the variation of the compass. In the usual navigable waters of the world the variation alters from 30° to the east to 45° to the west of the geographical meridian, being westerly in the Atlantic and Indian oceans, easterly in the Pacific. The vertical plane passing through the longitudinal axis of such a needle is known as the *magnetic meridian.* Following the first chart of lines of equal variation compiled by Edmund Halley in 1700, charts of similar type have been published from time to time embodying recent observations and corrected for the secular change, thus providing seamen with values of the variation accurate to about 30′ of arc. Possessing these data, it is easy to ascertain by observation the effects of the iron in a ship in disturbing the compass, and it will be found for the most part in every vessel that the needle is deflected from the magnetic meridian by a horizontal angle called the *deviation* of the compass; in some directions of the ship's head adding to the known variation of the place, in other directions subtracting from it. Local magnetic disturbance of the needle due to magnetic rocks is observed on land in all parts of the world, and in certain

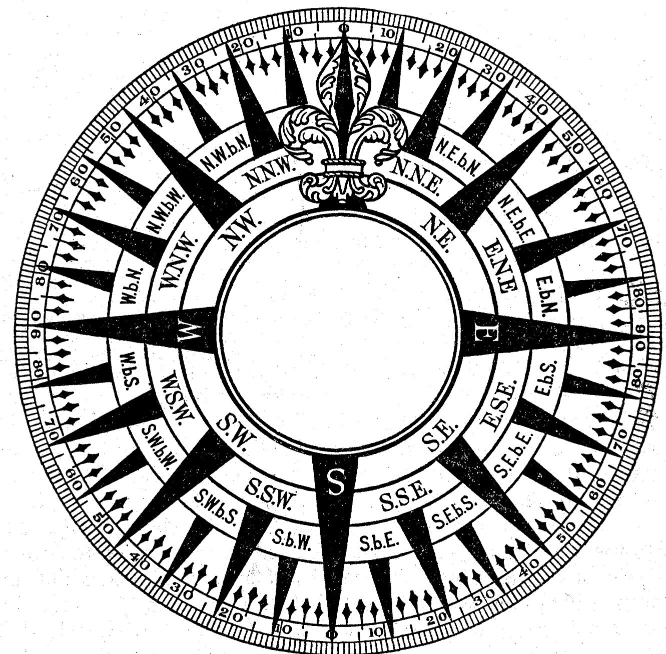

FIG. 1.—COMPASS CARD, SHOWING DIVISIONS INTO POINTS, QUARTER POINTS AND DEGREES. THE NORTH POINT IS EMBELLISHED WITH A "FLEUR DE LYS"

places extends to the land under the sea, affecting the compasses on board the ships passing over it. The general direction of these disturbances in the northern hemisphere is an attraction of the north-seeking end of the needle; in the southern hemisphere, it is repulsion. The approaches to Cossack, North Australia; Cape St. Francis, Labrador; the coasts of Madagascar and Iceland, are remarkable for such disturbance of the compass.

The compass as we know it is the result of the necessities of navigation which have increased from century to century. There are two main types of magnetic compass, the dry card and liquid compass; the former, known as the Thomson compass, invented by the late Lord Kelvin, is almost universally used in the mercantile marine but has been superseded in the British navy by the liquid type.

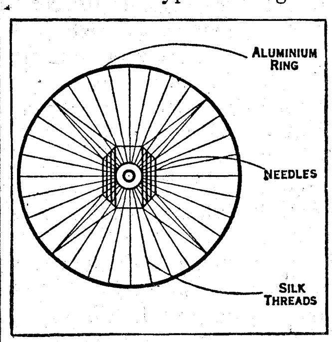

FIG. 2.—COMPASS FRAME TO WHICH CARD IS ATTACHED. THE NEEDLES, SUSPENDED FROM SILK THREADS, DIRECT THE CARD, AND THE WHOLE IS MOUNTED ON AN ALUMINIUM CAP AS SHOWN IN FIG. 3

The Compass Card.—The card consists of a paper ring marked with degrees and points similar to that shown in fig. 1. This is mounted on a frame, fig. 2, where an aluminium ring is connected by 32 radial silk threads to a central disc of aluminium; this is pierced in the centre to receive an aluminium cap with a highly polished sapphire centre worked to the form of an open cone. To direct the card eight short light needles are suspended by silk threads from the outer ring. The magnetic axis of any system of needles must exactly coincide with the axis passing through the north and south points of the card. Single needles are never used, two being the least number, and these are so arranged that the moment of inertia about every diameter of the card shall be the same. The combination of card, needles and cap is generally termed "the card"; on the continent of

Europe it is called the "rose." The section of a compass bowl in fig. 3 shows the mounting of a Thomson card on its pivot, which, in common with the pivots of most other compasses, is made of brass, tipped with osmium-iridium, which although very hard can be sharply pointed and does not corrode. Fig. 3 shows the general arrangement of mounting all compass cards in the bowl. In fig. 4 another form of compass called a liquid or spirit compass is shown partly in section. The card nearly floats in a bowl filled with distilled water, to which 35% of alcohol is added to prevent freezing; the bowl is hermetically sealed with pure india-rubber, and a corrugated expansion chamber is attached to the bottom to allow for the expansion and contraction of the liquid. The card is a mica disk, either painted as in fig. 1, or covered with linen upon which the degrees and points are printed, the needles being enclosed in brass.

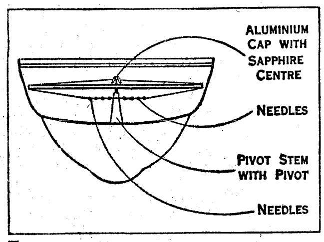

FIG. 3.—THOMSON'S COMPASS BOWL

The bowl is made of brass, a chamber filled with a viscous fluid being attached to the bottom to steady it when resting in the gimbal system of the binnacle

Mounting.—Great steadiness of card under severe shocks, combined with a minimum of friction in the cap and pivot, is obtained from this compass. All compasses are fitted with a gimbal ring to keep the bowl and card level under every circumstance of the ship's motion in a seaway, the ring being connected with the *binnacle* or pedestal by means of journals or knife edges. On the inside of every compass bowl a vertical black line is drawn, or pointer let in, called the "lubber's point," and it is imperative that when the compass is placed in the binnacle the line joining the pivot and the lubber's point be parallel to the keel of the vessel. Thus, when a degree on the card is observed opposite the lubber's point, the angle between the direction in which the ship is steering and the north point of the compass or course is at once seen, and if the magnetic variation and the disturbing effects of the ship's iron are known, the desired angle between the ship's course and the geographical meridian can be computed. In every ship a position is selected for the magnetic compass as free from neighbouring iron as possible. The compass is also provided with an *azimuth circle* or mirror, and a shadow pin or style is placed in the centre of the glass cover, by either of which the variable angle between the compass north and true north called the "total error," or variation and deviation combined can be observed. The binnacles or pedestals for compasses are generally constructed of wood about 4½in. high, and fitted to receive and alter at pleasure the several magnet and soft iron correctors. They are also fitted with different forms of suspension in which the compass is mounted to obviate the mechanical disturbance of the card caused by the vibration of the hull in ships driven by powerful engines.

Aircraft Compasses.—In Oct. 1909, a member of the Admiralty flew with Cody, taking an ordinary liquid compass resting in cotton waste in a box.

After the outbreak of the World War, as a result of the necessity of the situation, much pioneer work was done at the royal aircraft experimental station at Farnborough, and it was found that the main problems to be solved were (i.) to damp the vibrations of the engine to such an extent that they had no effect on the compass, (ii.) to so design the card that the effect on it of change of speed and course, or both, was as small as possible.

Definitely to accomplish (i.), it was necessary to produce a suspension so efficient that the vibrations were practically absorbed before they reached the bowl, and at the same time the compass had to be definitely located.

The bedding of cotton waste and that of horse-hair were later replaced by varying combinations of springs and felt pads, until finally a very efficient suspension was found in Sorbo rubber, which has since been generally employed.

In modern types, provision is made for securing Sorbo pads to the inside of the container in such a manner that they absorb vibrations in a lateral and vertical direction, special means are also provided for locating the compass inside the container so as to avoid any displacement of the lubber point.

Problem No. (ii.) arises owing to the fact that the true vertical is replaced by a false vertical when changes of speed and course, or both, are made. In the space at disposal, it is impossible to explain the effect on the compass under all conditions, but examples are given of the effect of change of speed only and of change of course only, in order to give a general idea of the complications that may arise.

Assume the magnet system to be replaced by a single needle suspended from a point above its centre of gravity and that the aeroplane is steering E. and begins to increase speed. The needle lags behind and is W. of the pivot; it will then swing to meet the line of dip through the pivot and settle there, producing easterly deviation. North and south accelerations have no effect because the line of the needle is not disturbed from the line of dip.

Supposing now a change of course from N. to E., the false vertical points down and W., the deviation is easterly as in the above case; if this deviation is less than the change of course, the compass underestimates the change; if the deviation is equal to the change of course, no turn is indicated at all; and if deviation exceeds the change, the sense of the turn as registered is opposite to the actual turn. The effect is the same turning from N. to W.

Turning from S. to either E. or W., the effect is to exaggerate the turn and is not therefore serious.

Turning from E. to W., there is no immediate effect, as the false vertical points down and N. or S.; but the angle of banking brings the false vertical nearer, or further, from the line of dip, thus diminishing or increasing the directive force.

From the above it will be seen that the most serious trouble arises when course is altered from N. and is commonly called "northerly turning error."

The above effects are the most important, but several others are introduced as well and may modify the former.

Development of the compasses was generally in the hands of the Admiralty compass department from the middle of 1917 onwards and proceeded fairly rapidly until finally, in 1918, the *aperiodic* compass was produced. Up to this time the card, consisting of card, float, and magnet system, was substantial, as, in ship compasses and when disturbed its oscillations were periodic.

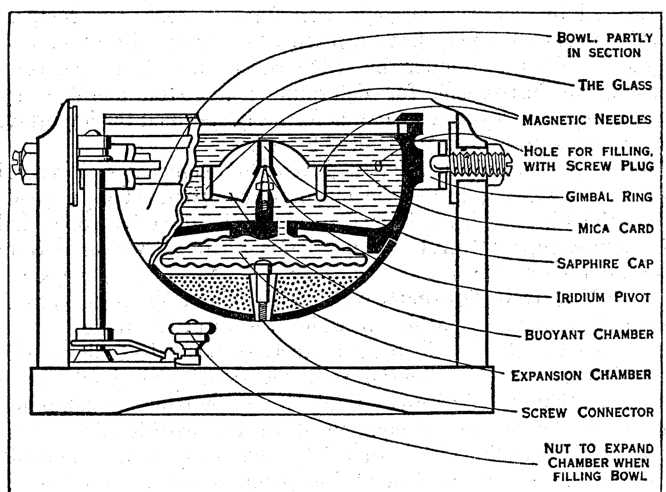

FIG. 4.—THE LIQUID COMPASS, USED IN THE BRITISH NAVY BECAUSE OF ITS COMPARATIVE STABILITY UNDER GUNFIRE

Compared with the dry card magnetic system, this compass is comparatively heavy and is therefore provided with a float. The cap is secured to the float which is so designed that when resting on the pivot the buoyancy is negative and there is a minimum of friction

The Aperiodic Compass.—The card and float were dispensed with, the magnets reduced in size, and wire or glass damping filaments radiating from the cap were introduced. When the system was disturbed, these filaments offered great resistance to passage through the liquid and the oscillations became aperiodic.

Without a card, however, it was difficult to use this instrument as a compass, and to overcome this, two very novel methods were

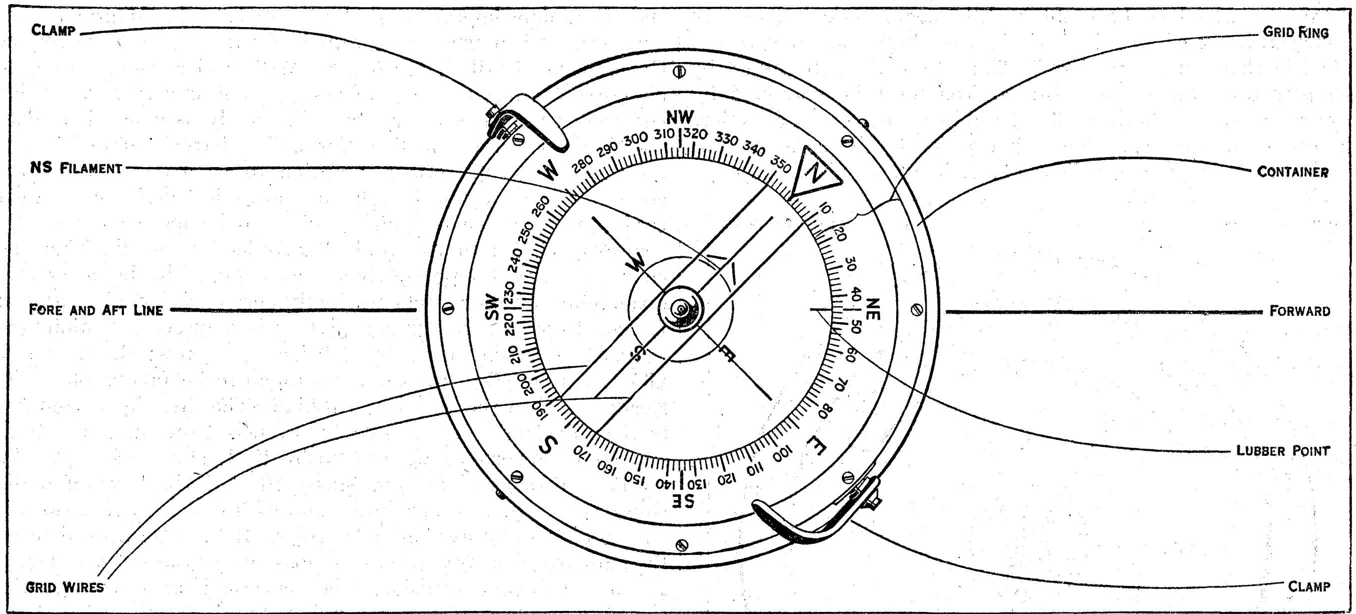

FIG. 5.—COMPASS TYPE P.4., SPECIALLY DESIGNED FOR USE IN AIRCRAFT

Engine vibrations are so successfully resisted that they become aperiodic and do not affect the magnetic system. To this end the card has been abandoned and the grid ring substituted. This is set to the course and the machine turned until the N.S. filament is parallel with the grid wires

introduced. In the first, a graduated ring was fitted to the top of the compass bowl, capable of being rotated and clamped in any position; grid wires were fitted across the inner diameter, running from 0° to 180°. To use this instrument as a compass, the ring is rotated until the course required is opposite the lubber point when it is clamped; the head of the machine is then brought round until the N. S. filament of the magnet system is parallel to the grid wires.

In the second method, a scale, graduated to 100°, is secured to the inner side of the bowl, the centre of the scale being in fore and aft line. The damping filaments are numbered 0, 1, 2, 3 clockwise looking down at the compass and spaced as follows:—100°, 100°, 100°, 60°, making 360° in all, and so secured to the cap that when the 0 filament coincides with the 0 on the scale the heading is North. Similarly with the No. 1 filament at 80° the heading would be South or 180°.

The fact that aeroplanes operate in extremes of temperature provides a further problem. Specifications for modern aeroplane compasses provide for a range of temperature from $-50°$ C to $+50°$. Pure alcohol is the most suitable liquid and will not freeze at the low temperatures. Unfortunately, it has been very difficult to find any paint or other coating which will stand it, the result being discoloration of the liquid and the formation of deposits.

Figures 5 and 6 show two aperiodic compasses, the former fitted with graduated rotatable ring, grid wires and clamp, the latter with the centesimal scale. The courses indicated are respectively N.E. or 45° and 83° or N. 83° E.

Deviation.—The effects of the iron and steel in ships upon the magnetic compass occupied the attention of the ablest physicists of the 19th century. The hull of an iron or steel ship is a magnet, and the distribution of its magnetism depends upon the direction of the ship's head when building, this result being produced by induction from the earth's magnetism, developed and impressed by the hammering of the plates and frames during the process of building. The disturbance of the compass by the magnetism of the hull is generally modified, sometimes favourably, more often unfavourably, by the magnetized fittings of the ship, such as masts, conning towers, deck houses, engines and boilers. Thus in every ship the compass needle is more or less subject to deviation differing in amount and direction for every azimuth of the ship's head. This was first demonstrated by Commander Matthew Flinders's experiments in H.M.S. "Investigator" in 1800–1803, and in 1810 led that officer to introduce the practice of placing the ship's head on each point of the compass and noting the amount of deviation whether to the east or west of the magnetic north, a process which is in full exercise at the present day and is called "swinging ship." When speaking of the magnetic properties of iron it is usual to adopt the terms "soft" and "hard." Soft iron is iron which becomes instantly magnetized by induction when exposed to any magnetic force, but has no power of retaining its magnetism. Hard iron is less susceptible of being magnetized, but when once magnetized it retains its magnetism permanently. The term "iron" used in these pages includes the "steel" now commonly employed in shipbuilding. If an iron ship be swung when upright for deviation, and the mean horizontal and vertical magnetic forces at the compass positions be also observed in different parts of the world, mathematical analysis shows that the deviations are caused partly by the permanent magnetism of hard iron, partly by the transient induced magnetism of soft iron both horizontal and vertical, and in a lesser degree by iron which is neither magnetically hard nor soft, but which becomes magnetized in the same manner as hard iron, though it gradually loses its magnetism on change of conditions, as, for example, in the case of a ship, repaired and hammered in dock, steaming in an opposite direction at sea. This latter cause of deviation is called sub-permanent magnetism. The horizontal directive force on the needle on board is nearly always less than on land, sometimes much less, whilst in armour-plated ships it ranges from ·8 to ·2 when the directive force on land=1·0. If the ship be inclined to starboard or to port additional deviation will be observed, reaching a maximum on N. and S. points, decreasing to zero on the E. and W. points. Each ship has its own magnetic character, but there are certain conditions which are common to vessels of the same type.

Instead of observing the deviation solely for the purposes of correcting the indications of the compass when disturbed by the iron of the ship, the practice is to subject all deviations to mathematical analysis with a view to their mechanical correction. The whole of the deviations when the ship is upright may be expressed nearly by five co-efficients, A, B, C, D, E. Of these A is a deviation constant in amount for every direction of the ship's head. B has reference to horizontal forces acting in a longitudinal direction in the ship, and caused partly by the permanent magnetism of hard iron, partly by vertical induction in vertical soft iron either before or abaft the compass. C has reference to forces acting in a transverse direction, and caused by hard iron. D is due to transient induction in horizontal soft iron, the direction of which passes continuously under or over the compass. E is due to transient induction in horizontal soft iron unsymmetrically placed with regard to the compass. When data of this character have been obtained the compass deviations may be mechanically corrected to within 1°—always adhering to the principle that "like cures like." Thus the part of B caused by the permanent magnetism of hard iron must be corrected by permanent magnets horizontally placed in a fore and aft direction, the other part caused by vertical soft iron by means of bars of vertical soft iron, called Flinders bars, before or abaft the com-

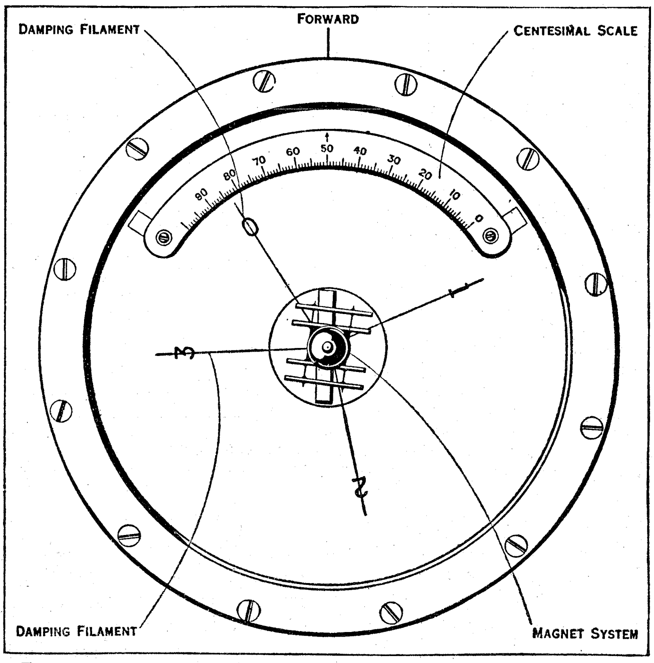

FIG. 6.—AIRCRAFT COMPASS TYPE 253, ANOTHER APERIODIC DESIGN
The absence of the card is here overcome in a different way. The course steered in degrees is the number indicated on the centesimal scale by the appropriate numbered filament, in this case 83°

pass. C is compensated by permanent magnets athwart-ships and horizontal; D by masses of soft iron on both sides of the compass, and generally in the form of cast-iron spheres, with their centres in the same horizontal plane as the needles; E is usually too small to require correction; A is fortunately rarely of any value, it is constant and can be adjusted by moving the lubber line in steering compasses. The deviation observed when the ship inclines to either side is due (1) to hard iron acting vertically upwards or downwards; (2) to vertical soft iron immediately below the compass; (3) to vertical induction in horizontal soft iron when inclined. To compensate (1), vertical magnets are used; (3) is partly corrected by the soft iron correctors of D; (2) and the remaining part of (3) cannot be conveniently corrected for more than one geographical position at a time. Although a compass may thus be made practically correct for a given time and place, the magnetism of the ship is liable to changes on changing her geographical position, and especially so when steaming at right angles or nearly so to the magnetic meridian, for then sub-permanent magnetism is developed in the hull. Some vessels are more liable to become sub-permanently magnetized than others, and as no corrector has been found for this source of deviation the navigator must determine its amount by observation.

Every compass and corrector supplied to ships of the British navy and machines belonging to the air ministry is examined and tested at the admiralty compass observatory.

The director is responsible for investigating the magnetic character of ships, selecting suitable positions for the compasses in the early stages of design and subsequently keeping records of their behaviour; similarly, in the case of machines for the Air ministry, he advises during the mock-up stage.

History.—The mariner's compass during the early part of the 19th century was still very imperfect, although numerous inventors had tried to improve it. In 1837 the admiralty compass committee was appointed to make a scientific investigation of the subject and propose a form of compass suitable alike for azimuth and steering purposes. The committee reported in July 1840, and after minor improvements by the makers the admiralty compass, the card of which is shown in fig. 1, was adopted by the Government. Until 1876, when Sir William Thomson introduced his patent compass, this compass was not only the regulation compass of the British navy, but was largely used in other countries in the same or a modified form. The introduction of powerful engines causing serious vibration to compass cards of the admiralty type, coupled with the prevailing desire for larger cards, the deviation of which could also be more conveniently compensated, led to the gradual introduction of the Thomson compass. Several important points were gained in the latter; the quadrantal deviation could be finally corrected for all latitudes; frictional error at the cap and pivot was reduced to a minimum, the average weight of the card being 200 grains; the long free vibrational period of the card was found to be favourable to its steadiness when the vessel was rolling. The first liquid compass used in England was invented by Francis Crow in 1813. Subsequent improvements were made by E. J. Dent, and especially by E. S. Ritchie, of Boston, Mass. In 1888 the form of liquid compass (fig. 4) was introduced, and with minor modifications is almost universally used in H.M. ships. It has also proved to be the most trustworthy magnetic compass under the shock of heavy gun fire at present available. The deflector is an instrument designed to enable an observer to reduce the deviations of the compass to an amount not exceeding 2° during fogs, or at any time when bearings of distant objects are not available. It is certain that if the directive forces on the N., E., S., and W. points of a compass are equal, there can be no deviation. With the deflector any inequality in the directive force can be detected, and hence the power of equalizing the forces by the usual soft iron and magnet correctors. Several kinds of deflector have been invented, that of Lord Kelvin (Sir William Thomson) being the simplest, but Dr. Waghorn's is also very effective.

The Magnetism of Ships.—In 1814 Flinders first showed (*see* Flinders's *Voyage,* vol. ii. appx. ii.) that the abnormal values of the variation observed in the wood-built ships of his day was due to deviation of the compass caused by the iron in the ship; that the deviation was zero when the ship's head was near the N. and S. points; that it attained its maximum on the E. and W. points, and varied as the sine of the azimuth of the ship's head reckoned from the zero points. He also described a method of correcting deviation by means of a bar of vertical iron so placed as to correct the deviation nearly in all latitudes. This bar, now known as a "Flinders bar," is still in general use. In 1820 Dr. T. Young (*see* Brande's *Quarterly Journal,* 1820) investigated mathematically the magnetism of ships. In 1824 Professor Peter Barlow (1776–1862) introduced his correcting plate of *soft* iron. Trials in certain ships showed that their magnetism consisted partly of hard iron, and the use of the plate was abandoned. In 1835 Captain E. J. Johnson, R.N., showed from experiments in the iron steamship "Garry Owen" that the vessel acted on an external compass as a magnet. In 1838 Sir G. B. Airy magnetically examined the iron steamship "Rainbow" at Deptford, and from his mathematical investigations (see *Phil. Trans.,* 1839) deduced his method of correcting the compass by permanent magnets and soft iron, giving practical rules for the same in 1840. Airy's and Flinders's correctors form the basis of all compass correctors to this day. In 1838 S. D. Poisson published his *Memoir on the Deviations of the Compass caused by the Iron in a Vessel.* In this he gave equations resulting from the hypothesis that the magnetism of a ship is partly due to the permanent magnetism of hard iron and partly to the transient induced magnetism of soft iron; that the latter is proportional to the intensity of the inducing force, and that the length of the needle is infinitesimally small compared to the distance of the surrounding iron. From Poisson's equations Archibald Smith deduced the formulae given in the *Admiralty Manual for Deviations of the Compass* (1st ed., 1862), a work which has formed the basis of numerous other manuals since published in Great Britain and other countries. In view of the serious difficulties connected with the inclining of every ship, Smith's formulae for ascertaining and providing for the correction of the heeling error with the ship upright continue to be of great value to safe navigation. In 1855 the Liverpool compass committee began its work of investigating the magnetism of ships of the mercantile marine, resulting in three reports to the Board of Trade, all of great value, the last being presented in 1861.

Archit.* (1860–62), *Report of Brit. Assoc.* (1862), *London Quarterly Rev.* (1865); also *Admiralty Manual* (1862–1920); Towson's *Practical Information on Deviations of the Compass* (1886). (E. W. C.; G. B. H.)

HISTORY OF THE MARINER'S COMPASS

The discovery that a lodestone, or a piece of iron which has been touched by a lodestone, will direct itself to point in a north and south position, and the application of that discovery to direct the navigation of ships, have been attributed to various origins. The Chinese, the Arabs, the Greeks, the Etruscans, the Finns and the Italians have all been claimed as originators of the compass. There is now little doubt that the claim formerly advanced in favour of the Chinese is ill-founded. In Chinese history we are told how, in the sixty-fourth year of the reign of Hwang-ti (2634 B.C.), the emperor Hiuan-yuan, or Hwang-ti, attacked one Tchi-yeou, on the plains of Tchou-lou, and finding his army embarrassed by a thick fog raised by the enemy, constructed a chariot (Tchi-nan) for indicating the south, so as to distinguish the four cardinal points, and was thus enabled to pursue Tchi-yeou, and take him prisoner. But, as other versions of the story show, this account is purely mythical. For the south-pointing chariots are recorded to have been first devised by the emperor Hian-tsoung (A.D. 806–820); and there is no evidence that they contained any magnet. There is no genuine record of a Chinese marine compass before A.D. 1297, as Klaproth admits. No sea-going ships were built in China before 139 B.C. The earliest allusion to the power of the lodestone in Chinese literature occurs in a Chinese dictionary, finished in A.D. 121, where the lodestone is defined as "a stone with which an attraction can be given to a needle," but this knowledge is no more than that existing in Europe at least five hundred years before. Nor is there any nautical significance in a passage which occurs in the Chinese encyclopaedia, *Poei-wen-yun-fou,* in which it is stated that under the Tsin dynasty, or between A.D. 265 and 419, "there were ships indicating the south."

The Chinese, Sir J. F. Davis informs us, once navigated as far as India, but their most distant voyages at present extend not farther than Java and the Malay Islands to the south (*The Chinese,* 1844). According to an Arabic manuscript, a translation of which was published by Eusebius Renaudot (Paris, 1718), they traded in ships to the Persian Gulf and Red Sea in the 9th century. Sir G. L. Staunton, in vol. i. of his *Embassy to China* (1797), after referring to the early acquaintance of the Chinese with the property of the magnet to point southwards, remarks (p. 445), "The nature and the cause of the qualities of the magnet have at all times been subjects of contemplation among the Chinese. The Chinese name for the compass is *ting-nan-ching,* or needle pointing to the south; and a distinguishing mark is fixed on the magnet's southern pole, as in European compasses upon the northern one." The number of points of the compass, according to the Chinese, is twenty-four, which are reckoned from the south pole; the form also of the instrument they employ is different from that familiar to Europeans. The needle is peculiarly poised, with its point of suspension a little below its centre of gravity, and is exceedingly sensitive; it is seldom more than an inch in length, and is less than a line in thickness. "It may be urged," writes Mr. T. S. Davies, "that the different manner of constructing the needle amongst the Chinese and European navigators shows the independence of the Chinese of us, as theirs is the *worse* method, and had they copied from us, they would have used the better one" (Thomson's *British Annual,* 1837, p. 291). On the other hand, it has been contended that a knowledge of the mariner's compass was communicated by them directly or indirectly to the early Arabs, and through the latter was introduced into Europe.

Sismondi has remarked (*Literature of Europe,* vol. i.) that it is peculiarly characteristic of all the pretended discoveries of the middle ages that when the historians mention them for the first time they treat them as things in general use. Gunpowder, the compass, the Arabic numerals and paper, are nowhere spoken of as discoveries, and yet they must have wrought a total change in war, in navigation, in science, and in education. G. Tiraboschi (*Storia della letteratura italiana,* IV. ii. p. 204, *et seq.,* ed. 2, 1788), in support of the conjecture that the compass was introduced into Europe by the Arabs, adduces their superiority in scientific learning and their early skill in navigation. He quotes a passage on the polarity of the lodestone from a treatise translated by Albertus Magnus, attributed by the latter to Aristotle, but apparently only an Arabic compilation from the works of various philosophers. As the terms *Zoron* and *Aphron,* used there to signify the south and north poles, are neither Latin nor Greek, Tiraboschi suggests that they may be of Arabian origin, and that the whole passage concerning the lodestone may have been added to the original treatise by the Arabian translators.

Dr. W. Robertson asserts (*Historical Disquisition concerning Ancient India,* p. 227) that the Arabs, Turks and Persians have no original name for the compass, it being called by them *Bossola,* the Italian name, which shows that the thing signified is foreign to them as well as the word. The Rev. G. P. Badger has, however, pointed out (*Travels of Ludovico di Varthema,* trans. J. W. Jones, ed. G. P. Badger, Hakluyt Soc., 1863, note, pp. 31 and 32) that the name of Bushla or Busba, from the Italian *Bussola,* though common among Arab sailors in the Mediterranean, is very seldom used in the Eastern seas,—*Daïrah* and *Beit el-Ibrah* (the Circle, or House of the Needle) being the ordinary appellatives in the Red Sea, whilst in the Persian Gulf *Kiblah-nāmeh* is in more general use. Robertson quotes Sir J. Chardin as boldly asserting that "the Asiatics are beholden to us for this wonderful instrument, which they had from Europe a long time before the Portuguese conquests," and proceeds to argue that the Arabs had neither instruments nor charts which were not copied from European ones. The observations of Chardin, who flourished between 1643 and 1713, cannot be said to receive support from the testimony of some earlier authorities. That the Arabs must have been acquainted with the compass, and with the construction and use of charts, at a period nearly two centuries previous to Chardin's first voyage to the East, may be gathered from the description given by Barros of a map of all the coast of India, shown to Vasco da Gama by a Moor of Guzerat (about the 15th of July 1498), in which the bearings were laid down "after the manner of the Moors," or "with meridians and parallels very small (or close together), without other bearings of the compass; because, as the squares of these meridians and parallels were very small, the coast was laid down by these two bearings of N. and S., and E. and W., with great certainty, without that multiplication of bearings of the points of the compass usual in our maps, which serves as the root of the others." Further, we learn from Osorio that the Arabs at the time of Gama "were instructed in so many of the arts of navigation, that they did not yield much to the Portuguese mariners in the science and practice of maritime matters." (See *The Three Voyages of Vasco da Gama,* Hakluyt Soc., 1869; note to chap. xv. by the Hon. H. E. J. Stanley, p. 138.) Also the Arabs that navigated the Red Sea at the same period are shown by Varthema to have used the mariner's chart and compass (*Travels,* p. 31).

Again, it seems that compasses of a primitive description, which can hardly be supposed to have been brought from Europe, were employed in the East Indies certainly as early as several years previous to the close of the 16th century, as appears from William Barlowe's *Navigator's Supply,* published in 1597. Bailak Kibdjaki, also, an Arabian writer, shows in his *Merchant's Treasure,* a work given to the world in 1282, that the magnetized needle, floated on water by means of a splinter of wood or a reed, was employed on the Syrian seas at the time of his voyage from Tripoli to Alexandria (1242), and adds:—"They say that the captains who navigate the Indian seas use, instead of the needle and splinter, a sort of fish made out of hollow iron, which, when thrown into the water, swims upon the surface, and points out the north and south with its head and tail" (Klaproth, *Lettre,* p. 57). Furthermore, although the sailors in the Indian vessels in which Niccola de' Conti traversed the Indian seas in 1420 are stated to have had no compass, still, on board the ship in which Varthema, less than a century later, sailed from Borneo to Java, both the mariner's chart and compass were used; it has been questioned, however, whether in this case the compass was of Eastern manufacture (*Travels of Varthema,* p. 249). We have already seen that the Chinese as late as the end of the 18th century made voyages with compasses on which but little reliance could be placed; and it may perhaps be assumed that the compasses early used in the East were mostly too imperfect to be of much assistance to navigators, and were therefore often dispensed with on customary routes. The Arab traders in the Levant certainly used a floating compass, as did the Italians before the introduction of the pivoted needle; the magnetized piece of iron being floated upon a small raft of cork or reeds in a bowl of water. The Italian name of *calamita,* which still persists, for the magnet, and which literally signifies a frog, is doubtless derived from this practice.

The Arabic geographer, Edrisi, who lived about 1100, is said by Boucher to give an account, though in a confused manner, of the polarity of the magnet (Hallam, *Mid. Ages,* iii. 9, part 2); but the earliest definite mention as yet known of the use of the mariner's compass in the middle ages occurs in a treatise entitled *De utensilibus,* written by Alexander Neckam in the 12th century. He speaks there of a needle carried on board ship which, being placed on a pivot, and allowed to take its own position of repose, shows mariners their course when the polar star is hidden. In another work (*De naturis rerum,* ii. 89) he writes,—"Mariners at sea, when, through cloudy weather in the day which hides the sun, or through the darkness of the night, they lose the knowledge of the quarter of the world to which they are sailing, touch a needle with the magnet, which will turn round till, on its motion ceasing, its point will be directed towards the north" (W. Chappell, *Nature,* 1876). The magnetical needle, and its suspension on a stick or straw in water, are clearly described in *La Bible Guiot,* a poem probably of the 13th century, by Guiot de Provins, wherein we are told that through the magnet (*la manette* or *l'amanière*), an ugly brown stone to which iron turns of its own accord, mariners possess an art that cannot fail them. A needle touched by it, and floated by a stick on water, turns its point towards the pole-star, and a light being placed near the needle on dark nights, the proper course is known (*Hist. littéraire de la France,* ix. p. 199; Barbazan, *Fabliaux,* ii. p. 328). Cardinal Jacques de Vitry, bishop of Acon in Palestine, in his *History* (cap. 89), written about the year 1218, speaks of the magnetic needle as "most necessary for such as sail the sea"; and another French crusader, his contemporary, Vincent de Beauvais, states that the adamant (lodestone) is found in Arabia, and mentions a method of using a needle magnetized by it which is similar to that described by Kibdjaki.

In 1248 Hugo de Bercy notes a change in the construction of compasses, which are now supported on two floats in a glass cup. From quotations given by Antonio Capmany (*Questiones Criticas*) from the *De contemplatione* of Raimon Lull, of the date 1272, it appears that the latter was well acquainted with the use of the magnet at sea, and before the middle of the 13th century the poets Gauthier d'Espinois and Guido Guinizzelli allude to the compass needle. Brunetto Latini also makes reference to the compass in his encyclopaedia *Livres dou trésor,* composed about 1260 (I. ii. 120). Dante (*Paradiso,* xii, 28–30) mentions the pointing of the magnetic needle toward the pole star. In Scandinavian records there is a reference to the nautical use of the magnet in the *Hauksbók,* the last edition of the *Landnámabók* (Book of the Colonization of Iceland):—"Floki, son of Vilgerd, instituted a great sacrifice, and consecrated three ravens which should show him the way (to Iceland); for at that time no men sailing the high seas had lodestones up in northern lands."

Haukr Erlendsson, who wrote this paragraph about 1300, died in 1334; his edition was founded on material in two earlier works, that of Styrmir Karason (who died 1245), which is lost, and that of Hurla Thordson (died 1284) which has no such paragraph. All that is certain is a knowledge of the nautical use of the magnet at the end of the 13th century. From T. Torfaeus we learn that the compass, fitted into a box, was already in use among the Norwegians about the middle of the 13th century (*Hist. rer. Norvegicarum,* iv. p. 345, Hafniae, 1711); and it is probable that the use of the magnet at sea was known in Scotland at or shortly subsequent to that time, though King Robert, in crossing from Arran to Carrick in 1306, as Barbour writing in 1375 informs us, "na nedill had na stane," but steered by a fire on the shore. Roger Bacon (*Opus majus* and *Opus minus,* 1266–1267) was acquainted with the properties of the lodestone, and wrote that if set so that it can turn freely (swimming on water) it points toward the poles; but he stated that this was not due to the pole-star, but to the influence of the northern region of the heavens.

The earliest unquestionable description of a pivoted compass is that contained in the remarkable *Epistola de magnete* of Petrus Peregrinus de Maricourt, written at Lucera in 1269 to Sigerus de Foncaucourt. Of this work twenty-eight mss. exist; seven of them being at Oxford. The first part of the epistle deals generally with magnetic attractions and repulsions, with the polarity of the stone, and with the supposed influence of the poles of the heavens upon the poles of the stone. In the second part Peregrinus describes first an improved floating compass with fiducial line, a circle graduated with 90 degrees to each quadrant, and provided with movable sights for taking bearings. He then describes a new compass with a needle thrust through a pivoted axis, placed in a box with transparent cover, cross index of brass or silver, divided circle, and an external "rule" or alhidade provided with a pair of sights. In the Leiden ms. of this work, which for long was erroneously ascribed to one Peter Adsiger, is a spurious passage, long believed to mention the variation of the compass.

Prior to this clear description of a pivoted compass by Peregrinus in 1269, the Italian sailors had used the floating magnet, probably introduced into this region of the Mediterranean by traders belonging to the port of Amalfi, as commemorated in the line of the poet Panormita: "Prima dedit nautis usum magnetis Amalphis." This opinion is supported by the historian Flavius Blondus in his *Italia illustrata,* written about 1450, who adds that its certain origin is unknown. In 1511 Baptista Pio in his *Commentary* repeats the opinion as to the invention of the use of the magnet at Amalfi as related by Flavius. Gyraldus, writing in 1540 (*Libellus de re nautica*), misunderstanding this reference, declared that this observation of the direction of the magnet to the poles had been handed down as discovered "by a certain Flavius." From this passage arose a legend, which took shape only in the 17th century, that the compass was invented in the year 1302 by a person to whom was given the fictitious name of Flavio Gioja, of Amalfi.

From the above it will have been evident that, as Barlowe remarks concerning the compass, "the lame tale of one Flavius at Amelphus, in the kingdome of Naples, for to have devised it, is of very slender probabilitie"; and as regards the assertion of Dr. Gilbert, of Colchester (*De magnete,* p. 4, 1600), that Marco Polo introduced the compass into Italy from the East in 1260, we need only quote the words of Sir H. Yule (*Book of Marco Polo*): "Respecting the mariner's compass and gunpowder, I shall say nothing, as no one now, I believe, imagines Marco to have had anything to do with their introduction."

When, and by whom, the compass card was added is a matter of conjecture. Certainly the *Rosa Ventorum,* or *Wind-rose,* is far older than the compass itself; and the naming of the eight principal "winds" goes back to the Temple of the Winds in Athens built by Andronicus Cyrrhestes. The earliest known wind-roses on the *portulani* or sailing charts of the Mediterranean pilots have almost invariably the eight principal points marked with the initials of the principal winds, Tramontano, Greco, Levante, Scirocco, Ostro, Africo (or Libeccio), Ponente and Maestro, or with a cross instead of L, to mark the east point. The north point, indicated in some of the oldest compass cards with a broad arrowhead or a spear, as well as with a T for Tramontano, gradually developed by a combination of these, about 1492, into a *fleur de lis,* still universal. The cross at the east continued even in British compasses till about 1700. Wind-roses with these characteristics are found in Venetian and Genoese charts of early 14th century, and are depicted similarly by the Spanish navigators. The naming of the intermediate subdivisions making up the thirty-two points or rhumbs of the compass card is probably due to Flemish navigators; but they were recognized even in the time of Chaucer, who in 1391 wrote, "Now is thin Orisonte departed in xxiiii. partiez by thi azymutz, in significacion of xxiiii. partiez of the world: al be it so that ship men rikne thilke partiez in xxxii." (*Treatise on the Astrolabe,* ed. Skeat, Early English Text Soc., 1872). The mounting of the card upon the needle or "flie," so as to turn with it, is probably of Amalphian origin. Da Buti, the Dante commentator, in 1380 says the sailors use a compass at the middle of which is pivoted a wheel of light paper to turn on its pivot, on which wheel the needle is fixed and the star (wind-rose) painted. The placing of the card at the bottom of the box, fixed, below the needle, was practised by the compass-makers of Nuremberg in the 16th century, and by Stevinus of Bruges about 1600. The gimbals or rings for suspension hinged at right-angles to one another, have been erroneously attributed to Cardan, the proper term being *cardine,* that is hinged or pivoted. The earliest description of them is about 1604. The term *binnacle,* originally *bittacle,* is a corruption of the Portuguese *abitacolo,* to denote the housing enclosing the compass, probably originating with the Portuguese navigators.

The improvement of the compass has been but a slow process. *The Libel of English Policie,* a poem of the first half of the 15th century, says with reference to Iceland (chap. x.)—

> Out of Bristowe, and costes many one,
> Men haue practised by nedle and by stone
> Thider wardes within a litle while.
> (Hakluyt, *Principal Navigations,* p. 201, 1599).

From this it would seem that the compasses used at that time by English mariners were of a very primitive description. Barlowe, in his treatise *Magnetical Advertisements,* printed in 1616 (p. 66), complains that "the Compasse needle, being the most admirable and useful instrument of the whole world, is both amongst ours and other nations for the most part, so bungerly and absurdly contrived, as nothing more." The form he recommends for the needle is that of "a true circle, having his Axis going out beyond the circle, at each end narrow and narrower, unto a reasonable sharpe point, and being pure steele as the circle it selfe is, having in the middest a convenient receptacle to place the capitell in." In 1750 Dr. Gowan Knight found that the needles of merchant-ships were made of two pieces of steel bent in the middle and united in the shape of a rhombus, and proposed to substitute straight steel bars of small breadth, suspended edge-wise and hardened throughout. He also showed that the Chinese mode of suspending the needle conduces most to sensibility. In 1820 Peter Barlow reported to the Admiralty that half the compasses in the British Navy were mere lumber and ought to be destroyed. He introduced a pattern having four or five parallel straight strips of magnetized steel fixed under a card, a form which remained the standard admiralty type until the introduction of the modern Thomson (Kelvin) compass in 1876. COMPASS PLANT, a native of the interior of North American prairies, which takes its name from the position assumed by the leaves. These turn their edges approximately to north and south, thus avoiding the excessive midday heat, while getting the full benefit of the morning and evening rays. The compass plant (*Silphium laciniatum*), called also pilot-weed and rosin-weed, belongs to the family Compositae. Another member of the same family, *Lactuca Scariola,* which has been regarded as the parent species of the cultivated lettuce (*L. sativa*), behaves in the same way when growing in dry exposed places; it is a native of Europe and northern Asia which has been widely introduced into North America.

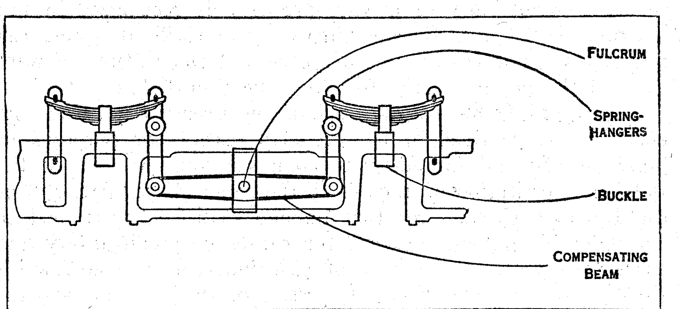
COMPAYRÉ, JULES GABRIEL (1843–1913), French educationalist, was born at Albi on Jan. 2, 1843, and died on Feb. 24, 1913, in Paris. After holding various educational appointments he became in 1881 deputy for Lavaur in the chamber, and took an active part in the discussions on public education. Defeated at the elections of 1889, he was appointed rector of the Academy of Poitiers in 1890, and five years later to the Academy of Lyons. His principal publications are his *Histoire critique des doctrines de l'éducation en France* (1879); *Éléments d'éducation civique* (1881), a work placed on the index at Rome, but very widely read in the primary schools of France; *Cours de pédagogie théorique et pratique* (1885, 13th ed., 1897); *L'évolution intellectuelle et morale de l'enfant* (1893); and a series of monographs on *Les Grands Éducateurs.*

COMPENSATING BEAM. The name given to a lever which connects mechanical actions in such a manner as to provide an equalizing effect, or else causes synchronization of movements.



SKETCH OF A COMPENSATING BEAM IN AN AMERICAN LOCOMOTIVE
Applied to the axle box springs, and pivoted by pins through the fulcrum blocks, it equalizes the pressures, thus minimizing shocks due to running on uneven road beds

The principal example is that extensively applied to the axle-box springs of locomotives, particularly in countries where the roads are rather uneven. Injurious jerks and shocks are transmitted by the constantly varying loads on the respective axles. But if a lever is pivoted at the centre of its length, and the ends attached to the ends of the hangers of two springs, the result will be an equalization of the loads. These beams are variously fitted, in some locomotives between the driving-wheel springs, in others also between a rear driving-wheel set and those of a trailing axle, while compensation between the springs of leading driving-wheels and those of a pony truck is often made. The pivoting of the beam may be by holes and pins through the fulcrum blocks, or else the beam has half-circles cut out for the pivot or, rather, roller pins. The former arrangement is depicted in the drawing from an American locomotive. Some designs of central buffers embody a compensating beam to obviate uneven working.

COMPENSATION, a term applied in English law to a number of different forms of legal reparation; *e.g.,* under the Forfeiture Act 1870 (s.4), for loss of property caused by felony, or—under the Riot (Damages) Act 1886—to persons whose property has been stolen, destroyed, or injured by rioters (*see* RIOT). It is due, under the Agricultural Holdings Act 1883-1906, for agricultural improvements (*see* LANDLORD AND TENANT; *cf.* also ALLOTMENTS and SMALL HOLDINGS); under the Workmen's Compensation Act 1906 to workmen, in respect of accidents in the course of their employment (*see* WORKMEN'S COMPENSATION). Under the Licensing Act 1904, it is payable on the extinction of licences to sell intoxicants; under the Government Obligations Acts 1914 to 1916, for damage to property resulting from hostile action; under the Workmen's Compensation (Illegal Employment) Act 1918, for injuries which have been sustained by workmen in certain cases of illegal employment; under the Allotments Act 1922, to tenants for growing crops; and under the Landlord and Tenant Act 1927, for improvements and goodwill to tenants of business premises.

Compensation, in its most familiar sense, is a legal term for the reparation or satisfaction made to the owners of property which is taken by the State or by local authorities or by the promoters of public utilities under statutory authority.

The right of individual ownership had, up to quite recent times, one exception, viz., slavery. Men were free or unfree. The latter, in law, had no rights, but the former could dispose freely of their persons and of their property. This right of individual ownership has recently been challenged in Russia, which has abolished the right to private property, and has expropriated it for alleged public purposes without compensation. To a large extent, however, the U.S.S.R. has been compelled to reverse this policy and to recognize the right of individual ownership. Its example was followed by most of the Succession States which arose as a result of the World War. Influenced by the wave of communism which almost overwhelmed them, these States in the name of agrarian reform have expropriated private landowners either with inadequate compensation or with none at all. It is alleged that although individual ownership is one of the fundamental rights according to natural law or morality, it possesses no juridical basis. It may, however, be stated with confidence that the inviolability of private property is recognized in (1) the municipal law of the great majority of civilized states; (2) international law (*a*) in time of peace and (*b*) in time of war; and (3) the Peace Treaties following the World War.

Municipal Law—By Art. 545 of the French Civil Code, no one may be deprived of his property except for purposes of public utility and for adequate compensation. Art. 11 of the Belgian Constitution of 1893 is to the same effect. Art. 438 of the Italian Code declares that no one shall be constrained to surrender his property, except for causes of public utility and subject to *previous* payment of just indemnity. The Spanish Code is to the same effect. By Art. 3 of the Law of 1879 expropriation must be preceded by (1) declaration of public utility, (2) declaration that the whole or part of the land is indispensably required, (3) a just valuation, and (4) payment of the compensation. The provisions for the protection of private property in most of the South American republics are similar, with the addition borrowed from the United States that no one may be deprived thereof without due process of law. By Art. 153 of the Constitution of the German Federation property is guaranteed. Expropriation is admissible only in the public interest and so far as authorized by law. Adequate compensation must be given unless a federal law otherwise determines. Expropriation by the Federal Government as against States, local communities and associations serving public interests is permitted only if accompanied by compensation. By Art. 80 of the Danish Constitution; Art. 625 of the Netherlands Civil Code; Art. 104 and 105 of the Constitution of Norway, and others, the same principles of inviolability and compensation are also recognized.

In England it used to be said that the Crown is entitled by its prerogative to take the property of the subject without compensation; but this is not borne out either by the judicial decisions or by the practice of the executive. By Magna Carta, ch. 39, "no freeman shall be deprived of his freehold"; by the Petition of Right, "the ancient and undoubted right of every freeman is that he hath a full and absolute property in his goods and estate"; and by the Bill of Rights, "whereas by the common law and statutes every freeman hath a proprietie in his goods and estate." In the *Case of the King's Prerogative in Saltpetre* (1606), although it was held that the king might dig for saltpetre in land of a subject for the defence of the realm, nothing was said about compensation. In *X's Petition of Right* (1915) 3 K.B. 649, Avory J. held that the king by virtue of his prerogative was entitled to take possession of land for the defence of the realm without compensation. This decision was affirmed by the Court of Appeal, but in *De Keyser's Royal Hotel, Ltd.* v. *The King* (1920) A.C. 508, where the Crown claimed to take property for administrative purposes without compensation, the Court of Appeal ordered an examination of the records to be made, from which it appeared that from a very early period—1492—to modern times the Crown had never taken a subject's land without paying for it, and that there was no trace of any claim by the Crown to such a prerogative. It was further held that where a matter within the prerogative is provided for by statute the prerogative is merged in the Crown, and that by the Defence Act 1842 provision is made for payment of compensation "either for the absolute purchase thereof or for the possession of the use thereof during such time as the exigence of the public service shall require." This decision was affirmed by the House of Lords, which held, *inter alia,* that the Crown had no power to take possession of the premises in right of its prerogative *simpliciter,* and that the suppliants were entitled to compensation under the Act of 1842. In the later case of *France, Fenwick & Co., Ltd.* v. *The King* (1926) 43 T.L.R. 18, Wright J. said, "I shall assume that the Crown has no right at common law to take a subject's property for reasons of State without paying compensation." Thus it is a well established principle of English law that when the Crown takes the property of a subject the dispossessed owner is, as of right, entitled to full compensation. Where land is taken by the Crown, by local authorities, or by promoters of undertakings under statutory authority the amount of compensation is determined by agreement or by arbitration under the provisions of the Land Clauses Act 1845 and the Land Clauses Consolidation Act 1860. Similar Acts have been enacted in Scotland, India, and most of the Colonies. Compensation is also payable for land compulsorily acquired under numerous statutes, *e.g.,* Acquisition of Land (Assessment of Compensation) Acts 1919; Housing Act 1923; Public Health Act 1925; Town Planning Act 1925, and Housing Act 1925.

International Law.—The principle of the inviolability of private property has long been recognized by international jurists and publicists. It has been applied both in time of peace and in time of war, and has been embodied in numerous treaties.

It is a general rule of international law that private rights and private property to whomsoever belonging are not affected by the conquest, annexation, or cession of the territory in which they are situate. This fundamental right has been judicially affirmed in the United States in numerous cases, *e.g., U.S.* v. *Percheman,* 7 Peters 51 (1883). Apart from treaties it has long been recognized, first that a State is entitled to protect its subjects in another State from injury to their property resulting from measures in the application of which there is *discrimination* between them and the subjects of such other State; and secondly, that a State is entitled to protect its subjects in another State from *injustice* at the hands of such other State even though the measure complained of is applied equally to the subjects of such State. "A sovereign," said the American secretary of state, Frelinghuysen, in 1885, "who departs from the principles of public law cannot find excuse therefore in his own municipal code."

It is probably true to say that down to the end of the 16th century all enemy property, public or private, found by a belligerent within his territory at or after the outbreak of hostilities was liable to seizure and confiscation. Private property of immediate use in war is still liable to seizure, but is now subject to an obligation of restitution or, if it has been destroyed or consumed, of payment of its value. With regard to private property of other kinds there has in practice been gradual mitigation of confiscation, until all property, whether land or goods, and choses in action, such as debts and credits, enjoyed immunity from confiscation. Since the beginning of the 19th century we find only two instances of confiscation. One was the confiscation of property of British subjects found in Denmark in 1807—for which there had been no precedent for more than a century—and the other the decree issued in 1861 by the Southern Confederacy during the American Civil War confiscating all property of whatsoever kind except public stocks and securities held by alien enemies. According to the Continental theory immunity is obligatory, subject only to such qualifications as may be imposed by military necessity or public emergency; whilst the Anglo-American theory recognizes a right of confiscation, subject to a general policy of immunity. In their practical application each would permit confiscation in exceptional circumstances, such as public necessity or by way of reprisal, whilst, apart from such exceptions, each would recognize immunity. See *Brown* v. *United*

States, 8 Cranch, 110 (1814); *In re Ferdinand Ex-Tsar of Bulgaria* (1921), 1 Ch. 107. Upon the outbreak of the World War none of the belligerents attempted to confiscate enemy private property. On the contrary measures were adopted by all of them for its safe custody.

Treaties.—The principle of the inviolability of private property was embodied in the Peace Treaties concluded during and after the World War. Thus the Brest-Litovsk Peace Treaty of March 3, 1918, declared that it was not permissible to expropriate property rights without adequate compensation. This principle was expressly recognized in the Peace Treaties of Versailles, St. Germain-en-Laye, Trianon and Neuilly. It is true that liquidation of enemy private property within their own territories was granted to the Allied and Associated Powers. The property, however, was not confiscated, but its value credited to the reparation account of the conquered State. There was no intention to confiscate, although as a rule confiscation resulted, through the failure of the conquered States to compensate their own nationals in accordance with the terms of the Treaties. Further the property rights and interests of former enemy nationals in the Succession States are protected by express provisions in the treaties. If such rights and interests are expropriated or interfered with, the amount of compensation or damages is to be determined by the Mixed Arbitral Tribunals which have been established by the treaties (*see* the Vienna Report, International Law Association, 1927). (H. H. L. B.)

United States.—The fifth amendment to the U.S. Constitution provides that "no person shall be . . . deprived of life, liberty or property without due process of law; nor shall private property be taken for public use without just compensation." This amendment is construed as limiting the power of the Federal Government alone. The 14th amendment, however, applies to the States, and while it contains no clause specifically requiring just compensation when property is taken for a public use, such a requirement is none the less assumed to be implied in the clause that no State shall "deprive any person of life, liberty or property without due process of law." Property rights, however, are not "inviolable" in any absolute sense. The Supreme Court said, in sustaining the emergency rent laws of the District of Columbia in 1921—"The fact that tangible property is also visible tends to give rigidity to our conception of our rights in it that we do not attach to others less concretely clothed. But the notion that the former are exempt from the legislative modification required from time to time in civilized life is contradicted not only by the doctrine of eminent domain, under which what is taken is paid for, but by that of the police power in its proper sense, under which property rights may be cut down, and to that extent taken, without pay. Under the police power the right to erect buildings in a certain quarter of a city may be limited to from eighty to one hundred feet. *Welch* v. *Swasey,* 214 U.S. 91. Safe pillars may be required in coal mines. *Plymouth Coal Co.* v. *Pennsylvania,* 232 U.S. 531. Billboards in cities may be regulated. *St. Louis Poster Advertising Co.* v. *St. Louis,* 249 U.S. 269. Watersheds in the country may be kept clear. *Perley* v. *North Carolina,* 249 U.S. 511. These cases are enough to establish that a public exigency will justify the legislature in restricting property rights in land to a certain extent without compensation. . . . The only matter that seems to us open to debate is whether the statute goes too far. For just as there comes a point at which the police power ceases and leaves only that of eminent domain, it may be conceded that regulations of the present sort pressed to a certain height might amount to a taking without due process of law . . ." (*Block* v. *Hirsh,* 256 U.S. 135). Where eminent domain (*q.v.*) is the power used, money compensation must be given, equivalent in general to what the owner loses. The concept is at times ambiguous and is generally said to call for the market value of the property, although that, too, is at times ambiguous and it may sometimes fail to protect the expropriated owner from loss, as in *Banner Milling Co.* v. *State* (240 N.Y. 533, *certiorari* denied, 269 U.S. 582, 1925), where compensation did not include loss due to the cost of moving the business or interrupting its good will. (R. L. Ha.)

COMPENSATION INSURANCE: *see* WORKMEN'S COMPENSATION.

COMPETITION FESTIVALS: *see* FESTIVALS, MUSICAL.

COMPETITION IN INDUSTRY. According to doctrines evolved in the course of the eighteenth century and formulated by economists from Quesnay to Adam Smith, the well-being of a community is better served by leaving the individual free to manage his own affairs in his own way in the light of what he conceives to be his own interest than by subjecting him to interference by even the best intentioned government. Left to his own devices under conditions of economic freedom the individual will find his greatest gain in furnishing those goods or services for which there is most demand, and will, in the long run, find little profit in exacting a price much higher than his total expense of production. During the course of the Industrial Revolution these doctrines gained general acceptance, and, by the middle of the 19th century, the beneficially self-impelling and self-regulating nature of the economic order was widely held as an article of faith, to be reinforced a little later by the application to human affairs of what was popularly understood to be the Darwinian theory of progress, proceeding by a struggle for existence in which the least fit go under and the most fit survive.

The outlook of the 19th century upon the economic order came therefore to be increasingly dominated by the view that supplies, prices, profits, and wages were best left to look after themselves. Let the State give no privileges and set no impediments, let it be content to make the rules, let it leave the business world to its own devices, and competition would ensure that all would be for the best. The desire for gain would urge each to maximum effort; and competition would harmonize supplies and requirements, would ensure that the level of wages, prices, and profits were about what they ought to be, and would make for the elimination of the less fit economic unit and the survival of the more fit—the better placed, the more energetic, the more adaptable.

Law of Competition.—The "law of competition" under which, in conditions of economic freedom, these eminently desirable results achieve themselves may be set out crudely as follow:—(a) whenever demand grows in proportion to supply, competition between would-be buyers sends up the price; (b) a relatively high price spells a relatively large profit; (c) a relatively large profit attracts capital and enterprise to the industry; (d) supplies increase; (e) competition between sellers brings down the price until it barely covers production expense including a normal profit: whenever supply grows in proportion to demand, (a) prices fall; (b) profits shrink; (c) the weaker producers drop out of business leaving the stronger to carry on; (d) supplies contract; (e) profits rise to normal; and the cycle begins afresh.

Similarly, wages tend to find their own "natural" level in the competition of employers for workpeople and of workpeople for the best-paid employment.

What was not sufficiently realized by those who pinned their economic faith to the "law of competition" was that the law will operate completely and effectively only where a condition of perfect economic freedom prevails and where buyers and sellers have the widest knowledge of present and prospective demands, supplies, and prices. A condition of economic freedom demands something more than non-interference on the part of the State; it demands the free access of buyers to sellers and the absence of all action in restraint of free competition on the part of those engaged in industry. At no time has such a condition prevailed over the whole of industry and trade. It was probably most nearly reached in the first half of the 19th century when, following upon the great inventions, the improvement in transport, and the extension of joint-stocks financing, new enterprises sprang up and offered their wares with a minimum of collusion over extensive areas; but even then economic freedom was far from perfect. And it was to become steadily less so. By the 'seventies or 'eighties a new "law" began to force itself on the attention of the economic world; the law that "competition begets combination." However natural competition may be, it is not in human nature that several sellers should go on undercutting each other to the advantage of buyers when by agreement between themselves they can establish a higher price or control the common output and so keep prices above the competitive level. It is this second "law" that has already come to engage the attention of governments in many countries and is likely to constitute one of the major problems of government for many generations to come.

None the less, competition still prevails over wide areas of trade and industry, and in examining the nature and governance of demand, supply, and price, it is still convenient first to assume free competition and then to enquire into the extent to which the limitation of competition by external circumstance or by the deliberate action of interested parties nullifies the conclusions reached.

Kinds of Competition.—Competition is not necessarily to be identified with harshness or aggression. A common form of competition between producers or sellers is competition *in service*. The grocer "serves" his customers, and if he can "serve" them more acceptably than the rival grocer in the next street he will increasingly attract their custom. He cannot thereby be considered as displaying a ruthless attitude towards his rival. The grocer in the next street may be a very good fellow, and it may be pitiable that his business should decline, but the increasingly patronized grocer would find little moral justification for relaxing, on that account, his efforts to serve his customers well. His highest obligation is to do as well as he can that to which he has set his hand. If both were class-conscious members of a Grocers' Trade Union, the stronger might go easy with his service in order not to set a standard which would force the pace of the weaker; but to sacrifice service to loyalty is only to forsake one virtue for another—not necessarily higher. The more successful grocer may in human fellowship give his rival a hand in improving his service and so acquire double merit, but the fact that rivals do not universally do so reflects not upon competition but upon human nature.

The creative competition which centres upon the rendering of better service, even though it leaves the weakest to go to the wall and the hindmost to the devil, is in itself honourable and beneficial. In this respect it commonly differs from competition not of service but of injury. If the prospering grocer, not content with excelling by service, sets himself deliberately to injure his rival's business—by blocking his sources of supply, by selling goods below cost until the rival is driven from the field, or by false advertising,—the morality and social advantage of his proceeding become highly questionable. Such aggressive competition aimed at the injury of a rival may be defended with much plausibility on the ground that it merely speeds up the process of weeding out the inferior, and the argument might be acceptable if it were true that the power of aggression is always a measure of fitness to serve. To assume that such is the case is, however, just as dubious as to claim that the competitor in a footrace who gained first place by doping or bludgeoning his rivals was necessarily the best runner. One of the commonest types of competition pertains to quality and price. Each competitor endeavours either to sell the same article at a price lower than that quoted by his rival, or a better article at the same price. Such competition is commonly aided by informative advertising—a device which helps the average person to satisfy his wants more cheaply, more satisfactorily, and far more easily than if this method of broadcasting information did not exist. In this connection, the fact should be noted that, to justify the advertising of an article on a wide scale, it must be of such a quality as to satisfy the desires of those who purchase it.

Wastefulness of Competition.—In so far as advertising fails to increase knowledge concerning the quality and availability of goods, but merely induces buyers to shift their purchasing without gain to themselves, it represents a waste of materials and human effort. The degree to which such waste occurs is a matter of dispute.

Aggressive competition often expends effort in nugatory combat which might much more beneficially be given to improving and cheapening method, process, and product. Undercutting among rival manufacturers may lead to goods being sold at "cut-throat" prices; but the price may none the less be higher than it might be if the individual firms were in friendly communication or if the manufacture were concentrated in a few, instead of spread over many, establishments. Competitive production often means a wasteful duplication of activity and plant; it results in each firm working out its technical and commercial problems without help from the others; it allows each manufacturer to go in for many varieties and patterns and to specialize in none; it leaves each firm to buy in small quantities, to market in small parcels, and to carry separate stocks. It leads to needless multiplication of shops of all types, with the result that most shopkeepers make but a meagre livelihood, and far too many persons are diverted to the mercantile field when they would benefit society more by working in other industries. Thus, competition may stimulate the will to serve and yet deny the means. For these reasons goods produced under a régime of free competition may be dear even though the competing producers are making less than a living profit.

One of the most serious defects of the competitive system in an advanced industrial order arises out of the time lag between the decision to produce and actual production; coupled with lack of knowledge, intensified, may be, by deliberate secretiveness, as to what others may be planning to do. Even in primary agricultural production a season will elapse between seedtime and harvest; a decade may elapse between planting and fruit-bearing; and a temporary shortage may induce many, unknown to each other, to sow or plant for the production of what is momentarily scarce and dear; with the result that the eventual yield is inordinate, the glut leads to low prices and waste, each separate cultivator decides to plant anything rather than what he overplanted before, and shortage comes again.

In manufacture, the same process is to be observed. If the cotton trade is prosperous a score of enterprisers may decide to build new mills with the object of partaking in the current prosperity, none reckoning on the action of his fellow, but more than a season will elapse between the forming of a company and the production of the first bale of cloth, and, by then, circumstances that made the boom may have passed away, and into the very depths of the slump may be poured the products of a score of new mills. In this respect the case of manufacture is worse than the case of agriculture. The cotton factory remains, useless for anything but textile production, and in the effort of redundant factories merely to keep going, at whatever loss, a whole industry may be brought to a ruinous condition which may endure until some of the weaker factories have to close down, thereby reducing supplies and allowing prices to rise again. Fluctuation is inherent in all economic competition, and violent in "blind" competition, but, where business men are well informed as to the state and prospects of the market and the action and plans of their competitors, its extent may be lessened somewhat.

Informed and Uninformed Competition.—In the United States, where concerted action in restraint of competition is forbidden by law, the substitution of informed for uninformed competition has made marked progress. Not only is business information issued on a voluminous scale by the Government and by private agencies, but associations of firms in the same line of industry collect information as to enquiries, quotations, orders, stocks, etc., from members, and issue digests of the information to contributing members. The legality of such activities under the Anti-Trust laws, particularly when they relate to prices or output, is, however, doubtful. (*See* ASSOCIATIONS, INDUSTRIAL.)

Hindrances to Free Competition.—The chief obstacles which prevent competition from operating effectively may be classified under three heads, namely custom, monopoly, and governmental interference. Custom interferes in many ways with the free play of competitive forces. For example, farm rents in a whole community are often set at a definite share of the crop, regardless of the quality of the land. Merchants mark up the prices of their goods by customary percentages, ignoring the state of trade. Common labour commands a customary wage despite striking differences in the efficiencies of individual workers.

For centuries, monopoly, either complete or partial, has limited the realm of competition. Nothing is more natural than for competitors to get together and agree to fix prices, curtail production, divide up territory, and drive out competitors by fair means or foul. Improvement in means of communication and growth of large-scale enterprise has facilitated the extension of monopoly. The 19th century witnessed a widespread development of powerful monopolistic labour unions which, by raising wage rates unduly, have seriously curtailed opportunities for employment. Similarly, huge manufacturing concerns have adopted the policy of maintaining selling prices in the face of falling demand, and have thus necessarily brought about a decline in production and accentuated depression. Governments have long interfered with competition by fostering monopolies, levying tariff duties, fixing wage rates, and placing numerous restrictions upon the freedom of enterprise.

In most nations, the 20th century has seen a great increase in such interference.

Despite its wastefulness and weaknesses, most economists agree that no other economic system has as yet been able to turn out an average volume of product per man-hour even approaching that produced under a system of free competition.

The enormous quantity and variety of goods thrown upon the markets of the world during the period in which competition has been in the ascendant affords sufficient proof that individualism is a potent conjuror of worldly goods. Furthermore, competition is socially beneficial in another way as well, for it provides a zest that might otherwise be lacking in industrial endeavour. The presence of an avowed trade enemy, the sense of danger, the imperative need for keeping in fighting trim have produced in the past qualities of alertness, vigour, and self-reliance which the more amiable objective of service might not have fostered so keenly. The type of character produced by these influences may not be wholly admirable, but it is at any rate strong and forceful and it is a commonplace that very many of those who are eminent in the new sphere of service by combination acquired their ability and strength in an environment of competitive struggle. (J. H.; W. I. K.)

COMPIÈGNE, a town of northern France, capital of an arrondissement, department of Oise, 52 mi. N.N.E. of Paris, famous for its château, park and forest. Pop. (1936) 17,929. The town, which is a favourite summer resort, stands on the northwest border of the forest of Compiègne and on the left bank of the Oise, near its confluence with the Aisne. The river is crossed by a bridge built in the reign of Louis XV.

Compiègne (*Compendium*) seems originally to have been a hunting lodge of the early Frankish kings. It was enriched by Charles the Bald with two castles, and a Benedictine abbey dedicated to Saint Corneille, the monks of which retained down to the 18th century the privilege of acting for three days as lords of Compiègne, with full judicial privileges. It was in Compiègne that King Louis I the Debonair was deposed in 833; and at the siege of the town in 1430 Joan of Arc was taken prisoner by the English. A monument to her faces the hôtel de ville. The treaty of Compiègne, between Richelieu and the Dutch, was signed there in 1624. In 1814 Compiègne offered a stubborn resistance to the Prussian troops. Under Napoleon III it was the annual resort of the court during the hunting season. From 1870 to 1871 it was one of the headquarters of the German army. The town was again occupied by the Germans in 1914, and was bombarded in 1918, but most of the older buildings escaped serious injury.

The hôtel de ville, with a graceful façade surmounted by a lofty belfry, is late Gothic (early 16th century). Of the churches, St. Antoine (13th and 16th centuries) has some fine Renaissance stained glass, and St. Jacques dates from the 13th and 15th centuries. The remains of the ancient abbey of St. Corneille are used as a military storehouse. Compiègne, from a very early period until 1870, was the occasional residence of the French kings. Its magnificent palace (château), now an art museum, was erected chiefly by Louis XV and restored by Napoleon I. It has two façades, one overlooking the town, the other facing toward a fine park and the forest (55 sq.mi.), which is chiefly of oak and beech and was formerly considered one of the strategic defenses of Paris.

Compiègne is the seat of a subprefect, and has tribunals of first instance and of commerce. The industries comprise boatbuilding, ropemaking, cooperage and copper and iron founding. Asparagus is cultivated in the environs. There is river-borne trade in timber and coal.

COMPLEMENT, that which fills up or completes anything, *e.g.*, the number of men necessary to man a ship (Lat. *complere*, to fill up). In general the complement of an entity is that which with the given entity makes up a whole. In geometry the complement of an angle A is that angle which when added to A makes a right angle.

In the theory of aggregates the complement of an aggregate S is the aggregate which remains when S is taken away from the aggregate U which forms the domain of discourse. Two colours which produce white when mixed are called *complementary colours*.

(See COLOUR.) (L. M. G.)

COMPLEMENTARY COLOURS, any two *colours* which together produce white light are said to be complementary colours. (*See* COLOUR.)

COMPLEX NUMBERS. Since certain algebraic equations such as $x^2+1=0$ have no solutions in real numbers, early mathematicians were led to consider purely formal solutions involving square roots of negative numbers.

Thus Heron of Alexandria (*c.* A.D. 100) obtained the solution $\sqrt{-63}$, and Girolamo Cardan (1545) wrote $40=(5+\sqrt{-15})(5-\sqrt{-15})$. These numbers were considered to be quite meaningless, and the term *imaginary* was applied to them.

Geometric Representation.—If i is by definition a solution of the equation $x^2+1=0$, numbers of the form $a+bi$ where a and b are real are called *complex* (Karl Friedrich Gauss, 1832). The modern development of complex numbers began with the discovery of a geometric interpretation for them. This was indistinctly set forth by John Wallis (1685), and in completely satisfactory form by Caspar Wessel (1799).

Wessel's work received no attention, and the geometric interpretation was rediscovered by Jean Robert Argand (1806) and again by Gauss (1831). It is frequently called the *Argand diagram* (fig. 1).

Just as the real numbers represent points on a line, the complex numbers can be put into correspondence with the points on a plane. The multiples of i are called *purely imaginary* numbers and are plotted as points on the imaginary axis perpendicular to the axis of reals at the o-point. Then the number $a+bi$ corresponds to the point P where OP is the diagonal of the rectangle whose sides are a and bi. If $a+bi$ is multiplied by -1, its corresponding line or *vector* OP is rotated through 180°. Similarly if $a+bi$ is multiplied by i, its vector is rotated through 90°. Thus two successive multiplications by i produce the same effect as one multiplication by -1, so that in this sense $i^2=-1$.

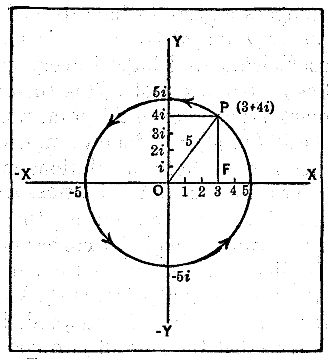


FIG. 1.—THE COMPLEX NUMBER

Logical Justification. The first satisfactory introduction of the complex numbers was given by Sir William Rowan Hamilton (*Trans. Royal Irish Acad.*) in 1835, although Gauss afterwards stated that the same idea had occurred to him in 1831.

Consider the set of all ordered couples $\alpha=(a_1, b_1)$, $\beta=(a_2, b_2)$, . . . of real numbers where $\alpha=\beta$ means that $a_1=a_2$ and $b_1=b_2$. Define the operations of addition and multiplication of couples by the equations

$$\alpha+\beta=(a_1+a_2,\ b_1+b_2),\ \alpha\beta=(a_1a_2-b_1b_2,\ a_1b_2+a_2b_1).$$

It can easily be shown that these couples combine according to the following rules:

$$\alpha+(\beta+\gamma)=(\alpha+\beta)+\gamma, \qquad \alpha(\beta\gamma)=(\alpha\beta)\gamma,$$
$$\alpha+\beta=\beta+\alpha, \qquad \alpha\beta=\beta\alpha,$$
$$\alpha(\beta+\gamma)=\alpha\beta+\alpha\gamma.$$

The couples of the form $(a,0)$ form a subset of the set of all couples which is abstractly identical with the set of real numbers. If $(a,0)$ corresponds to a, and $(b,0)$ corresponds to b, then $(a,0)+(b,0)$ corresponds to $a+b$, and $(a,0)\times(b,0)$ corresponds to ab. In this sense the real numbers are contained among these couples, and we may write $(a,0)=a$. In particular, $(0,0)=0$ and $(1,0)=1$. If k is real, $k(a,b)=(ka,kb)$. For every couple α, $\alpha+0=\alpha$ and $\alpha\times 1=\alpha$. For every $\alpha=(a,b)$ there is a couple $-\alpha=(-a,-b)$ such that $\alpha+(-\alpha)=0$; and for every $\alpha\neq 0$ there is a couple $1/\alpha=(a/(a^2+b^2),\ -b/(a^2+b^2))$ such that $\alpha\times(1/\alpha)=1$.

Thus the couples form a *number field.* All of the other rules of arithmetic which are valid for all fields are consequences of those enumerated. If one denotes the couple $(0,1)$ by the letter i, then $i^2=-1$ and

$$\alpha=(a,b)=a+bi.$$

These couples are precisely the complex numbers.

Another logical development of the complex field was given by Augustin Louis Cauchy (*Comptes Rendus,* Paris) in 1847. Consider the set of all polynomials

$$f(i)=c_0+c_1i+c_2i^2+\ .\ .\ .\ +c_ni^n$$

with real coefficients in the indeterminate i. Two polynomials are defined to be equal if they give the same remainder upon division by i^2+1. Thus every polynomial is equal to a polynomial c_0+c_1i of the first degree in i. Addition and multiplication are defined in the usual way. That is,

$$(a_1+b_1i)(a_2+b_2i)=a_1a_2+(a_1b_2+a_2b_1)i+b_1b_2i^2.$$

Upon dividing this product by i^2+1, the remainder $a_1a_2-b_1b_2+(a_1b_2+a_2b_1)i$ is obtained, which is therefore equal to the product. Since i^2+1 gives the remainder 0 upon division by i^2+1, it is true that i is a solution of the equation $x^2+1=0$. The laws of arithmetic are as readily provable as in Hamilton's approach.

It is significant that it is not possible to define *a* complex number separately from all other complex numbers. The complex field can be defined either by Hamilton's method or by Cauchy's method; a complex number is an element of the complex field.

Properties of the Complex Field.—Although the complex numbers appear to have been introduced to obtain a solution of the equation $x^2+1=0$, it is true that every equation with real coefficients, and indeed every equation with complex coefficients, has a complex root. This theorem, frequently called the Fundamental Theorem of Algebra, was proved by Gauss in his doctoral thesis (1799). It follows immediately that every equation of degree n has exactly n solutions, not necessarily distinct.

The Fundamental Operations.—Reference was made to the graphic representation of the complex numbers. The number $a+bi$ can be made to correspond to a point on the plane, or to the line segment or vector from the origin to this point. If the latter point of view is adopted, it is true that the sum of two complex numbers corresponds to the diagonal of the parallelogram whose edges are the summands. Since directed physical magnitudes such as forces and velocities add by the parallelogram rule, it is apparent that complex numbers are well suited for their computation.

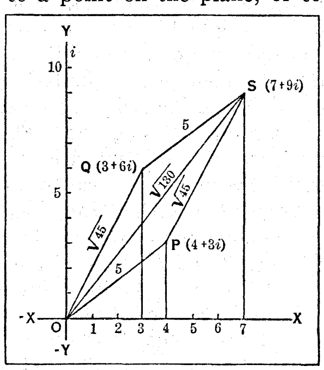

FIG. 2.—ADDITION OF COMPLEX NUMBERS

Multiplication of complex numbers is best treated through their polar representation (Roger Cotes, 1710; Abraham de Moivre, 1730; Leonhard Euler, 1743). If r represents the distance OP from the origin to the point $a+bi$, and if θ is the angle from the positive x-axis to OP, then

$$a+bi=r(\cos\theta+i\sin\theta)=r\ \mathrm{cis}\,\theta.$$

The number r is called the *absolute value* (Karl Weierstrass) or *modulus* (Cauchy) of $a+bi$, and θ is called the *argument* or *phase.*

By the usual definition of multiplication,

$$r_1\ \mathrm{cis}\,\theta_1\cdot r_2\ \mathrm{cis}\,\theta_2=r_1r_2\ \mathrm{cis}(\theta_1+\theta_2).$$

That is, the absolute value of a product is equal to the product of the absolute values of the factors, and the argument of the product is equal to the sum of the arguments of the factors. This leads to a simple graphic method of multiplying two complex numbers $a+bi$ and $c+di$. Construct a triangle upon the real unit segment with one of the vectors, say $a+bi$, as the other side. Construct a similar triangle upon the other vector $c+di$. The corresponding side to $a+bi$ of this second triangle will represent the product $(a+bi)(c+di)$.

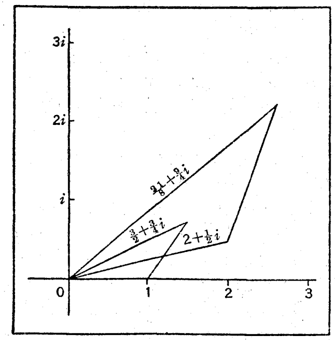

FIG. 3.—MULTIPLICATION

Since every equation such as $x^i-(a+bi)=0$ has n complex solutions, it follows that every complex number has n complex n-th roots. De Moivre's theorem states that

$$(r\ \mathrm{cis}\theta)^n=r^n\mathrm{cis}n\theta,\ r\ \mathrm{cis}\theta=(\sqrt[n]{r}\ \mathrm{cis}\frac{\theta+2k\pi}{n})^n,$$

$$k=0,1,2,\ \cdot\cdot\cdot\ ,n-1.$$

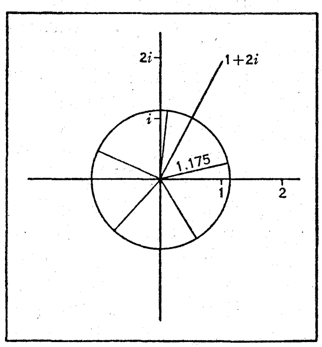

FIG. 4.—ROOTS OF A COMPLEX NUMBER

Thus to find the n-th roots of r cisθ, draw a circle of radius $\sqrt[n]{r}$ and draw a radius whose argument is θ/n. This is one root. Divide the circumference into n equal parts, and draw the n equally spaced radii of which the first root is one. These radii are the n n-th roots of r cisθ.

The power function in the complex field is, except in special cases, multiple-valued. That is,

$$(r\ \mathrm{cis}\theta)^{s\ \mathrm{cis}\varphi}=q\ \mathrm{cis}\xi$$

where q and ξ are defined by the equations

$$\xi=s\ \sin\varphi\cdot\log\ r+s(\theta+2n\pi)\cos\varphi,$$

$$\log\ q=s\ \cos\varphi\cdot\log\ r-s(\theta+2n\pi)\sin\varphi,\ n=0,\pm1,\pm2,\ \cdot\cdot\cdot\ .$$

Automorphisms.—Mathematicians have been bothered by their inability to draw any genuine distinction between the numbers i and $-i$. The number $a-bi$ is called the *conjugate* (Cauchy) of the number $a+bi$.

The conjugate of a sum is equal to the sum of the conjugates, and the conjugate of the product is equal to the product of the conjugates of the factors. In modern terminology, we say that the correspondence between $a+bi$ and $a-bi$ is an *automorphism* of the complex field. The complex solutions of an equation with real coefficients occur in conjugate pairs.

Number Theory.—The numbers of the form $a+bi$ where a and b are rational constitute the *Gaussian complex field.* The numbers of this type where a and b are rational integers form an *integral domain* or *ring* very like the ring of ordinary rational integers or whole numbers.

The *norm* (Gauss) of $a+bi$ is a^2+b^2, and the norm of a product is equal to the product of the norms of the factors. The numbers of norm 1 are the *units,* namely 1, -1, i and $-i$.

A number which is neither 0 nor a unit is called *composite* or *prime* according as it can or cannot be written as a product of two numbers neither of which is a unit. There exists a Euclid algorithm in this ring. That is, if $\beta\neq 0$ and α are two numbers of the ring, there exist two other numbers κ and ρ such that $\alpha=\beta\kappa+\rho$ where the norm of ρ is less than the norm of β. Then every two numbers have a greatest common divisor expressible linearly in terms of the numbers. Consequently the Fundamental Theorem of Arithmetic holds for this ring: Every number $\neq 0$ is factorable into a finite number of prime numbers and, save for unit factors and the order of the factors, this representation is unique. If p is a rational prime of the form $4k+1$, it is the product of two distinct conjugate complex primes; a rational prime of the form $4k+3$ is a complex prime; and $2=i(1-i)^2$ where $1-i$ is a complex prime. Much of ordinary number theory carries over to the complex integers.

Quaternions.—In 1843 Hamilton generalized the complex field to the algebra of *real quaternions* $a+bi+cj+dk$ where $i^2=j^2=k^2=-1$, $ijk=-1$. Most of the ordinary laws of arithmetic hold for such numbers except that the order of multiplication is not usually immaterial. This algebra is treated in detail elsewhere. (*See* QUATERNIONS.) In the hands of Josiah Willard Gibbs and Oliver Heaviside and others, the quaternion algebra has been developed into modern vector analysis, a method which is of great importance in mechanics, electricity and other branches of applied mathematics. (*See* VECTOR ANALYSIS.)

Hypercomplex Numbers.—This term is applied to numbers of the type $a_1e_1+a_2e_2+\ \ldots\ +a_ne_n$ where the a's are numbers of a field, the e's are linearly independent with respect to this field, and $e_ie_j=c_{ij1}e_1+c_{ij2}e_2+\ \ldots\ +c_{ijn}e_n$. Complex numbers and quaternions are special examples. The associative law of multiplication is usually assumed, but not the commutative law. (*See* LINEAR ALGEBRAS.)

Functions of a Complex Variable.—One of the most extensive and useful branches of mathematics is the theory of functions of a complex variable. Let $z=x+iy$ where x and y are real variables and $i^2=-1$. Then $w=u+iv$ is a function of z if u and v are functions of x and y. This function is *analytic* (or *regular*, or *holomorphic*, or *monogenic*) if u and v are differentiable and if the Cauchy-Riemann conditions hold, viz.

$$\partial u/\partial x=\partial v/\partial y, \qquad \partial u/\partial y=-\partial v/\partial x.$$

This theory is considered extensively elsewhere. (*See* FUNCTION.)

COMPLIANCE, a psychological term for one of the so-called "primary" emotions. When an animal or human being meets an opposing force which he recognizes as stronger than himself, he gives in to the opponent to avoid injury to himself, and takes whatever extra trouble is necessary to avoid a conflict inevitably disastrous to the weaker party. This feeling and reaction of compliance is the basic emotional mechanism which enables living organisms to escape destruction and suffering in the struggle for existence.

COMPLUVIUM, the open space left in the roof of the atrium of a Roman house for lighting (*see* CAVAEDIUM).

COMPOSITAE, the name given to the largest family of flowering plants. It includes approximately 900 genera and over 13,000 species comprising about one-fifteenth of the flowering plants. It is characterized by crowding of the flowers into heads. The family is cosmopolitan, and the plants show considerable variety in habit. The great majority, including most British representatives, are herbaceous, but in the warmer parts of the world shrubs and arborescent forms also occur; the latter are characteristic of the flora of oceanic islands. In herbaceous plants the leaves are often arranged in a rosette on a much shortened stem, as in dandelion, daisy and others; when the stem is elongated the leaves are generally alternate. The root is generally thickened, sometimes, as in dahlia, tuberous; root and stem contain oil passages, or, as in lettuce and dandelion, a milky white latex. The flowers are crowded in heads (*capitula*) which are surrounded by an involucre of green bracts,—these protect the head of flowers in the bud stage, performing the usual function of a calyx. The enlarged top of the axis, the receptacle, is flat, convex or conical, and the flowers open in centripetal succession. In many cases, as in the sunflower or daisy, the outer or ray-florets are larger and more conspicuous than the inner, or disc-florets; in other cases, as in dandelion, the florets are all alike. Ray-florets when present are usually pistillate, but neuter in some genera (as *Centaurea*); the disc-florets are hermaphrodite. The flower is epigynous; the calyx is sometimes absent, or is represented by a rim on the top of the ovary, or takes the form of hairs or bristles which enlarge in the fruiting stage to form the pappus, by means of which the seed is dispersed. The corolla, of five united petals, is regular and tubular in shape in the disc-florets, or irregular, when it is either strap-shaped (ligulate), as in the ray-florets of daisy, etc., or all the florets of dandelion, or more rarely two-lipped. The five stamens are attached to the interior of the corolla-tube; the filaments are free; the anthers are joined (syngenesious) to form a tube around the single style, ending in a pair of stigmas. The inferior ovary contains one ovule (attached to base of chamber), and ripens to form a dry one-seeded fruit, a typical achene; the seed is filled with the straight embryo.

SUNFLOWER, SHOWING DETAILS OF STRUCTURE

A. Ray flower, which has no stamens, style, or stigma

B. Vertical section through an inner floret

C. Inner floret; regular, with tubular five-toothed corolla, stamens and pistil

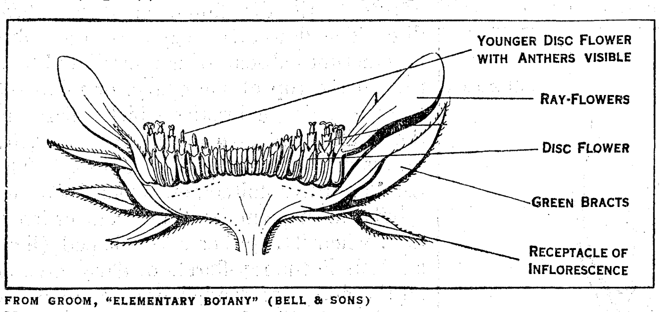
D. Vertical section of the one seeded fruit

The flower-heads are an admirable example of an adaptation for pollination by insects. The crowding of the flowers in heads ensures the pollination of a large number as the result of a single insect visit. Honey is secreted at the base of the style, and is protected from rain or dew and the visits of short-lipped insects by the corolla-tube, the length of which is correlated with the length of proboscis of the visiting insect. When the flower opens, the two stigmas are pressed together below the tube formed by the anthers, the latter split on the inside, and the pollen fills the tube; the style gradually lengthens and carries the pollen out of the anther tube, and finally the stigmas spread and expose their receptive surface which has hitherto been hidden, the two being pressed together. Thus the life history of the flower falls into two stages, an earlier or male and a later or female. This favours cross-pollination as compared with self-pollination. In many cases there is a third stage, as in dandelion, where the stigmas finally curl back so that they touch any pollen grains which have been left on the style below, thus ensuring self-pollination if cross-pollination has not been effected.

The devices for distribution of the fruit are very varied. Frequently there is a hairy or silky pappus forming a tuft of hairs, as in thistle or coltsfoot, or a parachute-like structure as in dandelion; these render the fruit sufficiently light to be carried by the wind. In *Bidens* the pappus consists of two or more stiff-barbed bristles which cause the fruit to cling to the coats of animals. Occasionally, as in sunflower or daisy, the fruits bear no special appendage and remain on the head until jerked off.

Compositae are generally considered to represent the most highly developed order of flowering plants. By the massing of the flowers in heads great economy is effected in the material required for one flower, as conspicuousness is ensured by the association; economy of time on the part of the pollinating insect is also effected, as a large number of flowers are visited at one time. The floral mechanism is both simple and effective, favouring cross-pollination, but ensuring self-pollination should that fail. The means of seed-distribution are also very effective.

A few members of the order are of economic value, *e.g., Lactuca* (lettuce; *q.v.*), *Cichorium* (chicory; *q.v.*), *Cynara* (artichoke



FROM GROOM, "ELEMENTARY BOTANY" (BELL & SONS)

VERTICAL SECTION THROUGH THE FLOWER HEAD OF THE SUNFLOWER

and cardoon; *q.v.*), *Helianthus* (Jerusalem artichoke). Many are cultivated as garden or greenhouse plants, such as *Solidago* (golden rod), *Ageratum, Aster* (*q.v.*) (Michaelmas daisy), *Helichrysum* ("everlasting"), *Zinnia, Rudbeckia, Helianthus* (sunflower), *Coreopsis, Dahlia* (*q.v.*), *Tagetes* (French and African marigold), *Gaillardia, Achillea* (yarrow), *Chrysanthemum, Tanacetum* (tansy), *Arnica, Doronicum, Cineraria, Calendula* (common marigold), *Echinops* (globe thistle), *Centaurea* (*q.v.*). Some are of medicinal value, such as *Anthemis* (chamomile), *Artemisia* (wormwood), *Tussilago* (coltsfoot), *Arnica.* Insect powder is prepared from species of *Pyrethrum* in the genus *Chrysanthemum.* A species of *Parthenium,* guayule, is a source of rubber.

The order is divided into two subfamilies:—*Tubuliflorae,* characterized by absence of latex, and the florets of the disc being not ligulate, and *Liguliflorae,* characterized by presence of latex and all the florets being ligulate. The first subfamily contains the majority of the genera, and is divided into a number of tribes. The family is well represented in Britain, in which 42 of the 900 genera are native. These include some of the commonest weeds, such as dandelion (*Taraxacum officinale*), daisy (*Bellis perennis*), groundsel (*Senecio vulgaris*) and ragwort (*S. Jacobaea*); coltsfoot (*Tussilago Farfara*) is one of the earliest plants to flower, and other genera are *Chrysanthemum* (ox-eye daisy and corn-marigold), *Arctium* (burdock), *Centaurea* (knapweed and cornflower), *Carduus* and *Cnicus* (thistles), *Hieracium* (hawkweed), *Sonchus* (sow-thistle), *Achillea* (yarrow, or milfoil, and sneezewort), *Eupatorium* (hemp-agrimony), *Gnaphalium* (cud-weed), *Erigeron* (fleabane), *Solidago* (golden-rod), *Anthemis* (may-weed and chamomile), *Cichorium* (chicory), *Lapsana* (nipplewort), *Crepis* (hawk's-beard), *Hypochaeris* (cat's-ear), and *Tragopogon* (goat's beard).

In North America over 200 genera are represented by many species distributed over the whole country.

COMPOSITE ORDER, in architecture, the last developed and most complex of the classical orders (*see* ORDER), so called because its capital is a compound of the volutes (spirals) of the Ionic order and the acanthus leaves of the Corinthian. The earliest example known is found in the arch of Titus at Rome (A.D. 81). The form became common, however, only after the time of Hadrian (A.D. 117–138). The entablature was usually Corinthian, but in the Renaissance period Vignola and the other architects who arranged codifications of the orders developed a separate type based largely upon the temple of Venus at Rome (reign of Hadrian).

COMPOSITION, the action of putting together and the product of such action (Lat. *compositio,* from *componere,* to put together). In philology, the putting together of two words to form a single word; in grammar, the combination of words into sentences, and sentences into periods; the art of producing a work in prose or verse, or the work itself. In music "composition" is used both of the art of combining musical sounds in accordance with the rules of musical form, and of the whole art of creation or invention. In the other fine arts the word is used of the balanced arrangement of the parts of a picture, a piece of sculpture or a building, so that they form one harmonious whole.

The word also means an adjustment of differences between two or more parties. A more particular use is the legal one, for an agreement by which a creditor agrees to take a sum less than his debt in satisfaction of the whole. (*See* BANKRUPTCY.) In logic (*q.v.*) "composition" is the name given to a fallacy of equivocation, where what is true distributively of each member of a class is inferred to be true of the whole class collectively. Composition, often shortened to "compo," is the name given to materials compounded of more than one substance, and is used in various trades and manufactures for a mixture, such as stucco, cement and plaster.

COMPOSITOR. One who "composes," or sets up, printing-type. The compositor is a highly skilled craftsman, who can only do his work effectively if he is well educated and especially well read, for he has constantly to handle ms. bristling with difficult terms and of varying degrees of legibility.

The first step in the actual production of any class of printed matter is the composition of the written word from the manuscript. In the early days of printing, when type faces were large, and all type was set by hand, the compositor's work was of a simple straightforward character, consisting in the main of type-setting for books, pamphlets and small news-sheets.

The compositor's time, however, is not wholly taken up in mere type-setting. The matter having been composed, stickful by stickful, and deposited on a long narrow frame called a galley, is proved or printed in slip form, when it is carefully read for errors by the "corrector of the press" or printer's reader, and afterwards sent to the author for possible alterations. The matter is then made up into columns and pages, the latter being "imposed" on a stone or metal surface to be prepared for the actual printing on the press.

Imposition consists in laying the made-up pages on the imposing surface in such a way as to ensure that when the printed sheet of eight, sixteen or more pages is folded, the folios all fall in correct order and the margins around the pages are in agreement with instructions. A compositor engaged mainly on imposition is called a "stone hand." Various implements are used for this work, such as mallets, planers, shooters, chases and quoins. Modern methods have not eliminated the old-time tools, which are still necessary even in up-to-date printing offices. Metal quoins and furniture and mechanical lock-ups have, however, largely taken the place of the wooden prototypes which were invariably used up to fifty years ago.

In the office of a daily newspaper, the compositor is not called upon to impose the pages in sheets. Each page, owing to its size, is prepared singly for the stereotyper, who casts the plates, which in turn are imposed direct on the cylinders of the press.

The introduction of bar-line composing machines brought about a revolution in type-setting, but did not materially alter other branches of the compositor's work. It is the more rapid production on the machines that has made possible the huge development which has taken place in newspaper production in recent years. The bar-line machine, in which the complete line, or slug, is the unit, as distinct from the single letter or movable type, is most in use, especially in newspaper work, but a machine producing single-letter composition also has a wide vogue for book and magazine printing. The machine compositor, although as an apprentice fully trained in all classes of work, is rarely called away from the machine. In one other respect the compositor's work has undergone a great change. In addition to the setting of displayed advertisements for newspapers and magazines, the compositor is called upon to produce jobbing work of all descriptions, such as posters, programmes, brochures, catalogues, etc.—each of these providing its own special appeal, and demanding expert interpretation by the compositor, who is usually the designer of the "lay-out" as well. He has thus become much more of a craftsman than the old-time compositor, who knew little or nothing of the principles or opportunities of artistic display. It is probably due to these intensive changes in the work that the compositors have been able to maintain the old conditions of seven-year apprenticeship. (*See* PRINTING.)

COMPOUND, a combination of various elements to form a whole. A "chemical compound" is a substance which can be resolved by ordinary chemical methods into simple constituents, as opposed to an element which cannot be so resolved. (*See* CHEMISTRY.) A "compound engine" is one where the expansion of the steam is effected in two or more stages (*see* STEAM ENGINE); in zoology, the "compound eye" of insects and crustacea is made up of several *ocelli* or simple eyes (*see* EYE, ANATOMY OF); in botany, the "compound leaf" has two or more separate blades on a common leaf-stalk; in surgery, in a "compound fracture" the skin is broken as well as the bone. Compound interest is interest paid upon interest.

The verb "to compound" is used of the settlement of differences, and especially of an agreement made to pay part of a debt in discharge of the whole (*see* BANKRUPTCY); similarly of the substitution of one payment for periodic payments. In the system of "compounding" for rates the occupier of premises pays an increased rent, and the owner is responsible for the payment of the rates. In law, to compound a felony is to agree with the felon not to prosecute him, in return for valuable consideration, or, in the case of a theft, on return of the goods stolen. Such an agreement is a misdemeanour punishable by fine and imprisonment.

The name "compounders" was given during the reign of William III. of England to the members of a Jacobite faction who were prepared to restore James II. to the throne on certain conditions. Until 1853, in the University of Oxford, those possessing private incomes of a certain amount paid special dues for their degrees and were known as grand and petty compounders. The corruption "compound" (from the Malay *kampung,* a quarter of a village) is the name of the enclosed ground which surrounds an Anglo-Indian house.

COMPOUND ENGINE, a steam-engine (*q.v.*) in which the expansion is performed in two stages, the first in the "high-pressure cylinder" and the second in the "low-pressure cylinder." If three or four stages are employed the engine is called a *triple* or a *quadruple expansion engine* respectively.

COMPOUNDING: *see* LARCENY.

COMPOUND PIER, an architectural term for a pier (*q.v.*) or column (*q.v.*) consisting of a number of vertical members or mouldings clustered around or attached to a central mass. It developed in Roman architecture to allow a single pier to support several arches. In the Romanesque and Gothic periods the idea was worked out in a more complicated way in order to furnish support, or the appearance of support, not only for cross, diagonal and wall ribs, but often to carry the main elements of the arch mouldings. In some cases in the late Gothic work of France and Germany, the mouldings of a compound pier are the identical mouldings of the arch or ribs carried down to the ground without a capital. Compound piers are usually built of continuous layers of stone, but occasionally, in English work, the clustering shafts are independent and sometimes of a different material.

COMPRADOR, originally, a native servant in European households in the East, but now the name given to the native managers in European business houses in China, and also to native contractors supplying ships in the Philippines and elsewhere in the East. The word is Portuguese, from Lat. *comparare,* to procure.

COMPRESSED AIR. It would be possible to enumerate some 200 distinct applications of compressed air in the operation of machines and in manufacturing processes. No other power agent has such a varied range of uses, or is so conveniently stored and conveyed. Its applications may be broadly divided

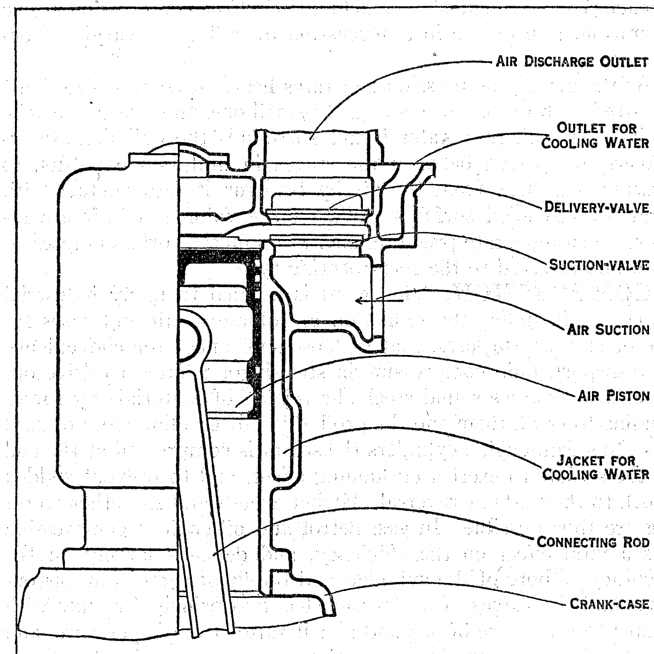

DIAGRAM SHOWING THE MECHANISM OF A SINGLE-ACTING AIR COMPRESSOR

Air, compressed to exert pressures varying from a few pounds to several thousand pounds per sq. inch, is a power agent of great utility, employed in some 200 different ways. Two of its most familiar uses are in instruments for breaking up roads, and in those for spraying paint on large surfaces

into free and enclosed action. In the former category are, for instance, the air-jets for cleaning machinery and fabrics, the nozzles for feeding air to gas and oil burners, the air-lifts for pumping, and operations such as the blowing out of tanks in submarines and oil ships, glass blowing, sand-blasting, and the spraying of whitewash, distemper, paint, varnish and enamel. These spraying processes are far more economic than the brush methods. In one case a ship required the services of six men for 136 hours to paint by hand, while with compressed-air spraying a similar ship was painted by two men in 40 hours.

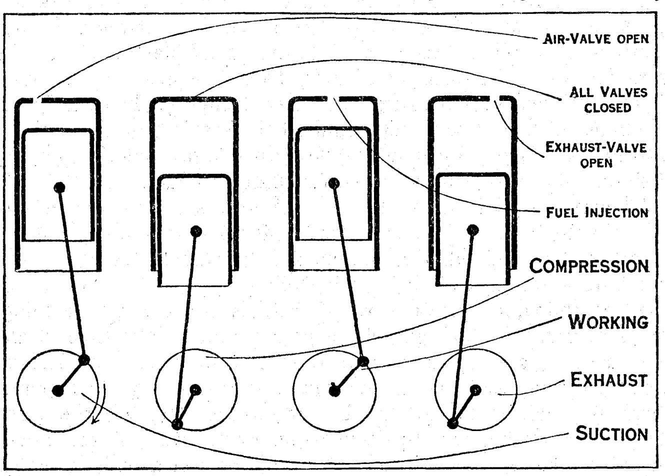
The category of enclosed action comprises scores of methods wherein the air acts in a cylinder to give a power movement, or is otherwise confined, *e.g.,* in portable pneumatic hammers for chipping, riveting, caulking, rock drilling, concrete breaking and sand ramming, and in the rotating tools for drilling, reaming, tapping, grinding, buffing, tube expanding and boiler-tube cleaning. Hoists, cranes, jacks and foundry moulding-machines, as well as forging and planishing hammers, resembling steam hammers in general type, are used in large numbers, and there are also chucks for machine-tools, to grip pieces of work on the movement of a hand or foot lever. Many actions on machines, which would otherwise be slowly and laboriously performed by hand, are effected in an instant by a pneumatic cylinder. Some kinds of engines, including those for torpedoes and coal-cutters, are air-driven, as are locomotives when fire or sparking is inadmissible. In railway service there are the air-brakes and the pneumatic signalling and switching apparatus. Large gas and oil engines are started up by a charge of compressed air, while caissons and tunnel shields are worked with its help. Other equipments for which it must be employed are those used in wreck raising and diving. In several industries testing is effected with air, besides inflation and the agitation of liquids.

Air pressures vary from a few to many thousand pounds per square inch. A hand compressor is used for small demands.

Power-driven machines include those actuated by belt pulley, steam cylinder, electric motor, gas, oil or petrol (gasolene) engine —the last especially for portable outfits for road-breaking. Single-acting compressors take in air through an inlet-valve at one stroke of the piston and force it through a discharge-valve to the storage receiver on the return stroke. This is sketched in the figure. Double-acting compressors have two sets of valves, and deliver air at each stroke. Single-stage machines effect the compression at one operation, multi-stage in a succession of cylinders, varying from two to five.

As the act of compression generates heat, all compressors must be fitted with means for cooling. In small ones fins are cast on the cylinder, in others a water-jacket surrounds the cylinder. Intercoolers are placed between the stages in multi-stage outfits, to abstract the heat from the air by bringing it into contact with large water-cooled surfaces. When large volumes of air are required at a moderate pressure, *e.g.*, in mining, a turbo-compressor is to be preferred to the reciprocating type.

COMPRESSION. This word is applied to many industrial processes, including the reduction in volume of air and gases for use or storage purposes, that of loose substances for convenience of transport, fluid compression in steel ingot making to drive out gases and produce sound steel, the testing of materials by forces tending to crush them and the production of gasoline from natural gas. In steam-engine cylinders the steam is compressed at the end of the stroke, to exert a cushioning effect, and to prevent sudden shock to the parts at reversal. Higher speeds and smoother working are thus possible. In gas, petrol and oil-engines compression has a vital effect on the efficiency, and depends largely on the accuracy of bore of the cylinder, and the fit of the piston, piston-rings and the valves. Compression has two principal results with regard to a mixture of gas and air; it raises the temperature, and also produces a more intimate mixture, through which the flame spreads more rapidly than it would do in an uncompressed mixture. *Compression ratio* is the ratio between the volume of gas in the cylinder with the piston at the outer end of its stroke, and the compressed volume when the piston is at the other end of its stroke. The degree of compression must be determined by the ignition temperature of the charge, which varies in different fuels. For instance, in the cylinder of a gas engine using the ordinary



THE CYCLE IN A 4-STROKE DIESEL ENGINE, SHOWING THE ACTION OF THE VALVES THROUGHOUT ONE REVOLUTION
The compression is very high in this engine, giving sufficient temperature to the air to ignite the charge of oil injected for the working stroke

town supply, the pressure ordinarily will not exceed 100 lb. per sq.in. Pre-ignition (*i.e.*, ignition during compression stroke) may be due to over-compression, and occurs when a certain supply of gas is changed for another kind, or when the gas comes in contact with overheated parts in the system, or when hot gases from the previous cycle are retained. The greatest pressures are used in the Diesel engine, in order to raise the temperature to a sufficient degree to ignite oil as it is sprayed into the cylinder gradually at the conclusion of the compressive stroke (*see* fig.). In practice, these range from about 450 to 480 lb. per square inch, the resultant temperature being about 1,000°. This is sufficient to cover the requirements for cold starting. A lower pressure can be used when a hot bulb, or similar heating device, is employed; lower compression allows a lighter construction of the engine parts.

COMPROMISE, a term, meaning strictly a joint agreement, which has come to signify such a settlement as involves a mutual adjustment, with a surrender of part of each party's claim. The equivalent word in Latin languages is *transactio* and its derivatives.

COMPROMISE MEASURES OF 1850, in American history, a series of measures the object of which was the settlement of five questions in dispute between the pro-slavery and anti-slavery factions in the United States. Three of these questions grew out of the annexation of Texas and the acquisition of western territory as a result of the Mexican War. The settlers who had flocked to California after the discovery of gold in 1848 adopted an anti-slavery State constitution on Oct. 13, 1849, and applied for admission into the Union. In the second place it was necessary to form a territorial Government for the remainder of the territory acquired from Mexico, including that now occupied by Nevada and Utah, and parts of Wyoming, Colorado, Arizona and New Mexico. The fundamental issue was in regard to the admission of slavery into, or the exclusion of slavery from, this region. Thirdly, there was a dispute over the western boundary of Texas. Should the Rio Grande be the line of division north of Mexico, or should an arbitrary boundary be established farther to the eastward; in other words, should a considerable part of the new territory be certainly opened to slavery as a part of Texas, or possibly closed to it as a part of the organized territorial section? Underlying all of these issues was, of course, the great moral and political problem as to whether slavery was to be confined to the south-eastern section of the country or be permitted to spread to the Pacific. The two questions not growing out of the Mexican War were in regard to the abolition of the slave trade in the District of Columbia, and the passage of a new fugitive slave law.

Congress met on Dec. 3, 1849. Neither faction was strong enough in both houses to carry out its own programme, and it seemed for a time that nothing would be done. On Jan. 29, 1850, Henry Clay presented the famous resolution which constituted the basis of the ultimate compromise. His idea was to combine the more conservative elements of both sections in favour of a settlement which would concede the Southern view on two questions, the Northern view on two, and the balance the fifth. Daniel Webster supported the plan in his great speech of March 7, although in doing so he alienated many of his former admirers. Opposed to the conservatives were the extremists of the North, led by William H. Seward and Salmon P. Chase, and those of the South, led by Jefferson Davis. Most of the measures were rejected and the whole plan seemed likely to fail, when the situation was changed by the death of President Taylor and the accession of Millard Fillmore on July 9, 1850. The influence of the administration was now thrown in favour of the compromise. Under a tacit understanding of the moderates to vote together, five separate bills were passed, and were signed by the president between Sept. 9 and 20, 1850. California was admitted as a free State, and the slave trade was abolished in the District of Columbia; these were concessions to the North. New Mexico (then including the present Arizona) and Utah were organized without any prohibition of slavery (each being left free to decide for or against, on admission to Statehood), and a rigid fugitive slave law was enacted; these were concessions to the South. Texas (*q.v.*) was compelled to give up much of the western land to which it had a good claim, and received in return $10,000,000.

This legislation had several important results. It helped to postpone secession and civil war for a decade, during which time the north-west was growing more wealthy and more populous, and was being brought into closer relations with the north-east. It divided the Whigs into "Cotton Whigs" and "Conscience Whigs," and in time led to the downfall of the party. In the third place, the rejection of the Wilmot Proviso and the acceptance (as regards New Mexico and Utah) of "Squatter Sovereignty" meant the adoption of a new principle in dealing with slavery in the territories, which, although it did not apply to the same territory, was antagonistic to the Missouri Compromise of 1820. The sequel was the repeal of the Missouri Compromise in the Kansas-Nebraska bill of 1854. Fourthly, the enforcement of the fugitive slave law aroused a feeling of bitterness in the North which helped eventually to bring on the war, and helped to make it, when it came, quite as much an anti-slavery crusade as a struggle for the integral preservation of the Union. The compromise measures are sometimes spoken of collectively as the Omnibus bill, owing to their having been grouped originally—when first reported (May 8) to the Senate—into one bill.

For the best account of the above Compromises *see* J. F. Rhodes, *History of the United States from the Compromise of 1850,* (1896). *See* also T. C. Smith, *Parties and Slavery* (1906). (W. R. Sm.)

COMPSA, ancient city of the Hirpini, Italy, near the sources of the Aufidus, on the boundary of Lucania and not far from that of Apulia, on a ridge 1,998 ft. above sea-level. It was betrayed to Hannibal in 216 B.C. after the defeat of Cannae, but recaptured two years later. It was probably occupied by Sulla in 89 B.C., and it was the scene of the death of T. Annius Milo in 48 B.C.

COMPTON, ARTHUR HOLLY (1892–), U.S. physicist, was born in Wooster, O., on Sept. 10, 1892. Graduating in 1913 at the College of Wooster, he pursued further studies at Princeton university, from which in 1916 he received the degree of doctor of philosophy. He was instructor in physics at the University of Minnesota in 1916–17, and research physicist for the Westinghouse Light company of East Pittsburgh, Pa., in 1917–19. After a year (1919–20) of research at Cambridge university, England, he became professor and head of the department of physics in Washington university at St. Louis, Mo. In 1923 he was made professor of physics in the University of Chicago. He returned to Washington university as chancellor in 1946. He made noteworthy investigations on the earth's rotation, on the specific heat of solids and especially on X-rays. He measured the wave length of the hard gamma rays and discovered the change in the wave length of X-rays when scattered and also the total reflection of X-rays. With C. H. Hagenow, he effected the complete polarization of X-rays and, with R. L. Doan, obtained X-ray spectra from ruled gratings. In recognition of his achievements in research he was awarded in 1927, jointly with C. T. R. Wilson, of England, the Nobel prize for physics. In addition to numerous scientific articles he published *Secondary Radiations Produced by X-rays* (1922) and *X-rays and Electrons* (1926).

COMPTON, HENRY (1632–1713), English divine, was educated at Queen's College, Oxford, then travelled in Europe, and was made bishop of Oxford in 1674, and in the following year was translated to the see of London. He was also appointed a member of the privy council, and was entrusted with the education of the two princesses—Mary and Anne. He showed unusual liberality to Protestant dissenters and held several conferences with the clergy of his diocese on the subject of reunion with them. On the accession of James II. he consequently lost his seat in the council and his deanery in the Chapel Royal; and for his firmness in refusing to suspend John Sharp, rector of St. Giles's-in-the-Fields, whose anti-papal writings had rendered him obnoxious to the king, he was himself suspended. At the Revolution Compton's old position was restored to him; and he was chosen as one of the commissioners for revising the liturgy. During the reign of Anne he remained a member of the privy council, and was one of the commissioners appointed to arrange the terms of the union of England and Scotland. He died at Fulham on July 7, 1713. He published, besides several theological works, *A Translation from the Italian of the Life of Donna Olympia Maladichini, who governed the Church during the time of Pope Innocent X., which was from the year 1644 to 1655* (1667), and *A Translation from the French of the Jesuits' Intrigues* (1669).

COMPTON, a city of Los Angeles county, California, U.S.A., midway between Los Angeles and Long Beach. It is served by the Southern Pacific and the Pacific Electric railways. In 1930 the population was 12,516; in 1940 it was 16,198 by the federal census. Compton is in a market-gardening region, and is surrounded by producing oil wells, oil-storage farms and refineries. The joint harbour of Los Angeles and Long Beach is but a few miles distant. On the southern border of the city is the new freight-classification yard of the Southern Pacific Company. The city is a residential suburb, and it also has substantial manufacturing industries of its own, whose products include rubber tyres, water bottles and fruit jars, ladders, tools and equipment for oil wells, and cooling towers for gasolene plants. Compton was founded about 1868, was incorporated as a city of the sixth class in 1888 and as a city of the fifth class in 1925. The new charter provides for a planning commission and for a city-manager form of government.

COMPTON EFFECT. The Compton Effect is the change in quality of a beam of X-rays when it is scattered. Imagine that a piece of paper when held between the eyes and a green light appears green, but that when the paper is moved to a position at right angles with the light its colour changes to yellow, and when turned to the opposite side from the light its colour becomes red. Such a change in colour would correspond to the increase in wave-length which X-rays undergo when they are scattered, a small change when scattered at a small angle, but a larger difference for the rays scattered at a large angle. This phenomenon owes its chief interest to the fact that it indicates a corpuscular structure for X-rays.

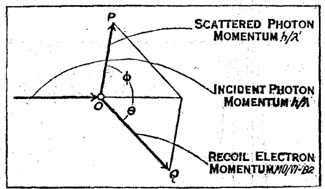


FIG. 1.—DIAGRAM OF PARALLELOGRAM OF MOMENTA IN COMPTON EFFECT

History.—The earliest experiments on secondary X-rays showed a difference in the penetrating power of the primary and the secondary rays. Barkla and his collaborators found (1908) that the secondary X-rays from heavy elements consist mostly of fluorescent radiations characteristic of the radiating element, and that it is the presence of these fluorescent rays which is chiefly responsible for the greater absorbability of the secondary rays. Later experiments, showed, however, a measurable difference in penetration even for the rays coming from light elements, such as carbon, from which no such fluorescent rays are emitted. It was established by J. A. Gray (1920) that in such cases the change in quality was an accompaniment of the process of scattering or diffuse reflection of the primary X-rays. A spectroscopic study of the scattered X-rays by A. H. Compton (1923) revealed the fact

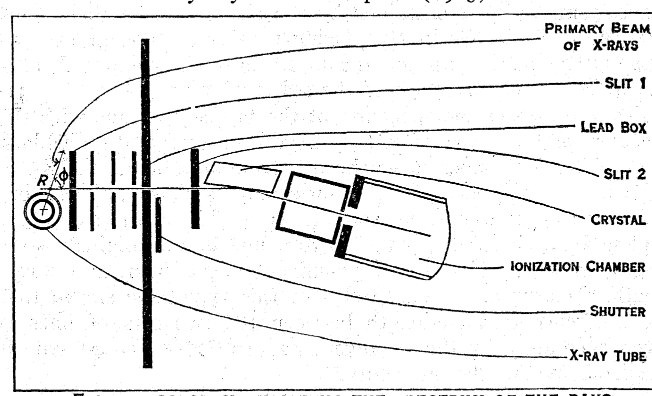

FIG. 2.—DIAGRAM ANALYZING THE SPECTRUM OF THE RAYS

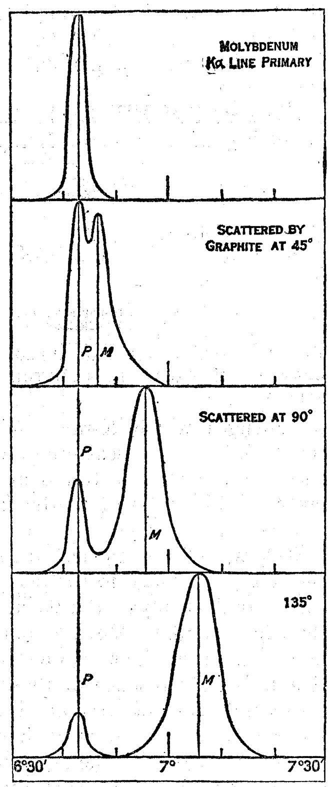
that different primary wave-lengths are increased in wave-length by the same amount when the rays are scattered, and he showed at the same time that this change could be explained if the X-rays are corpuscular in nature.

The Experiment and Its Explanation.—According to the theory that X-rays consist of electromagnetic waves, scattered X-rays are similar to an echo. When an X-ray wave passes through a piece of paper composed of electrons, each electron is set in vibration by the wave and, because of its forced vibrations, emits a new wave which goes in all directions as a scattered X-ray. The number of vibrations of these new waves per second is the same as the number of vibrations of the electron, which is in turn the same as the frequency of the original X-rays. Experiment, however, shows that the frequency of the scattered rays is less than that of the primary rays. This prediction of the wave theory of X-rays is thus incorrect.

The corpuscular theory of the scattering process supposes that each X-ray particle, or "photon" may collide with an electron of the scattering material and bounce off. In fig. 1 is shown a diagram of such a collision. The photon strikes the electron at O, and bounces off toward P, while the electron recoils from the impact in the direction OQ. The collision is supposed to be elastic; but a part of the energy of the photon is spent on the recoiling electron. It follows that the deflected or scattered photon must have less energy than it had before the collision. Such a decrease in the energy of the photon would be described in the language of the wave theory as a decrease in frequency or an increase in wave-length of the scattered X-ray. (*See* QUANTUM MECHANICS.)

As we shall show later, the photon theory can be put in a quantitative form, in which it predicts an increase in wave-length of the X-rays due to the scattering process of $2{\cdot}42 \times 10^{-10} \times (1 - \cos\phi)$ centimetre, where ϕ is the angle between the primary and the scattered rays.

A diagram of the apparatus used for testing this prediction is shown in fig. 2. X-rays pass through a radiator R, which may be for example a block of carbon or paraffin. Some of the rays are scattered through slits 1 and 2 into the X-ray spectrometer. In this instrument a crystal of calcite takes the place of the prism or the grating of an optical spectrometer and spreads the rays into a spectrum, which is examined by the ionization chamber. (*See* SPECTROSCOPY, X-RAY.) By placing the X-ray tube before the slits in place of the radiator, the spectrum of the primary X-rays can be compared with that of the scattered rays.



FROM "PHYSICAL REVIEW," 1923

FIG. 3.—SCATTERED X-RAY SPECTRUM

Line P is shown and one of increased wave-length, its position marked by M

Fig. 3 compares the spectrum of the primary X-rays with the spectrum of these rays after they have been scattered by a block of graphite. The upper curve shows a prominent line in the X-ray spectrum of molybdenum. The lower curves show the spectrum of these rays after being scattered from graphite at three different angles. In each case, in addition to a line of the original wave-length, there appears a more prominent line of increased wave-length. Measurements on spectra of this type have shown that the difference in wave-length between the two sets of lines is given accurately by the formula $2{\cdot}42 \times 10^{-10} \times (1 - \cos\phi)$ cm. as predicted by the photon theory.

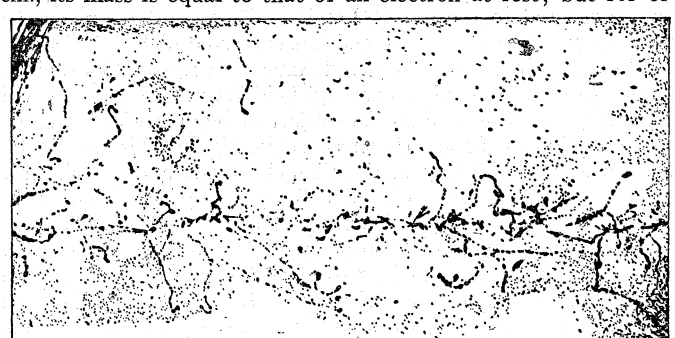
The line whose wave-length has not been changed is called the "unmodified" line. It may be accounted for as due to photons deflected by electrons that are too tightly held in the atom to recoil from the impact of the photon.

The Recoil Electrons.—We have seen that, according to the photon theory, when an X-ray particle collides with an electron, the electron recoils from the impact unless held too tightly by its atom. Electrons recoiling in this manner were discovered independently by C. T. R. Wilson and W. Bothe (1923) a few months after their prediction. Fig. 4 is a photograph of the trails of four such recoil electrons, taken by Ikeuti, using Wilson's method. It will be seen that the tracks of these electrons start nearly in the direction of the X-ray beam, as they should if they are recoiling from deflected X-ray photons. In fact a detailed study of such photographs shows that the number of these trails is about equal to the number of photons of scattered X-rays, and that their directions and ranges are in good accord with the predictions of the photon theory.

The corpuscular character of the scattered X-rays is shown most clearly by tracing the path of a photon after it has collided with an electron. This has been done (Compton and Simon, 1925) in the manner shown diagrammatically in fig. 5. A feeble beam of X-rays is admitted into a cloud expansion chamber of the type devised by Wilson to show the trails left by fast moving electrons. A photon is scattered by an electron at O, and the trail of the electron as it recoils is visible. If it starts along the line OQ, the X-ray particle must have proceeded in the direction OP, determined by the usual mechanical laws of elastic collisions. The deflected photon can make itself visible by exciting a second high-speed particle before it escapes through the wall of the chamber. The track at A represents such an occurrence. When such a second track appears it is possible to trace the path followed by the X-ray particle after its collision with the first electron. If the scattered X-rays did not consist of particles, but were propagated as waves spreading in all directions, when a second electron appears, there is no more reason why it should occur at A than at some other position such as B. The fact that in the experiments the scattered ray excited secondary electrons near the line OP, determined by the angle of recoil Θ, means that the X-rays go in definite directions.

Unless there is some improbably large error in the experiments, we may therefore infer that scattered X-rays go as discrete particles in definite directions. At the same time, experiments on the diffraction, interference and polarization of light and X-rays, and on electrical oscillations associated with electric waves, can leave no doubt but that electromagnetic radiation has the properties of waves. No satisfactory explanation has as yet been offered of how radiation may have at the same time the properties of waves and those of particles. Such a reconciliation does not, however, seem impossible.

The Photon.—The experiments associated with the Compton Effect thus seem to establish the existence of a particle of radiation. This particle, the photon, may be classified with the electron and the proton as one of the three fundamental units of matter. It does not possess an electric charge as do the electron and the proton, but it does have an electric "field," that is, it exerts a force on an electron in its neighbourhood. It also has mass, the essential characteristic of matter, its mass being $2{\cdot}19 \times 10^{-38}\ \lambda$ grams, where λ is the wave-length of the radiation expressed in centimeters. For a hard gamma ray, of wave-length $2{\cdot}4 \times 10^{-10}$ cm., its mass is equal to that of an electron at rest; but for ordinary light its mass is only about 0·000005 that of an electron. The photon seems to disappear when absorbed by an atom, and to be created again when the atom emits radiation. However, the suggestion has been made by G. N. Lewis (1926) that the photon is really retained by the atom and does not lose its identity. The motion of the photon is always with the speed of light, which in free space is about 3×10^{10} cm. per second.



FROM "PROCEEDINGS OF THE ROYAL SOCIETY," 1923, BY COURTESY OF THE COUNCIL, AND OF PROFESSOR C. T. R. WILSON

FIG. 4.—TRAILS OF ELECTRONS RECOILING FROM SCATTERED X-RAYS

Calculation of the Change of Wave-length of Scattered X-rays.—The photon theory can be put in quantitative form by making use of Einstein's postulate (1905) that the energy of the photon is proportional to the frequency of the corresponding wave. Einstein assumes that the energy of a light particle is $E=h\nu$, where ν is the number of vibrations per second of the corresponding wave and h is a universal constant which has the value $6{\cdot}55\times10^{-27}$ erg seconds. For a photon moving with the velocity of light, the theory of relativity demands that its momentum shall be E/c, where c is the velocity of light, *i.e.*, the momentum of a

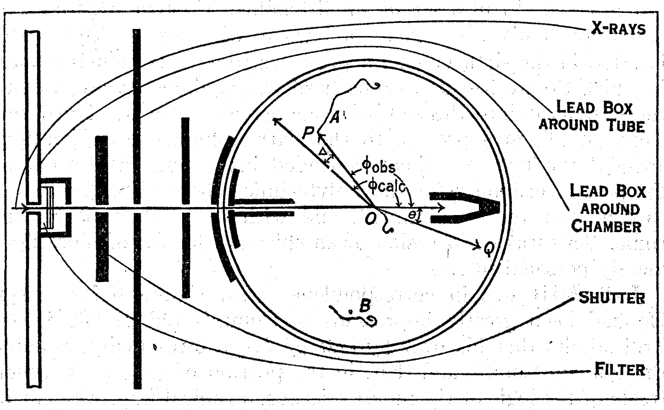


FIG. 5.—DIAGRAM SHOWING THAT A SECOND ELECTRON MAY BE EJECTED BY THE SCATTERED RAY AT A, BUT NOT AT B

photon is $h\nu/c$, or its equivalent h/λ, where λ is the wave-length of the corresponding wave.

The mathematical statement that the total energy after the collision between the photon and the electron is the same as before is,

$$h\nu = h\nu' + \tfrac{1}{2}mv^2, \qquad (1)$$

where ν' is the "frequency" of the photon after collision, and $\frac{1}{2}mv^2$ is the kinetic energy with which the electron recoils (neglecting higher powers of v^2/c^2, which become important only when the electron's speed v is comparable with that of light).

The statement that the total momentum of the photon and electron along the X axis remains equal to the $h\nu/c$ after the collision is, to the same degree of approximation,

$$\frac{h\nu}{c} = \frac{h\nu'}{c}\cos\phi + mv\cos\theta \qquad (2)$$

Similarly, along the Y axis the momentum is

$$O = \frac{h\nu'}{c}\sin\phi - mv\sin\theta \qquad (3)$$

In these three equations we have three unknown quantities, $=\nu'$, ν and θ (in the experiments ϕ is usually known), for which the equations may be solved. It is more convenient, however, to express the results of the solution thus:

$$\delta\lambda = \lambda' - \lambda = \frac{h}{mc}(1-\cos\phi) = 2{\cdot}42\times10^{-10}(1-\cos\phi) \qquad (4)$$

$$E_{kin} = \tfrac{1}{2}mv^2 = h\nu\times 2\alpha\cos^2\theta(\text{approx.}) \qquad (5)$$

$$\cot\theta = -(1+\alpha)\tan\tfrac{1}{2}\phi, \qquad (6)$$

where $\alpha = h/mc\,\lambda$. These equations represent the solutions of equations (1), (2) and (3) except for higher powers of v^2/c^2. Equations (4) and (6) are exact solutions if the relativity expressions for the kinetic energy and momentum of the electron are used.

Equation (4) expresses the difference in wave-length between the two sets of lines shown in fig. 3. It has been found to be as accurate as our knowledge of the constants, h, m, and c. Equation (5) describes the motion of the recoil electrons and has been found to agree with the experiments. The last equation (6) has been verified by experiments such as that pictured in fig. 5.

COMPTROLLER or **CONTROLLER,** the title of an official whose business primarily was to examine and take charge of accounts, hence to direct or control; *e.g.*, the English comptroller of the household, comptroller and auditor-general (head of the exchequer and audit department), comptroller-general of patents, etc., comptroller-general (head of the national debt office). The word is frequently spelt *controller,* as in controller of the navy, controller of the stationery office. The word is used in the same sense in the United States, as comptroller of the Treasury, an official who examines accounts and signs drafts, and comptroller of the currency, who administers the law relating to the national banks. In the United States a comptroller is also a principal business executive officer whose duty it is to translate information obtained in accounting and business records into instruments for administrative control. The general auditor is responsible to him, and his department deals with questions of insurance, compensation, taxation and costs.

COMPURGATION or **LAW WAGER,** a method of defence common to many of the tribes which overran the Roman empire and to the Welsh, and subsequently adopted by the Church. If the defendant could get a certain number of persons (compurgators) to support his denial on oath of the charge, he won his case.

COMPUTING MACHINES: *see* MATHEMATICAL INSTRUMENTS.

COMSTOCK, ANNA BOTSFORD (1854–1930), American naturalist and wood-engraver, was born at Otto, N.Y., on Sept. 1, 1854. She graduated at Chamberlain institute, Randolph, N.Y., in 1873, and at Cornell university in 1878, and studied art at Cooper Union, New York city. In 1878 she married J. H. Comstock (*q.v*). As a wood-engraver she attained success with nature subjects and exhibited engravings at the World's Columbian exposition at Chicago in 1893 and at other important expositions. She became an influential advocate of nature-study in education and, following a wide experience in university extension work in this field, was made in 1913 assistant professor and in 1920, professor of nature-study in Cornell university. Among her published works are: *Ways of the Six-Footed* (1903); *How to Know the Butterflies,* with J. H. Comstock (1904); *Handbook of Nature-Study* (Ithaca, N.Y., 1911, 16th ed., 1925); *The Pet Book* (1914); *Bird, Animal, Tree, and Plant Notebooks* (1914); and *Trees at Leisure* (1916).

COMSTOCK, ANTHONY (1844–1915), American anti-vice crusader, was born at New Canaan, Conn., on March 7, 1844. He received a high school education, and served (1863–65) with the 17th Connecticut Regiment in the Civil War. In 1872 he became an active worker with the Young Men's Christian Association in New York city and devoted himself chiefly to the suppression of salacious literature. He was instrumental in organizing the New York Society for the Suppression of Vice in 1873, and was appointed chief special agent of the society. In the same year he was able to secure the passage of the so-called Comstock Laws of 1873 through the Federal Congress, and was appointed special agent of the Post Office Department. For many years he carried on an energetic prosecution of such establishments, literature and practices as he deemed immoral and injurious to the public. He died in New York city on Sept. 21, 1915.

See H. Broun and M. Leech, *Anthony Comstock, Roundsman of the Lord* (1927).

COMSTOCK, JOHN HENRY (1849–1931), American entomologist, was born in Janesville, Wis., on Feb. 24, 1849. After his graduation at Cornell university in 1874, he pursued further study at Yale university in 1874–75 and at the University of Leipzig in 1888–89. He was instructor and assistant professor of entomology in 1875–78 at Cornell university, and, after serving as U.S. entomologist at Washington in 1879–81, was made professor of entomology at Cornell university and continued in that chair until 1914 when he became professor emeritus. By his influential work as a teacher and by his researches and writings, he contributed notably to the advancement of entomological science, and rose to foremost rank among American entomologists. Besides numerous articles in scientific journals his published writings include: *A Manual on the Study of Insects,* with Anna Botsford Comstock (Ithaca, N.Y., 1895, 1904, 1907); *Insect Life* (1897, 1891); *Introduction to Entomology* (Ithaca, 1888, 1920, 1924); *How to Know the Butterflies,* with Anna B. Comstock (1904); *The Spider Book* (1912); and *The Wings of Insects* (Ithaca, 1918).

COMTE, AUGUSTE (ISIDORE AUGUSTE MARIE FRANÇOIS XAVIER) (1798–1857), French Positive philosopher, was born on Jan. 19, 1798, at Montpellier, where his father was a receiver-general of taxes for the district. He went first to the local school, and in 1814 to the École Polytechnique, where he displayed, in addition to great intelligence, the strenuous application that marked him all his life. His tendency to rebellion against authority, however, was also strongly developed already, and before he had been there five years he was involved in a mutiny which resulted in the break-up of the school. In 1816 he returned to Paris to make his living by teaching mathematics.

Saint-Simon.—About 1818 Comte became associated with Saint-Simon, who was destined to exercise a very decisive influence upon the turn of his speculation. In after years he so far forgot himself as to write of Saint-Simon as a depraved quack, and to deplore his connection with him as purely mischievous. While the connection lasted he thought very differently. Saint-Simon is described as the most estimable and lovable of men, and the most delightful in his relations; he is one of the most worthy of philosophers. The most cursory glance into Saint-Simon's writings is enough to reveal the thread of connection between the ingenious visionary and the systematic thinker, though this is not to deny either Comte's originality of thought or his superiority to Saint-Simon. It was undoubtedly Saint-Simon who launched him, to take Comte's own word, by suggesting what became the two starting points of the Comtist system—first, that political phenomena are as capable of being grouped under laws as other phenomena; and second, that the true destination of philosophy must be social, and the true object of the thinker, the reorganization of the moral, religious and political systems. The occasion resulting in the breach between them (1824) was an attempt on Saint-Simon's part to print a production of Comte's as if it were in some sort connected with Saint-Simon's schemes of social reorganization. Not only was the breach not repaired, but long afterwards Comte, as we have said, with painful ungraciousness took to calling the encourager of his youth by very hard names.

In *Le Producteur* Comte began to expound the philosophic ideas that were now maturing in his mind. He announced a course of lectures (1826), which it was hoped would bring money as well as fame, and which were to be the first dogmatic exposition of the Positive philosophy. These attracted hearers so eminent as Humboldt the cosmologist, Poinsot the geometer, and Blainville the physiologist.

Unhappily, after the third lecture of the course, Comte suffered a severe attack of cerebral derangement. He did not recover his health for more than a year, and as soon as convalescence set in he was seized by so profound a melancholy at the disaster which had thus overtaken him, that he threw himself into the Seine. Fortunately he was rescued, and the shock did not stay his return to mental soundness.

The Course of Positive Philosophy began to be published in 1830; the lectures were renewed in 1828. In 1833 he was appointed examiner of the boys who in the various provincial schools aspired to enter the École Polytechnique at Paris. This and two other engagements as a teacher of mathematics secured him an income of some £400 a year. He made M. Guizot, then Louis Philippe's minister, the important proposal to establish a chair of general history of the sciences. If there are four chairs, he argued, devoted to the history of philosophy, that is to say, the minute study of all sorts of dreams and aberrations through the ages, surely there ought to be at least one to explain the formation and progress of our real knowledge. This wise suggestion, still unfulfilled, was at first welcomed, according to Comte's own account, by Guizot's philosophic instinct, and then repulsed by his "metaphysical rancour."

Every year from 1831 to 1848 he delivered a course of gratuitous lectures on astronomy, and this public spirit showed itself in other ways. He was imprisoned for refusing to serve in the National guard, his position being that, as a republican, though he would not take arms against the new monarchy, he would take no oath to defend it. His only relaxation was the opera, to which he was devoted.

In 1842, as already stated, the last volume of the *Positive Philosophy* was given to the public; but instead of the contentment which he had earned by 12 years' hard work, Comte found himself in the midst of a sea of small trouble. First in 1842 he separated from his wife. Next, a lawsuit with his publisher, who inserted in the sixth volume a protest against a certain footnote, in which Comte had used some hard words about Arago. Comte threw himself into the suit with energy and won it. Third and worst of all, in a preface to the sixth volume, he deliberately angered the men on whom depended his annual re-election to the post of examiner for the Polytechnic school. The result was that he lost the appointment, and with it, one-half of his income. This was the occasion of an episode which is of more than merely personal interest.

J. S. Mill was in correspondence with Comte before 1842. He had been greatly impressed by Comte's philosophic ideas; Mill admits that his own *System of Logic* owes many valuable thoughts to Comte, and that, in the portion of that work which treats of the logic of the moral sciences, a radical improvement in the conceptions of logical method was derived from the *Positive Philosophy*. Their correspondence turned principally upon the questions of the equality **between men** and women, and of the expediency and constitution of a sacerdotal or spiritual order. When Comte found himself straitened, he confided the entire circumstances to Mill. As might be supposed by those who know the affectionate anxiety with which Mill regarded the welfare of any one whom he believed to be doing good work in the world, he at once took pains to have Comte's loss of income made up to him, until Comte should have had time to repair that loss by his own endeavour. Mill persuaded Grote, Molesworth, and Raikes Currie to advance the sum of £240. At the end of the year (1845) Comte had taken no steps to enable himself to dispense with the aid of the three Englishmen. Mill applied to them again, but with the exception of Grote, who sent a small sum, they gave Comte to understand that they expected him to earn his own living. Mill had suggested to Comte that he should write articles for the English periodicals, and expressed his own willingness to translate any such articles from the French. Comte at first fell in with the plan, but he speedily surprised and disconcerted Mill by boldly taking up the position of "high moral magistrate," and accusing the three defaulting contributors of a scandalous falling away from righteousness and a high mind. Mill was chilled by these pretensions; and the correspondence came to an end. There is something to be said for both sides. Comte, regarding himself as the promoter of a great scheme for the benefit of humanity, might reasonably look for the support of his friends in the fulfilment of his designs, but his subsequent attitude of censorious condemnation put him entirely in the wrong.

From 1845 to 1848 Comte lived as best he could, as well as made his wife her allowance, on an income of £200 a year. His little account books of income and outlay, with every item entered down to a few hours before his death, are accurate and neat enough to have satisfied an ancient Roman householder. In 1848, through no fault of his own, his salary was reduced to £80. Littré and others, with Comte's approval, published an appeal for subscriptions, and on the money thus contributed Comte subsisted for the remaining nine years of his life. By 1852 the subsidy produced as much as £200 a year. It is worth noticing that Mill was one of the subscribers, and that Littré continued his assistance after he had been driven from Comte's society by his high pontifical airs. We are sorry not to be able to record any similar trait of magnanimity on Comte's part. His character, admirable as it is for firmness, for intensity, for inexorable will, for iron devotion to what he thought the service of mankind, yet offers few of those softening qualities that make us love good men and pity bad ones.

Comte's Literary Method.—It is best to think of him only as the intellectual worker, pursuing in uncomforted obscurity the laborious and absorbing task to which he had given up his whole life. His singularly conscientious fashion of elaborating his ideas made the mental strain more intense than even so exhausting a work as the abstract exposition of the principles of positive science need have been. He did not write down a word until he had first composed the whole matter in his mind. When he had thoroughly meditated every sentence, he sat down to write, and then, such was the grip of his memory, the exact order of his thoughts came back to him, and he wrote down what he had intended to write, without the aid of a note. It is hardly possible, however, to share the admiration expressed by some of Comte's disciples for his style. When compared with such philosophic writing as Hume's, Diderot's, Berkeley's, then Comte's manner is heavy, laboured, monotonous, without relief and without light. Only the interest of the matter prevents one from thinking of Rivarol's ill-natured remark upon Condorcet, that he wrote with opium on a page of lead. The general effect is impressive, not by any virtues of style, but by reason of the magnitude and importance of the undertaking and the visible conscientiousness and the grasp with which it is executed. It is by sheer strength of thought, by the vigorous perspicacity with which he strikes the lines of cleavage of his subject, that he makes his way into the mind of the reader; in the presence of gifts of this power we need not quarrel with an ungainly style.

Comte pursued one practice which ought to be mentioned in connection with his personal history, the practice of what he styled *hygiène cérébrale.* After he had acquired what he considered to be a sufficient stock of material, and this happened before he had completed the *Positive Philosophy,* he abstained from reading newspapers, reviews, scientific transactions and everything else, except two or three poets (notably Dante) and the *Imitatio Christi.* It is true that his friends kept him informed of what was going on in the scientific world. Still this partial divorce of himself from the record of the social and scientific activity of his time, though it may save a thinker from the deplorable evils of dispersion, moral and intellectual, accounts in no small measure for the exaggerated egoism, and the absence of all feeling for reality which marked Comte's later days.

In 1845 Comte made the acquaintance of Madame Clotilde de Vaux. Very little is known about her qualities. Her letters speak well for her good sense and good feeling, and it would have been better for Comte's later work if she had survived to exert a wholesome restraint on his exaltation. Their friendship had only lasted a year when she died (1846), but the period was long enough to give her memory a supreme ascendancy in Comte's mind. After her death Comte was inconsolable, he visited her tomb every week and invoked her memory three times every day.

Comte lost no time, after the completion of his *Course of Positive Philosophy,* in proceeding with the *System of Positive Polity,* for which the earlier work was designed to be a foundation. The first volume was published in 1851, and the fourth and last in 1854. In 1848 when the political air was charged with stimulating elements, he founded the Positive society, with the expectation that it might grow into a reunion as powerful over the new revolution as the Jacobin club had been in the revolution of 1789. The hope was not fulfilled, but a certain number of philosophic disciples gathered round Comte, and eventually formed themselves, under the guidance of the new ideas of the latter half of his life, into a kind of church, for whose use was drawn up the *Positivist Calendar* (1849), in which the names of those who had advanced civilization replaced the titles of the saints. Gutenberg and Shakespeare were among the patrons of the thirteen months in this calendar. In the years 1849, 1850 and 1851, Comte gave three courses of lectures at the Palais Royal. They were gratuitous and popular, and in them he boldly advanced the whole of his doctrine, as well as the direct and immediate pretensions of himself and his system. The third course ended in the following uncompromising terms "In the name of the past and of the future, the servants of humanity—both its philosophical and its practical servants—come forward to claim as their due the general direction of this world. Their object is to constitute at length a real Providence in all departments—moral, intellectual and material. Consequently they exclude once for all from political supremacy all the different servants of God—Catholic, Protestant or Deist—as being at once behindhand and a cause of disturbance." A few weeks after this invitation, a very different person stepped forward to constitute himself a real Providence.

The Catechism of Positivism was published in 1852. In the preface Comte took occasion to express his approval of Louis Napoleon's *coup d' état* of the 2nd of December—"a fortunate crisis which has set aside the parliamentary system and instituted a dictatorial republic." Whatever we may think of the political sagacity of such a judgment it is due to Comte to say that he did not expect to see his dictatorial republic transformed into a dynastic empire, and next, that he did expect from the Man of December freedom of the press and of public meeting. His later hero was the emperor Nicholas, "the only statesman in Christendom"—as unlucky a judgment as that which placed Dr. Franca in the Comtist Calendar. Comte died of cancer on Sept. 5, 1857. By his will he appointed 13 executors who were to preserve his rooms at 10 rue Monsieur-le-Prince as the headquarters of the new religion of Humanity.

Early Writings.—In proceeding to give an outline of Comte's system, we shall consider the *Positive Polity* as the more or less legitimate sequel of the *Positive Philosophy,* notwithstanding the deep gulf which so eminent a critic as J. S. Mill insisted upon fixing between the earlier and the later work. His letters when he was a young man of one-and-twenty, and before he had published a word, show how strongly present the social motive was in his mind, and in what little account he should hold his scientific works, if he did not perpetually think of their utility for the species. "I feel," he wrote, "that such scientific reputation as I might acquire would give more value, more weight, more useful influence to my political sermons." In 1822 he published a *Plan of the Scientific Works necessary to reorganize Society.* In this he points out that modern society is passing through a great crisis, due to the conflict of two opposing movements; the first, a disorganizing movement owing to the break-up of old institutions and beliefs; the second, a movement towards a definite social state, in which all means of human prosperity will receive their most complete development and most direct application. How is this crisis to be dealt with? What are the undertakings necessary in order to pass successfully through it towards an organic state? The answer to this is that there are two series of works. The first is theoretic or spiritual, aiming at the development of a new principle of co-ordinating social relations, and the formation of the system of general ideas which are destined to guide society. The second work is practical or temporal; it settles the distribution of power, and the institutions that are most conformable to the spirit of the system which has previously been thought out in the course of the theoretic work. As the practical work depends on the conclusions of the theoretical, the latter must obviously come first in order of execution.

In 1826 this was pushed farther in a most remarkable piece called *Considerations on the Spiritual Power*—the main object of which is to demonstrate the necessity of instituting a spiritual power, distinct from the temporal power and independent of it. In examining the conditions of a spiritual power proper for modern times, he indicates in so many terms the presence in his mind of a direct analogy between his proposed spiritual power and the functions of the catholic clergy at the time of its greatest vigour and most complete independence—that is to say from about the middle of the 11th century, until towards the end of the 13th. He refers to De Maistre's memorable book, *Du Pape,* as the most profound, accurate and methodical account of the old spiritual organization, and starts from that as the model to be adapted to the changed intellectual and social conditions of the modern time. In the *Positive Philosophy,* again (vol. v.p.344), he distinctly says that catholicism, reconstituted as a system on new intellectual foundations, would finally preside over the spiritual reorganization of modern society. Much else could be quoted to the same effect. If unity of career, then, means that Comte from the beginning designed the institution of a spiritual power, and the systematic reorganization of life, it is difficult to deny him whatever credit that unity may be worth, and the credit is perhaps not particularly great. Even the readaptation of the catholic system to a scientific doctrine was plainly in his mind 30 years before the final execution of *Positive Polity,* though it is difficult to believe that he foresaw the religious mysticism in which the task was to land him. A great analysis was to precede a great synthesis, but it was the synthesis on which Comte's vision was centred from the first. Let us first sketch the nature of the analysis. Society is to be reorganized on the base of knowledge. What is the sum and significance of knowledge? That is the question which Comte's first master-work professes to answer.

The Law of the Three States.—The *Positive Philosophy* opens with the statement of a certain law of which Comte was the discoverer, and which has always been treated both by disciples and dissidents as the key to his system. This is the Law of the Three States. It is as follows: Each of our leading conceptions, each branch of our knowledge, passes successively through three different phases; there are three different ways in which the human mind explains phenomena, each way following the other in order. These three stages are the theological, the metaphysical and the positive. Knowledge, or a branch of knowledge is, in the theological state, when it supposes the phenomena under consideration to be due to immediate volition, either in the object or in some supernatural being. In the metaphysical state, for volition is substituted abstract force residing in the object, yet existing independently of the object; the phenomena are viewed as if apart from the bodies manifesting them; and the properties of each substance have attributed to them an existence distinct from that substance. In the positive state inherent volition or external volition and inherent force or abstraction personified have both disappeared from men's minds, and the explanation of a phenomenon means a reference of it, by way of succession or resemblance, to some other phenomenon—means the establishment of a relation between the given fact and some more general fact. In the theological and metaphysical state men seek a cause or an essence; in the positive they are content with a law. To borrow an illustration from an able English disciple of Comte:—"Take the phenomenon of the sleep produced by opium. The Arabs are content to attribute it to the 'will of God.' Moliere's medical student accounts for it by a *soporific principle* contained in the opium. The modern physiologist knows that he cannot account for it at all. He can simply observe, analyse and experiment upon the phenomena attending the action of the drug and classify it with other agents analogous in character."—(*Dr. Bridges*).

The first and greatest aim of the positive philosophy is to advance the study of society into the third of the three stages—to remove social phenomena from the sphere of theological and metaphysical conceptions, and to introduce among them the same scientific observation of their laws which has given us physics, chemistry, physiology. Social physics will consist of the conditions and relations of the facts of society, and will have two departments—one, statical, containing the laws of order; the other dynamical, containing the laws of progress. While men's minds were in the theological state, political events, for example, were explained by the will of the gods, and political authority based on divine right. In the metaphysical state of mind, then, to retain our instance, political authority was based on the sovereignty of the people, and social facts were explained by the figment of a falling away from a state of nature. When the positive method has been finally extended to society, as it has been to chemistry and physiology, these social facts will be resolved, as their ultimate analyses, into relations with one another, and instead of seeking causes in the old sense of the word, men will only examine the conditions of social existence. When that stage has been reached, not merely the greater part, but the whole of our knowledge, will be impressed with one character, the character, namely, of positivity or scientificalness: and all our conceptions in every part of knowledge will be thoroughly homogeneous. The gains of such a change are enormous. The new philosophical unity will now in its turn regenerate all the elements that went to its own formation. The mind will pursue knowledge without the wasteful jar and friction of conflicting methods and mutually hostile conceptions; education will be regenerated; and society will reorganize itself on the only possible solid base—a homogeneous philosophy.

Classification of Sciences.—The *Positive Philosophy* has another object besides the demonstration of the necessity and propriety of a science of society. This object is to show the sciences as branches from a single trunk—is to give to science the ensemble or spirit or generality hitherto confined to philosophy, and to give to philosophy the rigour and solidity of science. Comte's special object is a study of social physics, a science that before his advent was still to be formed; his second object is a review of the methods and leading generalities of all the positive sciences already formed, so that we may know both what system of inquiry to follow in our new science, and also where the new science will stand in relation to other knowledge.

The first step in this direction is to arrange scientific method and positive knowledge in order, and this brings us to another cardinal element in the Comtist system, the classification of the sciences. In the front of the inquiry lies one main division, that, namely, between speculative and practical knowledge. With the latter we have no concern. Speculative or theoretic knowledge is divided into abstract and concrete. The former is concerned with the laws that regulate phenomena in all conceivable cases: the latter is concerned with the application of these laws. Concrete science relates to objects or beings; abstract science to events. The former is particular or descriptive; the latter is general. Thus, physiology is an abstract science; but zoology is concrete. Chemistry is abstract; mineralogy is concrete. It is the method and knowledge of the abstract sciences that the positive philosophy has to reorganize in a great whole.

Comte's principle of classification is that the dependence and order of scientific study follows the dependence of the phenomena. Thus, as has been said, it represents both the objective dependence of the phenomena and the subjective dependence of our means of knowing them. The more particular and complex phenomena depend upon the simpler and more general. The latter are the more easy to study. Therefore science will begin with those attributes of objects which are most general, and pass on gradually to other attributes that are combined in greater complexity. Thus, too, each science rests on the truths of the sciences that precede it, while it adds to them the truths by which it is itself constituted. Comte's series or hierarchy is arranged as follows:— (1) Mathematics (that is, number, geometry, and mechanics), (2) Astronomy, (3) Physics, (4) Chemistry, (5) Biology, (6) Sociology. Each of the members of this series is one degree more special than the member before it, and depends upon the facts of all the members preceding it, and cannot be fully understood without them. It follows that the crowning science of the hierarchy dealing with the phenomena of human society will remain longest under the influence of theological dogmas and abstract figments, and will be the last to pass into the positive stage. You cannot discover the relations of the facts of human society without reference to the conditions of animal life; you cannot understand the conditions of animal life without the laws of chemistry; and so with the rest.

This arrangement of the sciences, and the Law of the Three States, are together explanatory of the course of human thought and knowledge. They are thus the double key of Comte's systematization of the philosophy of all the sciences from mathematics to physiology, and his analysis of social evolution, which is the base of sociology. Each science contributes its philosophy. The co-ordination of all these partial philosophies produces the general positive philosophy. Thousands had cultivated science, and with splendid success; not one had conceived the philosophy which the sciences when organized would naturally evolve. A few had seen the necessity of extending the scientific method to all enquiries, but no one had seen how this was to be effected. . . . The positive philosophy is novel as a philosophy, not as a collection of truths never before suspected. Its novelty is the organization of existing elements. Its very principle implies the absorption of all that great thinkers had achieved; while incorporating their results it extended their methods. . . . What tradition brought was the results; what Comte brought was the organization of these results. He always claimed to be the founder of the positive philosophy. That he had every right to such a title is demonstrable to all who distinguish between the positive sciences and the philosophy which co-ordinated the truths and methods of these sciences into a doctrine—(*G. H. Lewes*).

Comte's classification of the sciences has been subjected to a vigorous criticism by Herbert Spencer. Spencer's two chief points are these:—(1) He denies that the principle of the development of the sciences is the principle of decreasing generality; he asserts that there are as many examples of the advent of a science being determined by increasing generality as by increasing speciality. (2) He holds that any grouping of the sciences in a succession gives a radically wrong idea of their genesis and their interdependence; no true filiation exists; no science develops itself in isolation; no one is independent, either logically or historically. Littré, by far the most eminent of the scientific followers of Comte, concedes a certain force to Spencer's objections, and makes certain secondary modifications in the hierarchy in consequence, while still cherishing his faith in the Comtist theory of the sciences. J. S. Mill, while admitting the objections as good, if Comte's arrangement pretended to be the only one possible, still holds the arrangement as tenable for the purpose with which it was devised. G. H. Lewes asserts against Spencer that the arrangement in a series is necessary, on grounds similar to those which require that the various truths constituting a science should be systematically co-ordinated, although in nature the phenomena are intermingled.

The first three volumes of the *Positive Philosophy* contain an exposition of the partial philosophies of the five sciences that precede sociology in the hierarchy. Their value has usually been placed very low by the special followers of the sciences concerned; they say that the knowledge is second-hand, is not coherent, and is too confidently taken for final. The Comtist replies that the task is philosophic, and is not to be judged by the minute accuracies of science. In these three volumes Comte took the sciences roughly as he found them. His eminence as a man of science must be measured by his only original work in that department—the construction, namely, of the new science of society. This work is accomplished in the last three volumes of the *Positive Philosophy*, and the second and third volumes of the *Positive Polity*. The Comtist maintains that even if these five volumes together fail in laying down correctly and finally the lines of the new science, still they are the first solution of a great problem hitherto unattempted. "Modern biology has got beyond Aristotle's conception; but in the construction of the biological science, not even the most unphilosophical biologist would fail to recognize the value of Aristotle's attempt. So for sociology. Subsequent sociologists may have conceivably to remodel the whole science, yet not the less will they recognize the merit of the first work which has facilitated their labours."—(*Congreve*).

Sociological Conceptions.—We shall now briefly describe Comte's principal conceptions in sociology, his position in respect to which is held by himself, and by others, to raise him to the level of Descartes or Leibnitz. Of course the first step was to approach the phenomena of human character and social existence with the expectation of finding them as reducible to general laws as the other phenomena of the universe, and with the hope of exploring these laws by the same instruments of observation and verification as had done such triumphant work in the case of the latter. Comte separates the collective facts of society and history from the individual phenomena of biology; then he withdraws these collective facts from the region of external volition, and places them in the region of law. The facts of history must be explained, not by providential interventions, but by referring them to conditions inherent in the successive stages of social existence. This conception makes a science of society possible. What is the method? It comprises, besides observation and experiment (which is, in fact, only the observation of abnormal social states), a certain peculiarity of verification. We begin by deducing every well-known historical situation from the series of its antecedents. Thus we acquire a body of empirical generalizations as to social phenomena, and then we connect the generalizations with the positive theory of human nature. A sociological demonstration lies in the establishment of an accordance between the conclusions of historical analysis and the preparatory conceptions of biological theory. As Mill puts it:—"If a sociological theory, collected from historical evidence, contradicts the established general laws of human nature; if (to use M. Comte's instances) it implies, in the mass of mankind, any very decided and natural bent, either in a good or in a bad direction; if it supposes that the reason in average human beings predominates over the desires, or the disinterested desires over the personal—we may know that history has been misinterpreted, and that the theory is false. On the other hand, if laws of social phenomena, empirically generalized from history, can, when once suggested, be affiliated to the known laws of human nature; if the direction actually taken by the developments and changes of human society can be seen to be such as the properties of man and of his dwelling-place made antecedently probable, the empirical generalizations are raised into positive laws, and sociology becomes a science." The result of this method is an exhibition of the events of human experience in co-ordinated series that manifest their own graduated connection.

Next, as all investigation proceeds from that which is known best to that which is unknown or less well known, and as, in social states, it is the collective phenomenon that is more easy of access to the observer than its parts, therefore we must consider and pursue all the elements of a given social state together and in common. The social organization must be viewed and explored as a whole. There is a nexus between each leading group of social phenomena and other leading groups; if there is a change in one of them, that change is accompanied by a corresponding modification of all the rest. "Not only must political institutions and social manners on the one hand, and manners and ideas on the other, be always mutually connected; but further, this consolidated whole must be always connected by its nature with the corresponding state of the integral development of humanity considered in all aspects of intellectual, moral and physical activity."—(*Comte*).

Is there any one element which communicates the decisive impulse to all the rest—any predominating agency in the course of social evolution? The answer is that all the other parts of social existence are associated with, and drawn along by, the contemporary condition of intellectual development. The reason is the superior and preponderant element which settles the direction in which all the other faculties shall expand. "It is only through the more and more marked influence of the reason over the general conduct of man and of society, that the gradual march of our race has attained that regularity and persevering continuity which distinguish it so radically from the desultory and barren expansion of even the highest animal orders, which share, and with enhanced strength the appetites, the passions, and even the primary sentiments of man." The history of intellectual development, therefore, is the key to social evolution, and the key to the history of intellectual development is the law of the Three States.

Among other central thoughts in Comte's explanation of history are these:—The displacement of theological by positive conceptions has been accompanied by a gradual rise of an industrial régime out of the military régime; the great permanent contribution of catholicism was the separation which it set up between the temporal and the spiritual powers; the progress of the race consists in the increasing preponderance of the distinctively human elements over the animal elements; the absolute tendency of ordinary social theories will be replaced by an unfailing adherence to the relative point of view, and from this it follows that the social state, regarded as a whole, has been as perfect in each period as the co-existing condition of humanity and its environment would allow.

The elaboration of these ideas in relation to the history of the civilization of the most advanced portion of the human race occupies two of the volumes of the *Positive Philosophy*, and has been accepted by very different schools as a masterpiece of rich, luminous, and far-reaching suggestion. Whatever additions it may receive, and whatever corrections it may require, this analysis of social evolution will continue to be regarded as one of the great achievements of human intellect.

The third volume of the *Positive Polity* treats of social dynamics, and takes us again over the ground of historic evolution. It abounds with remarks of extraordinary fertility and comprehensiveness, but it is often arbitrary; and its views of the past are strained into coherence with the statical views of the preceding volume. As it was composed in rather less than six months, and as the author honestly warns us that he has given all his attention to a more profound co-ordination, instead of working out the special explanations more fully, as he had promised, we need not be surprised if the result is disappointing to those who had mastered the corresponding portion of the *Positive Philosophy.* Comte explains the difference between his two works. In the first his "chief object was to discover and demonstrate the laws of progress, and to exhibit in one unbroken sequence the collective destinies of mankind, till then invariably regarded as a series of events wholly beyond the reach of explanation, and almost depending on arbitrary will. The present work, on the contrary, is addressed to those who are already sufficiently convinced of the certain existence of social laws, and desire only to have them reduced to a true and conclusive system."

The Positivist System.—The main principles of the Comtian system are derived from the *Positive Polity* and from two other works,—the *Positivist Catechism; a Summary Exposition of the Universal Religion, in twelve Dialogues between a Woman and a Priest of Humanity;* and second, *The Subjective Synthesis* (1856), which is the first and only volume of a work upon mathematics announced at the end of the *Positive Philosophy.* The system for which the *Positive Philosophy* is alleged to have been the scientific preparation contains a polity and a religion; a complete arrangement of life in all its aspects giving a wider sphere to intellect, energy and feeling than could be found in any of the previous organic types—Greek, Roman, or Catholic-feudal. Comte's immense superiority over such pre-revolutionary utopians as the Abbe Saint Pierre, no less than over the group of post-revolutionary utopians, is especially visible in this firm grasp of the cardinal truth that the improvement of the social organism can only be effected by a moral development, and never by any changes in mere political mechanism, or any violences in the way of an artificial redistribution of wealth. A moral transformation must precede any real advance. The aim, both in public and private life, is to secure to the utmost possible extent the victory of the social feeling over self-love, or altruism over egoism.[1] This is the key to the regeneration of social existence, as it is the key to that unity of individual life which makes all our energies converge freely and without wasteful friction towards a common end. What are the instruments for securing the preponderance of altruism? Clearly they must work from the strongest element in human nature, and this element is feeling or the heart. Under the catholic system the supremacy of feeling was abused, and the intellect was made its slave. Then followed a revolt of intellect against sentiment. The business of the new system will be to bring back the intellect into a condition, not of slavery, but of willing ministry to the feelings. The subordination never was, and never will be, effected except by means of a religion, and a religion to be final, must include a harmonious synthesis of all our conceptions of the external order of the universe. The characteristic basis of a religion is the existence of a power without us, so superior to ourselves as to command the complete submission of our whole life. This basis is to be found in the positive stage in humanity, past, present and to come, conceived as the Great Being.

"A deeper study of the great universal order reveals to us at length the ruling power within it of the true Great Being, whose destiny it is to bring that order continually to perfection by constantly conforming to its laws, and which thus best represents to us that system as a whole. This undeniable Providence, the supreme dispenser of our destinies, becomes in the natural course the common centre of our affections, our thoughts and our actions. Although this Great Being evidently exceeds the utmost strength of any, even of any collective, human force, its necessary constitution and its peculiar function endow it with the truest sympathy towards all its servants. The least amongst us can and ought constantly to aspire to maintain and even to improve this Being. This natural object of all our activity, both public and private, determines the true general character of the rest of our existence, whether in feeling or in thought; which must be devoted to love, and to know, in order rightly to serve our Providence, by a wise use of all the means which it furnishes to us. Reciprocally this continued service, whilst strengthening our true unity, renders us at once both happier and better."

The exaltation of humanity into the throne occupied by the Supreme Being under monotheistic systems made all the rest of Comte's construction easy enough. Utility remains the test of every institution, impulse, act; his fabric becomes substantially an arch of utilitarian propositions, with an artificial Great Being inserted at the top to keep them in their place. The Comtist system is utilitarianism crowned by a fantastic decoration. Translated into the plainest English, the position is as follows: "Society can only be regenerated by the greater subordination of politics to morals, by the moralization of capital, by the renovation of the family, by a higher conception of marriage, and so on. These ends can only be reached by a heartier development of the sympathetic instincts. The sympathetic instincts can only be developed by the religion of humanity." Looking at this problem in this way, even a moralist who does not expect theology to be the instrument of social revival, might still ask whether the sympathetic instincts will not necessarily be already developed to their highest point, before people will be persuaded to accept the religion, which is at the bottom hardly more than sympathy under a more imposing name. However that may be, the whole battle—into which we shall not enter—as to the legitimateness of Comtism as a religion turns upon this erection of humanity into a Being. The various hypotheses, dogmas, proposals, as to the family, to capital, etc., are merely propositions measurable by considerations of utility and a balance of expediencies. Many of these proposals are of the highest interest, and many of them are actually available; but there does not seem to be one of them of an available kind, which could not equally well be approached from other sides, and even incorporated in some radically antagonistic system. Adoption, for example, as a practice for improving the happiness of families and the welfare of society, is capable of being weighed, and can in truth only be weighed, by utilitarian considerations, and has been commended by men to whom the Comtist religion is naught. The singularity of Comte's construction, and the test by which it must be tried, is the transfer of the worship and discipline of catholicism to a system in which "the conception of God is superseded" by the abstract idea of humanity, conceived as a kind of personality.

And when all is said, the invention does not help us. We have still to settle what *is* for the good of humanity, and we can only do that in the old-fashioned way. There is no guidance in the conception. No effective unity can follow from it, because you can only find out the right and wrong of a given course by summing up the advantages and disadvantages, and striking a balance, and there is nothing in the religion of humanity to force two men to find the balance on the same side. The Comtists are no better off than other utilitarians in judging policy, events, conduct.

The particularities of the worship, its minute and truly ingenious re-adaptations of sacraments, prayers, reverent signs, down even to the invocation of a New Trinity, need not detain us. They are said, though it is not easy to believe, to have been elaborated by way of Utopia. If so, no Utopia has ever yet been presented in a style so little calculated to stir the imagination, to warm the feelings, to soothe the insurgency of the reason. It is a mistake to present a great body of hypotheses—if Comte meant them for hypotheses—in the most dogmatic and peremptory form to which language can lend itself. And there is no more extraordinary thing in the history of opinion than the perversity with

[1]For Comte's place in the history of ethical theory *see* ETHICS.

which Comte has succeeded in clothing a philosophic doctrine, so intrinsically conciliatory as his, in a shape that excites so little sympathy and gives so much provocation. An enemy defined Comtism as catholicism *minus* Christianity, to which an able champion retorted by calling it catholicism *plus* science. Comte's Utopia has pleased the followers of the catholic, just as little as those of the scientific spirit.

The elaborate and minute systematization of life, proper to the religion of humanity, is to be directed by a priesthood. The priests are to possess neither wealth nor material power; they are not to command but to counsel; their authority is to rest on persuasion, not on force. When religion has become positive and society industrial, then the influence of the Church upon the State becomes really free and independent, which was not the case in the middle ages. The power of the priesthood rests upon the special knowledge of man and nature; but to this intellectual eminence must also be added moral power and a certain greatness of character, without which force of intellect and completeness of attainment will not receive the confidence they ought to inspire. The functions of the priesthood are of this kind:—To exercise a systematic direction over education; to hold a consultative influence over all the important acts of actual life, public and private; to arbitrate in cases of practical conflict; to preach sermons recalling those principles of generality and universal harmony which our special activities dispose us to ignore; to order the due classification of society; to perform the various ceremonies appointed by the founder of the religion. The authority of the priesthood is to rest wholly on voluntary adhesion, and there is to be perfect freedom of speech and discussion. This provision hardly consists with Comte's congratulations to the tsar Nicholas on the "wise vigilance" with which he kept watch over the importation of western books.

The Condition of Women had always powerfully impressed Comte; to him it seemed absolutely essential to elevate it. (*See* a remarkable passage in his letters to M. Valat, pp. 84–87.) His friendship with Madame de Vaux had deepened the impression, and in the reconstructed society women are to play a highly important part. They are to be carefully excluded from public action, but they are to do many more important things than things political. To fit them for their functions they are to be raised above material cares, and they are to be thoroughly educated. The family, which is so important an element of the Comtist scheme of things, exists to carry the influence of woman over man to the highest point of cultivation. Through affection she purifies the activity of man. "Superior in power of affection, more able to keep both the intellectual and the active powers in continual subordination to feeling, women are formed as the natural intermediaries between humanity and man. The Great Being confides specially to them its moral providence, maintaining through them the direct and constant cultivation of universal affection, in the midst of all the distractions of thought or action, which are for ever withdrawing men from its influence. . . . Besides the uniform influence of every woman on every man, to attach him to humanity, such is the importance and the difficulty of this ministry that each of us should be placed under the special guidance of one of these angels, to answer for him, as it were, to the Great Being. This moral guardianship may assume three types—the mother, the wife and the daughter; each having several modifications, as shown in the concluding volume. Together they form the three simple modes of solidarity, or unity with contemporaries, obedience, union and protection—as well as the three degrees of continuity between ages by uniting us with the past, the present and the future. In accordance with my theory of the brain, each corresponds with one of our three altruistic instincts —veneration, attachment and benevolence."

How the positive method of observation and verification of real facts has landed us in this, and much else of the same kind, is extremely hard to guess. Seriously to examine an encyclopaedic system, that touches life, society and knowledge at every point, is evidently beyond the compass of such an article as this. There is in every chapter a whole group of speculative suggestions, each of which would need a long chapter to itself to elaborate or to discuss. There is at least one biological speculation of astounding audacity, that could be examined in nothing less than a treatise. Perhaps we have said enough to show that after performing a great and real service to thought Comte almost sacrificed his claims to gratitude by the invention of a system that, as such, and independently of detached suggestions, is markedly retrograde. But the world will take what is available in Comte, while forgetting that in this work which is as irrational in one way as Hegel is in another. (J. Mo.; X.)

REVIEWS.—The following reviews deal with positivism:—*El Positivismo* (Buenos Aires), and *La Revue Positiviste internationale* (Paris). Certain aspects of the Comtist philosophy are dealt with in *L'Armée sociologique* (Paris); and in the *Sociological Review* (London).

COMUS, the spirit of revelry (Gr. κῶμος, band of revellers); in art, occasionally shown as attendant on Dionysus (q.v.); described by Philostratus in *Imagines* i. 2. From this source, presumably, Ben Jonson got the name (*Pleasure reconciled to Virtue,* 1619). Milton's *Comus* is his own creation, only the name being classical.

See Roscher's *Lexikon,* art. "Komos," and *cf.* JONSON; MILTON.

COMYN, JOHN (d. *c.* 1300), Scottish baron, was a son of John Comyn (d. 1274), justiciar of Galloway, who was a nephew of the constable of Scotland, Alexander Comyn, earl of Buchan (d. 1289), and of the powerful and wealthy Walter Comyn, earl of Mentieth (d. 1258). The elder Comyn took a prominent part in the affairs of Scotland with his uncle the earl of Buchan and had interests in England as well as in his native land; he fought for Henry III. at Northampton and at Lewes, and was imprisoned for a short time in London. The younger Comyn, who had inherited the lordship of Badenoch from his great-uncle the earl of Mentieth, was appointed one of the guardians of Scotland in 1286, and shared in the negotiations between Edward I. and the Scots in 1289–90. When Margaret, the Maid of Norway, died in 1290, Comyn was one of the claimants for the Scottish throne, but he urged the claim of his brother-in-law, John Baliol. After supporting Baliol in his rising against Edward I., Comyn submitted to Edward in 1296.

JOHN COMYN (d. 1306), called the "red Comyn," was a grandson of the justiciar. Like Badenoch, his father, he assisted Baliol against Edward I., and was for some time a hostage in England. Having been made guardian of Scotland after the battle of Falkirk (1298) he led the resistance to the English king for about five years, and then early in 1304 surrendered. He is remembered for his quarrel with Robert the Bruce. The pair met at Dumfries in Jan. 1306; during a heated altercation charges of treachery were made, and Comyn was stabbed to death either by Bruce or by his followers.

Another member of the Comyn family active in Scottish affairs during these troubled times is JOHN COMYN, earl of Buchan (d. *c.* 1313). This earl, a son of Earl Alexander, was constable of Scotland, and was first an ally and then an enemy of Robert the Bruce.

CONACRE, in Ireland, a system of letting land, mostly in small patches, and usually for the growth of potatoes as a kind of return instead of wages. It is now practically obsolete.

CONANT, JAMES BRYANT (1893–), American educator, was born in Boston, Mass. March 26, 1893. He received both his A.B. and Ph.D (1916) degrees from Harvard University, and, after spending a year in the research division of the Chemical Warfare Service, returned to Harvard University as an instructor in chemistry. He was advanced in rank until he became professor of organic chemistry in 1929 and chairman of the department in 1931. On May 8, 1933 he was elected president of Harvard University to succeed A. Lawrence Lowell. He was recognized as one of the more brilliant of the younger organic chemists of the country by the award to him in 1932 of the Chandler Medal. Later in the same year he received the Nichols Medal of the American Chemical Society, in recognition of his researches into the chemical structure of chlorophyll. His research has also included work in reduction and oxidation processes, free radicals, and the quantitative study of organic reactions. His publications include papers in scientific journals, and textbooks.

CONATION, a psychological term, originally chosen by Sir William Hamilton (*Lectures on Metaphysics,* pp. 127 foll.), used generally of an attitude of mind involving a tendency to take *action* (Lat. *conari,* attempt), *e.g.,* when one decides to remove an object which is causing a painful sensation, or to try to interrupt an unpleasant train of thought. This use of the word tends to lay emphasis on the mind as self-determined in relation to external objects. Another less common use of the word is to describe the pleasant or painful sensations which accompany muscular activity; the *conative* phenomena, thus regarded, are psychic changes brought about by external causes. More usually the term conation is employed now as synonymous with willing, and denotes one of the ultimate kinds of mental process. It includes all that is known as impulse, desire and act of volition.

The chief difficulty in connection with conation is that of distinguishing it from "feeling," a term of very vague significance both in technical and in common usage. Thus the German psychologist F. Brentano holds that no real distinction can be made. He argues that the mental process from sorrow or dissatisfaction, through hope for a change and courage to act, up to the voluntary determination which issues in action, is a single homogeneous whole (*Psychologie,* pp. 308–309). The mere fact, however, that the series is continuous is no ground for not distinguishing its parts; if it were so, it would be impossible to distinguish by separate names the various colours in the solar spectrum, or indeed perception from conception. A more material objection, moreover, is that, in point of fact, the feeling of pleasure or pain roused by a given stimulus is specifically different from, and indeed may not be followed by, the determination to modify or remove it. Pleasure and pain, *i.e.,* hedonic experiences *per se,* are essentially distinct from appetition and aversion; the pleasures of hearing music or enjoying sunshine are not in general accompanied by any volitional activity. It is true that painful sensations are generally accompanied by definite aversion or a tendency to take action, but the cases of positive pleasure are amply sufficient to support a distinction. Therefore, though in ordinary language such phrases as "feeling aversion" are quite legitimate, accurate psychology compels us to confine "feeling" to states of consciousness in which no conative activity is present, *i.e.,* to psychic phenomena of pleasure or pain considered by themselves.

CON BRIO (It.), "with fire" (lit. "noise"), a familiar direction in musical scores, *e.g., Allegro con brio.*

CONCA, SEBASTIANO (1679–1764), Italian painter of the Florentine school, was born at Gaeta, and studied at Naples under Francesco Solimena. In 1706, along with his brother Giovanni, who acted as his assistant, he settled at Rome, where for several years he worked in chalk only, to improve his drawing. He was patronized by the Cardinal Ottoboni, who introduced him to Clement XI.; and a "Jeremiah" painted in the church of St. John Lateran was rewarded by the pope with knighthood and by the cardinal with a diamond cross. Of his many pictures the "Probatica," or "Pool of Siloam," in the hospital of Santa Maria della Scala, at Siena, is considered the finest.

CONCARNEAU, a fishing port of western France in the south of the department of Finistère, 14 mi. S.E. of Quimper. Pop. (1936), 5,878. The town is picturesquely placed on the Baie de la Forêt. The old portion stands on an island, and is surrounded by ramparts, parts of which are believed to date from the 14th century, while a fashionable little watering-place is growing up on the adjacent Sables-Blancs. Sardine-tinning is carried on. Of recent years the lace industry has revived among the women.

CONCENTRATION CAMPS are camps in which the civilian population of a conquered country or territory in a state of rebellion are gathered to end guerilla warfare waged by civilians wearing civilian clothes and therefore indistinguishable from the peaceful citizens. They were used by the Spaniards in Cuba and the British in South Africa. The Nazi regime used them in peace and war. In peace time recalcitrant citizens are put in such camps. (*See* SOUTH AFRICAN WAR, 1899–1902.)

CONCEPCIÓN, a province in the southernmost part of central Chile, lying between the province of Ñuble on the north and east, and Bío-Bío and Cautín on the south. Bounded by the Pacific on the west, Concepción is one of the few provinces of Chile whose eastern border is not adjacent to Argentina. Area 2,201 sq.mi.; population (1940 census) 308,241, one of the three most densely inhabited provinces of Chile. Concepción is the most important province in south central Chile because of its advantageous commercial position, fertility, mining and industries. The climate is mild and the rainfall abundant. The coast is indented by the large and sheltered bay of Concepción and the northern part of the gulf of Arauco. Talcahuano, on Concepción bay, is 8 mi. N. of the provincial capital (Concepción) and is its port. Other ports and industrial towns on the bay are Penco and Tomé. The province produces large quantities of grain, vegetables, wine, livestock and timber. Near the coast are extensive deposits of coal, which is shipped principally from Lota and Coronel on the gulf of Arauco. The coal mines at these places are the largest in the country, and the most productive in South America. The State central railway from Santiago to Puerto Montt crosses the eastern part of the province, and branch lines serve the important towns and industrial centres along the coast.

CONCEPCIÓN, a city of south central Chile, capital of a province and department of same name, on the right bank of the Bío-Bío river, 7 mi. above its mouth, and 355 mi. S.S.W. of Santiago by rail. Pop. (1940) 85,938. It is the commercial centre of a rich agricultural region, its trade passing in great part through the port of Talcahuano, 8m. distant by rail. The small port of Penco, situated on the same bay and 10m. distant by rail, also receives a part of the trade. Concepción is one of the southern termini of the Chilean central railway, by which it is connected with Santiago to the north, with Valdivia and Puerto Montt to the south, and with the port of Talcahuano. Another line extends southward through the Chilean coal-producing districts to Curanilhue, and a short line of 10m. runs northward to Penco. The districts tributary to Concepción produce wheat, wine, wool, cattle, coal and timber, and among the industrial establishments of the city are flour mills, furniture and carriage factories, distilleries and breweries. The city is built on a level plain but little above sea-level, and is laid out in regular squares with broad streets. It is an episcopal see with a cathedral and several fine churches, and is the seat of a university. The city was founded by Pedro de Valdivia in 1550. It was situated on the bay of Talcahuano where the town of Penco now stands but was destroyed by earthquakes in 1570, 1730 and 1751, and was then (1755) removed to the margin of the Bío-Bío. In 1835 it was laid in ruins, a graphic description of which is given by Charles Darwin in *The Voyage of H.M.S. Beagle,* and severe damage was suffered in the earthquake of 1939. The city was twice burned by the Araucanians during their long struggle against the Spanish colonists.

CONCEPCIÓN or **VILLA CONCEPCIÓN,** the principal town and a river port of northern Paraguay, on the Paraguay river, 138 mi. (234 mi. by river) N. of Asunción, and about 345 ft. above sea-level. Pop. (1940) 14,793, largely Indians and mestizos. It is a distributing centre for the towns on both sides of the Paraguay-Brazil border and is a port of call for the river steamers trading with the Brazilian town of Corumbá, Mato Grosso. The principal products of the sparsely inhabited country which surrounds Concepción are Paraguay tea, or "yerba maté," cattle and quebracho.

CONCEPT AND CONCEPTION, in philosophy, a term applied to a general idea derived from and considered apart from the particulars observed by the senses. The mental process by which this idea is obtained is called abstraction (*q.v.*). By the comparison, for instance, of a number of boats, the mind abstracts a certain common quality or qualities in virtue of which the mind forms the general idea of "boat." Thus the connotation of the term "boat," being the sum of essential qualities in respect of which all boats are regarded as alike, whatever their individual peculiarities may be, is described as a "concept." The mental process by which a concept is affirmed is called "conception," a term which is often loosely used in a concrete sense for "concept" itself. It is also used even more loosely as synonymous in the widest sense with "idea," "notion." Strictly, however, it is contrasted with "perception," and implies the mental reconstruction and combination of sense-given data. Thus when one carries one's thoughts back to a series of events, one constructs mentally a whole made up of parts which take definite shape and character by their mutual inter-relations. This process is called *conceptual synthesis,* the possibility of which is a *sine qua non* for the exchange of information by speech and writing. It should be noticed that this (very common) psychological interpretation of "conception" differs from the metaphysical or general philosophical definition given above, in so far as it includes mental presentations in which the universal is not specifically distinguished from the particulars. Some psychologists prefer to restrict the term to the narrower use which excludes all mental states in which particulars are cognized, even though the universal be present also.

In biology conception is the coalescence of the male and female generative elements, producing pregnancy.

CONCEPTUALISM (from "Concept"), in philosophy, a term applied by modern writers to a scholastic theory of the nature of universals, to distinguish it from the two extremes of nominalism and realism. The scholastic philosophers took up the old Greek problem as to the nature of true reality, whether the general idea or the particular object is more truly real. Between realism which asserts that the *genus* is more real than the *species,* and that particulars have no reality, and nominalism according to which *genus* and *species* are merely names (*nomina, flatus vocis*), conceptualism takes a mean position. The conceptualist holds that universals have a real existence, but only in the mind, as the concepts which unite the individual things; *e.g.,* there is in the mind a general notion or idea of boats, by reference to which the mind can decide whether a given object is, or is not, a boat. On the one hand "boat" is something more than a mere sound with a purely arbitrary conventional significance; on the other it has, apart from particular things to which it applies, no reality; its reality is purely abstract or conceptual. This was enunciated by Abélard in opposition to Roscellinus (nominalist) and William of Champeaux (realist). Abélard held that it is only by becoming a predicate that the class-notion or general term acquires reality. Thus similarity (*conformitas*) is observed to exist between a number of objects in respect of a particular quality or qualities. This quality becomes real as a mental concept when it is predicated of all the objects possessing it ("quod de pluribus natum est praedicari"). Hence Abelard's theory is alternatively known as sermonism (*sermo,* "predicate"). His statement of this position oscillates markedly, inclining sometimes towards the nominalist, sometimes towards the realist statement, using the arguments of the one against the other. Hence he is described by some as a realist, by others as a nominalist. When he comes to explain that objective similarity in things which is represented by the class-concept or general term, he adopts the theological Platonic view that the ideas which are the archetypes of the qualities exist in the mind of God. They are, therefore, *ante rem, in re* and *post rem,* or, as Avicenna stated it, *universalia ante multiplicitatem, in multiplicitate, post multiplicitatem* (universals exist before, in, and after the multiplicity of their particulars). The whole controversy suffers from a tendency to confuse "idea" in the sense of a concept or notion in the mind with "idea" in the Platonic sense of an ultimate archetype of phenomenal objects. (A. Wo.)

CONCERT, a term meaning, in general, co-operation, agreement or union; the more specific usages being in music and in diplomacy. The term "Concert of Europe" has been commonly applied, since the Congress of Vienna (1814–15), to the six great European Powers consulting or acting together in questions of common interest. This ceased to exist on the formation, before the World War, of the Triple Alliance and the Triple Entente.

A complete history of concerts, in the sense of musical entertainments, has yet to be written, but it appears that some of the earliest entertainments of this kind were given in England. This was as long ago as 1672 when on Dec. 30, John Banister, a well-known violinist of the day and leader of the King's Band, who was also a composer, announced the first of them as follows in the *London Gazette:*

"These are to give notice that at Mr. John Banister's house, now called the Musick School, over against the George Tavern, in White Friars, this present Monday, will be musick performed by excellent masters, beginning precisely at four of the clock in the afternoon, and every afternoon for the future, precisely at the same hour."

The charge of admission to these "musick" makings was one shilling and from the fact that they were continued by Banister till the year of his death (1679) they were evidently successful.

Another and better known pioneer in the same field was Thomas Britton (1643–1714) who lives in history as the "Musical Small-Coal Man." (He was an itinerant vendor of "small-coal" who was at the same time a man of wide general knowledge and intelligence and an enthusiastic music-lover.) His concerts given weekly in a room over his shop in Clerkenwell, were established in 1678 and enjoyed great popularity. The most eminent performers, including even Handel, appeared at them and they were attended by all the best people of the day, who paid the modest subscription of ten shillings a year for the privilege.

The first of London's regular concert rooms was formerly supposed to have been that known as "Hickford's," situated in the first instance in Panton street, Haymarket, but recent researches have shown that there were two earlier rooms. Of these the first and most important was one situated in Villiers street, Strand, known usually as the York Buildings Room, where concerts were being given at least as early as 1685, and the other, a smaller room in Covent Garden, known as "La Vendu," where concerts were also being regularly given about the same time.

It was not until some years later that Hickford's was opened, the first mention of it which is to be found in the newspapers of the period being contained in an advertisement in the *Post Boy* for 1697. But once established, Hickford's speedily eclipsed in popularity and importance both of its predecessors and remained for some three-quarters of a century the centre of London's musical life.

In 1739 Hickford shifted his quarters to Brewer street, Golden Square, where the "*new* Great Room" which he referred to in his advertisements remained in excellent preservation until 1934 when, with deplorable disregard of its unique interest and historical associations—Mozart had actually appeared here as a prodigy of eight—it was pulled down to make room for a neighbouring hotel.

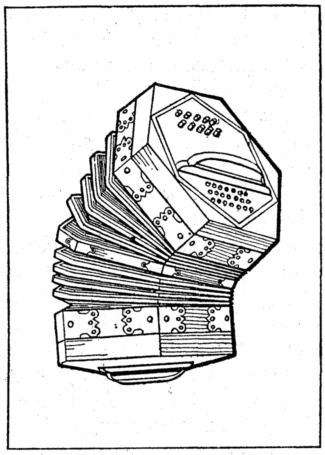
Hickford's Room, where concerts continued to be given till 1779, was succeeded as London's chief musical resort by the Hanover Square Rooms, where from 1774 onwards for the best part of a century many of the more important concerts took place. Much frequented also during this period were the Argyll Rooms (from about 1800 to 1830), while later (1858) came St. James's hall which, in turn, was for many years the centre of London's musical life.

Here were given the famous Monday and Saturday Popular concerts, the Richter concerts, those of the Philharmonic Society, and others, important and unimportant, in ever-increasing numbers as year by year the concert-giving industry steadily developed. Yet St. James's hall was never a satisfactory undertaking financially and it was pulled down in 1905 to make way for the Piccadilly hotel which occupies its site today.

In the meantime the somewhat larger Queen's hall had already been erected in Langham place, and this constitutes London's most important concert room to-day, though not the largest, this distinction belonging to the Royal Albert hall with its accommodation for 10,000 hearers.

On the Continent and in America concert-giving has followed much the same course as that sketched above, developing everywhere from the smallest beginnings into a veritable industry of prodigious dimensions. In Germany and Austria, under the patronage system, private performances in the residences of the sovereigns and great nobles at first checked the development of ordinary public concerts but by the beginning of the 18th century these were coming to be known, and by Beethoven's time they were well established; the like applying in the case of Paris, where the famous "Concerts spirituels" were founded by Philidor in 1725. (H. A. Sc.)

CONCERTINA, a wind instrument of the seraphine family with free reeds, forming a link in the evolution of the harmonium from the mouth organ, intermediate links being the cheng and the accordion. The concertina consists of two hexagonal or rectangular keyboards connected by a long expansible bellows of many folds similar to that of the accordion. The keyboards are furnished with rows of knobs, which, on being pressed down by the fingers, open valves admitting the air compressed by the bellows to the free reeds, which are thus set in vibration. The English concertina, or melodion, invented by Sir Charles Wheatstone in 1829, the year of the reputed invention of the accordion (*q.v.*), is constructed with a double action, the same note being produced on compressing and expanding the bellows, whereas in the German concertina or accordion two different notes are given out. Concertinas are made in complete families—treble, tenor, bass, and double bass, having a combined total range of nearly seven octaves.



THE CONCERTINA, A LINK BETWEEN THE MOUTH ORGAN AND THE HARMONIUM. THE SOUND IS PRODUCED BY THE PRESSURE OF AIR FROM THE BELLOWS ON FREE METALLIC REEDS

The timbre of the concertina is penetrating but soft, and the instrument is capable of the most delicate gradations of tone. It is possible to play on it diatonic and chromatic passages, or arpeggios in legato or staccato style, with rapidity, shakes single and double in thirds, and also to play in parts as on the pianoforte or organ, and to produce very rich chords. Concertos were written for concertina with orchestra by Molique and Regondi, a sonata with piano by Molique, while Chaikovski scored in his second orchestral suite for four accordions.

The aeola, constructed by the representatives of the original firm of Wheatstone, is a still more artistically developed concertina.

See also ACCORDION; CHENG; HARMONIUM; FREE-REED VIBRATOR.

CONCERTO, in music, a term which appears as early as the beginning of the 17th century, at first with vague meanings, but soon acquiring a sense justified by its etymology (Lat. *concertus*, from *certare*, to strive; also confused with *concentus*), being applied chiefly to compositions in which unequal instrumental or vocal forces are brought into opposition.

Although by Bach's time the concerto as a purely instrumental form was thoroughly established, the term frequently appears in the autograph title-pages of his church cantatas, even when the cantata contains no instrumental prelude. Indeed, so entirely does the actual concerto form, as Bach understands it, depend upon the opposition of masses of tone unequal in volume, with a compensating inequality in power of commanding attention, that Bach is able to rewrite an instrumental movement as a chorus without the least incongruity of style. The very title of his secular cantata, *Vereinigte Zwietracht der wechselnden Saiten* ("united contest of turn-about strings"), is a perfect definition of the earlier form of *concerto grosso,* in which the chief mass of the orchestra was opposed, not to a mere solo instrument, but to a small group called the *concertino;* unless, indeed, the whole work was for a large orchestral mass in which tutti passages alternate with passages in which the whole orchestra is dispersed in every possible kind of grouping.

But the special significance of this cantata is that its first chorus is arranged from the second movement of the first Brandenburg concerto and that, while the orchestral material is merely transposed and arranged for larger forces, the whole four part chorus has been evolved from the solo part for a kit-violin (*violino piccolo*). This shows that the true relation between the opposed factors in a concerto depends not on volume of sound, but on power to command attention.

A conveniently isolated individual will command more attention than the crowd, whether in real life, drama, or instrumental music. But in music the human voice, with human words, will thrust any orchestral force into the background, whether the voice be individual or choral. The full chorus is the equivalent of the kit-violin and the kit-violin is the equivalent of the full chorus because both assert personality against the orchestra.

Hence the polyphonic concerto is fundamentally identical with the vocal aria, as matured by Alessandro Scarlatti. The orchestra is entrusted with a short pregnant summary or ritornello of the main contents of the movement, and the solo, or the groups corresponding thereto, will either take up this material or first introduce new themes to be combined with it, and, in short, enter into relations with the orchestra very like those between the actor and the chorus in Greek drama. The polyphonic concerto, the vocal aria, and the forms of many of Bach's choruses, even including some that contain fugues, ought to be classed under the head of ritornello forms. (*See* ARIA.) Many of Bach's larger movements for solo instruments without orchestra will at once reveal the proper lines of their interpretation in the light of ritornello form. The harpsichord, no less than the organ, can obviously imitate contrasts between solos and tuttis with excellent effect.

In slow movements of concertos Bach uses the *ground bass* (*see* VARIATIONS), diversified by changes of key (klavier concerto in D minor), the more melodic types of binary form, sometimes with the repeats ornamentally varied or inverted (concerto for 3 klaviers in D minor, concerto for klavier, flute, and violin in A minor), are found besides aria-form on the aria scale. In finales the *rondo* form (violin concerto in E major, klavier concerto in F minor) and the binary form (3rd Brandenburg concerto) may be found.

When musical forms changed to those of the dramatic sonata style the problems of the concerto proved ridiculously easy to ordinary musicians and the tasks of the highest interest to the greatest composers. Bach's sons took important new steps. Philipp Emanuel Bach developed a romantic rhetoric. Johann Christian, the "London" Bach, initiated the all-important method of emphasizing a change of key so that it became a dramatic event irreversible except by other dramatic developments. Mozart, as a boy, modelled himself closely on Johann Christian Bach, and by the time he was 20 was able to write concerto ritornellos that gave the orchestra admirable opportunity for asserting itself by the statement, in charmingly epigrammatic style, of some five or six sharply contrasted themes, afterwards to be worked out with additions by the solo, with the orchestra's co-operation and intervention.

The problem changes rapidly as the scale of the composition grows. On a large scale a too-facile alternation between solo and tutti produces forms too sectional for the high organization required in first movements; yet frequent alternation is evidently necessary, as the solo is audible only above a very subdued orchestral accompaniment, and it would be inartistic to confine the orchestra to that function. Hence in the classical concerto the ritornello is never abandoned, in spite of the enormous dimensions to which the sonata style expanded it. Mendelssohn and most later composers evidently see in it only a conventional impediment easily abandoned. Yet its absence reduces the whole style to a more theatrical and lighter art-form. Hence it is restored to its place not only by Brahms in his four magnificent examples, but by Joachim in his Hungarian concerto and by Elgar in his violin concerto. The danger in so long an orchestral prelude is that the work may for some minutes be indistinguishable from a symphony and thus the entry of the solo may be unexpected without being inevitable. This will happen if the composer treats his tutti so like the exposition of a sonata movement as to make a deliberate transition from his first group of themes to a second group in a complementary key, even if the transition be only temporary—as in Beethoven's C minor concerto. But Beethoven's C minor concerto is the one which Spohr and Hummel and even Joachim took as their model, and thus the true solution of the problem remained for Brahms to rediscover.

Mozart keeps his whole tutti in the tonic, relieved only by his mastery of sudden subsidiary modulation. Beethoven, in turn, after the C minor concerto, grasped the true function of the opening tutti and enlarged it to his new purposes. With an interesting experiment of Mozart's before him, he, in his G major concerto, Op. 58, allowed the solo player to state the opening theme, making the orchestra enter *pianissimo* in a foreign key. In this concerto he also gave variety of key to the opening tutti by means of an important theme which modulates widely, an entirely different thing from a deliberate modulation from material in one key to material in another. His fifth and last pianoforte concerto in E flat begins with a rhapsodical introduction for the solo player, followed by a long tutti confined to the tonic major and minor with a strictness explained by the gorgeous modulations with which the solo subsequently treats the second subject. In this concerto Beethoven also organizes the only undigested convention of the form, namely, the *cadenza,* a custom elaborated from the operatic aria, in which the singer was allowed to extemporize a flourish on a pause near the end. A similar pause was made in the final ritornello of a concerto, and the soloist was supposed to extemporize what should be equivalent to a symphonic coda. Cadenzas are, to this day, a form of musical appendicitis, since the player (or cadenza-writer) cannot be the composer himself and is rarely so capable of entering into his intentions as Joachim, whose written cadenzas for classical violin concertos are unsurpassable.

Brahms's first concerto in D minor, Op. 15, was the outcome of many changes and, though on a mass of material originally intended for a symphony, was nevertheless so perfectly assimilated into concerto form that in his next essay, the violin concerto, Op. 77, he had no more to learn and was free to continue making true innovations. He found out how to include wide key contrasts in the opening tutti, thus giving the form a wider range in definitely functional key than any other instrumental music. Further, it may be noted that in this work Brahms develops a counterplot in the opposition between solo and orchestra; giving not only the development by the solo of material stated by the orchestra, but also a counter-development by the orchestra of material stated by the solo. This concerto is, on the other hand, remarkable as being the last in which a blank space is left for a cadenza; a testimony of confidence in Joachim. In the pianoforte concerto in B flat, and in the double concerto, Op. 102, the idea of an introductory statement in which the solo takes part before the opening tutti is carried out on a large scale, and in the double concerto both first and second subjects are thus suggested.

The forms of slow movements and finales in classical concertos, though often treated in special ways, present no general principles peculiar to the concerto; for a sectional opposition between solo and tutti is not of great disadvantage to slow movements and finales. The scherzo, on the other hand, is normally too sectional for successful adaptation to classical concerto style, and the solitary great example of its use is the second movement of Brahms' B flat pianoforte concerto, a movement in a very special form.

The post-classical concertos, in which the first movement dispenses with the opening tutti, began with Mendelssohn, whose violin concerto dominates the whole subsequent history of the form. The happy idea of putting a cadenza at the dramatic crisis of the return after development instead of in the coda has almost become a convention. The other movements of concertos have not been affected by Mendelssohn's changes, nor does the linking of all three movements uninterruptedly together make any essential difference to the scheme. But there is no limit to the expansion or reduction of the first movement. Spohr reduces it to an accompanied recitative in his *Gesangs-scene,* a work in which he discovered that a concerto could be an aria, which astonished him as the swimming of ducklings astonishes the fostering hen. Bruch's famous G minor concerto (not his only interesting experiment in new concerto-forms) also reduced the first movement to dramatic gestures without dramatic action. On the other hand, the huge first movement of Schumann's pianoforte concerto was originally intended to stand alone under the title of Fantasia. This example would cover the case of most first movements of this size in modern concertos, whether like Schumann's they have "second subjects" and recapitulations or not.

The case where the concerto as a whole is a fantasia (as with Liszt) needs no discussion. Another line has been struck out by Saint-Saëns, most neatly in his first violoncello concerto; namely, that the whole work is one movement, but that after an exposition comprising a "first" and "second" subject the development drifts into a slow movement (or scherzo), and this is followed by a finale of which the matter is partly independent and partly a recapitulation completing the first movement. In his C minor pianoforte concerto Saint-Saëns begins with a theme with variations and proceeds with a slow second theme, followed by a scherzo and finale which transform their own and the previous materials in various effective ways. But really the term Fantasia would adequately cover all post-classical forms of concerto. The only modern meaning of the word is "composition for one or more solo players with orchestra"; and no special aesthetic or formal questions remain to be considered within the limits of this article.

(D. F. T.)

CONCERT PROGRAMMES have been subject to many changes during recent times, not least in the matter of their length. More and more it has come to be recognized that, in the case at all events of serious music, the amount which can be properly assimilated and enjoyed at one sitting is strictly limited, and modern concert-goers read with amazement of the Gargantuan musical feasts which their robuster predecessors were apparently able to digest. Thus of a concert given by Beethoven in 1807 one reads that the programme consisted of no fewer than four of his symphonies (the first four); while that of another concert which he gave in the following year was even more astonishing, including the C minor and Pastoral symphonies, the Choral Fantasia, the G major piano concerto, two extracts from the Eisenstadt Mass, a vocal item ("Ah! perfido") and an improvisation on the piano. Modern concert programmes are not only more reasonable in length but also, in the best instances, far more thoughtfully and artistically arranged.

In this connection reference may be made to the analytical programme or concert programme with explanatory notes and comments. This is usually regarded as a recent invention, but it goes back considerably farther than is generally supposed. As early as 1783, according to Grove, something of the kind was tried in Berlin, while in Great Britain Thomson, the first Reid Professor of Music at Edinburgh university, in 1841 incorporated historical and analytical notes on the pieces to be performed in the programmes of the concerts of the Professional Society of Edinburgh. Later Ella, in connection with the concerts of the Musical Union, which began in 1845; Wylde in the programme books of the New Philharmonic Society, whose first concert was given in 1852; John Hullah, and others, adopted the same procedure, which has since become practically the rule in England and America in the case of concerts of a suitable type. Elsewhere the analytical programme has never established itself to anything like the same extent as in England and America.

CONCESSIONS. The term concession covers a wide range in time, space and variety of forms and uses. Many of the types of grant, franchise, contract, charter and license embraced within its meaning have been known for centuries in widely separated parts of the globe. It is, however, only since about 1900 that the word has come to have an interest for the general reader. In the discussions preceding, during and subsequent to the World War, the subject of concessions came to more general public notice. They were revealed as the legal means, the forms of contract and agreement, under which the industrial development of large parts of the world, especially those parts known as backward countries, has recently been accelerated. Hostile critics have described them as instruments for "economic penetration," devices for control of markets and raw materials, disguises for aggression, means for undermining the sovereignty of weak States, and even—instancing the Baghdad railway concession—as the ultimate cause of the World War. So grandiose and sinister a conception serves only to illustrate the Protean and fascinating character of concessions.

Origin and History.—Though concessions have a long history, their origin is obscure. A concession meant at first a grant from prince or king; the older form of grant usually reading, in royal phrase, "concessimus" or "damus et concedimus." They may be said to have existed in one form or another from time immemorial; but they seem to have appeared first in Europe during the middle ages and since that time their history can be traced in nearly all parts of the civilized world. That history breaks into three divisions: The first or feudal period was confined largely to grants of land and runs from the early middle ages apparently down to the time of the discovery of America. In this period those concessions were granted upon which the great landed estates of western Europe and of England were founded. Some authorities maintain that the greater part of the landed estates in France under the *ancien régime* were based upon concessions from the Crown, and the English law writer Coke, referring in the year 1660 to the great English estates, remarked, "and so . . . their estates, which were nothing but concessions from the Crown." The second period is that of the early chartered companies such as the East India company, the London company, the Massachusetts company, the Hudson Bay company, and of various individual adventurers who received grants of land and a greater or less measure of sovereign power over the territories they were to develop and their inhabitants. The third period in the history of concessions runs parallel with the modern industrial era. In this period concessions have taken increasingly the form of franchises with which during most of the period they have gone step by step and side by side on a similar course. Both alike have undergone an evolution, proceeding from an agreement, permission, license, or title, more or less secret, in which favour, privilege, grant, grace or gift was the predominant element, to a form of contract in which the chief element is bargain, exchange and open competition, and from which the elements of privilege, favour and secrecy have practically disappeared.

Nature of Concessions.—Concessions partake of the character of franchises, permits, charters, licenses and contracts, and vary with the industries and conditions which call them into being. In Latin American countries concession covers a very wide latitude. A writer summing up the situation says, "a contract to lay sewers, to lay a pipe line, to sell mules, to build a factory, or a hospital, or a school, to buy timber tracts on the public domain, to explore a given section for mineral or water, to supply beef or coal or oil to any public institution, is called a concession."

During a period of more than three years' duration the bulletin of the Pan American union recorded an average of 300 concessions per year and the list was not exhaustive. Some of these concessions are mere permits—police or administrative formalities; such are water permits. Some have a traditional quality as if they were survivals or inheritances from an early period; such are certain land grants for colonization. Some are licenses existing for the preservation of governmental authority over certain spheres of business; such are banking concessions. Some are arrangements for economy; such are concessions of a portion of a tract of land in return for the surveying of the whole tract. Some are reciprocal contracts for the development of resources, for improvement of communications and for increased control of territory; such are concessions for building railroads. Some are business contracts in which the Government offers inducements to capital, usually foreign, for the development of industries or natural resources; such are the oil concessions. It is this last type of concessions which most of those who have written or spoken upon the subject have in mind; it is concessions of this type which constitute concessions *par excellence.* Such concessions are issued under general provisions of laws and are in a broad sense open on similar terms to all applicants. It is in this type that we find the predominant motive for concessions both in Latin America and elsewhere. That motive on the part of the grantor is the desire on the part of undeveloped or partially developed countries to bring in outside capital and industrial skill for the establishment or extension of industries and for the exploitation of natural resources. On the part of the concessionaire the motive is twofold—to secure favourable conditions for the adventure of capital, and to secure protection from injury by new or unfair impositions after the capital has been adventured and a prospect appears of a return. The chief specific benefit sought through concessions is exemption from taxation—first from local or import taxes, secondly from export taxes. Such exemptions are not unusual in the United States: municipalities seeking the establishment of new industries, or the erection of new plants within their limits, frequently offer exemption from local taxation for a given period; export taxes, on the other hand, are expressly prohibited under the Constitution, which states that "no tax or duty shall be laid on articles exported from any State."

The geographical range of concessions is as wide as its range in time. Not only are they numerous in Latin America but also in Europe, Africa and Asia. They are frequent in France, Spain, Italy, Bulgaria, Turkey, Russia, Persia, the Dutch East Indies, the Philippine islands and China. They occur in British colonial possessions and are not unknown in the United States. Numbers of concessions were issued in the former South African republic and on the annexation of that country were the subject of an inquiry instituted under a commission, appointed by the British Government. The report of this commission is among the most authoritative and illuminating sources available to the student of the subject.

Political Concessions.—The various types of concessions already referred to are chiefly if not wholly of the industrial or commercial type. There is another type of concession—the political—which has the essential character of a treaty, both parties being Governments and the documents constituting international agreements. Examples of this type of concession are found as early as 1557 when China granted to Portugal the concession of Macao, which has remained in the control of Portugal ever since. They include the famous Chinese concessions: to Russia for the

Chinese Eastern railway (1896); to Germany for the Shantung railway (1897); to Germany the city, port and environs of Kiauchau (1898); to Great Britain Weihaiwei (1898); to Belgium, part of the port of Tientsin (1902). Of the same general type are the concessions of Guantanamo bay made by Cuba to the United States in 1899, that of Fonseca bay granted by Nicaragua to the United States in 1916, and that for the Baghdad railway granted to Germany by Turkey in 1911.

Similar to these in one respect—that the grantor surrenders certain prerogatives of sovereignty to the concessionaire—is the famous concession granted by the sultan of Borneo to Sir James (Rajah) Brooke in 1842 under which the principality of Sarawak has been governed by the Brooke family ever since. Other concessions of the kind are those made by the sultan of Zanzibar to the British East Africa company and the German East Africa Association and those granted by the sultans of Brunei and Sulu in 1877 to Alfred Dent and Baron de Overbeck. As a rule concessions of this type are conditional upon payment of a nominal annual rent.

To this type of concessions is due a development of some interest—that of "concessions within concessions." These are found in the chartered companies which sprang up about the end of the 19th century, such as the Royal Niger company, the Imperial British East Africa company, the British South Africa company, and the British North Borneo company. Some if not all of these companies were originally based upon concessions made by chiefs or tribes of the various regions described, and they in turn granted concessions for the development of industries and of the natural resources within their boundaries.

Mining Concessions.—Concessions have provided the customary basis for development in the mining industry through many centuries and over the greater part of the world. Since the year 1256, mining has been conducted under concessions in Spain; it has been so conducted in France since feudal times, and in portions of Germany from the earliest records. Concessions have afforded and still afford the customary basis of mining operations not only in those countries, but also in Latin America, in Turkey, and the Balkan States, in the East Indies, in portions of China, and in considerable portions of Africa. Under the law of 1791 in France mining operations can be conducted only by virtue of an act of concession from the State, and the law of France has established legal forms for such concessions—the most recent adopted in 1882—which are models for such regulations in all French colonies and possessions, and have been much used in drawing similar forms and regulations in other portions of the globe.

Oil Concessions.—One of the most ancient, most numerous and most widely distributed types of concession and one that has been prolific of controversy is the concession for oil. A concession for the collection of petroleum, which was then used, it appears, chiefly for medicinal purposes, was granted in the district of Miano de Medisano by the ducal chamber of Parma, Italy, in the year 1400. Since that time petroleum concessions have increased in number and have spread over nearly all of the known world. There are few countries however remote where they have not appeared and their number is beyond computation. The rapid industrial development of the first quarter of the 20th century, however, with its new applications of petroleum for power and fuel, particularly to automotive engines, has given the oil concession a fresh and fateful importance. Statesmen and engineers have declared that oil is the chief factor in progress and that the nation which controls the oil supply will control the future of the world. Great Governments have striven to secure a share in oil fields and oil concessions. The Government of the United States has interposed to prevent concessions in the Caribbean region being granted to transatlantic companies and to secure to her citizens a share in the oil-fields of Mesopotamia. The British Government has meantime become an actual partner in one great oil corporation and has a voice in the management of at least two others. The situation recalls that of the 16th and 17th centuries when bullionism was the prevalent economic doctrine and the possession of the precious metals and the mines thereof was regarded as the chief end of individual and governmental effort.

Though oil concessions are operated in different lands and couched in different languages, they are surprisingly alike in character. If one examines the texts of a hundred or more, ranging from China to Peru, he will find them essentially similar. They are true, bilateral contracts with obligations upon the concessionaire always substantial and often onerous. The concessionaire is usually obliged to make an investment or do a prescribed amount of drilling within a certain time and, in the event of finding oil, to pay a royalty upon each ton or barrel obtained. A typical example is afforded by the Tabasco contract—one of the Pearson concessions of Mexico. The terms required S. Pearson and Son to deposit in advance the sum of $20,000, to invest within seven years the sum of $350,000 and to pay a royalty to 10% of the profits. Though it was at one time denounced by politicians and others as an iniquitous contract, draining the natural wealth of Mexico for the benefit of foreigners, the fact is that after considerable expenditure no production was obtained. The terms of many concessions are less onerous than these, yet as a rule concessions are burdensome to all but very wealthy holders.

The terms of concessions may be illustrated by the royalties required in typical cases in different parts of the world:—Burma, Yomah Oil Co. Ltd., 16c per barrel; Egypt, Anglo-Egyption Oil Co. Ltd., 36c per ton; Germany, the Allgemeine Erdoelgesellschaft, 5% of gross production; Italy, Anglo-Italian Petroleum Co. Ltd., 5% of the net product; Mexico, Sres. Flores and Loaeza, 10% of the net profit; Panama, Lincoln G. Valentine, 5% of gross production; Persia, Anglo-Persian Oil Co. Ltd., 16% of the net profits plus £3,000 per annum; United States, Edwin B. Foster (Osage Indian Lease), 10% of the gross production; Venezuela, General Asphalt Co., 5% of gross production; Caribbean Petroleum Co., 40c per ton, also rent of 8c per acre; West Indies, United British West Indies Petroleum Syndicate, Ltd., 48c per ton.

The payment of royalty is often the least onerous obligation to be met by the holder of an oil concession. More burdensome are the requirements of investment and of performance of drilling, etc., within a given period. For example, the Valentine concession in Panama required an investment of $5,000,000, and the Pearson concessions in Mexico required an investment of $2,975,000. The difficulties of conducting engineering operations in remote and tropical countries such as Colombia, Panama, Persia, China, where natural conditions are adverse and means of transportation are lacking, are very great.

Because of the enormous economic and financial interests involved and because of the ease with which the popular imagination can be inflamed over international competition, oil concessions contain many possibilities of friction. Recent events in Iraq, in Colombia, in Persia, in Venezuela, in Mexico, show what explosive political material they conceal. In the course of time, as the present furore for possession of oil reserves dies down, to be replaced by other prizes of international competition, oil concessions will lose their present prominence. Meanwhile it may be hoped that that competition, which has often been pursued with a zeal worthy of a better cause, may be tempered with moderation and so guided as to prevent it from imperilling the peace of the world.

CONCH. In architecture, the term is sometimes given to the half dome over the semicircular apse of the basilica (*q.v.*). In late Roman and in Renaissance buildings shells are frequently carved in the heads of circular niches. A low class of the negro or other inhabitants of the Bahamas and the Florida Keys are sometimes called "Conches" or "Conks" from the shell-fish which form their staple food.

CONCHOID: *see* CURVES, SPECIAL.

CONCHOLOGY, the study of shells, especially those of the Mollusca (*q.v.*); it formerly included the study of lamp shells, barnacles, and even of certain worm tubes.

CONCIERGE, in modern usage, a hall-porter or janitor, but originally the important guardian of a house or castle; in the middle ages a court official who was the custodian of a royal palace.

In Paris, when the *Palais de la Cité* ceased about 1360 to be a royal residence and became the seat of the courts of justice, the *Conciergerie* was turned into a prison. The word is of unknown origin; the Latinized form was *Concergius* or *Concergerius.*

CONCILIATION IN INDUSTRIAL RELATIONS: *see* INDUSTRIAL RELATIONS.

CONCINI, CONCINO (d. 1617), COUNT DELLA PENNA, MARSHAL D'ANCRE, Italian adventurer, minister of Louis XIII. of France, was a native of Florence. He came to France in the train of Marie de' Medici, and married the queen's lady-in-waiting, Leonora Dori, known as Galigai. In 1610 he had purchased the marquisate of Ancre and the position of first gentleman-in-waiting. Then he obtained successively the governments of Amiens and of Normandy, and in 1614 the bâton of marshal. As first minister of the crown from that date, he abandoned the policy of Henry IV., allowed the treasury to be pillaged, and drew upon himself the hatred of all classes. The nobles were bitterly hostile to him, particularly Condé, with whom he negotiated the treaty of Loudun in 1616, and whom he had arrested, on the advice of Richelieu, in September, 1616. But Louis XIII. was tired of Concini's tutelage. Concini was killed by the guards on April 24, 1617. Leonora was accused of sorcery and sent to the stake in the same year.

See E. Lavisse, *Histoire de France,* vol. vi.

CONCLAVE, strictly a room or set of rooms, locked with a key (from Lat. *conclave,* from *cum,* together, and *clavis,* a key); in this sense the English word is obsolete. Its present loose application to any private or close assembly, especially ecclesiastical, is derived from its technical application to the assembly of cardinals met for the election of the pope, with which this article is concerned, and in which connection it is applied to that system of strict seclusion to which the electors of the pope have been and are submitted, formerly as a matter of necessity, and subsequently as the result of a legislative enactment; hence the word has come to be used of the electoral assembly of the cardinals. The system was instituted by Gregory X in 1274.

Episcopal appointment by election can be traced back to an early date. The method of election at Rome was the same as in other towns; the Roman clergy and people and the neighbouring bishops each took part in it in their several capacities. The people would signify their approbation or disapprobation of the candidates more or less tumultuously, while the clergy were, strictly speaking, the electoral body, met to elect for themselves a new head, and the bishops acted as presidents of the assembly and judges of the election. We can well imagine that in an assembly of such size, in which the candidates were acclaimed rather than elected by counting votes, the various functions were not very distinct, and that persons of importance, whether clerical or lay, were bound to influence the elections, and sometimes decisively. Moreover, this form of election lent itself to cabals; and these frequently gave rise to quarrels, sometimes involving bloodshed and schisms, *i.e.,* the election of antipopes, as they were later called. The remedy for this abuse was found in having recourse, more or less freely, to the support of the civil power. The emperor Honorius, for example, upheld Boniface (418) against his competitor Eulalius, at the same time laying down that cases of contested election should henceforth be decided by a fresh election; but this would have been a dangerous method and was consequently never applied. Theodoric upheld Symmachus (498) against Laurentius because he had been elected first and by a greater majority.

The accepted fact soon became law, that the candidate should not receive the episcopal consecration until he had obtained the confirmation of the emperor. Hence arose long vacancies of the See, indiscreet interference in the elections by the imperial officials, and sometimes cases of simony and venality. This deplorable state of affairs lasted almost without interruption till the middle of the 11th century. When the emperors were at Rome, they presided over the elections; when they were away, the rival factions of the barons struggled for the spiritual power as they did for the temporal. During this period were seen cases of popes imposed by a faction rather than elected, and then, at the mercy of sedition, deposed, poisoned, or thrown into prison, sometimes to be restored by force of arms. After the death of Clement II. the delegates of the Roman clergy actually went to Polden to ask Henry III. to give them a pope, and similar steps were taken after the death of Damascus II., who reigned only 20 days. Fortunately on this occasion Henry III. appointed, just before his death, a man of high character, his cousin Bruno, bishop of Toul, who presented himself in Rome in company with Hildebrand. From this time began the reform. Hildebrand had the election of Victor II. (1055), Stephen IX. (1057), and Nicholas II. (1058) carried out according to the canonical form, including the imperial ratification. The celebrated bull *In nomine Domini* of April 13, 1059 determined the electoral procedure. Out of respect for tradition, it preserved all the former factors in the election though their scope was modified. The election was reserved to the members of the higher clergy, to the cardinals, among whom the cardinal bishops have the preponderating position. The consent of the rest of the clergy and the people was now only a formality. The same was the case of the imperial intervention; the emperor had no rights save those he had received as a concession from the Holy See. Further, by this bull, the emperors would have to deal with the *fait accompli;* for it provided that, in the event of disturbances aroused by mischievous persons at Rome preventing the election from being carried out there freely and without bias, the cardinal bishops, together with a small number of the clergy and of the laity, should be empowered to hold the election where they should think fit; that should difficulties of any sort prevent the enthronement of the new pope, the pope elect would be empowered immediately to act as if he were actually pope. This legislation was definitely accepted by the emperor by the concordate of Worms (1119). Two other points of great importance were established by Alexander III. at the Lateran Council of 1179. The constitution *Licet de vitanda discordia* makes all the cardinals equally electors, and no longer mentions the lower clergy or the people; it also requires a majority of two-thirds of the votes to decide an election. This latter provision, which still holds good, made imperial antipopes henceforth impossible.

Abuses nevertheless arose. An electoral college too small in numbers, which no higher power has the right of forcing to haste, can prolong disagreements and draw out the course of the election for a long time. It is this period during which we actually find the Holy See left vacant most frequently for long spaces of time. Thus, after the death of Clement IV. in 1268, the cardinals, of whom 17 were gathered together at Viterbo, allowed two years to pass without coming to an agreement; the magistrates of Viterbo had recourse to the method of seclusion: they shut up the electors in the episcopal palace, blocking up all outlets; and since the election still delayed, the people removed the roof of the palace and allowed nothing but bread and water to be sent in. Under the pressure of famine and of this strict confinement, the cardinals finally agreed, on Sept. 1, 1271, to elect Gregory X., after an interregnum of two years, nine months and two days.

Taught by experience, the new pope considered what steps could be taken to prevent the recurrence of such abuses; in 1274, at the council of Lyons, he promulgated the constitution *Ubi periculum,* the substance of which was as follows: At the death of the pope, the cardinals who were present are to await their absent colleagues for ten days; they are then to meet in one of the papal palaces in a closed conclave; none of them is to have to wait on him more than one servant, or two at most if he were ill; in the conclave they are to lead a life in common, not even having separate cells; they are to have no communication with the outer world, under pain of excommunication for any who should attempt to communicate with them; food is to be supplied to the cardinals through a window which would be under watch. Finally, the election is to be the sole business of the conclave, and the magistrates of the town where it was held are called upon to see that these provisions be observed. Adrian V. and John XX. were weak enough to suspend the constitution *Ubi periculum,* and the abuses at once reappeared. This further proof was therefore decisive, and Celestine V., who was elected after a vacancy of more than two years, took care, before abdicating the pontificate, to revive the constitution of Gregory X., which was inserted in the Decretals (lib. i. tit. vi., *de election. cap.* 3).

Electoral Reform.—Pius IV. undertook the task of reforming and completing the legislation of the conclave. The bull *In eligendis* (of Oct. 1, 1562), signed by all the cardinals, is a model of precision and wisdom. In addition to the points already stated, we may add the following: that every day there was to be a scrutiny, *i.e.,* a solemn voting by specially prepared voting papers (concealing the name of the voter, and to be opened only in case of an election being made at that scrutiny), and that this was to be followed by the "accessit," *i.e.,* a second voting, in which the cardinals might transfer their suffrages to those who had obtained the greatest number of votes in the first. Except in case of urgent matters, the election was to form the whole business of the conclave. The cells were to be assigned by lot. The functionaries of the conclave were to be elected by the secret vote of the Sacred College, and the most stringent measures were to be taken to ensure seclusion.

All previous legislation concerning the conclave was codified and renewed by Pius X.'s bull, *Vacante Sede Apostolico* (Dec. 25, 1904), which abrogates the earlier texts, except Leo XIII.'s constitution *Praedecessores Nostri* (May 24, 1882), authorizing occasional derogations in circumstances of difficulty, *e.g.,* the death of a pope away from Rome or an attempt to interfere with the liberty of the Sacred College. The bull of Pius X. is rather a codification than a reform, the principal change being the abolition of the scrutiny of accession and the substitution of a second ordinary scrutiny during the same session.

Until after the Great Schism the conclaves were held in various towns outside of Rome; but since then they have all been held in Rome, with the single exception of the conclave of Venice (1800), and in most cases in the Vatican. There was no place permanently established for the purpose, but removable wooden cells were installed in the various apartments of the palace, grouped around the Sistine chapel, in which the scrutinies took place. The arrangements prepared in the Quirinal in 1823 did duty only three times, and for the most recent conclaves it was necessary to arrange an inner enclosure within the vast but irregular palace of the Vatican. Each cardinal is accompanied by a clerk or secretary, known for this reason as a conclavist, and by one servant only. With the officials of the conclave, this makes about two hundred and fifty persons who enter the conclave and have no further communication with the outer world save by means of turning-boxes. Since 1870 the solemn ceremonies of earlier times have not been seen; for instance the procession which used to celebrate the entry into conclave; or the daily arrival in procession of the clergy and the brotherhoods to enquire at the "rota" (turning-box) of the auditors of the Rota: "Habemusne Pontificem?" and their return accompanied by the chanting of the *"Veni Creator";* or the "Marshal of the Holy Roman Church and perpetual guardian of the conclave" visiting the churches in state. But a crowd still collects morning and evening in the great square of St Peter's, towards the time of the completion of the vote, to look for the smoke which rises from the burning of the voting-papers after each session; when the election has not been effected, a little straw is burnt with the papers, and the column of smoke then apprises the spectators that they have still no pope. Within the conclave, the cardinals, alone in the common hall, usually the Sistine chapel, proceed morning and evening to their double vote, the direct vote and the "accessit." Sometimes these sessions have been very numerous; for example, in 1740, Benedict XIV. was only elected after 255 scrutinies; on other occasions, however, and notably in the case of the last few popes, a well-defined majority has soon been evident, and there have been but few scrutinies. Each vote is immediately counted by three scrutators, appointed in rotation, the most minute precautions being taken to ensure that the voting shall be secret and sincere. When one cardinal has at last obtained two-thirds of the votes, the dean of the cardinals formally asks him whether he accepts his election, and what name he wishes to assume. As soon as he has accepted, the first cardinal deacon goes to the *Loggia* of St. Peter's and announces the news to the assembled people. The conclave is dissolved; on the following day the election is officially announced to the various governments. A few days after his election, takes place the coronation, from which the pontificate is officially dated, and the pope receives the tiara with the triple crown, the sign of his supreme spiritual authority (*see* TIARA).

Right of Veto.—In conclusion, a few words should be said with regard to the right of *veto.* During the 16th and 17th centuries, the various Catholic Courts instructed the Cardinals of their own nation to secure, as far as lay in their power, the removal of candidates distasteful to their party; and the governments could even make public their desire to exclude certain candidates. But they soon claimed an actual right of formal and direct exclusion, which should be notified in the conclave in their name by a cardinal charged with this mission, and should have a decisive effect; that is what has been called the right of veto. We cannot say precisely at what time during the 16th century this transformation of the practice into a right, tacitly accepted by the Sacred College, took place. The fact remains, however, that it was a right based on custom, and was not supported by any text or written concession; but the diplomatic right was straightforward and definite, and was better than the intrigues of former days. During the 19th century Austria exercised, or tried to exercise, the right of veto at all the conclaves, except that which elected Leo XIII. (1878); it did so again at the conclave of 1903. On Aug. 2 Cardinal Rampolla had received 29 votes, when Cardinal Kolzielsko Puzina, bishop of Cracow, declared that the Austrian government opposed his election; the Sacred College considered that it ought to yield, and on Aug. 4 elected Cardinal Sarto, who took the name of Pius X. By the bull *Commissum Nobis* (Jan. 20, 1904), Pius X. suppressed all right of "veto" or "exclusion" on the part of the secular governments, and forbade, under pain of excommunication reserved to the future pope, any cardinal or conclavist to accept from his government the charge of proposing a "veto," or to exhibit it to the conclave under any form.

CONCORD, a town of Middlesex county, Massachusetts, U.S.A., 20m. N.W. of Boston, served by the Boston and Maine Railroad. It has an area of 25 sq.mi., and a population in 1940 (federal census) of 7,972. The state reformatory for men is situated here.

The village of Concord, where the confluence of the Sudbury and the Assabet forms the beautiful little Concord river celebrated by Thoreau, has a wealth of historic and literary associations. A county convention held here in Aug. 1774 recommended the calling of the first provincial congress of Massachusetts, which met here on Oct. 11, 1774, and in March and April 1775. After that the colonists began storing military supplies in the village, and it became the objective of the British expedition which at Lexington on April 19, 1775, engaged in the first battle of the Revolution. In a brief engagement at Lexington early in the morning, blood was shed on both sides, but no British were killed. At Concord

500 minute-men confronted the British troops and drove them back on Lexington. A granite obelisk, erected in 1837, when Emerson wrote his ode on the battle, marks the spot where the first British soldiers fell. Across the stream, "where once the embattled farmers stood, and fired the shot heard round the world," is a fine bronze "minute-man" by D. C. French. Many notable orations have been delivered here on the anniversary of the battle, among them one by Edward Everett in 1825 and one by George William Curtis in 1875.

The town was settled and incorporated in 1635. It was the home of Ralph Waldo Emerson, Henry D. Thoreau, Nathaniel Hawthorne, A. Bronson Alcott and his daughter Louisa, and other distinguished writers and philosophers. From the "Old Manse," built in 1765 for William Emerson, his grandson wrote *Nature*, and Hawthorne wrote his *Mosses from an Old Manse*. "Orchard house" still stands—the home of the Alcotts during the years when the "Concord Summer School of Philosophy and Literature" (1879–88) was held in a rude building adjoining. The "Concord" grape was first grown here by Ephraim Bull in 1853, marking the beginning of the cultivation of table grapes in America on a commercial scale.

CONCORD, a city in the southern part of North Carolina, U.S.A., on the Rocky river, 21 mi. N.E. of Charlotte; the county seat of Cabarrus county. It is on federal highway 29, and is served by the Southern railway. The population in 1920 was 9,903, of whom 1,746 were Negroes, and was 11,820 in 1930 and 15,572 in 1940 by the federal census. It is in a cotton-growing district, and has textile mills. Concord was laid out in 1793 and incorporated in 1851.

CONCORD, the capital of New Hampshire, U.S.A., and the county seat of Merrimack county, on the Merrimack river, near the centre of the southern part of the state. It is on federal highways 3, 4 and 202; is served by the Boston and Maine railroad; and has a municipal airport. The area is 64 sq.mi. The population was 25,228 in 1930 and 27,171 in 1940 (85% native born) by the federal census.

Concord has broad, well shaded streets, several parks, and many fine public buildings. The state capitol is an impressive structure of fine-grained white granite from the neighbouring quarries. The state hospital for the insane and the state prison are situated here, and there are several homes and hospitals founded by private philanthropy. St. Paul's school for boys (Protestant Episcopal, 1853) is 2 mi. W. of the city. There is abundant water power. The factory product (with leather belting and printing and publishing leading) was valued in 1939 at $10,729,380. Large quantities of granite are shipped from Concord.

A trading-post was established here about 1660. In 1725 Massachusetts granted the land to some of her citizens, who established a settlement called Pennycook (the name of the Indians who had formerly occupied it), but New Hampshire in 1727 issued an overlapping grant, and the conflicting claims gave rise to a celebrated land case. The settlement was incorporated by the Massachusetts general court in 1734 as Rumford, and the settlers finally (1755) were confirmed in their possession, but under the jurisdiction of New Hampshire. In 1765 the name was changed to "the parish of Concord," and in 1784 the town of Concord was incorporated. A city charter granted in 1849 was accepted in 1853. In 1778 and again in 1781–82 a State Constitutional Convention met in Concord; in 1782, the first State legislature; and in 1788, the convention which ratified the Federal Constitution. The State capital was definitely established there in 1808. The *New Hampshire Patriot*, founded (1808) and for 20 years edited by Isaac Hill, was a leading exponent of Jacksonian democracy in New England. Concord was the home of the picturesque and versatile Benjamin Thompson (Count Rumford) and of Mary Baker Eddy, founder of the Christian Science movement. The site of Mrs. Eddy's home is occupied by a home for aged Christian Scientists.

CONCORD, BOOK OF, the collective documents of the Lutheran confession, consisting of the *Confessio Augustana*, the *Apologia Confessionis Augustanae*, the *Articula Smalcaldici*, the *Catechismi Major et Minor* and the *Formula Concordiae*. This last was a formula issued on the 25th of June 1580 (the jubilee of the Augsburg Confession) by the Lutheran Church in an attempt to heal the breach which, since the death of Luther, had been widening between the extreme Lutherans and the Crypto-Calvinists. Previous attempts at concord had been made at the request of different rulers, especially by Jacob Andreä with his Swabian Concordia in 1573, and Abel Scherdinger with the Maulbronn Formula in 1575. In 1576 the elector of Saxony called a conference of theologians at Torgau to discuss these two efforts and from them produce a third. The *Book of Torgau* was evolved, circulated and criticized; a new committee, prominent on which was Martin Chemnitz, sitting at Bergen near Madgeburg, considered the criticisms and finally drew up the *Formula Concordiae*. It consists of (*a*) the "Epitome," (*b*) the "Solid Repetition and Declaration," each part comprising twelve articles; and was accepted by Saxony, Württemberg, Baden among other states, but rejected by Hesse, Nassau and Holstein. Even the free cities were divided, Hamburg and Lübeck for, Bremen and Frankfort against. Hungary and Sweden accepted it, and so finally did Denmark, where at first it was rejected, and its publication made a crime punishable by death. In spite of this very limited reception the *Formula Concordiae* has always been reckoned with the five other documents as of confessional authority.

See P. Schaff, *History of Creeds* ch. vi., and *Creeds of the Evangelical Protestant Churches;* W. A. Curtis, art. "Confessions" in Hasting's, *Encyclopaedia of Religion and Ethics* (§ 13, "Confessions in the Lutheran Churches") with references.

CONCORDANCE, literally agreement, harmony; hence derivatively a citation of parallel passages, and specifically an alphabetical arrangement of the words contained in a book with citations of the passages in which they occur. Concordances in this last sense were first made for the Bible. Originally the word was only used in this connection in the plural *concordantiae*, each group of parallel passages being properly a *concordantia*.

The original impetus to the making of concordances was due to the conviction that the several parts of the Bible are consistent with each other, as parts of a divine revelation. To Anthony of Padua (1195–1231) tradition ascribes the first concordance, the anonymous *Concordantiae Morales*, of which the basis was the Vulgate. The first authentic work was due to Cardinal Hugh of St. Cher, a Dominican monk (d. 1263), who, in preparing for a commentary on the Scriptures, found the need of a concordance. It became the basis of one by Conrad of Halberstadt (*c.* 1290) and of another by John of Segovia in the next century. The first Hebrew concordance was compiled in 1437–45 by Rabbi Isaac Nathan b. Kalonymus of Arles (printed at Venice in 1523 by Daniel Bomberg, in Basel in 1556, 1559 and 1581). It was published under the title *Meir Natib*, "The Light of the Way," and in 1556 was translated into Latin by Johann Reuchlin. Its errors were corrected by Mario di Calasio, a Franciscan friar, who published a four-volume folio *Concordantiae Sacr. Bibl. Hebr. et Latin*, at Rome, 1621, much enlarged, with proper names included. Another concordance based on Nathan's was Johann Buxtorf the elder's *Concordantiae Bibl. Ebraicae nova et artificiosa methodo dispositae*, Basel, 1632. Calasio's concordance was republished in London under the direction of William Romaine in 1747–49, in four volumes, folio. In 1754 Dr. John Taylor, a Presbyterian divine in Norwich, published in two volumes the *Hebrew Concordance adapted to the English Bible*. In the middle of the 19th century Dr. Julius Fürst issued a thoroughly revised edition of Buxtorf's concordance. The *Hebräischen und chaldäischen Concordanz zu den Heiligen Schriften Alten Testaments* (Leipzig, 1840) carried forward the development of the concordance in several directions. It gave (1) a corrected text founded on Hahn's Vanderhoogt's Bible; (2) the Rabbinical meanings; (3) explanations in Latin, and illustrations from the three Greek versions, the Aramaic paraphrase, and the Vulgate; (4) the Greek words employed by the Septuagint as renderings of the Hebrew; (5) notes on philology and archaeology, so that the concordance contained a Hebrew lexicon. An English translation by Dr. Samuel Davidson was published in 1867. A revised edition of Buxtorf's work with additions from Fürst's was published by B. Bär (Stettin, 1862). A new concordance embodying the matter of all previous works with lists of proper names and particles was published by Solomon Mandelkern in Leipzig (1896; smaller edition, 1900). There are also concordances of biblical proper names by G. Brecher (Frankfort-on-Main, 1876) and Schusslovicz (Wilna, 1878).

A Concordance to the Septuagint, published at Frankfort in 1602 by Conrad Kircher of Augsburg, gave the Hebrew words in alphabetical order and the Greek words by which they are translated under them. A Septuagint concordance, giving the Greek words in alphabetical order, was published in 1718 in two volumes by Abraham Tromm, a learned minister at Groningen, then in the eighty-fourth year of his age. It gives the Greek words in alphabetical order; a Latin translation; the Hebrew word or words for which the Greek term is used by the Septuagint; then the places where the words occur in the order of the books and chapters; at the end of the quotations from the Septuagint places are given where the word occurs in Aquila, Symmachus and Theodotion, the other Greek translations of the Old Testament; and the words of the Apocrypha follow in each case. Besides an index to the Hebrew and Chaldaic words there is another index which contains a lexicon to the *Hexapla* of Origen. In 1887 (London) appeared the *Handy Concordance of the Septuagint giving various readings from Codices Vaticanus, Alexandrinus, Sinaiticus and Ephraemi, with an appendix of words from Origen's Hexapla, not found in the above manuscripts,* by G.M., without quotations. A work of the best modern scholarship was brought out in 1897 by the Clarendon Press, Oxford, entitled *A Concordance to the Septuagint and the other Greek versions of the Old Testament including the Apocryphal Books,* by Edwin Hatch and H. A. Redpath, assisted by other scholars; this was completed in 1900 by a list of proper names.

The first Greek concordance to the New Testament was published at Basel in 1546 by the Lutheran Sixt Birck or Xystus Betuleius (1500–54). This was followed by Stephen's concordance (1594) planned by Robert Stephens and published by Henry, his son. Then in 1638 came the ταμιεῖον of Erasmus Schmied or Schmid, which has been the basis of subsequent concordances to the New Testament. Revised editions of it were published at Gotha in 1717, and at Glasgow in 1819. In the middle of the 19th century Bruder brought out a beautiful edition (Tauchnitz) collating the readings of Erasmus, R. Stephens' third edition, the Elzevirs, and others, and presenting a selection from ancient patristic mss. and various interpreters. Bruder was edited, with readings of S. P. Tregelles, in 1888, by Westcott and Hort. The *Englishman's Greek Concordance of the New Testament,* and the *Englishman's Hebrew and Chaldee Concordance* are intended to put the results of the above-mentioned works at the service of those who know little Hebrew or Greek. They are the work of George V. Wigram assisted by W. Burgh and superintended by Tregelles, B. Davidson and W. Chalk (1843; 2nd ed. 1860). Mention should also be made of *A Concordance to the Greek Testament with the English version to each word; the principal Hebrew roots corresponding to the Greek words of the Septuagint, with short critical notes and an index,* by John Williams, LL.D., London (1767).

In 1884 Robert Young brought out a *Concordance to the Greek New Testament with a dictionary of Bible Words and Synonyms:* this contains a concise concordance to eight thousand changes made in the Revised Testament. Another important work of modern scholarship is the *Concordance to the Greek Testament,* edited by the Rev. W. F. Moulton and A. E. Geden, according to the texts adopted by Westcott and Hort, Tischendorf, and the English revisers.

The first concordance to the English version of the New Testament was published in London, 1535, by Thomas Gybson. It is a black-letter volume entitled *The Concordance of the New Testament most necessary to be had in the hands of all soche as delyte in the communication of any place contayned in ye New Testament.* The first English concordance of the entire Bible was John Marbeck's, *A Concordance, that is to saie, a worke wherein by the order of the letters of the A.B.C. ye maie redely find any worde conteigned in the whole Bible, so often as it is there expressed or mentioned,* Lond. 1550. Although Robert Stephens had divided the Bible into verses in 1545, Marbeck does not seem to have known this and refers to the chapters only. In 1550 also appeared Walter Lynne's translation of the concordance issued by Bullinger, Jude, Pellican and others of the Reformers. Other English concordances were published by Cotton, Newman, and in abbreviated forms by John Downham or Downame (ed. 1652), Vavasor Powell (1617–70), Jackson and Samuel Clarke (1626–1701). In 1737 Alexander Cruden (*q.v.*) published his *Complete Concordance to the Holy Scriptures of the Old and New Testament, to which is added a concordance to the books called Apocrypha,* superseding all its predecessors. Three editions were published during Cruden's life, and many since his death. Later concordances only supersede his notably accurate work by combining an English with a Greek and Hebrew concordance (*a*) the *Critical Greek and English Concordance,* by C. F. Hudson, H. A. Hastings and Ezra Abbot, Boston (Mass.), and (*b*) the *Critical Lexicon and Concordance to the English and Greek New Testament,* by E. L. Bullinger, 1892. James Gall's *Interpreting Concordance to the New Testament,* shows the Greek original of every word, with a glossary explaining the Greek words of the New Testament with their varied renderings in the Authorized Version. The most convenient is (*c*) *Young's Analytical Concordance* (Edinburgh, 1879), giving (1) the original Hebrew or Greek of any word in the English Bible; (2) the literal and primitive meaning of every such original word; (3) thoroughly reliable parallel passages. There is a *Students' Concordance to the Revised Version of the New Testament* showing the changes embodied in the revision, published under licence of the universities; and a concordance to the Revised Version by J. A. Thoms for the Christian Knowledge Society. Biblical concordances having familiarized students with the value and use of such books for the systematic study of an author, the practice of making concordances has now become common. There are concordances to the works of Shakespeare, Browning, and many other writers. (D. M.)

CONCORDAT, a term originally denoting an agreement between ecclesiastical persons or secular persons, but later applied to a pact concluded between the ecclesiastical authority and the secular authority on ecclesiastical matters which concern both, and, more specially, to a pact concluded between the pope, as head of the Catholic Church, and a temporal sovereign for the regulation of ecclesiastical affairs in the territory of such sovereign (*pactum concordatum* or *solemnis conventio*). It is to concordats in this later sense that this article refers.

For the purposes of a concordat the state recognizes the official *status* of the church and of its ministers and tribunals; guarantees it certain privileges; and sometimes binds itself to secure for it subsidies representing compensation for past spoliations. The pope on his side grants the temporal sovereign certain rights, such as that of making or controlling the appointment of dignitaries; engages to proceed in harmony with the government in the creation of dioceses or parishes; and regularizes the situation produced by the usurpation of church property, etc. The great advantage of concordats—indeed their principal utility—consists in transforming necessarily unequal unilateral claims into contractual obligations analogous to those which result from an international convention. Whatever the obligations of the state towards the ecclesiastical society may be in pure theory, in practice they become more precise and stable when they assume the nature of a bilateral convention by which the state engages itself with regard to a third party. And reciprocally, whatever may be the absolute rights of the ecclesiastical society over the appointment of its dignitaries, the administration of its property and the government of its adherents, the exercise of these rights is limited and restricted by the stable engagements and concessions of the concordatory pact, which bind the head of the church with regard to the nations.

Concordats have therefore the perpetuity of conventions which contain no time limitation; but, like every human convention, they can be denounced, in the form in use for international treaties, and for good reasons, which are summed up in the exigencies of the general good of the country. Nevertheless, there is no example of a concordat having been denounced or broken by the popes, whereas several have been denounced or broken by the civil powers, sometimes in the least diplomatic manner, as in the case of the French concordat in 1905. The rupture of the concordat at once terminates the obligations which resulted from it on both sides; but it does not break off all relation between the church and the state, since the two societies continue to coexist on the same territory. To the situation defined by concordat, however, succeeds another situation, more or less uncertain and more or less strained, in which the two powers legislate separately on mixed matters, sometimes not without provoking conflicts.

Objects of Concordatory Conventions.—These cannot be described in detail; they bear upon very varied matters and we must confine ourselves here to a brief *résumé*. In the first place there is the official recognition by the state of the Catholic religion and its ministers. Sometimes the Catholic religion is declared to be the state religion, and at least the free and public exercise of its worship is guaranteed. As regards candidates for ecclesiastical offices, the concordats concluded with Catholic nations regularly give the sovereign the right to nominate or present to bishoprics, often also to other inferior benefices, such as canonries, important parishes and abbeys; or at least the choice of the ecclesiastical authority is submitted to the approval of the civil power. In all cases canonical institution (which confers ecclesiastical jurisdiction) is reserved to the pope or the bishops. In countries where the head of the state is not a Catholic, the bishops are regularly elected by the chapters, but the civil power has the right to strike out objectionable names from the list of candidates which is previously submitted to it. Certain concordats deal with the orders and congregations of monks and nuns with a view to subjecting them to a certain control while securing to them the legal exercise of their activities. Ecclesiastical immunities, such as reservation of the criminal cases of the clergy, exemption from military service and other privileges, are expressly maintained in a certain number of pacts. One of the most important subjects is that of church property. An agreement is come to as to the conditions on which pious foundations are able to be made; the measure in which church property shall contribute to the public expenses is indicated; and, in the 19th century, the position of those who have acquired confiscated church property is regularized. In exchange for this surrender by the church of its ancient property the state engages to contribute to the subsistence of the ministers of public worship, or at least of certain of them.

Concordats in History.—Scholars agree in associating the earliest concordats with the celebrated contest about Investitures (*q.v.*), which so profoundly agitated Christian Europe in the 11th and 12th centuries. The first in date is that which was concluded for England with Henry I. in 1107 by the efforts of St. Anselm. The convention of Sutri of 1111 between Pope Paschal II. and the emperor Henry V. having been rejected, negotiations were resumed by Pope Calixtus II. and ended in the concordat of Worms (1122), which was confirmed in 1177 by the convention between Alexander III. and the emperor Frederick I. In this concordat a distinction was made between spiritual investiture, by the ring and pastoral staff, and lay or feudal investiture, by the sceptre. The emperor renounced investiture by ring and staff, and permitted canonical elections; the pope on his part recognized the king's right to perform lay investiture and to assist at elections. Analogous to this convention was the concordat concluded between Nicholas IV. and the king of Portugal in 1289.

The lengthy discussions on ecclesiastical benefices in Germany ended finally in the concordat of Vienna, promulgated by Nicholas V. in 1448. Already at the council of Constance attempts had been made to reduce the excessive papal reservations and taxes in the matter of benefices, privileges which had been established under the Avignon popes and during the Great Schism; for example, Martin V. had had to make with the different nations special arrangements which were valid for five years only, and by which he renounced the revenues of vacant benefices. The council of Basel went further: it suppressed annates and all the benefice reservations which did not appear in the *Corpus Juris*. Eugenius IV. repudiated the Basel decrees, and the negotiations terminated in what was called the "concordat of the princes," which was accepted by Eugenius IV. on his death-bed (bulls of Feb. 5 and 7, 1447). In Feb. 1448 Nicholas V. concluded the arrangement, which took the name of the concordat of Vienna. This concordat, however, was not received as law of the Empire. In Germany the concessions made to the pope and the reservations maintained by him in the matter of taxes and benefices were deemed excessive, and the prolonged discontent which resulted was one of the causes of the success of the Lutheran Reformation.

In France the opposition to the papal exactions had been still more marked. In 1438 the Pragmatic Sanction of Bourges adopted and put into practice the Basel decrees, and in spite of the incessant protests of the Holy See the Pragmatic was observed throughout the 15th century, even after its nominal abolition by Louis XI. in 1461. The situation was modified by the concordat of Bologna, which was personally negotiated by Leo X. and Francis I. of France at Bologna in Dec. 1515, inserted in the bull *Primitiva* (Aug. 18, 1516), and promulgated as law of the realm in 1517, but not without rousing keen opposition. All bishoprics, abbeys and priories were in the royal nomination, the canonical institution belonging to the pope. The pope preserved the right to nominate to vacant benefices *in curia* and to certain benefices of the chapters, but all the others were in the nomination of the bishops or other inferior collators. However, the exercise of the pope's right of provision still left considerable scope for papal intervention, and the pope retained the annates.

The concordats drawn up during the 17th and 18th centuries either fell to the ground or had to be recast. In the 19th century we find a long series of concordats, of which a good number are still in force. The first in date and importance is that of 1801, concluded for France between Napoleon and Pius VII. after laborious negotiations. The first consul was given the right to nominate bishops, the bishoprics and parishes were redistributed and the erection of seminaries allowed. The pope condoned those who had acquired church property; and by way of compensation the government engaged to give the bishops and curés suitable salaries. The concordat was solemnly promulgated on Easter Day 1802, but the government had added to it unilateral provisions of Gallican tendencies, which were known as the Organic Articles. After having been the law of the Church of France for a century, it was denounced by the French Government in 1905.

A concordat with England was proposed by Castlereagh in 1814, but the negotiations broke down over the question of episcopal nominations. In addition to the case of France, important concordats were concluded during the 19th century with Germany, Bavaria (1817), Prussia (1821), Hanover (1824); Austria (1855, denounced by the Austrian Government on the proclamation of papal infallibility in 1870); Spain (1851, 1855, 1904); Switzerland (1828, 1845, 1888) and Portugal (1857, 1886). In the case of Russia, a formal concordat was found inapplicable even as far back as 1847. In the case of Holland and Belgium, concordats were replaced by an amicable *modus vivendi*. After the World War of 1914–1918 many new concordats were made. The most important were with Poland (1925), Lithuania and Rumania (1927), Italy (1929) and Germany (1933).

See J. Turmel's article on "Concordat" in Hastings *Encyclopaedia of Religion and Ethics; Catholic Encyclopaedia*, art. "Concordat"; Mirbt, art. "Konkordate" in Herzog-Hauck, *Realencyklopädie*, 3rd ed. (with reff.); A. Mercati, *Raccolta di Concordati* (1919); F. M. Cappello, *De natura concordatorum* (1928); M. Bierbaum, *Das Konkordat in Kultur, Politik, und Recht* (1928); On the Italian Concordat *see* W. Parsons, *The Pope and Italy* (1929); on the French concordats: Thomas, *Le concordat de 1516* (1910).

CONCORDIA, a Roman goddess, the personification of civic concord. Several temples in her honour were erected at Rome, the most ancient being one on the Capitol, dedicated to her by Camillus (367 B.C.), subsequently restored by Livia, the wife of Augustus, and consecrated by Tiberius (A.D. 10). Concordia was represented as a matron holding in her right hand either a *patera* or an olive branch, and in her left either a *cornu copiae* or a sceptre.

CONCORDIA (mod. CONCORDIA SAGITTARIA), an ancient town of Venetia, in Italy, 16ft. above sea-level, 31m. W. of Aquileia, at the junction of roads to Altinum and Patavium, to Opitergium (and thence either to Vicetia and Verona, or Feltria and Tridentum), to Noricum by the valley of the Tilaventus (Tagliamento), and to Aquileia. Previously a mere village, Augustus made it a colony. Under the later empire it was one of the most important towns of Italy; it had a strong garrison and a factory of missiles for the army. In the garrison cemetery many important inscriptions have been discovered. It was taken and destroyed by Attila in A.D. 452. Parts of the ancient city walls, the sites of the forum and the theatre, and probably that of the arms factory have been found. The ancient see of Concordia was transferred in 1339 to Portogruaro, where it still remains. The old Romanesque cathedral and baptistery are preserved.

CONCORDIA, a city of northern Kansas, U.S.A., on the Republican river, 155m. W. of Atchison; the county seat of Cloud county. It is on the Meridian national highway, and is served by the Burlington, the Missouri Pacific, the Santa Fe and the Union Pacific railways. The population in 1930 federal census was 5,792 and in 1940, 6,255. It has a large wholesale trade, and manufactures flour, brick, brooms, butter and cheese, and ice. Coal, building stone and clay are found near by. Concordia was settled about 1871, and was incorporated in 1872.

CONCRETE, a term used in various technical senses, with the general significance of combination, conjunction, solidity. Thus the building material made up of separate substances combined into one is known as concrete (*see* below). In mathematics and music, the adjective has been used as synonymous with "continuous" as opposed to "discrete," *i.e.*, "separate," "discontinuous." This antithesis is no doubt influenced by the idea that the two words derive from a common origin, whereas "discrete" is derived from the Latin *discernere* (to discriminate), as "concrete" is derived from *concrescere* (to grow together). In logic and also in common language concrete terms are those which signify persons or things as opposed to abstract terms which signify qualities, relations, attributes (so J. S. Mill). Thus the term "man" is concrete, while "manhood" and "humanity" are abstract, the names of the qualities implied. Confusions between abstract and concrete terms are frequent; thus the word "relation," which is strictly an abstract term implying connection between two things or persons, is often used instead of the correct term "relative" for people related to one another. Concrete terms are further subdivided as singular, the names of things regarded as individuals, and general or common, the names which a number of things bear in common in virtue of their possession of common characteristics. These latter terms, though concrete in so far as they denote the persons or things which are known by them (*see* DENOTATION), have also an abstract sense when viewed connotatively, *i.e.*, as implying the quality or qualities in isolation from the individuals. The ascription of adjectives to the class of concrete terms, upheld by J. S. Mill, has been disputed on the ground that adjectives are applied both to concrete and to abstract terms. Hence some logicians make a separate class for adjectives, as being the names neither of things nor of qualities, and describe them as attributive terms.

See J. S. Mill, *System of Logic,* 1874; J. N. Keynes, *Formal Logic,* 1906; H. W. B. Joseph, *Introduction to Logic,* 1916; A. Wolf, *Essentials of Logic,* 1926.

CONCRETE is a building material made by mixing stone, sand, water and a cementing material. The ingredients are mixed together with the addition of clean water into a plastic mass which gradually hardens into a rock-like substance of the nature of conglomerate. As a building material it is distinguished by the facility with which it can be deposited and moulded while plastic into almost any shape. Materials suitable for its manufacture are almost universally available and the mixing and placing do not require expert labour. It is adapted to an infinite variety of uses in engineering and architecture, including massive structures such as heavy foundations, retaining walls, dock walls, breakwaters, bridges and dams, and more intricate construction in ferro-concrete for floors, columns, buildings, arches, domes, towers, water tanks, pontoons, foundation cylinders, piles, open-work jetties and many other purposes. It has been used in masses of over 30 million cu.ft. in a single dam.

Concrete made with lime as the cementing material was largely used by the Romans in the construction of aqueducts, bridges and other massive work, generally with a facing of brickwork or masonry on the exposed surfaces, and some specimens of the ancient works have exhibited extraordinary durability. Lime in some form was almost the only binding material available until the introduction in the 19th century of Portland cement. The latter material is so superior in strength and reliability that it has almost superseded lime, except for unimportant work. Limited use is also made of other cements having qualities similar to Portland cement, such as natural cement and cement made from blast furnace slag (*see* CEMENT). When water is added to cement a slow chemical action takes place with liberation of some heat, and the cement in a few hours begins to harden into a stone-like substance. When it is mixed with sand a mortar is formed which sets hard, but with less ultimate strength than neat cement, and if broken stones are mixed with the mortar, concrete is obtained. In practice the materials are mixed together at one time and sound dense concrete is obtained when the mortar is in such volume and so mixed as to fill all the interstices among the broken stones. The sand used should be clean and sharp, entirely free from clay, loam, silt or vegetable matter, and it will give best results when it is a good blend of grains of all sizes from $\frac{1}{4}$in. down to $\frac{1}{1000}$inch. It may be obtained in a natural state from pit, river or seashore, or may be produced by crushing natural rock such as granite, trap or hard sandstone.

The stone may be pebbles or flints from gravel beds, or crushed hard rock, or broken artificial material such as slag, bricks, clinker or even concrete. Cinders and coke are sometimes used to form a light concrete, but should be excluded from important work. Hard limestone is generally suitable but has been found unsatisfactory in concrete conduits for conveyance of soft water, and is not the best material for producing fire-resisting concrete. Granite, gneiss, trap and hard sandstone rock produce good aggregate for concrete. Generally the angular stones produced by crushing rock are less easily formed into dense concrete without voids than the rounded stones of natural gravel which slip past each other readily and are thus more easily compacted together. Smoothness of surface of the stones is no disadvantage from the point of view of adhesion of the materials when the stones are small. The water used for mixing should be clean and free from acid alkali, oil or vegetable contamination. Sea water can be used without adverse effect other than the production of some surface efflorescence. Water from peat moors should not be used.

Concrete Mixtures.—Concrete may be mixed in very different proportions according to the strength required, and the size of stone used may be varied in accordance with the massiveness of the rock. The general principle to be followed in proportioning the mixture is that the volume of mortar produced by the mixing together of the cement and sand should be rather more than sufficient to fill the interstices of the broken stone so that no unfilled voids remain. The voids in broken stone are usually under 50% so that a quantity of sand equal to half the broken stone will normally suffice for complete filling. Relative proportions of cement, sand and stone, are frequently stated thus 1 : 3 : 6, which indicates a mixture in the proportions of one part of cement to three parts of sand and six parts of stone. Such a mixture with stone of a maximum size of 3in. is suitable for foundations of mass concrete and similar work where great strength is not required. A 1 : 2 : 4 mixture is generally appropriate for reinforced concrete building construction with stone not exceeding $\frac{3}{4}$in. so that the concrete may be readily filled between and around the reinforcing bars. Mixtures still richer in cement are required for concrete piles to obtain adequate strength and for tanks and hydraulic structures to obtain watertightness. The richest mixture in common use is 1 : 1 : 2 which is suitable for reinforced concrete in marine works, and for reinforced conduits to convey water under pressure. The proportions given are in round numbers, but the best proportions to use for particular materials should be determined by ascertaining by experiment the nature of the grading and the percentage of voids. The densest mixture of stones and sand, *i.e.,* the one which weighs most per unit volume, will be capable of furnishing the strongest concrete. The tests for grading are used to indicate whether a part of the constituent materials should be augmented or diminished. Addition of fine sand to promote water-tightness is often useful in concrete for hydraulic and marine works. The proportion of water to be used is almost as important as that of the other constituents. Enough water should be added to produce, after thorough mixing a plastic mass which can be rammed and tamped into position, so as to fill completely all corners and enclose solidly all reinforcement where such occurs. Too dry a mixture will give rise to inevitable voids and surface defects, while excess of water causes marked diminution of strength. Small quantities of concrete may be mixed by hand on a wooden platform, the dry materials being turned over by shovel two or three times before water is added, and the mixture again turned over twice while wet or until a uniform consistency is obtained. Most concrete mixing is now done by machines, in quantities of from 6 cu.ft. to 60 cu.ft. at a time. In one type the mixing is done in a power-operated drum having internal vanes which cause rapid and thorough mixture of the materials as the drum rotates. The machine includes power-operated loading and discharging apparatus and a measuring tank for water.

The question of the endurance of concrete under exposure to chemicals is important. Sea water contains salts which sometimes penetrate and affect pervious concrete and any steel reinforcement contained therein. It is considered that magnesium sulphate is the most injurious of such salts. The fundamental precaution to be taken in the case of concrete for marine structures is to make the concrete so dense that penetration by water is prevented. A mixture in the proportions 1 : 1 : 2 formed with well graded small aggregate and an adequate proportion of very fine material in the sand will give good endurance under most circumstances. Concrete is readily attacked by strong acids, but where thoroughly hardened and of dense quality it offers considerable resistance to weak acid solutions. In certain arid regions soluble alkaline salts contained in the ground are injurious to concrete. Such salts include the sulphates and chlorides of magnesium sodium and calcium. The remedy, as in the case of sea water appears to be the use of dense impervious concrete. Mineral oils such as petroleum, engine and transformer oils have little effect on good concrete. Vegetable oils, such as palm oil, have on the other hand a very injurious effect, as they unite with the lime of the cement and cause softening and disintegration.

Properties of Concrete.—The most important quality of concrete is the facility with which it can be formed into large and strong monolithic structures. Its usefulness depends on high compressive strength in conjunction with great durability and adequate tensile strength to ensure cohesion. The strength of concrete naturally depends on the quality and proportions of the constituents as well as the methods of mixing and placing, and obviously the proportion of cement used will have a large effect on the result. In England compressive strength is commonly determined by the force required to crush 6in. cubes of concrete. In the United States 6in. by 12in. cylinders are usually specified. When cement is used complying with the British Standard Specification 1925, the crushing stress for cubes 28 days old should be not less than 2,000lb. per sq.in. for a 1 : 2 : 4 mixture, rising to 3,000lb. per sq.in. for a 1 : 1 : 2 mixture. Much higher results are commonly obtained. The tensile strength is only a fraction of the compressive strength, usually about one-tenth. Concrete expands and contracts with rise and fall of temperature and it is a curious and important fact that the rate of expansion is almost the same as that of steel, a condition which enables the two materials to act together in the structural combination known as ferro-concrete, where primarily the concrete sustains the forces of compression and the steel resists the forces of tension. The question of the elasticity of concrete is important in relation to the stresses in ferro-concrete construction. Concrete yields much more than steel under the same stress, so that relatively the concrete is more elastic to an extent which for convenience is expressed by a ratio termed the modulus ratio. The actual ratio for matured concrete is commonly from 7 to 10, whereas for purposes of calculation a ratio of 15 is often assumed. While undergoing the chemical changes that transform it from a plastic to a hard material, concrete is subject to shrinkage, which, while introducing some secondary stresses in the materials of ferro-concrete, causes it to close around and hold the reinforcing bars with firm grip. Watertightness is of special importance in hydraulic and marine structures and is promoted by having a mixture in which the mortar is rather more than sufficient to fill the interstices in the aggregate and is watertight in itself. As a rule watertightness cannot be relied on where the mortar is a 1 : 2 mixture, whereas a 1 : 1 mixture will usually be satisfactory. Proper grading of the sand and a sufficiency of fine sand are necessary for the attainment of the best results.

Concrete is largely used as a casing around structural steelwork for protection against fire. It is well known that bare steelwork, owing to its excellent heat conducting properties, soon attains a dangerous temperature in a fire with consequent failure from softening. Concrete in comparison with steel is a poor conductor of heat and furnishes protection by delaying the passage of heat to the steelwork. As the temperature of the concrete rises on the surface to a high level dehydration takes place, accompanied by increase in the heat insulating properties, so that although the surface layers of the concrete are damaged the penetration of heat is thereby further hindered. A thickness of 2in. of concrete well bound to the steelwork with wire or metal mesh reinforcement meets the requirements of certain building authorities and fire associations. Concrete is frequently used as the wearing surface on floors subject to foot traffic and occasionally also to floors to sustain wheeled traffic. The wearing surface is usually a coating of fine concrete or mortar from 1 to 2in. thick applied on top of the concrete floor. The requirements of such a coating are strength and resistance to abrasion, as well as good adhesion to the concrete below, and they are in the main to be attained by the use of fine hard aggregate such as quartz, granite or flint, in a well graded mixture from ¼in. down to fine sand. Two parts of such aggregate mixed with one part of cement, applied before the floor concrete has completely set, and well trowelled to produce a smooth surface, should produce a satisfactory result. Carborundum offers very high resistance to abrasion and in a finely divided form like fine sand is sometimes mixed with the surface floor layer. Small proportions of powdered cast-iron or steel are also sometimes used to improve the density and wearing qualities of floors, but it is doubtful whether they add anything to the wearing properties of good concrete made with quartz or granite. Silicate of soda is an acid-resisting liquid chemical "hardener" which may be added to the mixing water or applied on the surface of finished concrete, with the object of hardening the surface and improving the resistance to abrasion.

Uses of Plain Concrete.—Plain or mass concrete though not so adaptable to architectural treatment can be used for almost all building purposes for which massive masonry or brickwork is suitable. It is particularly suitable for the construction of monolithic foundation slabs to distribute the load from buildings, walls, piers and all classes of heavy erections, from the fact that it is deposited in a plastic condition and thereby takes perfect and uniform bearing even on irregular ground. The spreading of the load so as to keep the pressure on the ground within its safe bearing power is effected by making the foundation slab wider than the wall or other part which is sustained. The use of concrete as a foundation for important roads is a reversion after many centuries to the excellent practice of the Romans. A substantial foundation of concrete is almost indispensable where a large volume of heavy traffic has to be borne. Plain concrete is well adapted to the construction of gravity retaining walls for the holding up of a vertical face of earth. The foundation slab for such a wall usually has considerable projection beyond its face and is deposited in a trench without the use of shutters or forms. The wall itself requires to be built within shutters or forms back and front which are held against a series of standing timbers stayed from the ground by raking or horizontal struts as the circumstances may require. The shutters may be of timber or sheet steel and are usually arranged in horizontal courses of a few feet in height. The concrete is deposited and well rammed in layers between the shutters and after a course has set firm the shutters are removed and raised into position for the next course. A sound smooth surface is obtained on the concrete by working a spade or other suitable tool repeatedly up and down on the inside of the shutters whereby the coarse stones are kept back, finer material is brought to the face and air is expelled. High retaining walls may be very massive and are suitable for the use of a variety of concrete known as rubble or cyclopean concrete in which large blocks of stone are embedded. Such concrete is made with ordinary concrete as a matrix and with the large stone as an exceedingly coarse aggregate. Good results are obtained when the large stones, which according to circumstances may be as large as a man or a crane can lift, are placed and embedded in a soft layer of plain concrete, and then covered over by the succeeding layer of plain concrete which must be rammed and worked so as to surround every stone. The large stones must be kept sufficiently far from the shutters and from each other to ensure that the plain concrete will flow into and completely fill all interstices.

Dams, dock walls and graving docks are classes of structure in which concrete is used in enormous masses and where cyclopean concrete may often be used to advantage. In the case of a dam, various classes of concrete are used to suit the conditions in different parts of the work. In the heart of the dam, mass and weight are required, and proportions varying from 1 : 2 : 4 to 1 : 3 : 6 are commonly used. Watertightness is obtained by providing a richer and denser layer next to the water face with a mixture varying from 1 : 1 : 2 to 1 : 2 : 4. In the case of a high dam large compressive stresses will be developed in the concrete near the inner and outer surfaces at the bottom under varying conditions of water level, so that richer and stronger concrete may be necessary in these regions. Where climatic conditions are severe rich concrete may be necessary on all exposed surfaces and sometimes it is advisable to have the surfaces protected with a facing of granite or other durable masonry. Somewhat similar conditions obtain in the case of concrete for dock walls and graving docks. The construction should be watertight and surfaces exposed to wear and abrasion should be protected either by rich concrete or by a separate facing of granite or similar material. A number of dock walls have been provided with foundations in an interesting manner by sinking large cellular structures of concrete through the ground until a firm foundation is reached. Such constructions are known variously as caissons or monoliths and are usually built up on a metal shoe formed with cutting edges. The sinking is effected by excavating the earth from the cellular interior spaces by hand excavation or by mechanical means, using a grab. As excavation proceeds the structure sinks and at the same time building upwards with mass concrete or concrete blocks takes place so that the top is kept above ground level. When a firm foundation has been reached the interior spaces may be filled with concrete or the bottom may simply be plugged with concrete and the rest of the spaces filled with sand or broken stone. Such a foundation structure is generally used as a base on which to build a wall of mass concrete. In the case of breakwaters (*q.v.*) very large use has been made of concrete in the form of huge pre-cast blocks. Where the depth of water is not great the whole structure may be formed of such blocks, but more frequently their use is confined to the upper part of the construction resting on top of a broad bank of rubble deposited in the water. The blocks are made and cured in a large construction yard ashore and are handled and lowered into position by heavy travelling cranes and set into correct position by the aid of divers. At the port of Dublin, blocks of 350 tons weight were used which were handled and deposited by heavy floating sheers.

Deposition Under Water.—It is sometimes necessary to deposit concrete in water and as concrete sets as well in water as in air excellent concrete can be obtained provided it is not disturbed during the setting period. The danger to be feared is that motion of the water will carry away some of the cement and so weaken the concrete. One method is to fill the concrete into large canvas bags which are lowered into position through the water. Such a "bag block" is plastic and flexible and adapts and fits itself when deposited to the sea bed or to adjacent blocks. Where the under water space in which the concrete is to be deposited is confined, so that disturbance from currents or motion of the water is eliminated, the plastic concrete may be deposited through a large tube reaching almost to the bottom of the space. This method is appropriate where under water shutters have been erected, or where the concrete is confined within the walls of cylinders, caissons, monoliths and similar constructions. Concrete deposited through the tube is conveyed directly to the bottom of the space to be filled and as further concrete is sent down the space is gradually filled with quiet displacement of the water as the surface of the concrete rises. There is no need to raise the tube as filling proceeds and indeed best results are obtained when the lower end of the tube is kept near the bottom of the space. The filling should proceed without intermission until the whole quantity is deposited. Some "laitance" or scum formed of material washed out of the cement will always be found on the upper surface of concrete. Such scum should be carefully removed before any further concrete is placed on top.

Ferro-concrete.—The introduction of ferro-concrete is generally attributed to Joseph Monier, a French gardener, who about the year 1868 developed the idea of strengthening concrete by incorporating in it a network of small iron rods for the purpose of constructing water basins. Many other inventors, some even before Monier, have contributed to the scientific development of the combination which is now almost indispensable in civil engineering work. In almost any engineering structure certain members or parts have to sustain forces of compression tending to crush them while other parts have to sustain tensile stresses which exert a tearing effect and other parts again are subject to transverse stresses tending to shear them through. The fundamental basis of the ferro-concrete combination is that concrete is provided to sustain the compressive stresses and to act as the universal binding material of the system, while steel is provided to withstand the tensile stresses and to assist in resisting shearing stresses. From broad theoretical considerations controlled by the results of many experiments and much practical experience, laws have been formulated which enable ferro-concrete members and parts to be accurately and economically proportioned for the duty they have to perform. The fundamental properties that enable the two elements to act in combination are the equality of the coefficients of expansion and the adhesion and grip with which even plain round steel rods are held so that stresses are transmitted to them without giving rise to slipping. Other properties which conduce to the economy and usefulness of the system of construction are the facility with which it can be formed within moulds to any desired shape, the excellent protection against corrosion afforded to the steelwork by its coating with cement, and the permanence and fire resisting quality of the construction.

Floor Slabs.—Fire resisting floors are frequently formed with a series of small rolled steel joists filled in with plain concrete, the joists being arranged to carry the load, but this type of construction is not classed as reinforced concrete. In a reinforced concrete floor slab steel rods are used in the bottom of the slab to take the tensile stresses and the concrete itself resists the compressive stresses and shearing stresses which in the other case are taken by the top flanges and the webs of the steel joists. A simple reinforced floor slab of this kind is shown in cross-section in fig. 1. Main steel rods to provide the cross-section ascertained by calculation are disposed regularly across the span in the bottom of the slab which is subject to tension, and a smaller quantity of distribution rods are arranged at right angles to bind the slab in the other direction. Fig. 2 illustrates the difference introduced by continuity of a slab over more than one span whereby tension occurs in the upper part of the slab over intermediate supports so that there the

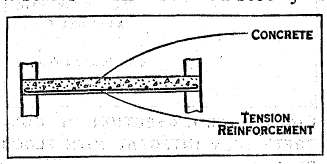

FIG. 1.—CROSS-SECTION OF SIMPLE REINFORCED FLOOR SLAB

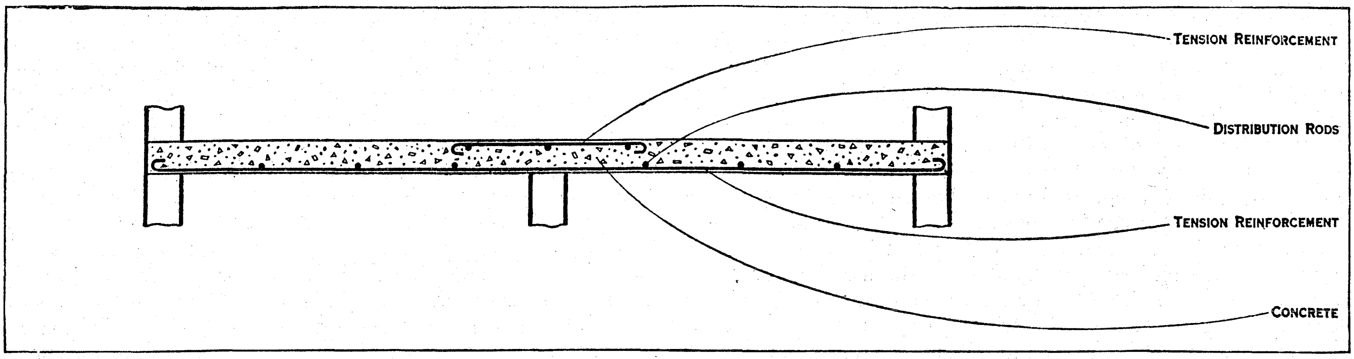

FIG. 2.—CROSS-SECTION OF FLOOR SLAB, SHOWING THE ARRANGEMENT OF REINFORCEMENT RODS IN THE CENTRE, WHERE TENSION OCCURS

reinforcing rods must be arranged near the upper surface.

Beams.—Beams of plain rectangular form are frequently used as lintels bridging over openings in walls, and are usually formed of the same thickness as the wall and with a depth arranged to suit the load. The tensile flange is constituted by a number of rods in the bottom of the beam while an area of concrete in the top of the beam constitutes the compression flange as shown in fig. 4. Reinforcement of vertical "stirrups" or other form may be provided to aid the concrete in resisting shearing stresses. Beams in reinforced construction are most frequently required to carry reinforced concrete floor slabs which when cast integrally with the beams can be utilized to augment their cross section and strength. Such a beam is indicated in fig. 5. In this case the concrete in the vertical stem or web is called upon to sustain proportionately larger stresses so that web reinforcement may become essential, and this is provided either by vertical links or "stirrups" as shown, or by bending up in a diagonal direction certain of the main tension rods in the end portions of the beam, or by a combination of the two methods. Suitable arrangements for continuity may be provided, as shown in fig. 2, which represents a beam continuous over two spans. It is noteworthy that by bending up certain of the main rods and overlapping them in the top of the beam over a support not only is provision made for resisting shearing stresses but also for withstanding the reverse bending which occurs. Continuous beams are usually more heavily stressed at intermediate supports than in the central portions of spans so that it is often appropriate to increase the depth by forming the bottom with a downward slope for a short distance next to each support.

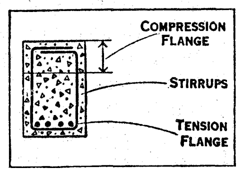

FIG. 3.—CROSS-SECTION OF RECTANGULAR CONCRETE BEAM

Columns.—A ferro-concrete column for the support of vertical loads, when properly designed and constructed, is at once economical, durable and fire resisting. It consists of a shaft of concrete containing a number of vertical steel bars bound together at close intervals by smaller steel bars either in the form of a continuous spiral or of separate links. The shaft may have any shape appropriate to the conditions and site. Sections of circular or octagonal shape are commonly adopted when spiral hooping is used, while square and rectangular cross sections are more commonly used with a binding of separate links. Typical cross sections of a square and an octagonal column are shown in fig. 6. The square column has four main vertical rods with a binding of separate links while the octagonal column has eight main rods with a continuous spiral binding. The thickness of concrete covering the main rods should in no case be less than 1½in. The load is borne partly by the concrete and partly by the steel, the greater portion being usually allocated to the concrete. The distribution of the load takes place in accordance with the elastic properties of the materials, so that if the modular ratio (referred to above) is 15, each square inch of cross section of main steel rod will bear 15 times as much load as a square inch of concrete. Thus if the cross section of a particular column had 300 sq.in. of concrete and 10 sq.in. of steel, the steel would carry as much as 10 x 15 = 150 sq.in. of concrete and would therefore carry half as much as the actual concrete or one-third of the total load. If the average working stress on such a column were fixed at 500lb. per sq.in. the capacity of the column for sustaining load would be ascertained thus:—

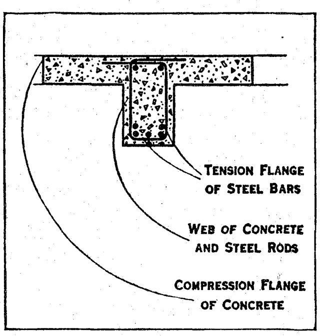

FIG. 4.—CROSS-SECTION OF CONCRETE BEAM INTEGRAL WITH FLOOR SLAB

Concrete	300×500	=150,000lb.
Steel	10×50×500=	75,000lb.
	Total	225,000lb.
		or 100 tons.

It is seldom possible to arrange that columns shall be loaded uniformly over their cross section in the manner assumed in the foregoing simple calculation. In actual building construction they are usually employed to support ferro-concrete floors in a monolithic construction whereby the bending of the floor beams induces bending effects also in the columns, which must be taken into consideration along with the loads in determining the cross sections required. Fig. 7 is a perspective section showing a typical construction in a building where the columns support main beams which in turn carry a series of subsidiary beams over which a slab floor is formed. It is readily understood that considerable labour is involved in fabricating and supporting the moulds for the beams in a construction of this type, and efforts at simplification have resulted in patented floors of the flat slab type in which all beams projecting below the floor slab are dispensed with and a thicker floor slab is supported directly on the columns through large circular or square capitals. Such a floor is usually reinforced by several systems of rods radiating from the columns and disposed near the under surface of the slab in the central portions of floor panels and near the top where they pass over the capitals. The design of floors of this type is based on approximate theory controlled by the results of stress measurements in tests of actual floors. The method has hitherto found little application in Britain, where much more use has been made of light flat-ceilinged floors having in their lower part rows of hollow tile blocks set so as to leave intermediate spaces for the formation of narrow reinforced beams, the floor being completed by a continuous concrete layer placed over the tiles and beams. Floors of this type are well adapted for filling in the panels between the main floor beams of structural steel-framed buildings, and have the advantages of lightness and good insulating qualities, while a plaster ceiling can be applied to the grooved soffits of the tiles.

Foundations.—Reinforced concrete construction is adapted to varied uses in foundation work. Thus, retaining walls of ample strength can be readily constructed in places where there is no room for a wall of mass concrete. Heavy columns can be supported in a relatively thin but wide-spread foundation of reinforced concrete with great saving in weight, volume and depth of construction, as compared with mass concrete. On weak ground, a complete layer of light reinforced concrete in the shape of a plain or ribbed slab may be provided to distribute the entire load over

the whole basement area of a structure in an economical and efficient manner unattainable with other methods of construction.

Ferro-concrete piles have largely superseded timber piles as a means of transmitting heavy loads down through layers of weak material to a firm stratum of ground, without the necessity for deep excavation. They are usually made of one or other of the types of column section shown in fig. 6, and are manufactured in a horizontal position in moulds laid out on a prepared floor. A fine concrete mixture of the order of $1 : 1\frac{1}{2} : 3$ is desirable for piles, to enable them to withstand the severe stresses produced in handling and driving with a heavy hammer, and a still richer mixture is of advantage for marine work. When ordinary Portland cement is used piles will normally be fit for driving in 30 days; if first quality rapid hardening Portland cement is used the piles may be driven at seven days, and with the use of "ciment fondu" they may be driven when 24 hours old. Concrete piles require to be driven with a heavy hammer which for satisfactory results should weigh at least half as much as the pile. A steel helmet or collar fitted over the head of the pile receives the strokes of the hammer and transmits them to the pile head through a cushioning layer of canvas or rope. Fig. 8 shows the method of pile driving in progress for the foundations of a large power station where 6,000 concrete piles from 25ft. to 46ft. long were used. A close wall of piling driven from the surface can be readily provided in soft or wet ground in many cases where the construction of an ordinary wall within a deep timbered trench would be prohibitive owing to excessive difficulty and cost. The special piles used for such work are known as "sheet piles" and are formed with bevelled points and grooved ends so that they drive close together in a regular line. A satisfactory form has semi-circular grooves at each end and a short projecting tongue on the cast-iron

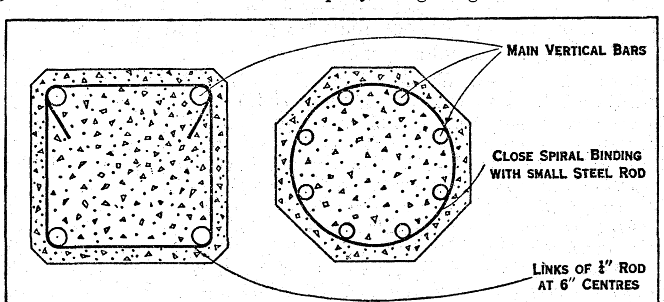

FIG. 6.—TYPICAL SECTIONS OF CONCRETE COLUMN
Left, a square column with four main vertical rods and a binding of separate links. Right, an octagonal column with eight main vertical rods and a continuous spiral binding

point which engages with the groove on the last driven pile, while the upper end may be held to line between timber walings during the driving. The circular hole formed by the grooves of the meeting piles is filled with cement mortar after being cleaned out with a water jet. This type of pile is shown in fig. 8 which also indicates the restricted driving head which is provided to enable the driving helmet to pass the last driven pile.

Caissons and Floating Craft.—An important development in subaqueous foundation work, such as dock walls, jetties, breakwaters and bridge piers, consists in the employment of reinforced concrete caissons of rectangular, cylindrical or other form which may be constructed in dry dock or on a staging on dry land, then launched or floated out, towed to the site, and deposited in position on a bed prepared by dredging or by divers. Such caissons form a permanent part of the construction and are generally used as a working base for further operations of sinking downwards and building upwards, the top being kept always above water. Sinking

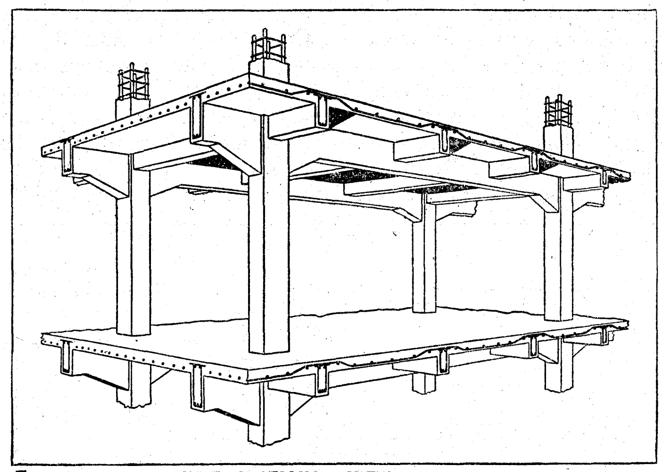

FIG. 7.—PERSPECTIVE SECTIONAL VIEW OF REINFORCED CONCRETE STRUCTURE, SHOWING COLUMNS, BEAMS AND FLOOR SLABS

downwards through suitable materials may be effected by grabbing through open wells in the interior of the caisson, while for difficult cases the excavation may be carried on by men working under compressed air. Large concrete caissons have been applied in the construction of the upper portions of breakwaters as at Valparaiso and elsewhere. In the Oswald street bridge at Glasgow cylindrical caissons 20ft. in diameter were used for the foundations of the piers. These caissons were constructed on a staging ashore, fitted with a false bottom, lowered into the water, floated out to position, deposited on the prepared bed, and after removal of the temporary bottom, sunk to the necessary depth by grabbing and excavation inside, the pier on top of a group of caissons being built up as the sinking proceeded.

Concrete Ships.—The results of the construction of reinforced concrete cargo vessels at the close of the World War were satisfactory and indeed surprising as regards watertightness, main longitudinal and transverse strength and lightness of construction. The hull weight in careful design was less than that of a wooden vessel, though somewhat greater than that of a steel hull. The principal disadvantage lay in the relative tenderness of the thin skin construction under the bumping and rubbing to which a vessel is often subject when in port and when touching ground. The results were instructive as regards the possibilities of carrying out light watertight concrete constructions with rich concrete of small aggregate without the addition of any special waterproofing material and with very fine limits of cover of concrete and spacing of bars. In Great Britain, in addition to numerous barges and steam tugs, a few self-propelled cargo vessels were constructed, the principal being the "Armistice" of about 1,100 tons dead weight which at the beginning of 1928 had been in continuous service for eight years.

Roads.—Concrete, either plain or containing a mesh of reinforcement, has been used for many years as a foundation layer for roads subject to heavy traffic, particularly in cities. A more recent development, to some extent still in the experimental stage, is its use to form the finished road surface. Such use has been rendered practicable by great improvement in the quality of cement and increased knowledge of the methods of attaining dense wear-resisting concrete. The principal requirements are: (*a*) Adequate strength to sustain the heaviest loads imposed by the traffic and distribute them on to the ground. This is a matter of the design of a plain or reinforced slab of sufficient strength. (*b*) Resistance to abrasion. This is dependent on quality of concrete, and satisfactory results can be obtained when aggregate and sand of the hardest and most wear-resisting nature, such as quartz, granite or flint, are used in properly graded proportions with a somewhat rich mixture of the best cement and no avoidable excess of mixing water. Particular care is also required to see that the surface is not exposed to the sun or dry winds during the first week or two after laying, as otherwise perfect setting and hardening will be prevented by evaporation of water. A coating of sand two or three inches thick, kept damp by frequent spraying, forms a useful protection during the period of curing. (*c*) Adequate precautions to prevent cracking. Cracking due to shrinkage in large flat areas of concrete is unavoidable, and large, unsightly cracks are most readily avoided by laying the concrete in bays with construction joints arranged on definite lines. In one method alternate transverse strips are laid and allowed to set, and the intermediate bays are then filled in. In another method the concrete is laid in two or more longitudinal strips of a maximum width

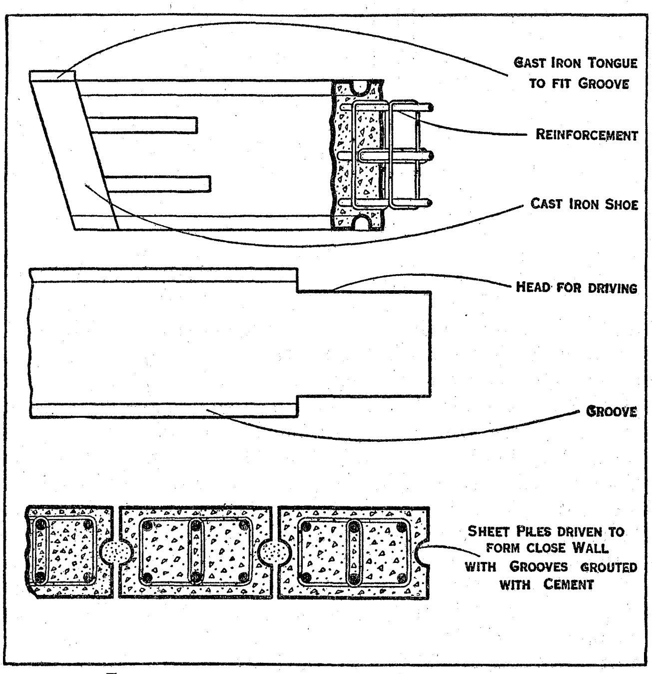

FIG. 8.—REINFORCED CONCRETE SHEET PILING
Upper, point of pile fitted with sloping iron shoe; centre, head of pile restricted in width to receive the driving helmet; lower, cross-section through row of piles driven vertically to form a close wall of concrete in the ground

of about 15ft. The length of a strip may be about 25 to 50ft. according as the concrete is plain or reinforced.

Bridges and Arches.—Bridges of moderate span may be formed of simple beams and slabs, but the field for this class of construction is limited by the rapidly increasing deadweight of the structure itself. The particular form of bridgework for which ferro-concrete is pre-eminently suited is arch construction which compels consideration wherever abutment and headroom conditions are suitable and the span is not small. The particular advantage of the arch is that a single main member serves to carry the load as compared with two main members and a web system in the case of a beam or truss. Further, the arch has the economical advantage that the thrust is principally taken by concrete, which is cheaper for this purpose than steel, and in large arches only a relatively small proportion of reinforcement is required to withstand such tensile stresses as may develop in consequence of irregular distribution of live load and the effects of shrinkage, temperature and rib-shortening in the concrete. The arch form, in addition, lends itself to the attainment of good appearance. The largest arch bridge completed in 1928 is the road bridge of 432ft. span across the Seine at St. Pierre du Vauvray, France. Whereas formerly 400ft. was looked on as being near the practicable limit for a concrete arch, recent developments have greatly extended the limits, and completely worked-out projects are now in existence for more than one bridge with spans of about 600ft., while spans of 1,000ft. do not appear to be unattainable.

Hydraulic Works.—There has been rapid extension in the use of ferro-concrete in all classes of hydraulic construction (*see* AQUEDUCTS and DAMS). It is employed for all classes of tank construction, including underground covered tanks, tanks erected on the ground and tanks supported on high towers. For the latter class a circular form is usually most appropriate with circumferential hoop reinforcement to resist the bursting effect of the water pressure on the sides. Where water pressure has to be resisted a rich concrete mixture not leaner than $1 : 1\frac{1}{2} : 3$ is called for, and an internal rendering of cement mortar will give added security against percolation. It is also of great importance that the risk of formation of cracks should be eliminated as far as practicable, and consideration of the elastic co-operation of the materials and the desirability of keeping the actual tensile stress on the concrete below its rupture value lead to the employment of low tensile stresses on the steel. Satisfactory results may be expected when the sections of concrete and steel are suitably proportioned and the stress on the steel, when the latter is considered as taking the whole of the tension, is limited to about 10,000lb. per sq.in. The reinforcement must be consistently proportioned throughout and be without sudden breaks in the quantity or arrangement. Surfaces of concrete do not lend themselves very readily to satisfactory architectural treatment, so that in many fine buildings the supporting framework of reinforced concrete is entirely hidden behind facework of masonry or other material. Good effects in buildings can be attained when the visible concrete is well finished and confined to well-proportioned and suitably lined vertical and horizontal bands of the framework, the rest of the elevation being formed of panelling and face-work of other materials. In bridges principal reliance must be placed on satisfactory form and proportions combined with very careful work in constructing and setting the moulds which form the exposed surfaces. Parapets and pillars of good finish and appearance may be pre-cast in small pieces in carefully finished moulds, preferably of metal.

CONCRETION, in petrology, a name applied to nodular or irregularly shaped masses of various size occurring in a great variety of sedimentary rocks, differing in composition from the main mass of the rock, and in most cases obviously formed by some process which ensued after the rock was deposited. As these bodies present so many variations in composition and structure, it will conduce to clearness if some of the commonest be briefly described. In sandstones there are often hard rounded lumps, which separate out when the rock is broken or weathered. They are mostly siliceous, but sometimes calcareous, and may differ very little in general appearance from the bulk of the sandstone. Through them the bedding passes uninterrupted, thus showing that they are not pebbles; often in their centres shells or fragments of plants are found. Argillaceous sandstones and flagstones very frequently contain "clay galls" or concretionary lumps richer in clay than the remainder of the rock. Nodules of pyrite and marcasite are common in many clays, sandstones and marls. Their outer surfaces are tuberculate; internally they commonly have a radiate fibrous structure. Usually they are covered with a dark brown crust of limonite produced by weathering; occasionally imperfect crystalline faces may bound them. Not infrequently (*e.g.,* in the Gault) these pyritous nodules contain altered fossils.

Another type of concretion, very abundant in many clays and shales, is the "septarian nodule." These are usually flattened, disk-shaped or ovoid, often lobulate externally like the surface of a kidney. When split open they prove to be traversed by a network of cracks, which are usually filled with calcite and other minerals. These white infillings of the fissures resemble partitions; hence the name from the Latin *septum,* a partition. Sometimes the cracks are partly empty. They vary up to ½in. in breadth, and are best seen when the nodule is cut through with a saw. These concretions may be calcareous or may consist of carbonate of iron. The former are common in some beds of the London Clay, and were formerly used for making cement. The clay-ironstone nodules or sphaerosiderites are very abundant in some Carboniferous shales, and have served as iron ores; some of the largest are 3ft. in diameter, and in the centre fossils are often found, *e.g.,* coprolites, pieces of plants, fish teeth and scales. Phosphatic concretions are often present in certain limestones, clays, shelly sands, and marls.

Another very important series of concretionary structures are the flint nodules which occur in chalk, and the patches and bands of chert which are found in limestones. Flints consist of dark-coloured cryptocrystalline silica. They weather grey or white by the removal of their more soluble portions by percolating water. Their shapes are exceedingly varied, and often they are studded with tubercules and nodosities. They sometimes have internal cavities and very frequently contain shells of echinoderms, molluscs, etc., partly or entirely replaced by silica, but preserving their original forms. Chert occurs in bands and tabular masses rather than in nodules; it often replaces considerable portions of a bed of limestone (as in the Carboniferous limestone). Corals and other fossils frequently occur in chert, and when sliced and microscopically examined both flint and chert often show silicified foraminifera, polyzoa, etc., and sponge spicules.

These examples will indicate the great variety of substances which may give rise to concretions, which seem to arise from the tendency of chemical compounds to be slowly dissolved by interstitial water, either while the deposit is unconsolidated or at a later period; it is highly probable that such solutions are usually in the colloidal state. Certain nuclei, present in the rock, then determine reprecipitation of these solutions, and the deposit once begun goes on till either the supply of material for growth is exhausted, or the physical character of the bed is changed by pressure and consolidation till it is no longer favourable to further accretion. The process resembles the growth of a crystal in a solution by slowly attracting to itself molecules of suitable nature from the surrounding medium; but in the majority of cases it is not the crystalline forces, or not these alone, which attract the particles. The structure of a flint, for example, shows that the material had so little tendency to crystallize that it remained permanently in cryptocrystalline or subcrystalline state. That the concretions grew in the solid sediment is proved by the manner in which lines of bedding pass through them and not round them. (J. S. F.)

CONCUBINAGE. The state of a man and woman cohabiting as married persons without the full sanctions of legal marriage. (Lat. *concubina,* a concubine; from *con-,* with, and *cubare,* to lie.)

In early historical times, when marriage laws had scarcely advanced beyond the purely customary stage, the concubine was definitely recognized as a sort of inferior wife, differing from those of the first rank mainly by the absence of permanent guarantees. The history of Abraham's family shows us clearly that the concubine might be dismissed at any time, and her children were liable to be cast off equally summarily with gifts, in order to leave the inheritance free for the wife's sons (Genesis xxi. 9 ff., xxv. 5 ff.).

Roman Law.—The Roman law recognized two classes of legal marriage: (1) with the definite public ceremonies of *confarreatio* or *coemptio,* and (2) without any public form whatever and resting merely on the *affectio maritalis, i.e.* the fixed intention of taking a particular woman as a permanent spouse. The difference between English and Scottish law, which once made "Gretna Green marriages" so frequent, is due to the fact that Scotland adopted the Roman law which on this particular point was followed by the whole mediaeval Church.

Next to these strictly lawful marriages came concubinage as a recognized legal status, so long as the two parties were not married and had no other concubines. It differed from the formless marriage in the absence (1) of *affectio maritalis,* and therefore (2) of full conjugal rights. For instance, the concubine was not raised, like the wife, to her husband's rank, nor were her children legitimate, though they enjoyed legal rights forbidden to mere bastards, *e.g.,* the father was bound to maintain them and to leave them (in the absence of legitimate children) one-sixth of his property; moreover, they might be fully legitimated by the subsequent marriage of their parents. In the East, the Emperor Leo the Philosopher (d. 911) insisted on formal marriage as the only legal status; but in the Western Empire concubinage was still recognized even by the Christian emperors. The early Christians had naturally preferred the formless marriage of the Roman law as being free from all taint of pagan idolatry; and the ecclesiastical authorities recognized concubinage also. The first Council of Toledo (398) bids the faithful restrict himself "to a single wife or concubine, as it shall please him"; and there is a similar canon of the Roman synod held by Pope Eugenius II. in 826. Gratian, in the 12th century, tried to explain this away by assuming that the concubinage here referred to meant a formless marriage; but in 398 a church council can scarcely so have misused the technical terms of the then current civil law.

Even as late as the Roman councils of 1052 and 1063, the suspension from communion of a layman who had a wife and a concubine *at the same time* implies that mere concubinage was tolerated. It was also recognized by many early civil codes. In Germany "left-handed" or "morganatic" marriages were allowed by the Salic law between nobles and women of lower rank. In different States of Spain the laws of the later middle ages recognized concubinage under the name of *barragania,* the contract being lifelong, the woman obtaining by it a right to maintenance during life, and sometimes also to part of the succession, and the sons ranking as nobles if their father was a noble. In Iceland, the concubine was recognized in addition to the lawful wife, though it was forbidden that they should dwell in the same house. The Norwegian law of the later middle ages provided definitely that in default of legitimate sons, the kingdom should descend to illegitimates.

Handfasting.—In the Danish code of Valdemar II., which was in force from 1280 to 1683, it was provided that a concubine kept openly for three years shall thereby become a legal wife; this was the custom of *hand vesten,* the "handfasting" of the English and Scottish borders, which appears in Scott's *Monastery.* In Scotland, the laws of William the Lion (d. 1214) speak of concubinage as a recognized institution; and, in the same century, the great English legist Bracton treats the "concubina *legitima*" as entitled to certain rights. There seems to have been at times a pardonable confusion between some quasi-legitimate unions and those marriages by mere word of mouth, without ecclesiastical or other ceremonies, which the Church, after some natural hesitation, pronounced to be valid. Thus, in the case of Richard d'Anesty, decided by papal rescript in 1143, "a marriage solemnly celebrated in church, a marriage of which a child had been born, was set aside as null in favour of an earlier marriage constituted by a mere exchange of consenting words." The great mediaeval canon lawyer Lyndwood illustrates the difficulty of distinguishing, even as late as the middle of the 15th century, between concubinage and a clandestine, though legal, marriage. He falls back on the definition of an earlier canonist that if the woman eats out of the same dish as the man, and if he takes her to church, she may be presumed to be his wife; if, however, he sends her to draw water and dresses her in vile clothing, she is probably a concubine.

Clerical Celibacy and Concubinage.—Another and more serious confusion between concubinage and marriage was caused by the gradual enforcement of clerical celibacy (*see* CELIBACY). During the bitter conflict between laws which forbade sacerdotal marriages and long custom which had permitted them, it was natural that the legislators and the ascetic party generally should studiously speak of the priests' wives as concubines, and do all in their power to reduce them to this position. This very naturally resulted in a too frequent substitution of clerical concubinage for marriage; and the resultant evils form one of the commonest themes of complaint in church councils of the later middle ages. It may be gathered from the Dominican C. L. Richard's *Analysis Conciliorum* (vol. ii., 1778) that there were more than 110 such complaints in councils and synods between the years 1009 and 1528. Dr. Rashdall (*Universities of Europe in the Middle Ages*) points out that a master of the University of Prague, in 1499, complained openly to the authorities against a bachelor for assaulting his concubine.

Concubinage in general was struck at by the concordat between the Pope Leo X., and Francis I. of France in 1516; and the Council of Trent, while insisting on far more stringent conditions for lawful marriage than those which had prevailed, imposed heavy penalties on concubinage and appealed to the secular arm for help against contumacious offenders (Sessio xxiv. cap. 8).

See also J. A. and Aug. Theiner, *Einfuhrung d. erzwungenen Ehelosigkeit* (1828, re-issued in 1845); Du Cange's *Glossarium, s.v. Concubina*, the article "Concubinat" in Wetzer and Welte's *Kirchenlexikon* (2nd ed., Freiburg i/B., 1884), and Dr. H. C. Lea's *History of Sacerdotal Celibacy* (3rd ed., 1907). (G. G. C.)

CONDÉ, PRINCES OF. The French title of prince of Condé, assumed from the ancient town of Condé-sur-l'Escaut, was borne by a branch of the house of Bourbon. The first who assumed it was the famous Huguenot leader, Louis de Bourbon (*see* below), the fifth son of Charles de Bourbon, duke of Vendôme. His son, HENRY, prince of Condé (1552–1588), also belonged to the Huguenot party. Fleeing to Germany he raised a small army with which in 1575 he joined Alençon. He became leader of the Huguenots, but after several years' fighting was taken prisoner of war. Not long after he died of poison, administered, according to the belief of his contemporaries, by his wife, Catherine de la Trémouille. This event, among others, awoke strong suspicions as to the legitimacy of his heir and namesake, HENRY, prince of Condé (1588–1646). In 1609 King Henry IV. arranged for him a marriage with Charlotte de Montmorency, whom shortly after Condé was obliged to save from the king's persistent gallantry by a hasty flight, first to Spain and then to Italy. On the death of Henry, Condé returned to France, and intrigued against the regent, Marie de' Medici; but he was seized, and imprisoned for three years (1616–19). His wife elected to share his captivity. On his release Condé strove to blot out the memory of the Huguenot connections of his house by affecting the greatest zeal against Protestants. His son Louis, the great Condé, is separately noticed.

The next in succession was HENRY JULES, prince of Condé (1643–1709), son of the great Condé and of Claire Clémence de Maillé-Brézé, niece of Richelieu. His grandson, Louis Henry, duke of Bourbon (1692–1740), Louis XV.'s minister, did not assume the title of prince of Condé which properly belonged to him.

The son of the duke of Bourbon, LOUIS JOSEPH, prince of Condé (1736–1818), distinguished himself in the Seven Years War, and most of all by his victory at Johannesburg. As governor of Burgundy he improved the industries and means of communication of that province. At the Revolution he took up arms in behalf of the king, became commander of the "army of Condé," and fought in conjunction with the Austrians till the peace of Campo Formio in 1797, being during the last year in the pay of England. He then served the emperor of Russia in Poland, and after that (1800) returned into the pay of England, and fought in Bavaria. In 1800 Condé arrived in England, where he resided for several years. On the restoration of Louis XVIII. he returned to France. He died in Paris in 1818. He wrote *Essai sur la vie du grand Condé* (1798).

LOUIS HENRY JOSEPH, duke of Bourbon (1756–1830), son of the last named, was the last prince of Condé. At the Revolution he fought with the army of the *emigrés* in Liège. Between the return of Napoleon from Elba and the battle of Waterloo, he headed an abortive royalist rising in La Vendée (*see* VENDÉE, WARS OF THE). On Aug. 27, 1830, he was found hanged.

See Muret, *L'Histoire de l'armée de Condé;* Chamballand, *Vie de Louis Joseph, prince de Condé;* Crétineau-Joly, *Histoire des trois derniers princes de la maison de Condé;* and *Histoire des princes de Condé*, by the duc d'Aumale (translated by R. B. Borthwick, 1872).

CONDE, JOSÉ ANTONIO (1766–1820), Spanish Orientalist, was born at Peraleja (Cuenca), and educated at the University of Alcalá. His *Historia de la Dominación de los Árabes en España* was published in 1820–21. Only the first volume was corrected by the author, the other two being compiled from his manuscript by Juan Tineo. This work was translated into German (1824–25), French (1825) and English (1854). Conde's pretensions to scholarship have been severely criticized by Dozy, and his history is now discredited.

CONDÉ, LOUIS DE BOURBON, PRINCE OF (1530–1569), fifth son of Charles de Bourbon, duke of Vendôme, younger brother of Antoine, king of Navarre (1518–62), was the first of the famous house of Condé. After his father's death in 1537 Louis was educated in the principles of the reformed religion. Brave though deformed, gay but extremely poor for his rank, Condé was led by his ambition to a military career. He fought with distinction in Piedmont under Marshal de Brissac; in 1552 he forced his way with reinforcements into Metz, then besieged by Charles V.; he led several brilliant sorties from that town; and in 1554 commanded the light cavalry on the Meuse against Charles. In 1557 he was present at the battle of St. Quentin. But descendants of the constable de Bourbon were still looked upon with suspicion in the French court, and Condé's services were ignored. The court designed to reduce his narrow means still further by despatching him upon a costly mission to Philip II. of Spain. His personal griefs thus combined with his religious views to force upon him a rôle of political opposition. He was concerned in the conspiracy of Amboise, which aimed at forcing from the king the recognition of the reformed religion. He was consequently condemned to death, and was only saved by the decease of Francis II. At the accession of the boy-king Charles IX., the policy of the court was changed, and Condé received from Catherine de Medici the government of Picardy. But the struggle between the Catholics and the Huguenots soon began once more, and henceforward the career of Condé is the story of the wars of religion (*see* FRANCE: *History*). He was the military as well as the political chief of the Huguenot party, and displayed the highest generalship on many occasions, and notably at the battle of St. Denis. At the battle of Jarnac, with only 400 horsemen, Condé rashly charged the whole Catholic army. Worn out with fighting, he at last gave up his sword, and a Catholic officer named Montesquiou treacherously shot him through the head on March 13, 1569.

CONDÉ, LOUIS II. DE BOURBON, PRINCE OF (1621–1686), called the great Condé, son of Henry, prince of Condé, and Charlotte de Montmorency, was born in Paris on Sept. 8, 1621, and educated by the Jesuits at Bourges. The duc d'Enghien, as he was styled during his father's lifetime, served in the campaigns of 1640 and 1641 in northern France, and at twenty-two, was compelled, for political reasons, to marry Richelieu's niece, Claire Clémence de Maillé-Brézé, a child of thirteen. He was passionately attached to Marthe du Vigean, and resented his forced marriage. He was present with Richelieu during the dangerous plot of Cinq-Mars, and afterwards fought in the siege of Perpignan (1642).

In 1643 Enghien was appointed to command against the Spaniards in northern France and at the battle of Rocroy (May 18) at the age of 22 won his place amongst the great captains of modern times. Enghien returned to Paris in triumph, and in gallantry and intrigues strove to forget his hated marriage. In 1644 he was sent to Germany with reinforcements for Turenne, who was hard pressed, and took command of the whole army. The battle of Freiburg (Aug.) was desperately contested, but in the end the French army won a great victory over the Bavarians and Imperialists under Count Mercy. The summer campaign of 1645 opened with the defeat of Turenne by Mercy, but this was retrieved in the brilliant victory of Nördlingen, in which Mercy was killed, and Enghien himself received several serious wounds. The capture of Philipsburg was the most important of his other achievements during this campaign. In 1646 Enghien served under the duke of Orleans in Flanders, and when, after the capture of Mardyck, Orleans returned to Paris, Enghien, left in command, captured Dunkirk (Oct. 11th). (*See* THIRTY YEARS' WAR.)

It was in this year that the old prince of Condé died. The enormous power that fell into the hands of his successor, together with his own military renown, alarmed the court. Condé himself held Burgundy, Berry, the marches of Lorraine, and other important territories; his brother Conti held Champagne, his brother-in-law, Longueville, Normandy. The government, therefore, determined to permit no increase of his already overgrown authority, and Mazarin determined at once to find him employment and to tarnish his fame as a general. He was sent to lead the revolted Catalans. Ill-supported, he was forced to raise the siege of Lerida, and returned home in bitter indignation. In 1648, however, he received the command in the Low Countries; and at Lens (Aug. 19) a battle took place, which ended in a victory that fully restored his prestige.

In September of the same year Condé was recalled to court, for the regent Anne of Austria required his support. Influenced by the fact of his royal birth and by his arrogant scorn for the bourgeois, Condé lent himself to the court party, and finally, after much hesitation, he consented to lead the army which was to reduce Paris (Jan. 1649).

On his side, insufficient as were his forces, the war was carried on with vigour, but the political situation inclined both parties to peace, which was made at Rueil on March 20 (*see* FRONDE, THE). But Condé soon became estranged from the court. His own pride and ambition, and the personal resentment of Anne caused the sudden arrest of Condé, Conti and Longueville on Jan. 18, 1650. Others, including Turenne and his brother the duke of Bouillon, made their escape. Vigorous efforts for the release of the princes were made. The women of the family were now its heroes. The young princess of Condé, having collected an army, obtained entrance into Bordeaux. But the delivery of the princes was brought about in the end by the junction of the old Fronde (the party of the parlement and of Cardinal de Retz) and the new Fronde (the party of the Condés); and Anne was at last, in February 1651, forced to liberate them from their prison at Havre. A later shifting of parties left Condé and the new Fronde isolated. With the court and the old Fronde in alliance against him, Condé made common cause with the Spaniards, who were at war with France. At the battle of the Faubourg St. Antoine (Sept. 1651) Condé and Turenne, two of the foremost captains of the age, measured their strength (July 2, 1652), and the army of the prince was only saved when La Grande Mademoiselle, daughter of the duke of Orleans, persuaded the Parisians to admit him within their gates and to turn the cannon of the Bastille on Turenne's army. Paris underwent a new investment, which ended in the flight of Condé to the Spanish army (Sept. 1652), and thenceforward, up to the peace, he was in open arms against France, and held high command in the army of Spain. But his genius found little scope in the cumbrous and antiquated system of war practised by the Spaniards, and his disastrous defeat at the Dunes near Dunkirk (June 14, 1658), in which an English contingent of Cromwell's veterans took part on the side of Turenne, led Spain to open negotiations for peace. After the peace of the Pyrenees in 1659, Condé obtained his pardon (January 1660) from Louis XIV., who thought him less dangerous as a subject than as possessor of the independent sovereignty of Luxemburg, which had been offered him by Spain as a reward for his services.

Condé now accepted, and loyally maintained henceforth, the position of a chief subordinate, even subservient, to a masterful sovereign. At Chantilly he gathered round him a brilliant company, which included many men of genius—Molière, Racine, Boileau, La Fontaine, Nicole, Bourdaloue and Bossuet. Proposals for the election, at first of Condé's son Enghien, and afterwards of Condé himself, to the throne of Poland, were eventually vetoed (1674) by Louis XIV., and John Sobieski was elected. In 1668 Condé proposed to Louvois, the minister of war, a plan for seizing Franche-Comté, the execution of which was entrusted to him, and successfully carried out. With Turenne he was the principal French commander in the campaign of 1672 against the Dutch. At the forcing of the Rhine passage at Tollhuis (June 12) he received a severe wound, after which he commanded in Alsace against the Imperialists. In 1673 he was again engaged in the Low Countries, and in 1674 he fought his last great battle at Seneff against the prince of Orange (Aug. 11). His last campaign was that of 1675 on the Rhine, where the army had been deprived of its general by the death of Turenne; and where by his careful and methodical strategy he repelled the invasion of the Imperial army of Montecucculi. He spent the last eleven years of his life in retirement at Chantilly, where he specially sought the companionship of Bourdaloue, Nicole and Bossuet, and devoted himself to religious exercises. He died on Nov. 11, 1686.

His fame rests on his military genius. Unlike his great rival Turenne, Condé was equally brilliant in his first battle and in his last. The one failure of his generalship was in the Spanish Fronde, and in this everything united to thwart his genius. In private life he was harsh and unamiable, seeking only the gratification of his own pleasures and desires. Condé's unhappy wife had some years before her husband's death been banished to Châteauroux on a trumped-up charge of infidelity. Condé placed her in confinement, and in his last letter to the king requested him never to allow her to be released.

CONDÉ, the name of some 20 villages in France. The important ones are: Condé-en-Brie (Lat. *Condetum*) a seat of a principality in the middle ages; Condé-sur-Aisne (*Condatus*) given in 870 by Charles the Bold to the abbey of St. Oven at Rouen, and which also gave its name to a seigniory during the middle ages; Condé-sur-Marne (*Condate*) has a fine church with Romanesque tower, and was once a place of some importance. Condé-sur-l'Escaut in the department of Nord at the junction of the canals of the Scheldt and the Condé-Mons (pop. [1936] 6,288), lies 7 mi. north by east of Valenciennes and 2 mi. from the Belgian frontier. Condé (*Condate*) dates from the late Roman period. It passed into French possession by the Treaty of Nijmwegen (1678). It was taken by the Austrians (1793) and in 1815 it again fell to the allies. It was from this place that the princes of Condé (*q.v.*) took their title (*see* P. L. Perron-Gélineau, *Condé ancien et moderne* [Nantes, 1886]). There is also a town in the department of Calvados, 33 m. south-south-west of Caen, called Condé-sur-Noireau (*q.v.*), important for cotton-spinning and weaving.

CONDENSATION: *see* METALLURGY.

CONDENSATION OF GASES: *see* LIQUEFACTION OF GASES.

CONDENSATION TRAILS are artificial clouds, usually of small ice crystals, formed in the wakes of aircraft. Such trails are most often formed at heights of 25,000 ft. and above, but occasionally at much lower levels. Condensation trails are more readily visible than the aeroplane and therefore favour the defense and reduce surprise in military missions.

Although condensation trails occasionally result from the mechanical mixing of two adjacent moist air strata of different temperatures, they are usually due to the water vapour contained in the exhaust gases. The engine discharges somewhat more water vapour than the weight of gasoline consumed. At low temperatures this provides sufficient water vapour to supersaturate the air and form a cloud. The exhaust gases also supply a copious number of nuclei of condensation.

The cloud will persist only if the relative humidity is initially high, so that moist air and low temperatures are the favourable conditions. As the aeroplane approaches its ceiling, the power output and hence the vapour output decrease and condensation trails become less likely. (*See* METEOROLOGY; CLOUDS.)

CONDENSED MILK: *see* FOOD PRESERVATION.

CONDENSER, an instrument for compressing air, gas, steam, or a device for concentrating electricity (*see* p. 216). Condenser also is used in textile work to denote an apparatus which doffs the web from the carding machines and separates it into slivers of soft yarn. It is also used in photography as a lens to produce powerful illumination of a slide or other object which is being viewed. A lantern condenser causes light rays to converge after passing through the slide, so that they may also pass through the remaining lenses, which focus the picture on the screen.

Perhaps the best known type of condenser is that used in connection with steam. James Watt in 1769 first patented a device for the condensation of steam in a vessel separate from the steam-cylinder. In the early atmospheric engine a vertical cylinder was open at the top, and the piston was connected by a chain to a pivoted beam, the other end of which worked a pump rod. On admission of steam the piston was pushed up to the top, then steam was turned off, and a spray of cold water thrown on to the piston. The steam in the cylinder condensed, creating a partial vacuum, with the consequence that the piston was forced down by atmospheric pressure, and became ready for another cycle. The great waste of power due to this alternate heating and cooling of the cylinder led Watt to invent the separate condenser, in which he closed the cylinder at each end, and jacketed

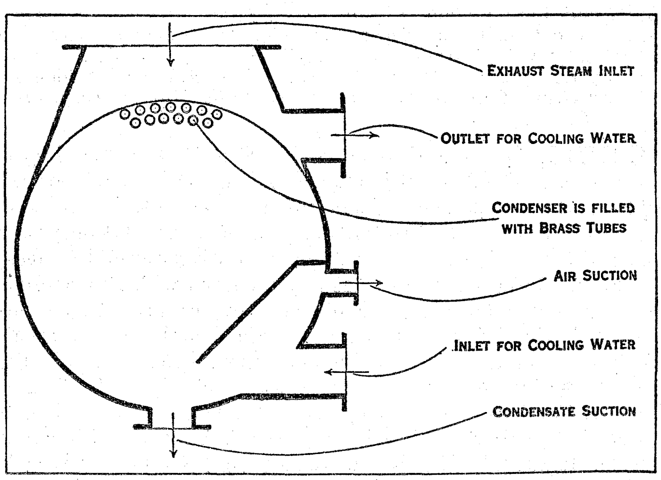

FIG. 1.—CROSS-SECTION OF A SURFACE CONDENSER, SHOWING THE MOVEMENT THROUGHOUT THE SYSTEM

The cooling water circulates through the tubes, and the exhaust steam from the engine or turbine, becoming condensed by contact with these cold surfaces, falls to the bottom

it, to conserve the heat. It will be apparent from this that the purpose of a condenser is to create a partial vacuum at the exhaust branch of a prime mover. The air pump improves this condition by removing air which has leaked into the system. The expansive properties of the steam in the cylinder or turbine are utilized to the best advantage. The vacuum is measured in inches of mercury, and the effect of increase in vacuum is very marked in the case of turbines; thus, an increase of from 27 in. to 29 in. has resulted in some cases in a saving of over 13% in steam consumption. For reciprocating steam engines it is not quite so important to attain a high vacuum, because of the limited volume of cylinder space for expansion. Steam condensers are divided into the two main classes of surface and jet condenser.

A surface condenser is a vessel filled with brass tubes, passing through plates near the ends; cooling water circulates through these tubes, and the exhaust steam being admitted becomes condensed by contact with the great number of cold surfaces, and falls to the bottom, being then the condensate, which goes from there into a reservoir termed a hot well, or is pumped direct to the boiler. The cooling water is dealt with in the manner explained under COOLING SYSTEMS. Improvements in the ordinary condenser (fig. 1) are made in several cases, the object being to expose a large area of tubes to the incoming steam. Regenerative condensers are designed so that the temperature of the condensate does not fall so much as usual; this reduces heat losses caused by the lower boiler-feed temperature.

In a jet condenser the steam and water mingle for the purpose of cooling. The jet condenser may be of three types; the barometric, siphon or ejector. The ejector condenser (fig. 2) is the simplest in design. A stream of cooling water is discharged down through a nozzle, and the steam enters a passage at right angles and is directed on to the water by the set of guides—direct condensation being thus effected. An evaporative condenser comprises a mass of tubes arranged upon a platform or roof; the steam passes through the numerous tubes, and the cooling water, trickling over their outsides, produces rapid evaporation of the water film and condensation of the steam. Condensers in gas-making practice cool the gas and remove all substances which are not permanent gases at normal temperatures. These include atmospheric condensers, which have the exteriors of the tubes through which the gas passes cooled by the air, and water condensers. The latter are supplied with a flow of water surrounding the gas tubes while in another class the water goes through tubes, and the gas around them. Water-cooling by flow or by submergence in a tank is also done in the case of ammonia and CO_2, in refrigerating plants. Condensers used in ammonia plants are classified as atmospheric, double-pipe and submerged. Other manufactures requiring the use of condensing apparatus are those of petroleum and perfumes.

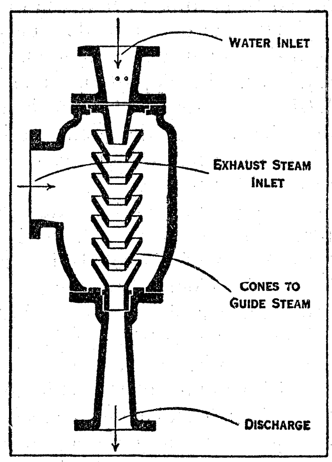

FIG. 2.—SECTION OF AN EJECTOR CONDENSER

The stream of cooling water rushes down through the cones and the exhaust steam entering at the side is directed on to the water, so becoming condensed

(F. H.)

CONDENSER (ELECTRICAL), a piece of electrical apparatus used originally solely for storing an electric charge, but now having many forms and diverse industrial and scientific applications. Until comparatively recent years the term condenser had been associated almost exclusively with the leyden jar, although the name was not used until some time after the discovery of the jar. It was first bestowed by Alessandro Volta (1745–1827) upon a different apparatus used by him in the course of his investigations upon atmospheric electricity. Volta's apparatus more resembled an electrophorus (*q.v.*), and was used as a condenser of variable capacity. At that time electricity was regarded as a fluid which could be condensed if the proper procedure were adopted, but it is now known that the action of a condenser is to store electricity by an accumulation of charges on the plates, electrodes or armatures of the condenser.

The electrical condenser is distinct in its properties from other electrical apparatus in that energy is stored in it in electrical form, and the energy which is passed into it during the charging process by connecting the condenser to a source of electromotive force is entirely or almost entirely returned again, when the condenser is discharged by connecting its plates or coatings by a wire. In the early days of electrical experiment in the 17th and 18th centuries many attempts were made to store up the "electric fire."

Leyden Jar.—The first real success in this direction was achieved by the discovery of the device subsequently called the leyden jar. This discovery was first made in October 1745 by Dean E. G. von Kleist of the cathedral of Kamin, who used a small apothecary's vial with a nail or piece of wire to make connection inside, the vial being held in the hand. By presenting the nail to the conductor of an electrical machine he found that the electricity passed into the vial as he showed by taking it into another room where it was possible to set fire to spirits of wine with the discharge spark, and to receive a shock by touching the nail. Some three months later, in Jan. 1746, Pieter van Musschenbroek, a professor in the University of Leyden, independently discovered the same phenomenon using a glass bottle filled with water and having an iron wire dipping into the water and projecting out through the cork so that it could be hung from a musket barrel suspended horizontally by silk threads. After electrifying the bottle, a violent shock could be obtained if the musket barrel and the jar were simultaneously grasped.

The leyden jar was in the succeeding years developed into various forms and put to many uses, both for purposes of science and amusement; and it is still used in laboratories, though the interest in it is largely historical. For many electrical experimental applications it forms a useful condenser which is not costly, but for most industrial applications it has been superseded by other forms of condenser having greater efficiency and other desirable electrical properties. The leyden jar of today consists of a wide-mouthed jar or bottle of good quality glass, as free as possible from bubbles or other irregularities and coated inside and outside with a layer of tinfoil extending over the bottom of the jar and for a distance up the side of one-half to two-thirds of the height of the jar. The exposed upper surface is generally coated with shellac or similar varnish to reduce surface leakage. The top of the jar is usually closed with a wooden stopper through which a brass rod is passed to make connection with the tinfoil. Various sizes of jars are in use, these giving different electrical capacity values—the electrical capacity of a condenser being the measure of its electrical size or, in other words, the measure of the charge it can store under the application of a given charging voltage.

Fundamental Units.—The fundamental unit of electrical capacity in the electrostatic system of measurement is the centimetre or abstatfarad (*see* ELECTRICITY), and this unit is employed to some extent in Europe, while an old unit of capacity, called after the leyden jar and equal to 1,000 cm., still has some adherents. The practical unit of capacity in terms of the workaday electrical units of the volt and the coulomb (one ampere is one coulomb per second) is called the farad, after Michael Faraday (*q.v.*), whose researches were so intimately associated with electrical discovery and who also carried out fundamental work on the dielectric of the condenser. This unit is rather large, so that for most purposes the microfarad (equal to one-millionth of a farad, *i.e.*, 10^{-6}F) is employed as the unit of measurement. For still smaller condensers, such for example as many of those employed in radio communication there is employed the still smaller unit, the micromicrofarad (equal to one billionth of a farad, *i.e.*, 10^{-12}F), convenient in order to avoid the use of very small fractions in expressing the capacity.

Construction and Properties.—The essential components of any form of condenser are: first, the metal plates, foils, or armatures forming the conducting connections or parts where the electric charges accumulate; and, second, the insulating dielectric (so designated by Faraday) which separates the plates. In the leyden jar the dielectric is the glass which separates the two tinfoil coatings, and the main differences between the jar and the more modern forms of condenser lie in the use of different dielectric materials, some being more suited for certain conditions than others. The most important dielectrics now in use in condensers are air, mica, paper impregnated with various other insulating materials, glass, ebonite, oil and certain cellulose compounds, such as celluloid and cellulose acetate. These are but a very few of the insulating materials which could possibly be used as condenser dielectrics, but they possess special properties fitting them for some particular application of the condensers. The dielectric properties of most importance in condenser construction are specific inductive capacity, or dielectric constant; dielectric strength; resistivity; and phase difference. The relative importance attachable to each of these depends upon the use to which the condenser is to be applied.

The first mentioned of these properties, specific inductive capacity, determines the capacity of a condenser of given physical dimensions. It is expressed as the ratio of the capacity of a condenser having the particular material as dielectric to the capacity of the same condenser, or of a condenser of exactly similar physical dimensions but having the plates separated by air only. The higher the value of this constant, therefore, the greater is the capacity of a condenser of given dimensions. The materials giving high values for the dielectric constant have, however, in many cases other harmful properties which prohibit their practical use in condensers. Most useful condenser dielectrics have a dielectric constant below 8, while insulating oil, and oil- or wax-impregnated paper dielectrics have values usually between 2 and 4.

The second property—dielectric strength—expresses the ability of a condenser to withstand the application to it of high voltages. When the voltage applied between the plates of a condenser is gradually increased the electric stress in the dielectric is increased also, until ultimately a value is reached at which the dielectric gives way—or breakdown occurs—and a discharge, generally in the form of a spark, passes through the material. The breakdown voltage per unit thickness of the material depends to some extent upon the thickness itself and upon the nature of the conducting electrodes that are applied to its surfaces. In general the breakdown voltage is relatively greater for the thinner sheets of the material, with the result that it is generally economical to subdivide high voltage condensers into a number of smaller elements, connected electrically in series, each element having a thinner dielectric adapted to withstand the appropriate fraction of the total voltage applied to the whole composite condenser.

The resistivity of the dielectric expresses a measure of the leakage or passage of electricity from one terminal to the other when voltage is applied. The property is of most interest for condensers which are subjected to steady or direct voltages. It is a quantity which is most commonly measured in connection with condenser dielectrics as a means of estimating the quality of the dielectric, not only from the point of view of the quality of the material itself but chiefly as a guide to the efficiency with which it has been freed from moisture. Minute traces of water, whether in the form of moisture condensed on the surfaces of the dielectric or actually absorbed into the pores of the material, bring about a very marked reduction of the resistivity, and such reduction is generally accompanied also by a marked decrease in the breakdown voltage, or dielectric strength of the substance.

The dielectric phase difference is a property which is encountered only when a condenser is subjected to alternating voltages, and it then expresses the departure of the condenser from the ideal. When a condenser is subjected to an alternating voltage there is a charging current flowing into it during all the time that the voltage across its terminals is increasing. This charging current falls to zero when the voltage reaches its maximum value, and during all the time that the voltage is decreasing a discharge current will flow out of the condenser, this falling to zero again when the voltage reaches its minimum value and is about to commence increasing again. Thus, if the applied voltage waveform is sinusoidal, the waveform of the current flowing in the circuit—made up of the successive charging and discharging currents—will likewise be sinusoidal, but there will be a phase displacement between the two, the current wave being 90° in advance of the voltage wave. In a condenser with an ideal or perfect dielectric—if such could be constructed—this phase displacement would be exactly 90° and no energy would be expended in the dielectric; but in all practical dielectrics a phenomenon known as electric absorption is observed, the effect of which is that the charging current does not cease at the instant that the voltage reaches a steady value, but persists for some time after in the form of a gradually decreasing absorption current. Likewise the discharge from most dielectrics does not cease immediately the applied voltage has been removed or has decreased to its steady minimum value, but it persists in the form of a gradually decreasing absorption discharge. Thus the zero points of the current waveform of the condenser subjected to an alternating voltage do not coincide in time with the instants of maximum and minimum value of the voltage waveform, but are delayed by a small fraction of a period. The phase displacement between current and voltage is thus very slightly less than 90°. The departure from exactly 90° is the phase difference. The amount of energy expended in the dielectric is directly proportional to the sine of this phase difference angle—or, since in almost all cases this difference is small, the losses become directly proportional to the phase difference itself. This quantity is sometimes also expressed as the power factor of the dielectric (numerically equal to the sine of the phase difference, or the cosine of the phase angle).

For many condenser dielectrics the phase difference increases with frequency, with the result that condensers employing these substances are unsuited for use in high frequency circuits. With some other materials, however, the increase is either small or negligible while in some a maximum value is reached in the ordinary range of practical frequencies so that there is relatively a reduction of losses at the higher or radio frequencies. This property is one which has a very considerable bearing upon the choice of condenser dielectric for any given use, since in practice so many condensers are required for use in alternating current circuits either of high or low frequency.

Types, Uses and Materials.—There are today many varieties of condensers, although the number of different dielectrics is limited. The wide variety of applications for which they are used, however, has involved the development of a correspondingly wide variety in designs produced primarily to fit the condenser for its particular application. In the field of radio communication alone many types of condensers have been produced from time to time, and are in common use for the different purposes for which condensers are needed both in transmitting and in receiving apparatus, the design of the condenser depending to a considerable extent upon the nature of the voltage to which it is to be subjected.

The chief practical uses to which the early Leyden jars were applied was in conjunction with wireless telegraphy apparatus, and a modification of the original jars is still occasionally used for such purposes. An improvement was introduced about 1904 by Moscicki in the form of elongated glass tubes with silvered coatings for the conductors, and a thickening of the glass adjacent to the edges of the metal coatings so as to reduce the intensity of the electric stress in the material at these points, and so to reduce the liability to breakdown. For ships' wireless transmitting sets another modification has been much used. This consists of interleaved glass and metal sheets mounted in an oil-filled container. The glass dielectric of these condensers has not inconsiderable dielectric losses, when subjected to high voltages. The general growth in the power of wireless stations of recent years, accompanied by the replacement in many cases of the spark or damped-wave transmitters by continuous-wave ones, has rendered it imperative to make use of condenser dielectrics having the lowest possible electrical losses. In some cases air dielectric condensers have certain advantages for radio uses, particularly for the short wave-length stations. They are, however, also used sometimes in the longer wave stations, where bulk is of no particular importance.

Mica as a dielectric for condensers for radio transmitters has been particularly developed during the last decade, apart from the use of smaller condensers for ship spark transmitters. With it it has become possible to construct condensers for use in high frequency circuits wherein they often have to pass very large high frequency currents produced by valve oscillators, the condensers causing an energy loss of not more than 0.02% of the reactive kilovoltamperes flowing in the circuit. The electrical efficiency of such condensers can thus be said to exceed 99.98%.

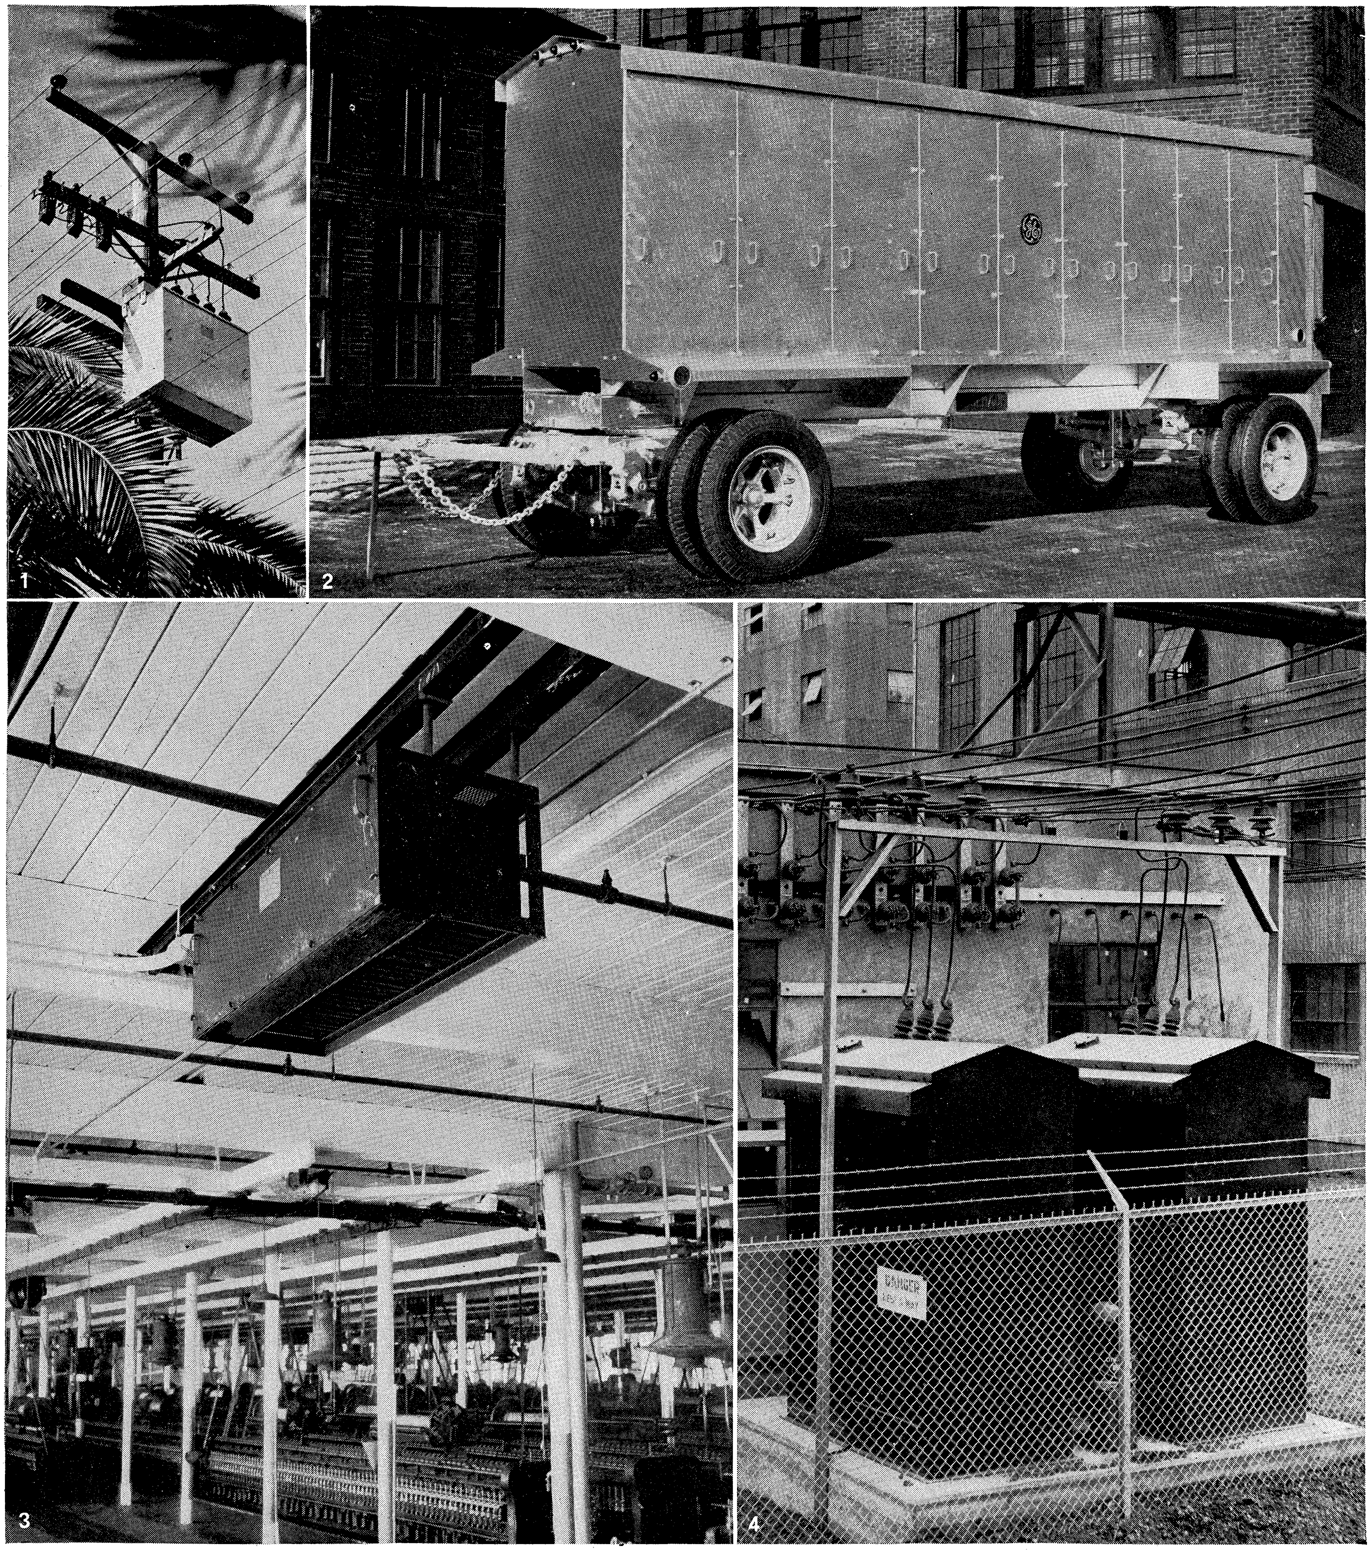
For radio transmitters using frequencies in excess of about 2,000 kilocycles quite small condensers with mica dielectric suffice. At the other end of the scale are the huge condensers used in high-power radio stations, where very large currents and high voltages are involved.

These condensers are all constructed of a very large number of small condenser elements arranged in groups connected together in series and parallel to provide sufficient bulk of dielectric for the electrical loading. Each of these elements consists of interleaved thin sheets of mica and metallic foil—usually copper or tin—securely held together to prevent relative movement. Each of these elements, therefore, has to support only a fraction of the total voltage applied to the condenser, depending upon the number of such elements connected in series; while likewise it has to carry only a fraction of the total current flowing into the condenser, depending upon the number of such elements connected in parallel.

In the application of condensers to radio apparatus operating upon the very high frequencies necessary for "short wave" and "beam" transmissions, further difficulties have been encountered owing to the energy losses in the dielectric forming the terminal insulators for the condenser. The proper subdivision of the current in the interior of the condenser to ensure that no part of the condenser is overloaded also presents some difficulty unless great care is taken to ensure that all the current paths through the condenser have as nearly as possible the same inductance. In condensers for long wave-length radio circuits this factor is of little importance, but with frequencies in excess of a few million per second excessive heating of parts of the condenser may occur if it is not considered in the design of the condenser. A recent form of condenser, with a mica dielectric, specially produced for use in these very high frequency circuits, consists of several small condensers mounted upon one another, so that they are all joined in series. Each is enclosed in an insulating tube, which provides the insulation between the top and bottom metal parts which form the terminals of the condenser. The electrical stress in this insulator is by this means reduced to a reasonably small figure, while inside each of the condenser parts the current flow is subdivided into several channels, each consisting of a number of condenser elements connected in series, as requisite for the operating voltage and frequency.

So in radio transmitters and in receiving sets as now commonly used for the reception of broadcast transmissions, a variety of condenser arrangements is commonly employed including both fixed and variable condensers. Of the fixed condensers those of smallest capacity—below about 0.01 microfarad—are customarily made with a mica dielectric, while for the larger capacities paper dielectric condensers are generally used. Still larger capacity condensers of similar type, up to about 20 microfarads, are used in the filter circuits of the so-called battery eliminators which are often used to enable a radio receiver to obtain its current supplies from electric lighting mains, in which application they perform the functions of providing a low impedance bypass path for unwanted currents of audio frequency.

Variable condensers used in radio receiving sets are constructed in as simple a manner as possible in order to avoid unnecessary expense in their manufacture. They are now almost always of the rotary vane type in which a number of fixed metal vanes are mounted on a supporting framework and a similar set of slightly smaller vanes are mounted upon a spindle carried in the same framework, so that by turning the spindle the one set of vanes can be moved so as to interleave with the other set to a greater or less extent. In these condensers the dielectric is the air between the two sets of plates; and some form of insulation is provided, so that although both sets of vanes are supported by the same framework they are electrically insulated from one another. The capacity of these condensers is almost directly proportional to the amount by which the two sets of vanes overlap one another, so that if the rotary set of vanes is semicircular the capacity of the condenser will be very closely proportional to the angular rotation



BY COURTESY OF GENERAL ELECTRIC COMPANY

LARGER CAPACITORS AND THEIR USES

1. Pole-mounted Pyranol capacitor installed to increase the current-carrying capacity of distribution feeders by improving the power factor
2. Large mobile capacitor for substation service which can be moved readily from one location to another to increase the current-carrying capacity of central-station or industrial circuits
3. Dust-tight capacitor installed in an industrial plant to improve the power factor of the distribution circuit
4. Large Pyranol capacitors for substation service. (The word "Pyranol," registered, U.S. patent office, is the name of the liquid dielectric with which the capacitors are treated)

CONDENSER (ELECTRICAL)

BY COURTESY OF GENERAL ELECTRIC COMPANY

VARIOUS TYPES OF CAPACITORS

1. Small Pyranol capacitor for increasing the current-carrying capacity of fluorescent-lamp circuits by improving the over-all power factor
2. Electrolytic capacitor for motor-starting service
3. Small Pyranol capacitors for suppression of radio interference
4. Pyranol capacitors for radio transmitters
5. Subway-type Pyranol capacitor for use on underground distribution systems

The word "Pyranol" is registered, U.S. patent office of the spindle from its initial or "zero" position. Until recently all variable condensers were constructed of this form, the differences in design consisting mainly in the means adopted to support the various parts and to insulate the two sets of vanes; in recent years, however, other variations have been introduced primarily in order to facilitate the tuning of the circuits of the radio receiver in which the condensers are used. By appropriate shaping of the vanes of the condenser the capacity can be made proportional to the square of the angular rotation of the spindle, or to the reciprocal of the square of the angle, or to the logarithm of it, or to almost any other desired mathematical function. The object of such modifications is to facilitate the use of the apparatus by making the scale-reading of the dial attached to the condenser spindle proportional, for example, to the resonance wave-length of the circuit in which the condenser is used, or proportional to its frequency, etc.

Such condensers for accurate experimental work need to be constructed in a much more robust manner and on a larger scale than are those used in radio receivers.

The most mechanically robust patterns can also be used as capacity standards for testing and measurement purposes, when they have been accurately calibrated. In some cases the space between the plates is filled with insulating oil to increase the capacity of the condenser.

Paper as a dielectric for electrical condensers has been used for many years, condensers using large sheets of this material, soaked in paraffin wax and interleaved with tinfoil sheets, having been employed since the early days of both telegraphic and telephonic communication. With the increasing use of telephones—every instrument usually requires at least one condenser, and the exchanges large numbers—the methods of manufacturing these condensers have been very much simplified. Today they are made by rolling long strips of paper and foil together on a machine until the required capacity is obtained, the condenser "plate" thus obtained being pressed flat and impregnated with some form of insulating wax. Various grades of paper are employed, depending to some extent upon the uses for which the condensers are intended, while for the conducting "plates" of the condenser either very thin tinfoil or aluminium foil is used, or a foiled paper, viz., a thin paper into the substance of which a deposit of tin is pressed to form a conducting coating. This latter conductor was introduced in 1900 by G. F. Mansbridge at a time when the manufacture of long strips of tinfoil of sufficient thinness for use in paper condensers presented almost insuperable difficulties. The condenser plates, after the impregnation, are sealed into a metal or insulating casing which must also prevent the access of moist air to the condenser paper, since this would cause rapid deterioration of the insulation.

Condensers of this type, constructed with a type of paper that allows only of low electrical losses, are used on alternating current electric power circuits for improvement of the power factor of the circuit. Particularly for voltages of about 500 and upwards similar condensers are often treated with an oil impregnation in place of wax, and are sealed in a metal tank or container filled with a high flash-point insulating oil. The oil being fluid permits of the flow of convection currents if any appreciable heat is liberated in the condenser, and so aids in the cooling of the condenser and tends to prevent failure of the dielectric. These condensers have also found application in conjunction with electric railway signalling equipment where they provide a means of resonating the circuits of the signalling relays. For the electric induction furnace, too, these condensers are also used to form a resonant circuit tuned to the frequency of the generator supplying the electrical energy to the furnace, the winding of the furnace coil providing the inductance of the circuit, so that the requisite large current can flow through the circuit of the coil and condenser while the generator has only to provide the energy required to melt the metal in the furnace, the electrical losses in the condenser being negligible. These furnaces are commonly worked with alternator supply, at frequencies of between 500 and 5,000 cycles. Under these conditions the electrical losses in the condensers, if of paper dielectric, become of importance unless adequate cooling of the dielectric is provided by the oil. For still higher frequencies, valve oscillators are often used, usually with mica dielectric condensers immersed in oil.

The readiness of a condenser to allow the passage of high frequency currents has furnished two other important applications of condensers in conjunction with high voltage electric power lines. When these lines are carried overhead they are liable to disturbances due to lightning and similar atmospheric electrical effects, which often cause damage to the transformers and other apparatus connected to the lines. With condensers connected between the lines and earth the high frequency disturbances and surges can be drained away to earth and their harmful energy dissipated. Similar condensers joined to the lines and connected to a special type of radiotelephone apparatus provide a means of guiding speech communication along the power lines, and thus furnish a valuable and very reliable means of communication between the power stations and substations connected with the power line network. This communication is not so liable to interruption and other disturbances as are separate telephone lines of the ordinary type.

In all these and many other applications of condensers the real heart of the condenser is the dielectric, and a proper use of the materials and knowledge of their properties has been the only means of building up the present known types of condensers. Many insulating materials besides those mentioned here are known, and may yet be applied in condenser construction as appropriate uses for them develop.

See P. R. Coursey, *Electrical Condensers, their Construction, Design and Industrial Uses* (1927), for extensive bibliography. (P. R. C.)

CONDER, CHARLES (1868–1909), English artist, son of a civil engineer, was born in London, and spent his early years in India. After an English education he went into the government service in Australia, but in 1890 determined to devote himself to art, and studied for several years in Paris, where in 1893 he became an associate of the Société Nationale des Beaux-Arts. About 1895 his reputation as an original painter, particularly of Watteau-like designs for fans, spread among a limited circle of artists in London, mainly connected first with the New English Art Club, and later the International Society; and his unique and charming decorative style, in dainty pastoral scenes, gradually gave him a certain vogue.

Conder died on Feb. 9, 1909.

CONDÉ-SUR-NOIREAU, a town in the department of Calvados, France, at the union of the Noireau and Drouance, 33 mi. S.S.W. of Caen by rail. Pop. (1936), 4,479. Throughout the middle ages Condé (*Condatum, Condetum*) was the seat of an important castellany, which was held by a long succession of powerful nobles and kings. The place was held by the English from 1417 to 1449. Of the castle some ruins of the keep survive. The church of St. Martin has a choir of the 12th and 15th centuries, and a stained-glass window (15th century) representing the Crucifixion.

The town is the seat of a tribunal of commerce, a board of trade-arbitrators and a chamber of arts and manufactures. It is important for its cotton-spinning and weaving, and for its fairs. It should not be confused with Condé sur l'Escaut, from which the princes of Condé (*q.v.*) took their title.

CONDILLAC, ÉTIENNE BONNOT DE (1715–1780), French philosopher, was born at Grenoble of a legal family and, like his elder brother, the well-known political writer, abbé de Mably, took orders and became abbé de Mureau.[1] His works are *Essai sur l'origine des connaissances humaines* (1746), *Traité des systèmes* (1749), *Traité des sensations* (1754), *Traité des animaux* (1755), a comprehensive *Cours d'études* (1767–73), written for the young Duke Ferdinand of Parma, a grandson of Louis XV, *Le Commerce et le gouvernement, considérés relativement l'un à l'autre* (1776), and two posthumous works, *Logique* (1781) and the unfinished *Langue des calculs* (1798). In his earlier days in Paris he came much into contact with the circle of Diderot. A friendship with Rousseau, which lasted in

[1] *i.e.,* abbot *in commendam* of the Premonstratensian abbey of Mureau in the Vosges.—(Ed.)

some measure to the end, may have been due in the first instance to the fact that Rousseau had been domestic tutor in the family of Condillac's uncle, M. de Mably, at Lyons.

Though Condillac's genius was not of the highest order, he is important both as a psychologist and as having established systematically in France the principles of Locke, whom Voltaire had lately made fashionable. In setting forth his empirical sensationism, Condillac shows many of the best qualities of his age and nation, lucidity, brevity, moderation and an earnest striving after logical method. Nevertheless, in the analysis of the human mind on which his fame chiefly rests, he has missed out the active and spiritual side of human experience. His first book, the *Essai sur l'origine des connaissances humaines,* keeps close to his English master. He accepts with some indecision Locke's deduction of our knowledge from two sources, sensation and reflection, and uses as his main principle of explanation the association of ideas. His next book, the *Traité des systèmes,* is a vigorous criticism of those modern systems which are based upon abstract principles or upon unsound hypotheses. His polemic, which is inspired throughout with the spirit of Locke, is directed against the innate ideas of the Cartesians, Malebranche's faculty-psychology, Leibnitz's monadism and pre-established harmony, and, above all, against the conception of substance set forth in the first part of the *Ethics* of Spinoza. By far the most important of his works is the *Traité des sensations,* in which he questions Locke's doctrine that the senses give us intuitive knowledge of objects, that the eye, for example, judges naturally of shapes, sizes, positions and distances. To clear up such questions we must study our senses separately, to distinguish precisely what ideas we owe to each sense, to observe how the senses are trained, and how one sense aids another. The result, he is confident, will show that all human faculty and knowledge are transformed sensation only, to the exclusion of any other principle, such as reflection. The plan of the book is that the author imagines a statue organized inwardly like a man, animated by a soul which has never received an idea, into which no sense-impression has ever penetrated. He then unlocks its senses one by one, beginning with smell, as the sense that contributes least to human knowledge. At its first experience of smell the consciousness of the statue is entirely occupied by it; and this occupancy of consciousness is attention. The statue's smell-experience will produce pleasure or pain; and pleasure and pain will thenceforward be the master-principle which, determining all the operations of its mind, will raise it by degrees to all the knowledge of which it is capable. The next stage is memory, which is the lingering impression of the smell-experience upon the attention: "memory is nothing more than a mode of feeling." From memory springs comparison: the statue experiences the smell, say, of a rose while remembering that of a carnation; and "comparison is nothing more than giving one's attention to two things simultaneously." And "as soon as the statue has comparison it has judgment." Comparisons and judgments become habitual, are stored in the mind and formed into series, and thus arises the powerful principle of the association of ideas. From comparison of past and present experiences in respect of their pleasure-giving quality arises desire; it is desire that determines the operation of our faculties, stimulates the memory and imagination, and gives rise to the passions. The passions, also, are nothing but sensation transformed. So runs the argument in the first section of the treatise. In the second section Condillac invests his statue with the sense of touch, which first informs it of the existence of external objects. In a very careful and elaborate analysis, he distinguishes the various elements in our tactile experiences—the touching of one's own body, the touching of objects other than one's own body, the experience of movement, the exploration of surfaces by the hands; he traces the growth of the statue's perceptions of extension, distance and shape. The third section deals with the combination of touch with the other senses. The fourth section deals with the desires, activities and ideas of an isolated man who enjoys possession of all the senses; and ends with observations on a "wild boy" who was found living among bears in the forests of Lithuania. The conclusion of the whole work is that in the natural order of things everything has its source in sensation, and yet that this source is not equally abundant in all men; and, finally, that man is nothing but what he has acquired; all innate faculties and ideas are to be swept away.

Condillac's work on politics and history, contained, for the most part, in his *Cours d'études,* offers few features of interest, except so far as it illustrates his close affinity to English thought: he had not the warmth and imagination to make a good historian. In logic, on which he wrote extensively, he is far less successful than in psychology. He enlarges with much iteration, but with few concrete examples, upon the supremacy of the analytic method; argues that reasoning consists in the substitution of one proposition for another which is identical with it, and further he rejects the mediaeval apparatus of the syllogism. It is obvious enough that Condillac's anti-spiritual psychology, with its explanation of personality as an aggregate of sensations, leads straight to atheism and determinism. There is, however, no reason to question the sincerity with which he repudiates both these consequences. What he says upon religion is always in harmony with his profession; and he vindicated the freedom of the will in a dissertation that has very little in common with the *Traité des sensations* to which it is appended. The common reproach of materialism should certainly not be made against him. He always asserts the substantive reality of the soul; and in the opening words of his *Essai,* "Whether we rise to heaven, or descend to the abyss, we never get outside ourselves—it is always our own thoughts that we perceive," we have the subjectivist principle that forms the starting-point of Berkeley.

As was fitting to a disciple of Locke, Condillac's ideas have had most importance in their effect upon English thought. In matters connected with the association of ideas, the supremacy of pleasure and pain, and the general explanation of all mental contents as sensations or transformed sensations, his influence can be traced upon the Mills and upon Bain and Herbert Spencer. And, apart from any definite propositions, Condillac did a notable work in the direction of making psychology a science. His method, however, of imaginative reconstruction was by no means suited to English ways of thinking. In spite of his protests against abstraction, hypothesis and synthesis, his allegory of the statue is in the highest degree abstract, hypothetical and synthetic. In France, however, Condillac's doctrine, so congenial to the tone of 18th century philosophism, reigned in the schools for over 50 years, challenged only by a few who, like Maine de Biran, saw that it gave no sufficient account of volitional experience. Early in the 19th century the romantic awakening of Germany had spread to France, and sensationism was displaced by the eclectic spiritualism of Victor Cousin.

Bibliography.—Condillac's collected works were published in 1798 and two or three times subsequently; the last edition (1822) has an introductory dissertation by A. F. Théry. The *Encyclopédie méthodique* has a very long article on Condillac (Naigeon). Biographical details and criticism of the *Traité des systèmes* in J. P. Damiron's *Mémoires pour servir à l'histoire de la philosophie au dix-huitième siècle,* tome iii.; a full criticism in V. Cousin's *Cours de l'histoire de la philosophie moderne,* ser. i. tome iii.

(H. St.)

CONDITION, a stipulation, agreement. (Lat. *condicio,* from *condicere,* to agree upon, arrange; not connected with *conditio* from *condere, conditum,* to put together.) The term is applied technically to any circumstance, action or event which is regarded as the indispensable requisite of some other circumstance, action, or event. It is also applied generally to the sum of the circumstances in which a person is situated, and more specifically to favourable or prosperous circumstances; thus a person of wealth or birth is described as a "person of condition," or an athlete as being "in condition," *i.e.,* physically fit, having gone through the necessary course of preliminary training. In all these senses there is implicit the idea of limitation or restraint imposed with a view to the attainment of a particular end.

(1.) *In Logic* the term "condition" is closely related to "cause" in so far as it is applied to prior events, etc., in the absence of which another event, called the effect, would not take place. It is, however, different from "cause," inasmuch as a cause usually consists of a multiplicity of conditions each of which is indispensable, but only the totality of which is adequate to the production of the effect. It is customary to distinguish between positive and negative conditions. Positive conditions are those which actually contribute something to the result; negative conditions consist in the absence of whatever may frustrate or modify the effect in question. Thus light, warmth, and moisture are each a positive condition of the healthy growth of a plant; the absence of wire-worms and other pests, on the other hand, would be called a negative condition.

Assertions concerning the relation between conditions and results are called *conditional* assertions (judgments or propositions). They are of two main types known as *hypothetical* and *disjunctive* respectively. In the hypothetical assertion this condition is usually contained explicitly in the antecedent, and the result in the consequent. Thus, *e.g., if the temperature of a metal is raised, its volume is increased,* (or generally *if A, then C, i.e.,* if a certain antecedent is true, a certain consequent is true). In the disjunctive assertion the condition is implicit rather than explicit, but still it is there. Thus, *e.g., either the volume of a metal remains the same or its temperature has changed* (or generally *either A1 or A2, i.e.,* alternative A1 or alternative A2 is true). But this means *if the temperature of a metal has not changed, its volume remains the same* (or generally *if not A2, then A1,* or vice versa).

(2.) *In Philosophy* the above uses of the term condition have led to the contrast between "conditioned" and "absolute" being (or "dependent" versus "independent" being). Thus all finite things exist in certain relations not only to all other things, but possibly also to thought; in other words, all finite existence is "conditioned." Hence Sir Wm. Hamilton speaks of the "philosophy of the unconditioned," *i.e.,* of thought in distinction to things which are determined by thought in relation to other things (*see* ABSOLUTE). An analogous distinction is made (*cf.* H. W. B. Joseph, *Introduction to Logic,* pp. 380, foll.) between the so-called universal laws of nature and conditional principles which, though they are regarded as having the force of law, are yet dependent or derivative, *i.e.,* cannot be treated as universal truths. Such principles hold good under present conditions, but other conditions might be imagined under which they would be invalid; they hold good only as corollaries from the laws of nature under existing conditions.

(3.) *In Law,* condition in its general sense is a restraint annexed to a thing, so that by the non-performance the party to it shall receive prejudice and loss, and by the performance commodity or advantage. Conditions may be either (1) condition in a deed or *express* condition, *i.e.,* the condition being expressed in actual words; or (2) condition in law or *implied* condition, *i.e.,* where, although no condition is actually expressed, the law implies a condition. The word is also used indifferently to mean either the event upon the happening of which some estate or obligation is to begin or end, or the provision or stipulation that the estate or obligation will depend upon the happening of the event. A condition may be of several kinds: (1) a condition *precedent,* where, for example, an estate is granted to one for life upon condition that, if the grantee pay the grantor a certain sum on such a day he shall have the fee simple; (2) a condition *subsequent,* where, for example, an estate is granted in fee upon condition that the grantee shall pay a certain sum on a certain day, or that his estate shall cease. Thus a condition precedent gets or gains, while a condition subsequent keeps and continues. A condition may also be *affirmative,* that is, the doing of an act; *negative,* the not doing of an act; *restrictive, compulsory,* etc. The word is also used adjectivally in the sense set out above, as in the phrases "conditional legacy," "conditional limitation," "conditional promise," etc., that is, the legacy, the limitation, the promise is to take effect only upon the happening of a certain event.

CONDITIONAL FEE, in common law, an estate or property granted to a man and to the heirs of his body, or to the heirs male of his body. As developed in English law, it was called a conditional fee by reason of the condition expressed or implied in the donation of it, that if the donee died without such particular heirs, the land should revert to the donor. In other words it was a fee simple on condition that the donee had issue, and as soon as such issue was born, the estate was supposed to become absolute by the performance of the condition. A conditional fee was converted by the statute *De Donis Conditionalibus* into an estate tail (*see* ENTAIL; LAWS RELATING TO REAL PROPERTY).

CONDITIONAL LIMITATION, in law, a phrase used in two senses. (1) The qualification annexed to the grant of an estate or interest in land, providing for the determination of that grant or interest upon a particular contingency happening. An estate with such a limitation can endure only until the particular contingency happens; it is a present interest, to be divested on a future contingency. The grant of an estate to a man so long as he is parson of Dale or while he continues unmarried are instances of conditional limitations of estates for life (resolutive condition). (2) A future use or interest in land limited to take effect upon a given contingency. For instance, a grant to X. and his heirs to the use of A., provided that when C. returns from Rome the land shall go to the use of B. in fee simple. B. is said to take under a conditional limitation, operating by executory devise or springing or shifting use (investitive condition). (*See* REMAINDER, REVERSION.)

CONDITIONED REFLEX, (1) the neural mechanism by which, under certain definite conditions, (*a*) a new stimulus is substituted for the one originally effective in bringing about a specific reaction or (*b*) a new response takes the place of the originally adequate reaction to a specific stimulus. Thus, with a horse, the snap of the whip is a substitute stimulus for the smart of the lash. The exclamation of an adult who stubs his toe is a substitute response for the child's howl of pain. (2) Modification of reflex behaviour as a result of alteration of the conditions under which the behaviour in question occurs, without assumption as to the neural mechanisms involved.

The first conditioned reflex experiments were conducted by Pavlov, a Russian physiologist. He discovered that certain signal stimuli, like sight and smell of food, are just as effective as the taste of food for evoking the salivary flow. This raised the question: Can *any* neural stimulus, such as the ringing of an electric bell, be substituted for the natural stimulus in arousing reflex reaction? In putting this problem to test, Pavlov used dogs as subjects, and worked chiefly with the alimentary and reject reflexes. The dog was fastened in position before a partition which could be opened for the presentation of food. An electric bell was sounded and kept ringing until after the food was presented. After about 30 trials, it was found that the sounding of the bell alone was sufficient to evoke the salivary flow. Thus, a new reflex had been built up. The dog responded to the sounding of the bell in the same way that he did to the taste of food. This new reaction was named by Pavlov the conditioned reflex.

Control of Subject and Stimulus.—The subject of a conditioned reflex experiment, whether animal, child or adult, must be in a physical condition which permits the functioning of the natural or unconditioned reflex. That is, if the salivary reflex is being conditioned to a new stimulus, the dog must be hungry. The environment must be controlled so that all stimuli more potent biologically than the ones under test are eliminated.

Presentation of Stimulus.—There are three possible ways of combining the neutral stimulus with the adequate stimulus. The bell may be sounded before presentation of food; simultaneously with presentation of food; or after food is given. Only the first two methods result in a conditioned reflex. 427 successive presentations of the odour of vanillin 5 to 10 sec. after acid was introduced into the mouth failed to develop a conditioned rejection reflex. On the other hand, a single trial with the vanillin presented before the acid sufficed to build up a conditioned response. For the most efficient conditioning the new stimulus must not only precede the natural stimulus, but it must also overlap the other in point of time. It is possible, however, to build up a conditioned reflex, even though an appreciable interval occurs between the cessation of the new stimulus and the beginning of the natural stimulus. After a considerable number of trials, the response will occur upon presentation of the conditioned stimulus, but only after an interval of time equal to the period of separation occurring in the original trials. This is called a trace reflex because the proximate cause of the response is not supposed to be the neural stimulus, but rather its trace left on the central nervous system. The longest latent period reported is about 30 minutes.

Conditions for Modifying the Response.—The natural response to an electric shock is withdrawal. The natural response to food may be smacking the lips together with increased salivary flow. By suitable presentation of these two stimuli it has been found that the electric shock will combine with the food as stimulus to the extent of inhibiting the defence reflex and establishing salivary flow as the new response to the shock stimulus. If, however, the electric current is applied to skin over bone, it will not become conditioned to the food response. In a situation of this sort the result will depend in each instance on the relative strength of the two unconditioned responses. The one which is physically weaker and biologically less important is lost while the more fundamental reflex wins out. This principle is particularly vital in the reconditioning of children.

Use and Adaptability of the Conditioned Reflex.—In animal psychology the conditioned reflex has been particularly useful in investigating sensory discrimination. A conditioned reflex is first built up to a specific sensory stimulus, let us say, auditory. Then a different stimulus of the same category is substituted. If the animal does not respond to the new sound it is inferred that he discriminates between the two. By this method of differential conditioning it has been found that a dog's hearing is more sensitive than a man's. In experiments with children, Mateer suggests using the speed with which a conditioned reflex can be developed as an index of intelligence. Extension of Pavlov's technique to human subjects was made possible by apparatus designed by Lashley for catching and measuring salivary secretion. Cason in combining the eye wink with a substitute stimulus proved that the conditioned response occurs more quickly than the voluntary eye wink. He also succeeded, after 400 repetitions, in bringing about contraction of the pupil in response to the ringing of the bell, although the normal response to the bell is a slight dilation. Watson and Jones have proved that emotional responses of children can be reconditioned. Although a child is not naturally afraid of a furry animal, he becomes afraid if a naturally frightening sound accompanies presentation of the animal. In this way many unnatural emotional responses are built up. Jones has demonstrated the possibility of removing undesirable fears by what is known as a reconditioning technique. If the animal the child fears is brought into the room when the child is eating, the eating, being a stronger biological response, controls and the withdrawal response is eliminated. (*See* BEHAVIOURISM.)

Evaluation of the Conditioned Reflex.—With regard to the supposed underlying neural mechanism, the question has been raised as to whether or not the conditioned reflex is a true reflex. An experiment by Lang and Olmsted may indicate that it is not. A true reflex is a predetermined necessary response of the organism to a given stimulus. If an experimentally created, conditioned reflex wherein saliva flows at the beat of a metronome is a true reflex, it should still function even though the salivary receptor tract is destroyed. Lang and Olmsted found that the removal of afferent connections from the salivary gland abolishes the conditioned reaction. This demonstrates a dependence upon a second neural mechanism which is not present in a true reflex. Nevertheless the conditioned reflex is an accepted method for changing behaviour. As such it is firmly established in the animal laboratories and widely recognized as a basic method of child training all over the world.

See I. P. Pavlov, *Conditioned Reflexes* (Eng. trans. by G. V. Anrep, 1927) and W. H. Burnham, *The Normal Mind* (1924); W. Kohler, *The Mentality of Apes* (Eng. trans. 1925). (E. H. MA.)

CONDOM, a town of south-western France, capital of an arrondissement in the department of Gers, 27 mi. N.N.W. of Auch, on the right bank of the Baïse, a tributary of the Gironde. Pop. (1936), 4,064. Condom (Condomus) was founded in the 8th century, but in 840 was sacked and burnt by the Normans. A monastery, built here *c.* 900 by the wife of Sancho of Gascony, destroyed by fire, was rebuilt in 1011 by Hugh, bishop of Agen. Round this abbey the town grew up, and in 1317 was made into an episcopal see by Pope John XXII. The line of bishops, which included Bossuet (1668–1671), came to an end in 1790 when the see was suppressed. Condom was, during the middle ages, a fortress of considerable strength. During the Hundred Years' War, after several unsuccessful attempts, it was captured and held by the English. In 1569 it was sacked by the Huguenots under Gabriel, count of Montgomery. The Gothic church of St. Pierre (1506 to 1521), till 1790 a cathedral, is without aisles or transept. On the south is a beautifully sculptured portal. An adjoining cloister of the 16th century is occupied by the *hôtel de ville.* The former episcopal palace with its graceful Gothic chapel is used as a law-court. There are a subprefecture, a tribunal of first instance, and a communal college. The town is the chief centre of the brandy trade of Armagnac.

CONDOR, a South American vulture (*Vultur gryphus*), almost the largest of existing birds of flight. It usually measures about 4 ft. in length and 9 ft. between the tips of its wings, but large specimens span 10 ft. or more. The head and neck are destitute of feathers, and the head, which is much flattened above, is in the male crowned with a caruncle or comb, while the skin of the neck in the same sex forms a wattle. The adult plumage is of a uniform black, with the exception of a frill of white feathers nearly surrounding the base of the neck, and certain wing feathers which have large patches of white. The middle toe is greatly elongated, and the hinder one but slightly developed, while the talons are comparatively straight and blunt. The female, contrary to the usual rule among birds of prey, is smaller than the male.

The condor is a native of the South American Andes, from the Straits of Magellan to 4° north latitude. It is often seen on the shores of the Pacific, especially during the rainy season, but its favourite haunts are at elevations of 10,000 to 16,000 ft. There, during February and March, on inaccessible ledges of rock, it deposits two white eggs, from 3 to 4 in. in length, its nest consisting merely of a few sticks. Incubation lasts for seven weeks, and the young are covered with a whitish down until almost as large as their parents. They are unable to fly till a year old. By preference condors feed on carrion, but do not hesitate to attack sheep, goats and deer. They are exceedingly voracious. When gorged with food, they are sluggish and may then be readily caught. They sleep during the greater part of the day, searching for food in the morning and evening. They are heavy sleepers, and hunters climb the trees on which they roost, noosing them before they wake. They can exist, it is said, without food for more than 40 days. On wing the movements of the condor are remarkably graceful. The birds flap their wings on rising from the ground, but after attaining a moderate elevation they seem to sail on the air. Thus Darwin watched one for half an hour without once observing a flap of its wings. Humboldt observed them over Chimborazo at a height of more than 23,000 ft.

THE CALIFORNIA CONDOR

The California condor (*Gymnogyps californianus*) is found in the Coast ranges of southern California from Monterey bay south to Lower California. It has white under-wing coverts, with a wing spread of 10 ft. It is sometimes larger than the condor of South America, though not of as heavy build. (*See* VULTURE.)

CONDORCET, MARIE JEAN ANTOINE NICOLAS CARITAT, MARQUIS DE (1743–1794), French mathematician, philosopher and revolutionary, was born at Ribemont, in Picardy, on Sept. 17, 1743. He descended from the ancient family of

Caritat, who took their title from Condorcet, in Dauphiné. He was educated at the Jesuit college in Rheims and at the College of Navarre in Paris, where he showed his first promise as a mathematician. In 1769 he became a member of the Academy of Sciences, to which he contributed papers on mathematical and other subjects.

He was the friend of almost all the distinguished men of his time, and a zealous propagator of the religious and political views then current among the *literati* of France. He was induced by D'Alembert to take an active part in the preparation of the *Encyclopédie*. He was elected to the perpetual secretaryship of the Academy of Sciences in 1777, and to the French Academy in 1782, and was a member of other European academies. In 1785 he published his *Essai sur l'application de l'analyse aux probabilités des décisions prises à la pluralité des voix,* a remarkable work which has a distinguished place in the history of the doctrine of probability; a second edition, greatly enlarged and completely recast, appeared in 1804, under the title of *Éléments du calcul des probabilités et son application aux jeux de hazard, à la loterie, et aux jugements des hommes, etc.* In 1786 he married Sophie de Grouchy, a sister of Marshal Grouchy, said to have been one of the most beautiful women of her time. Her *salon* at the Hôtel des Monnaies, where Condorcet lived in his capacity as inspector-general of the mint, was one of the most famous of the time. In 1786 Condorcet published his *Vie de Turgot,* and in 1787 his *Vie de Voltaire*. Both works were widely and eagerly read, and are perhaps, from a purely literary point of view, the best of Condorcet's writings.

The outbreak of the Revolution, which he greeted with enthusiasm, involved him in a great deal of political activity. He was elected to represent Paris in the Legislative Assembly, and became its secretary. He was chief author of the address to the European Powers. On April 21 and 22, 1792, he presented to the Assembly a scheme for a system of State education, which was the basis of that ultimately adopted. Condorcet was one of the first to declare for a republic, and drew up the memorandum which led to the suspension of the king and the summoning of the national convention (Sept. 4, 1792). In the convention he represented the department of Aisne, and was a member of the committee on the Constitution. His draft, however (presented Feb. 15, 1793), was rejected in favour of that of H. de Séchelles. In the trial of Louis XVI. he voted against the death penalty. But his independent attitude was becoming dangerous and his opposition to the arrest of the Girondists led to his condemnation and outlawry. He found a refuge at the house of Mme. Vernet, widow of the sculptor.

To occupy his mind, some of his friends prevailed on him to engage on the work by which he is best known, the *"Esquisse d'un tableau historique des progrès de l'esprit humain."* Other works were written at the same time, including the *"Avis d'un proscrit à sa fille."* Some of them were published by friends at the time and others were issued after his death. Still interested in public affairs and believing that the house of Mme. Vernet was watched, he escaped, and after hiding in thickets and quarries for three days, entered the village of Clamart on the evening of April 7, 1794. His appearance betrayed him, and he was taken to Bourg-la-Reine and imprisoned. Next morning he was found dead, whether from exhaustion or by poison is unknown.

His philosophical fame rests chiefly on the *Esquisse* mentioned above. Its fundamental idea is that of the continuous progress of the human race to an ultimate perfection. The disorders and violence of the revolution he attributed to bad institutions, from which humanity would ultimately free itself. He conceived the history of humanity as divided into nine epochs, advancing from the primitive life of hunting and fishing, through the pastoral to the agricultural age; with the invention of the alphabet at this stage the third period closes and authenticated history begins. The subsequent stages are the epochs of Greece and Rome and the middle ages, in two divisions, one closing with the crusades and the other with the invention of printing. The eighth epoch extends to the philosophical revolution effected by Descartes, and the ninth to the revolution of 1789, including the discoveries of Loke, Newton and Rousseau. In the tenth epoch, that of the future, he pictures man advancing to the destruction of all inequalities of opportunity and the perfection of individual human nature. The basis of all progress, he thought, was popular education. The book is notable for its intense aversion to all religion, especially Christianity, and to monarchy. It had considerable influence on Comte.

Madame de Condorcet (b. 1764), who was some 20 years younger than her husband, was rendered penniless by his proscription and compelled to support not only herself and her four-year-old daughter but her younger sister, Charlotte de Grouchy. After the end of the Jacobin Terror she published an excellent translation of Adam Smith's *Theory of Moral Sentiments;* in 1798 a work of her own, *Lettres sur la sympathie;* and in 1799 her husband's *Éloges des académiciens*. Later she co-operated with Cabanis, who had married her sister, and with Garat in publishing the complete works of Condorcet (1801–04). She adhered to the last to the political views of her husband, and under the Consulate and Empire her *salon* became a meeting-place of those opposed to the autocratic régime. She died at Paris on Sept. 8, 1822.

A *Biographie de Condorcet,* by M. F. Arago, is prefixed to A. Condorcet-O'Connor's edition of Condorcet's works, in 12 volumes (1847–49). There is an able essay on Condorcet in Lord Morley of Blackburn's *Critical Miscellanies*. On Condorcet as a historical philosopher *see* Comte's *Cours de philosophie positive,* iv. 252–253, and *Système de politique positive,* iv. Appendice Général, 109–111; F. Laurent, *Études,* xii. 121–126, 89–110; and R. Flint, *Philosophy of History in France and Germany,* i. 125–138. The *Mémoires de Condorcet sur la Révolution française, extraits de sa correspondance et de celles de ses amis* (2 vols., Ponthieu, 1824), which were in fact edited by F. G. de la Rochefoucauld-Liancourt, are spurious. *See* also J. F. E. Robinet, *Condorcet, sa vie et son oeuvre,* and more especially L. Cahen, *Condorcet et la Révolution française* (1904). On Madame de Condorcet *see* Antoine Guillois, *La Marquise de Condorcet, sa famille, son salon et ses oeuvres* (1897); S. Krynska, "Entwicklung und Fortschritt nach Condorcet und A. Comte," in vol. 67 of *Berner Studien z. Phil. u. ihrer Gesch.* (1908).

CONDOTTIERE (plural, *condottieri*), an Italian term, derived ultimately from Latin *conducere,* meaning either "to conduct" or "to hire," for the leader of the mercenary military companies, often several thousand strong, which used to be hired out to carry on the wars of the Italian states. The word is often extended so as to include the soldiers as well as the leader of a company. The condottieri played a very important part in Italian history from the middle of the 13th to the middle of the 15th century. The special political and military circumstances of mediaeval Italy, and in particular the wars of the Guelphs and Ghibellines, brought it about that the condottieri and their leaders played a more conspicuous and important part in history than the "free companies" elsewhere. Amongst these circumstances the absence of a numerous feudal cavalry, the relative luxury of city life and the incapacity of city militia for wars of aggression were the most prominent. From this it resulted that war was not merely the trade of the condottiere, but also his monopoly, and he was thus able to obtain whatever terms he asked, whether money payments or political concessions. These companies were recruited from wandering mercenary bands and individuals of all nations, and from the ranks of the many armies of middle Europe which from time to time overran Italy.

Montreal d'Albarno, a gentleman of Provence, was the first to give them a definite form. A severe discipline and an elaborate organization were introduced within the company itself, while in their relations to the people the most barbaric licence was permitted. Montreal himself was put to death at Rome by Rienzi, and Conrad Lando succeeded to the command. The grand company, as it was called, soon numbered about 7,000 cavalry and 1,500 select infantry, and was for some years the terror of Italy. They seem to have been Germans chiefly. On the conclusion (1360) of the peace of Bretigny between England and France, Sir John Hawkwood (*q.v.*) led an army of English mercenaries, called the white company, into Italy, which took a prominent part in the confused wars of the next thirty years. Towards the end of the century the Italians began to organize armies of the same description. This ended the reign of the purely mercenary company, and began that of the semi-national mercenary army which endured in Europe till replaced by the national standing army system. The first company of importance raised on the new basis was that of St. George, originated by Alberigo, count of Barbiano, many of whose subordinates and pupils conquered principalities for themselves. Shortly after, the organization of these mercenary armies was carried to the highest perfection by Muzio Attendolo Sforza, condottiere in the service of Naples, who had been a peasant of the Romagna, and by his rival Brancaccio di Montone in the service of Florence. The army and the renown of Sforza were inherited by his son Francesco Sforza, who became duke of Milan (1450). Less fortunate was another great condottiere, Carmagnola, who first served one of the Visconti, and then conducted the wars of Venice against his former masters, but at last awoke the suspicion of the Venetian oligarchy, and was put to death before the palace of St. Mark (1432). Towards the end of the 15th century, when the large cities had gradually swallowed up the small states and Italy itself was drawn into the general current of European politics, and became the battlefield of powerful armies—French, Spanish and German—the condottieri, who proved unequal to the gendarmerie of France and the improved Italian troops disappeared.

The soldiers of the condottieri were almost entirely heavy armoured cavalry (men-at-arms). They had, at any rate before 1400, nothing in common with the people among whom they fought, and their disorderly conduct and rapacity seem often to have exceeded that of other mediaeval armies. They were always ready to change sides at the prospect of higher pay. They were connected with each other by the interest of a common profession, and by the possibility that the enemy of to-day might be the friend and fellow-soldier of to-morrow. Further, a prisoner was always more valuable than a dead enemy. In consequence of all this their battles were often as bloodless as they were theatrical and skilful. Splendidly equipped armies were known to fight for hours with hardly the loss of a man (Zagonara, 1423; Molinella, 1467).

CONDOURIOTES, PAUL (1855–1935), Greek admiral and statesman, was born April 14 (new style), 1855, in the island of Hydra. He adopted a naval career and served in the Greco-Turkish War of 1897. He commanded the fleet in the Balkan War of 1912–13, and twice defeated the Turkish navy in the Dardanelles. In the Zaïmes and Skouloudes cabinets of 1915 he was Minister of Marine, but followed M. Venizelos to Salonika in 1916 and formed with him and Gen. Danglès the Provisional Government, opposed to that of King Constantine. After the king's first deposition in 1917, he again became Minister of Marine in the third Venizelos cabinet, resigning in 1919, when parliament bestowed on him the title of "admiral" for life. In 1920, on the death of King Alexander, he was for a short time regent. Soon after the defeat of M. Venizelos he resigned and went abroad, but returned, and on Dec. 20, 1923, the day after George II. left Greece, was again appointed regent. On March 25, 1924, the National Assembly, after deposing the dynasty, confirmed his mandate until after the plebiscite of April 13, and his title was then changed to that of president of the republic. On March 19, 1925, he resigned but resumed the Presidency on Aug. 24, after the fall of Pangalos, and remained in office until Dec. 1929.

CONDUCTION: *see* HEAT: *Conduction of Heat in Solids* and *in Gases and Liquids;* ELECTRICITY, CONDUCTION OF.

CONDUCTIVITY, in heat, is the quantity of heat (*q.v.*) passing per second through a slab of unit cross-sectional area when the temperature gradient between the two faces is unity. Electrical conductivity is the current, or the quantity of electricity (*q.v.*) passing per second, through a similar slab when the potential gradient is unity, and it is the reciprocal of the resistivity. In sound (*q.v.*) the conductivity of the orifice or neck of a resonator is the ratio of the area to the length of the orifice.

CONDUIT, a channel for the conveyance of liquids. The word is chiefly applied to artificial channels or pipes through which water is conveyed (*see* AQUEDUCTS).

CONE, in its earliest geometric use, denoted the solid space swept over by a right triangle rotating about one side (altitude or *axis, a*) the other side (*base, r*) tracing out the circle *base* of the cone, and the hypotenuse (*slant height, s*) its *curved surface,* the *vertex* V of triangle, and cone being the same (fig. 1).

Cones and Conics.—At first the size of the vertical angle of such a *right circular* cone (twice that of the triangle) appeared important, and hence such cones were divided into three classes, according to its size, and hence were named "acute-, right-, obtuse-angled." The natural position of a plane cutting through a cone seemed to be perpendicular to the slant height (*i.e.,* the hypotenuse or *generatrix* in any position, called also an *element, e,* of the surface). It is said that Menaechmus (*c.* 350 B.C.), in striving to construct the so-called double mean proportional, $a:x=x:y=y:b$, discriminated three corresponding types of conic sections, afterwards named, respectively, ellipse, parabola and hyperbola. It was the "great geometer," Apollonius, born at Perga in Pamphylia (*fl. c.* 225 B.C.), student in the Euclid school of Alexandria, who perceived and showed that the type of cone was indifferent, any plane section of any circular cone, parallel to an element, yielding a parabola, and other sections yielding either an ellipse or hyperbola.

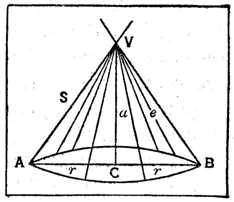

FIG. 1.—A CONE AND ITS ELEMENTS

Volume and Area.—The conception of a cone as solid called for the measurement of its content, a fact enunciated first by the travelling philosopher Democritus (*c.* 460–*c.* 370 B.C.), proved by Eudoxus of Cnidos (*c.* 408–*c.* 355 B.C.), and later completed by the great reckoner, Archimedes (287–212 B.C.), who showed that a cone, hemisphere and cylinder, all of the same base and height (fig. 2) have volumes respectively as 1, 2, 3,—a relation holding for any type of the extremes—the cone and cylinder. If they had equal bases and heights, the volume of the one is one third that of the other, which is the product of base and height. Plainly the curved surface of a right circular cone may be thought as slit all along any element and then flattened out on a plane (tangent along the opposite element) into a circular sector; hence the curved surface equals in area the sector area, *i.e.,* the half-product of base-circumference as arc and slant height as radius.

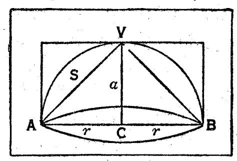

FIG. 2.—RELATION OF CONE, CYLINDER AND HEMISPHERE

Oblique Cone.—The circular cone is defined by Apollonius more generally as the surface (or its enclosed volume) traced by a right line passing through a fixed point (vertex) and gliding along a fixed circle. The right line through this vertex and the centre of this circle is the *axis;* if this be at right angles to the *base* (the plane of the circle), the cone is *right;* otherwise, it is *oblique,* in which case the vertical angle is not of constant size. Any plane containing the axis cuts the solid in such a vertical angle, and the surface in its sides (elements of the cone). The plane containing the axis and being perpendicular to the base of the cone forms the "principal section"; any plane perpendicular thereto and inclined equally but inversely (with the base) to the generator-elements therein is called a "subcontrary section." This cuts the cone in a circle, as do all planes parallel to it or to the base, all which are therefore called "cyclic planes" (fig. 3).

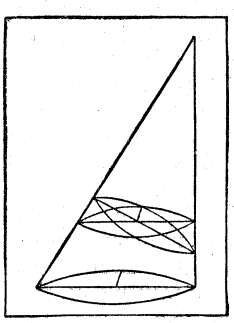

FIG. 3.—CYCLIC PLANES

Cone as Surface.—It was natural to regard and define the solid first rather than the bounding curved surface, and hence the early Greek achievements were largely in stereometry. Only very gradually it came to be felt that the surface alone possessed peculiar properties, the enclosed space being indifferent. Hence the very recent change in definition and treatment from three to two dimensions. From the new point of view the cone concept undergoes a broad generalization, designating any path of (or surface traced by) a right line (the *generatrix, g*) that passes always through a fixed point V. This path, to be definite, is directed by some curve (the *directrix* D), along which the line glides always (fig. 4). Thus, in the right circular cone, *D* is the circle bounding the cone's base, the track of the moving end of the hypotenuse (g). In the oblique circular D is still a circle, but no longer traced by one certain point of the line g. If D be a conic (as an ellipse) the surface is called a "quadric cone." If a fixed direction (or line called the *axis*) be assumed as passing through the fixed vertex V, the motion of the tracing line g might be directed by ordered variation in the vertical angle between the fixed and the moving line. In the most important case, the right circular cone, this variation is the simplest possible; O, the angle is constant; the two lines are rigidly joined at V; and the generatrix swings freely round the axis (which may be thought as turning *in itself*).

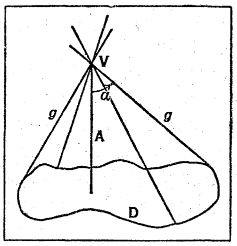

FIG. 4.—CONE AS SURFACE

Tangency.—Such seems to be the simplest and most vivid conception of the right circular cone; the two halves meeting at V and extending oppositely without end are called *nappes* or *sheets*. If slit throughout along an element, and rolled out (developed) on the plane tangent along the opposite element, the nappes would appear as centrically symmetric sectors of an infinite circle about V as centre. Any plane tangent to a cone passes through V and touches the cone along some element throughout. All such planes would touch the whole cone-surface and would envelop it completely. The tangent plane at any given point of the surface (except V) is quite definite, but at V this definiteness disappears. All tangent-planes pass alike through V—a matter of importance in treating the umbilical points in Fresnel's wave-surface, in connection with Hamilton's discovery of the conical refraction of light.

Equation.—In analytic geometry the equation of the right circular cone traced by rotating the line $y=mx$ round the y axis is $y^2=m^2\ (x^2+z^2)$. This simply means that, as any point P (of the line) rotates round the y axis, its y remains unchanged and also its distance $\sqrt{x^2+z^2}$ from the y axis (OY), and the fixed ratio of these two lengths is m.

Intersection.—The doctrine of the intersection of a cone with other surfaces belongs rather to constructive geometry, where it is developed and applied. Its importance may be presumed from the fact that central projection is cone-like, the lines of projection issuing like rays of light from a point, the vertex of the cone. An interesting special case is the *sphero-conic*, the intersection of any quadric cone with a sphere about the vertex of the cone as centre.

Truncation.—In more elementary measurement we meet with the *frustum* (fig. 5), especially of the right circular cone. The word, meaning *piece*, denotes a truncated cone, or the portion of a cone (viewed as a solid) between the base and a cutting plane generally parallel thereto. The problem of computation was apparently first proposed with respect to truncated pyramids, and very naturally in Egypt. Indeed, one of the earliest extant computations of volume is Egyptian and relates to such a figure. Much later, and in the *Stereometrica* of the encyclopedic Heron "the mechanic" of Alexandria (*c.* A.D. 50? or as late as A.D. 200?) the volume is calculated for a pyramid-frustum on a square base (100), the top-section a square (4), the oblique edge 9; the height is found to be 7, which multiplied by $\left\{\left(\frac{10+2}{2}\right)^2+\frac{1}{3}\left(\frac{10-2}{2}\right)^2\right\}$ gives $289\frac{1}{3}$, a correct result as seen by the now well known rule or formula, one-third the product of height by the sum of the bases and their geometric mean. But in a second example the sides of the square (base and top) are given as 28 and 4, and the slant edge as 15, which is impossible, since even the projection of any such slant on the base plane would be $\sqrt{12^2+12^2}$ or $\sqrt{288}$, which is more than $15=\sqrt{225}$. Accordingly the reckoner in applying his method, of which the foregoing rule is the resultant formula, meets with $\sqrt{-63}$, which he treats as $\sqrt{63}$. Whether or not this be the work of Heron, it is notable as the oldest known appearance of the so-called "imaginary," the square root of a negative number. (*See* COMPLEX NUMBERS.) The rule or formula used above holds for all such frustums of cones and pyramids. It was used much later by the leading Hindu mathematician Brahmagupta (*c.* 628) in his *Brāhma-sphuta-sidd'hānta.* The surface of such a frustum is plainly the difference between two circular sectors of the same angle and centre, into which the cone and the top could be rolled out on a tangent-plane (fig. 5). Heron recommends similar practical methods for measuring other surfaces, as wrapping the solid in a thin cover and then spreading this out (*Metrica*, I. Fin.).

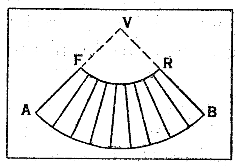

FIG. 5.—SURFACE OF A FRUSTUM

Limiting Case.—If the vertex of the right-circular cone retire indefinitely along the axis, the cone passes over into a cylinder (*q.v.*) or cylindric surface, and the frustum becomes an ordinary (right-circular) cylinder, its volume the product of base and altitude, its curved surface the product of the circle of the base by the altitude. This limiting case of the cone-frustum is of course much simpler than the general case. (*See* also ANALYTIC GEOMETRY; CONIC SECTION: *Bibliography*.) (W. B. SM.)

CONECTE, THOMAS (d. 1434), French Carmelite, was born at Rennes. He travelled through Flanders and Picardy, denouncing the vices of the clergy and the extravagant dress of the women. He taught that he who is a true servant of God need fear no papal curse, that the Roman hierarchy is corrupt, and that marriage is permissible to the clergy, of whom only some have the gift of continence. In Italy, despite the opposition of Nicholas Kenton (d. 1468), provincial of the English Carmelites, he introduced several changes into the rules of that order. He was finally condemned and burnt for heresy.

An account of his preaching and its effect is given by Enguerrand de Monstrelet, provost of Cambrai (d. 1453), in his continuation of Froissart's *Chronicles*.

CONE-FLOWER, the popular name given in North America to species of *Rudbeckia* and other closely related genera of the family Compositae, many of which are cultivated as ornamentals. The large, solitary flower heads, often 4 in. or more across, consist of a cone-shaped central portion (disk) surrounded by numerous brightly coloured ray flowers. A striking example is the purple cone-flower (*Echinacea purpurea*), called also red sunflower and black sampson, native to the central United States. It is a coarse, stout perennial herb, 2 ft. to 5 ft. high, bearing lance-shaped leaves and long leafless flower stalks each ending in a single head, sometimes 5 in. across, with a purplish centre and purple or crimson rays.

CONEGLIANO, a town and episcopal see of Venetia, Italy, province of Treviso, 17 mi. N. by rail from the town of Treviso, 230 ft. above sea level. Pop. (1936) 7,544 (town); 15,434 (commune). It is commanded by a large castle and contains many picturesque old houses. It was the birthplace of the painter Cima da Conegliano, a fine altar-piece by whom is in the cathedral (1493). The place is noted for its wine, chiefly sweet champagne. A branch railway runs north-west to Vittorio Veneto (9 miles).

CONESTOGA, an extinct tribe of North American Indians of Iroquoian stock. Their country was Pennsylvania and Maryland on the lower Susquehanna river and at the head of Chesapeake bay. They were sometimes known as Susquehannas.

CONEY ISLAND, a seaside resort about 9m. S.E. of Manhattan island, New York, U.S.A. It was formerly an island separated from the mainland by Gravesend bay, Sheepshead bay, Coney island creek, a tidal inlet, and a broad stretch of salt marshes, much of which has been filled in. It lies within the limits of the borough of Brooklyn, New York city. The island is the westernmost of a chain of outlying sandbars that extends along the southern shore of Long Island for about 100 miles; it is about 5 mi. long and varies from $\frac{1}{4}$ mi. to 1 mi. in width. It is served by several lines of electric railway and (in summer) by steamboats.

The island is the most popular seashore resort of the United States. It is now a popular all-year residential community. Its all-year population is close to 100,000. At the extreme western extremity is the district known as Sea Gate, lying between Gravesend bay and lower New York bay. It is an exclusive residential section which in later years has become an all-year community with the natural influx of summer residents. Surf avenue connects it on the east with the part of Coney Island usually of interest to the average visitor. Coney Island's wide expanse of white sandy beach, its 3½-mi. boardwalk running from Sea Gate to Manhattan beach, its amusement parks, amusement devices of all kinds, "side shows," rides, cafes, annual Mardi Gras and weekly fireworks displays have helped Coney Island retain its popularity throughout the years. To the east are Brighton and Manhattan beach.

CONFALONIERI, FEDERICO, Count (1785–1846), Italian revolutionary, was born at Milan, descended from a noble Lombard family. In 1806 he married Teresa Casati. During the Napoleonic period Confalonieri was among the opponents of the French régime, and was regarded as one of the leaders of the *Italiani puri,* or Italian National Party. At the time of the Milan riots of 1814, when the minister, Prina, was assassinated, Confalonieri was unjustly accused of complicity in the deed. After the fall of Napoleon he went to Paris with the other Lombard delegates to plead his country's cause, advocating the formation of a separate Lombard State under an independent prince. But neither there nor in London, where he subsequently went, did he receive any encouragement. He then joined the freemasons and returned to Milan, where he found the Austrians in possession.

Early in 1821 he visited various parts of Italy to sound the liberal leaders, and also corresponded with the Piedmontese officers who, believing that they had the approval of Prince Charles Albert of Carignano, the heir to the throne, were planning a military revolt. Confalonieri warned them that Lombardy was not ready. On the outbreak of the Piedmontese revolt (March–April 1821) the Austrian authorities arrested Silvio Pellico and Maroncelli and afterwards Confalonieri. After a long trial Confalonieri was condemned to perpetual imprisonment in the fortress of Spielberg (Jan. 1824). He was taken to Vienna and had a long interview with Prince Metternich, who tried, without success, to extract confessions incriminating other persons, especially Charles Albert. His wife died in 1830, and in 1836, on the death of the emperor, Francis, he was pardoned and exiled to America. He came back to Europe after a year's absence, and in 1840 obtained permission to return to Milan to see his dying father. He himself, broken in health and spirits, died on Dec. 10, 1846.

Bibliography.—*Memorie e Lettere di Federico Confalonieri* (ed. by G. Casati, Milan, 1890). A. D'Ancona's *Federico Confalonieri* (Milan, 1898) is based on the memoirs and a large number of secret documents from the archives of Vienna and Milan. A. Luzio's *Antonio Salvotti e i processi del Venturo* (1901), in T. Casini and V. Florini's *Biblioteca storica del risorgimento italiano.* Ser. 3. Nos. 1, 2 (1897, etc.), contains many fresh documents which to some extent exonerate Salvotti from the charge of cruelty; among other papers Metternich's account of his interview with Confalonieri is given in full. *See* also A. Luzio, *Nuovi documenti sul processo Confalonieri* (1908), in T. Casini, etc., *Biblioteca storica del risorgimento,* etc., Ser. 5. No. 5; R. Huch, *Das Leben des Grafen Federigo Confalonieri,* 2 vol. (Leipzig, 1910).

CONFARREATIO, the ancient patrician form of marriage among the Romans, especially necessary at the nuptials of those whose children were intended to be vestal virgins or flamens of Jupiter. The name originated in the bride and bridegroom sharing a cake of spelt (*far* or *panis farreus*), in the presence of the *pontifex maximus, flamen dialis,* and ten witnesses. This form of marriage could only be dissolved by another equally solemn ceremony, which was called *diffarreatio.* In later republican times, confarreatio became obsolete except in the case of the most sacred priesthoods—the *flamines* and the *rex sacrorum.* Confarreatio was the most solemn of the three forms of marriage (*see* Marriage, Law of), but later the ceremony fell into disuse, and Cicero mentions but two, *coemptio* and *usus.* (*See* Roman Law.)

CONFECTIONERY MANUFACTURE. Confectionery is a term of wide application, covering all food preparations of the nature of sweetmeats which have sugar as their principal constituent.

The manufacture of confectionery on a large scale has grown in half a century from an insignificant trade into an industry of international importance. This rapid advance is largely due to the remarkable development of automatic machinery and to the greatly increased purchasing power of the people of the white nations.

In America, according to the 1925 report of the census bureau of the department of commerce, the establishments manufacturing confectionery to the extent of not less than $5,000 in value per annum numbered 1,931. The total value of the products of these establishments in that year was $379,081,441. In addition, some 60 establishments were engaged primarily in the manufacture of chocolate, cocoa and cocoa butter, the value of their products being $106,642,474. The value of the ice cream products in 1925 was $317,554,289, and of chewing gum, $47,838,150.

Great Britain produced in 1924 5,350,800cwts. of confectionery, (including chocolate confectionery), the value being £31,197,000; of manufactured chocolate and cocoa the output was 1,171,400 cwts., valued at £8,479,000. The third census of production, from which these figures were obtained, also showed that the output of manufactured chocolate and confectionery exceeded that of 1907 (the time of the second census) by nearly 90%, and that the increase in confectionery (including chocolate confectionery) was about 42%.

Chocolate and confectionery are manufactured on a large scale in nearly all the British Dominions. Other large producing countries are Switzerland (where milk chocolate is the specialty), Holland, Germany, France and Belgium.

Sugar Boiling.—The principal ingredient of all confectionery is sucrose, the ordinary sugar of commerce, and the main process in confectionery manufacture is sugar boiling. A saturated solution of sugar and water can be boiled to a number of stages between 220° F. and 360° F., at each of which a definite change in the solution is produced. At 240° F., for instance, the syrup, if agitated, becomes fondant, a mass of crystals so minute that they are not visible to the naked eye. At a further stage the syrup becomes of the consistency required for toffee, and finally it becomes a solution of brittle sugar used in hard boiled goods.

For hard boiled goods the latest method of manufacture involves the use of the automatic continuous cooker. The main part of this machine consists of a steam-jacketted vertical tube containing a hollow taper-spiral of gunmetal. The sugar solution is pumped into the machine at the top of the spiral and in a thin film is propelled downwards, at the same time being subjected to the action of the heat from the outer steam jacket. The syrup is in contact with the heat only from eight to ten seconds, but the heat is so intense and the quantity of syrup in contact with it so minute that the syrup issues from the spiral completely cooked and of perfectly transparent colour. The cooked syrup is poured on to a warm table, mixed with essence and colour as required, and passed through rollers to take the desired shape.

In order to obtain the beautiful and popular "satin" effects, the candy-pulling machine is used and this is necessary also for such goods as butter-creams and other light confections.

Toffee, in which butter is added to the sugar syrup, may be made in a continuous cooker which has been adapted for the purpose. It is also made in steam-jacketted mixing pans fitted with beaters or mixers which are driven at a high speed, the apparently immiscible ingredients thus being completely blended in a highly efficient manner. This is the basic principle also in the manufacture of caramels and similar goods.

Fondant.—Fondant is produced by cooking a sugar syrup, to which glucose is added, to 240° F., at which point the syrup quickly dries on stirring and is easily powdered, the sugar crystallizing spontaneously. If it is slowly cooled and there is an absence of movement, large crystals are formed; but if it is cooled and stirred rapidly the result is small crystals. The mass becomes dry because the water in the syrup is driven off entirely by the rapid evolution of heat as the sugar crystallizes. The best fondant is soft and smooth, and is produced by rapid cooling and heating.

The large scale method of manufacturing fondant is by the use of a complete automatic cream-boiling and fondant-making plant. The syrup is cooked as in the continuous cooker and passed to a gunmetal revolving water-cooled drum which cools it practically instantaneously, the film of cooled syrup being automatically scraped from the drum to fall into a continuous cream-beating machine. The latter, of which there are many types, rapidly beats the cream, to which flavouring and colouring are added, to a fine consistency.

When the fondant cream has been prepared, it is moulded for subsequent crystallizing (or dipping in sugar syrup) or for chocolate dipping or covering. This moulding is done in starch and the whole process may be completed automatically and continuously. The operations of the plant employed cover the filling of trays with starch; the levelling of the trays; the printing in the starch with moulds; the depositing of fondant cream (or other similar candy) into these imprints and the delivering of the trays filled with freshly cast goods for setting; the emptying of the set creams and the starch from the trays; the final cleaning of the creams, and their ejection for crystallizing or chocolate dipping.

The manufacture of lozenges requires the preparation of powdered sugar with gelatine and other ingredients made into a dough which is compressed and stamped out by machine. Other confectionery is made by one or other of the foregoing processes.

Chocolate Confectionery.—The constituents of chocolate are cocoa, sugar and cocoa butter. (*See* CHOCOLATE.)

The chocolate covering of confectionery may be performed either by hand or by machine. If by hand, the liquid chocolate is placed in slightly heated shallow pans; the centres are thrown into the mass and quickly withdrawn with a special fork, coated. They are then placed on glazed papers ready for cooling. Sometimes the covering is done almost entirely by hand.

The most up-to-date plant for covering automatically is the enrober. The centres are fed into this machine on a travelling canvas belt. They pass over a bath of chocolate on a wire belt conveyor and receive a bottom coating. They then pass within an enclosed case on a second wire belt conveyor and travel through a shower of liquid chocolate, which is made continuous by means of a pumping arrangement. The surplus chocolate is removed from the covered pieces by an air blast and a slight automatic tapping movement, and the goods, leaving the case, pass on to plaques on another travelling conveyor, where their tops are decorated by girl operatives. To secure the much desired gloss on chocolates rapid cooling is an essential, and accordingly the goods are taken on the travelling conveyor through a cooling chamber and emerge at the other end ready for packing. (C. T. J.)

UNITED STATES

The basic principles of the manufacture of confectionery in the United States are practically the same as obtain in England, with the possible exception that more open-fire, pure sugar hard candy is used. Hard candy is manufactured by cooking over gas or coke stoves at 320° to 340° F. The gloss or satin-finish obtained is the result of manipulation on the part of the spinner. The spinner takes the finished batch after it has been pulled and, protected by heavy buckskin gloves, feeds it into machines, frictional heat being caused by rubbing. This brings a high gloss which is known as the finish to the surface of the candy.

The greatest volume of confectionery business in the United States is done in the lower prices, particularly the penny-goods class. Next in sales, is the 5 cent chocolate-covered bar. The third class of confectionery in volume of sales is the candy sold in bulk, principally in small candy and grocery stores and in the chain stores. The consumption of milk chocolate, both in solid-bar form and as a coating for candies, has been steadily increasing and in 1928 had reached approximately 40% of the total consumption of chocolate. The increase in the consumption of 5 and 10 cent bars, accentuated by the popularity created for this type of goods during and after the World War, has been somewhat responsible for a decrease in the sale of chocolates in bulk. This decrease has been offset, however, by the advance in the sale of finished, packaged chocolates. The sale of 5 cent bars has so developed that some large manufacturers have devoted their entire plant facilities to one or more bars. In some instances it has been necessary to establish three or four factories, strategically situated across the continent, to supply the demand. The penny-goods business has similarly grown, so that many large manufacturing plants have given over their entire production to this particular type of goods.

Since 1918 there has also been developed on outlet for the "home-made" type of candy retailing at popular prices. This is made up in various types of goods bringing back a number of the older kinds such as were commonly used during the last generation. These pieces are large, have home-made characteristics and embody such items as caramels, nougats, hard candy, toffees, *bon bons* and hand-rolled, chocolate-dipped creams. These goods are offered by chain store organizations that often outfit their stores to resemble kitchens, with unique fixtures and window displays. (P. F. C.)
