The Little Entente was then in its last stages. With the seizure of Austria by Germany in March 1938, Germany was brought to the borders of Yugoslavia and Czechoslovakia was almost surrounded. On Sept. 30, 1938, as a result of the so-called Munich "agreement," Germany was permitted to annex the Sudeten regions of Czechoslovakia. The last conference of the council of the Little Entente, meanwhile, had been held at Sinaia, Rum., on Aug. 21, 1938, when an attempt was made to conciliate Hungary by an offer of equality in armaments in return for the promise of a peaceful policy on the part of that country. When the test finally came in the period of the Munich crisis, despite the reluctance of the Stoyadinovich government in Yugoslavia, both Yugoslavia and Rumania, in accordance with the terms of their alliance with Czechoslovakia, warned Hungary not to attack the republic. But the attitude of Great Britain and France being what it was, there was little question of the outcome. The Munich accord destroyed the Little Entente by destroying the keystone of the system—the republic of Czechoslovakia.

Conclusion.—The Little Entente, composed of Czechoslovakia, Yugoslavia and Rumania, and organized for the purpose of the mutual defense of these nations and their other common interests, had its imperfections. The common ties which bound the three members, involving only an attempt on the part of Hungary forcibly to revise the treaty of Trianon or an attempt to restore the Habsburg monarchy in the Danubian region, did not provide for an attack by Germany against Czechoslovakia, an Italian aggression against Yugoslavia, or a Russian move against Rumania. More universal obligations were a necessity for a viable regional organization, though the point of wisdom at the time of the origin of the Little Entente seemed to lie in the rigid limitation of common obligations to specifically common interests. The formation of the economic council of the Little Entente came too late to lay the necessary foundations for a genuine economic organization of the Danubian area. Despite attempts to extend the principles of the Little Entente to other nations in the Danubian area, especially Austria and Hungary, it was impossible to extend the membership or collaboration, particularly in the case of Hungary, which refused co-operation as long as its political claims against Czechoslovakia, Yugoslavia and Rumania were not met.

It is well to note, however, that the faults of the Little Entente were essentially those of Europe as a whole, on a somewhat smaller stage. Though the organization of the Little Entente failed to meet the problems of central Europe in the sense indicated and ultimately succumbed before the forces which triumphed at Munich in Sept. 1938, the work accomplished and the foundations laid in the period from 1920 to 1938 may yet prove their worth when the time comes once more to attempt a more rational and genuinely viable reorganization of Danubian Europe on the basis of the free association of the peoples of that region. (E. Be.; H. N. H.)

LITTLE FALLS, a city of Minnesota, U.S.A., 97 mi. N.W. of Minneapolis, on the Mississippi river; the county seat of Morrison county. It is served by the Northern Pacific railway. The population was 6,047 in 1940. The city has a hydro-electric power plant, creameries, flour mills and other manufacturing industries, and there are granite quarries near by. It was settled about 1850 and chartered as a city in 1889.

Here was buried the Chippewa chief, Hole-in-the-Day (*c.* 1827–68), who is credited with having prevented the Chippewas from joining the Sioux in their uprising of 1862, but later his body was removed by relatives. Little Falls was the childhood home of Charles A. Lindbergh.

LITTLE FALLS, a city of Essex county, New Jersey, U.S.A., about 10 mi. N.N.E. of Newark, served by the Erie railroad. The population by the federal census of 1940 was 5,561. The city takes its name from adjoining falls of the Passaic river. In 1940 Little Falls had about 30 industries, including one of the largest laundries of the world, with some 800 employees and more than 250,000 customers. There, in May 1937, the United Laundry Workers Union, supported by the Congress of Industrial Organizations, staged a strike which attracted national notice. The township later passed a special ordinance to curb the activities of the union.

Little Falls was settled by eight Passaic farmers who purchased a large tract of land from the Indian inhabitants of the vicinity in 1711.

LITTLE FALLS, a city of Herkimer county, New York, on the Mohawk river, 21 mi. E.S.E. of Utica. It is served by the New York Central lines. The population was 11,105 in 1930; in 1940 it was 10,163. The city takes its name from the cascade rapids of the Mohawk at this point (a total fall of 45 ft. in less than a mile), which furnish abundant water power. Its manufactures include knit goods, leather, bicycles, felt shoes, sectional bookcases, paper, knitting machines, hammers, rennet and junket preparations, milking machines and dairy products. The aggregate output in 1937 was valued at $12,404,558. The surrounding country is engaged largely in dairying. Little Falls was settled by Germans in 1782, and had a gristmill which served most of the Mohawk valley.

It was destroyed almost immediately by Indians and Tories, rebuilt in 1790, incorporated as a village in 1811, and chartered as a city in 1895.

LITTLEFIELD, WALTER (1867–), U.S. author and journalist, was born at Boston March 17, 1867. After studying at Harvard university he taught in Boston for two years, then joined the editorial staff of the *New York World.* He was with the *New York Tribune* for a short time, and then was employed by the *New York Times,* in the foreign news department. During the Dreyfus case in France, Littlefield was first to identify Lt. Col. du Paty de Clam as author of an article which told the circumstances of Dreyfus' arrest and revealed the secret evidence admitted at the first trial.

He wrote several works about the affair, including *The Story of the Dreyfus Case* (1936). Littlefield in 1932 became foreign editor emeritus of the *New York Times*.

LITTLEHALES, GEORGE WASHINGTON (1860–1943), U.S. hydrographer, was born in Schuylkill county, Pa. Oct. 14, 1860. He was graduated from the U.S. naval academy in 1883 and then studied at Columbian (later George Washington) university, Washington, D.C. He was hydrographic engineer of the U.S. Hydrographic office from 1900 until his retirement in 1932, and professor of nautical science at George Washington university from 1913 to 1927. From 1919 to 1922 he was chairman of the American Geophysical union's section of physical oceanography, and from 1921 to 1932 vice-president of the section of oceanography of the International Union of Geodesy and Geophysics.

He was the author of numerous works on navigation, hydrography and related subjects.

The results of his research were published in more than 100 papers. He also published some 3,000 navigational charts used throughout the world, and edited the mathematical tables used by U.S. seamen. Littlehales died Aug. 12, 1943.

LITTLEHAMPTON, a seaport, watering place and urban district in Sussex, England, at the mouth of the Arun, 62 mi. S.W. from London by the S.R. Pop. (1938) 11,340. Area, 4.5 sq.mi. The harbour is easily accessible in all weathers, and has a small trade.

Imports include wood, coal, slate, granite, cement, manure and cereals and exports are hoops, timber, etc.

LITTLE MASTERS: *see* LINE ENGRAVING.

LITTLE ROCK, the capital and largest city of Arkansas, U.S.A., and the county seat of Pulaski county; on the south bank of the Arkansas river, near the centre of the state. It is the intersection point for federal highways 65, 67, 167 and 70; is served by the Missouri Pacific, the Rock Island, and the St. Louis Southwestern railways; and has an airport of 701 ac., 2 mi. from the centre of the city.

The population was 65,142 in 1920 (26·8% Negro), 81,679 in 1930; and 88,039 in 1940 by the federal census. The aggregate population of the urban unit, including North Little Rock, across the river, and other suburbs, or the metropolitan area, was 126,724 in 1940.

Little Rock lies at the edge of the gulf coastal plain, at an altitude of 250 to 400 ft., with the foothills of the Ozarks rising to the west. Its area is 17·5 sq. miles. Besides three railway bridges, there are two beautiful highway bridges of concrete across the Arkansas, memorials to the men of the army and of the navy who died in World War I. The state capitol, of Arkansas marble (built in 1912), has a fine site in a park of 12 ac. Fair park, located in a beautiful grove of trees, includes the municipal zoo, the municipal golf course, Traveler's field for Southern league baseball games and other amusement features. Many of the state institutions are in Little Rock, including the deaf-mute institute, the school for the blind, the library, the hospital for nervous diseases and the Confederate home. The medical school of the state university is there, and among the other educational institutions are Little Rock junior college, Philander Smith college (for Negroes), the Arkansas Law school and St. John's theological seminary (Roman Catholic).

The city is the see of Roman Catholic and Protestant Episcopal bishops, and there are numerous charitable institutions under private auspices. The philanthropic agencies are financed jointly through a community chest.

There is a branch of the federal reserve bank there, a U.S. land office, a U.S. district court, and a U.S. Veterans' bureau and U.S. Veterans' hospital facility. The airport is the headquarters of the 154th observation squadron of the Arkansas national guard, and is also used for commercial purposes. Camp Joseph T. Robinson, 5 mi. N of the city, is the training area for more than 25,000 soldiers.

The fertile agricultural region surrounding Little Rock produces large crops of cotton, corn, alfalfa, potatoes, small grains, fruits and vegetables. Within a short distance are vast stands of high-grade timber and deposits of coal (including a smokeless semi-anthracite), oil and natural gas, marble, clay, flint and many other mineral resources.

The bauxite mines just outside the city produce 90% of the country's total output. At Remmel dam, 60 mi. southwest of Little Rock, is the first unit of the great hydro-electric development on the Ouachita river. There are over 300 industrial plants in Greater Little Rock (including large railroad shops across the river), and the annual value of the manufactured products in 1940 was estimated at $30,000,000.

Chief among them are cotton-seed and lumber products. Little Rock has a large trade in cotton, lumber and agricultural products. The wholesale houses do an annual business of $75,000,000, and annual retail sales aggregate $45,000,000. Bank clearings in 1940 were $406,425,913. The assessed valuation of property was $42,617,225.

In 1722 Sieur Bernard de la Harpe, exploring the Arkansas river, gave the names of La Petite Roche and La Grande Roche (or *Le Rocher Français*) to two conspicuous rocky formations on the banks of the stream, one of which (the "little rock") is now the abutment of a railway bridge. The big rock, 2 mi. upstream on the north bank, once the site of a U.S. army post, is the location of U.S. Veterans' facility. Near the smaller rock was a settlement of Quapaw Indians, which De la Harpe made his trading post.

In 1812 William Lewis, a hunter and trapper, built his home here. In 1819, when Arkansas was made a territory, preparations were made to move the seat of government to Little Rock from Arkansas Post (founded in 1686 by Henri de Tonti near the mouth of the river), and in 1821 the town was surveyed. It was incorporated as a town in 1831 and chartered as a city in 1836. Construction of the first state house (now the War Memorial building) was begun in 1833. The leading daily newspaper, the *Arkansas Gazette,* established at Arkansas Post in 1819 and soon moved to the new capital, was one of the first papers published west of the Mississippi. At the outbreak of the Civil War, Little Rock was enthusiastically antiunion. The U.S. arsenal was seized by the state authorities in Feb. 1861. In Sept. 1863, Federal forces captured the city, and it remained under Federal control for the rest of the war.

The decades of most rapid growth in the city's history are 1860–70, when the population increased from 3,727 to 12,380, and 1880–90, when it almost doubled.

LITTLE THEATRE MOVEMENT. In its beginnings, the history of community drama is the history of the drama in general. That history is dealt with in another place (*see* DRAMA). Here it is only necessary to recall that the origins of theatre art are bound up with the ritual of the tribe, and that the tribal rite offers the purest type of community drama which it is possible to conceive.

Throughout the great period of Greek classical drama the method and atmosphere of stage production were more nearly allied to those of community drama as we know it today than to the modern professional theatre. The same may be said of the drama in mediaeval times. For in both periods stage production was not primarily the work of a definite class of professional stage workers or managers. It was undertaken by a whole community as represented by the City state (in Greece) or by the church or the trade guilds (in mediaeval Europe).

THE MOVEMENT IN EUROPE

While the Renaissance was changing the whole intellectual and artistic world of Europe, we find the religious guild plays beginning to decline; a new professional theatre was being born, but at the same time there came a new impetus of community drama from the universities and schools. In England, some of the first Elizabethan dramatic literature was written for academic performances. Classical Latin plays were translated or adapted for English use, and one Nicholas Udal, headmaster of Eton college, wrote one of our first English comedies, *Ralph Roister Doister.* While the modern schoolboy might find it somewhat lengthy and involved, it is, nevertheless, full of healthy humour, interesting as one of the first examples of the modern school play. How far the earlier guild drama had degenerated at this time may be seen from the skit on the amateur play of "rude mechanicals" which Shakespeare gives us in *A Midsummer Night's Dream*. Bottom, the weaver, and his associates were obviously drawn from life, and their crude art might be paralleled by some of the less developed types of village drama which are to be seen at this day.

The Puritan movement was a severe setback to the English theatre as a whole, and at the Restoration the drama developed mainly on professional lines. On the Continent, however, amateur playing had continued to flourish, *e.g.*, the famous Passion Play at Oberammergau, first performed in 1633, and, with only one period of suppression, continued ever since. "Private Theatricals," however, were not unknown in England throughout the 18th century. In the 19th century, Charles Dickens was an enthusiastic amateur, and there came into existence a somewhat debased form of amateur drama conducted mainly as a fashionable social exercise under the cover, often, of some charitable object. In 1855, however, an important event occurred; the foundation of the Cambridge University Amateur Dramatic Club by Sir Francis Burnand, and some years later, Oxford followed suit. From that time a new interest in amateur drama became prevalent which was to culminate in the modern Little Theatre movement. These tendencies were by no means confined to England. In Russia, Stanislavsky's Moscow Art Theatre, in Paris the theatres of Antoine and Copeau, in Ireland the Abbey Theatre, Dublin, were instances of stage work initiated outside the professional theatre and destined to influence the whole conception of the theatre's aim and method. At the end of the World War the new spirit in the theatre was so well established that drama at once occupied an important place in all schemes for social and cultural reconstruction.

In Soviet Russia, community or proletarian drama was officially encouraged. One of the first acts of the revolutionary Government was, indeed, to turn the whole Russian theatre into a community theatre. Every professional playhouse was declared national property, and the work of every theatre company was placed under Government control, and supported by Government finance. The Government also encouraged the production of revolutionary drama written, acted and produced by the workers themselves. But, according to Bakshy, there is no sign that this amateur movement is destined at any time to take the place of the professional theatre.

In Germany, though the Government has not concerned itself specifically with the theatre, there have been various attempts on the part of labour and socialist organizations to gain control of professional playhouses. In some cases, *e.g.*, in Berlin, this object has been achieved, and a similar tendency is observable in Austria. France, Spain and the Scandinavian countries have felt the influence of the community movement rather less, although the traveller in France may be faced unexpectedly with the dramatic activities of a university. At Poitiers, for example, the students have built up an artistic section called *Le Studio*, which, besides helping other local societies, has produced monthly a new play of literary value. As for Italy, *Fascismo* does what it can to encourage drama in Italian schools and factories under the aegis of the *Opera Nazionale Dopolavoro*.

Great Britain.—The remarkable growth of community drama in post-war England is shown by the success of the British Drama League. The league was founded in 1919, and affiliated one small village group at Chaldon in Surrey. Ten years later there were 1,500 societies on the register of the league, the large majority being play-producing societies engaged in the study or practice of community drama. Many of these are humble village groups, attached, as likely as not, to the Federation of Women's Institutes, but there are many bands of village players working on their own, and some have actually won fame far and away beyond their own countryside. Such are the Grasmere players in the Lake district, the Hardy players of Dorchester and the Stoneland players of Sussex. The last named, in a picturesque and ancient farmyard, produce Greek plays in the English versions of Gilbert Murray. Village acting also is specially the concern of the Village Drama Society, while the company of the Arts League of Service founded just after the war, has brought to many a remote hamlet, plays and interludes of high artistic standard, thus setting an example of what can be done on a simple stage and with few material resources.

Urban community drama is, in the nature of things, likely to attain a higher degree of elaboration and permanence than is possible in the country. The Everyman Theatre, founded in Hampstead by Norman Macdermott in 1920, had a great influence in stimulating interest in the Little Theatre movement not only in London but in the provinces. That was a professional undertaking. But in cities like Hull, Huddersfield, Manchester, Liverpool, Stockport, Bath, Birmingham, Bristol and Norwich, there are Little Theatres more or less continuously occupied by companies of amateur players. The Unnamed Society of Manchester has found in Sladen-Smith a dramatist whose work is well-known to the Little Theatre players throughout the country, though it is worth while noting that the amateur Little Theatre movement in Great Britain has, on the whole, proved strangely barren in playwrights whose work has been utilized by the professional stage. A note of exception must be made in regard to the Abbey theatre, Dublin, which has been the means of endowing English dramatic literature with the works of J. M. Synge, W. B. Yeats, Lady Gregory and W. Sean O'Casey. Mr. John Drinkwater also is a playwright who owes much to his early work at the Birmingham Repertory Theatre.

Lastly, the modern movement has not been untouched by religion. Modern mystery plays have been acted in many churches, and there are even instances where a local theatre has been hired for so long as a week at a time for the performance of a religious play or pageant, created and acted by the congregation of a simple parish church. Hofmannsthal's *Great World Theatre* has been performed in a church at Leeds, and the movement may be said to have culminated in the production of an original nativity play by John Masefield in the nave of Canterbury cathedral. The costumes for this play were designed by Charles Ricketts, and the music composed by Gustav Holst.

COMMON PROBLEMS

Reaction from Materialism.—Deep impulses in national psychology must have been at work to account for so striking a revival in so many countries in Europe. The simplest explanation would seem to be that the materialism rampant in life during the World War, and in thought during the period immediately succeeding it, has brought about a natural reaction which seeks to revive faith in the reality of the human spirit by the objective manifestation of it through the medium of drama. This impulse has been unable to find satisfactory or sufficient outlet through the passive witnessing of professional stage plays. Men and women have desired to come to closer grips with the fundamentals of dramatic art.

Take an average town or city; some social workers may have established a dramatic class in connection with a working men's club. This work becomes known to two or three keen students of the drama, and they determine to establish a little theatre, either in the centre of the town or in a convenient suburb. A meeting is called, a committee formed, and important people in the district give their sympathy, and even a few subscriptions are received. The new society rents a hall, and a programme of half-a-dozen plays is chosen, these to be spread over a season of three or four months, each production to last, say, a week, giving an interval of two or three weeks between each new play. The plays themselves will be chosen by a special committee, which will draw up a list of 20 or more plays, from which the producer will make his own choice, with due regard to the character of the players and the money available. All this may seem easy enough in print, but it is not so easy in practice. With little or no experience to guide it, the society will be at once confronted with countless problems. In the first place, the hall or room will almost certainly have to be specially adapted for stage performances. Even if there be electric light, a special stage equipment must be installed. Footlights are useful but not necessary, provided that flood lights

LITTLE THEATRES IN THE UNITED STATES

1. The Provincetown Playhouse, New York city, founded in 1916; one of the earliest art theatres in the United States. In 1918 the Provincetown group moved into this building, first a carriage-house, then a bottling plant, and last an experimental theatre for playwrights
2. The Lobero Theatre, Santa Barbara, Calif.; a community theatre with every modern equipment, built by the citizens and financed by them
3. The Yale University Theatre, New Haven, Conn., 1926; a modern college theatre and workshop combined, founded by Prof. George Pierce Baker. The tower-like structure in the background is the stage building, containing modern equipment and lighting plant
4. The Pasadena Community Playhouse, Pasadena, Calif.; a playhouse built and financed by the citizens of Pasadena in 1925
5. The Little Theatre, Dallas, Texas, opened April 9th, 1928. This little art theatre became nationally famous for its unusual productions under Oliver Hinsdell's direction
6. The Cleveland Playhouse, Cleveland, Ohio, 1927; a model art theatre. Deriving from amateur beginnings, it has advanced to professional stature in building, direction, productions and repertory. Architect, Philip Lindsay Small

PRODUCTIONS BY LITTLE THEATRES IN THE UNITED STATES

1. "The Sunken Bell," Act III., by Gerhart Hauptmann, produced at the Cleveland Playhouse. Design by Frederic McConnell, director. From a photograph by Clifford Norton
2. Permanent setting for "The Great God Brown," by Eugene O'Neill, produced at the Cleveland Playhouse. Frederic McConnell, director. Design by K. Elmo Lowe, from a photograph by Clifford Norton
3. Scene from "Gas," by Georg Kaiser, the first play with a constructivist setting to be given in America. It was produced at the Kenneth Goodman Memorial Theatre, Chicago, under the direction of Thomas Wood Stevens. Produced by Marion Gering, with settings by Louis Lozowick
4. "Caste," by Tom Robertson, produced by The Cornish Players, Seattle, Washington, Nov. 1927, under the direction of Mr. and Mrs. Burton W. James. Settings designed by Floragnes Smith
5. "Clay," a tragedy of a Farm Boy, by David Ried Hoggin, a Carolina Folk-Play, produced by the Carolina Playmakers, University of North Carolina. Director Frederick H. Koch
6. "The Life of Man," by Leonid Andreiev, produced at the Carnegie Institute of Technology, Pittsburgh. Staged by Theodore Viehman; settings designed by Lee Mitchel, and executed under his direction

can be installed; these, in the form of lamps placed in five or six empty biscuit tins, with the necessary coloured gelatine screens, can be secured at a cost of £3 or £4. But ingenuity must be shown in their fixture. They must be movable, and easily suspended out of sight of the audience and just behind the proscenium arch. If scenery is impossible, it may be decided to play entirely to curtains. And then it must be discovered if the hall is so constructed as to qualify for a licence for the performance of stage plays. When all these difficulties have been surmounted, care must be taken to fulfil the conditions of stage copyright with regard to the plays produced.

The most interesting problem which confronts the Little Theatre movement is its relation to the professional and commercial theatre. In England both the Stage Guild (the representative body of the professional actors) and the Touring Managers' Association have taken official cognizance of the amateur movement; relations between the professional and the amateur have continued to be friendly. Unemployment in the theatre is a pressing and often a tragic condition, but it would be difficult to maintain that the smaller amateur groups attract a sufficient audience to make them in any real sense competitive with professional theatres. The few really important amateur theatres, some of them combining professional and amateur players, which tend to develop into full-time professional undertakings, thereby become at once new centres for professional employment.

Exactly the same tendency is seen in other countries wherever an amateur undertaking has found itself under the control of an amateur producer whose gifts and opportunities have been such as to draw him to professionalize the undertaking. The most famous instance of this is undoubtedly to be found in the genesis of the Moscow Art theatre, which began as a small enterprise of amateur theatricals in a country house near Moscow. The history of this movement is written in full by Constantin Stanislavski in *My Life in Art,* a book which should be in the hands of every student of community drama.

Endowment.—The municipally endowed theatre, as the logical extension of the community theatre idea, has been widely canvassed in England. On the continent of Europe, where public taste is usually considered to have reached a higher and more widespread level than elsewhere, State or municipal endowment has for long been a normal feature of the theatrical system. In France or Germany it is freely admitted that the more noble manifestations of stage art are seldom paying propositions, and that private enterprise cannot be expected to make impossible and continual sacrifices for the general good. The result is that few of the continental nations are without their national and municipal theatres. In many towns in central Europe the municipal theatre is the only reputable playhouse. Among English speaking peoples a great deal of the contemporary enthusiasm for community drama arises from dissatisfaction with the fare provided by the professional theatre. The amateur does his best to fill the gap, but to confine the work of the community stage within amateur limits is to narrow its scope unduly. The national theatre problem and the influence it might exercise upon the art of the professional stage will, in its solution, determine the future of the community theatre, for a national theatre is nothing more or less than the community theatre on a large scale.

(G. Wh.)

THE UNITED STATES

For many years there have been theatres and amateur acting groups in America with features similar to those of present-day Little Theatres. Some of the early experiments made by Mary Austin in the west and south-west bore the stamp of authentic community theatre and community drama. But during the years 1906 and 1907 three groups were organized in Chicago which may safely be said to represent the beginning of the Little Theatre movement. Two of these groups were the New Theatre, directed by Victor Mapes, and the Robertson Players, under the leadership of Donald Robertson. The theatre of the trio that survived and that has had a vigorous and intensely useful life was the Hull House theatre, under the direction of Laura Dainty Pelham. In 1911 came the Wisconsin Dramatic Society, which exists under the direction of Laura Sherry. In the next year Maurice Browne started the Little Theatre of Chicago, and Mrs. Lyman Gale the Toy Theatre of Boston. In New York city organizations like the Festival Players of the Henry Street Settlement, which later became the Neighborhood Playhouse, the Provincetown Players, the Washington Square Players, which later became the Theatre Guild, form a vital part of the little theatre movement. Soon the Arts and Crafts Society of Detroit, with Sam Hume as director, founded a magazine of the theatre as a part of its activities. This journal, *Theatre Arts,* has been much enlarged in scope. It is now published in New York, and has established a means of communication between little theatres throughout the country.

The Growth of the Community Drama.—In the next 15 years little theatres sprang up like mushrooms in cities and towns all over the United States, hundreds of new organizations and scores of new playhouses being added to the record every year as the impulse toward a fuller dramatic life grew in strength and volume. The theatres ranged from rebuilt barns and bowling alleys, seating from 50 to 100 people, giving five or six single performances a year with amateur actors and makeshift scenery and lighting equipment, to theatres having the most complete modern building and equipment, including the most advanced stage mechanisms, and giving repertories of from 8 to 20 plays during a long season. The prices at these theatres range from $.50 to $2.00 or more. Most of them have some form of membership organization and subscription audience. Increasingly they are under the leadership of a professional director with the additional professional service of designer, stage carpenter, electrician and so forth, as the budget and necessity require. But the spirit still is and probably will remain always largely amateur. A great many of the ideals of the little theatre come directly from Europe, where experimental theatre organizations, variously called "Free Theatre," "Independent Theatre," "Art Theatre," "Stage Society," etc., have thriven under the leadership of distinguished men like Gordon Craig, André Antoine, Max Reinhardt, Constantin Stanislavski, Jacques Copeau, Granville-Barker and others. The American movement is distinguished from the European by its largely amateur leadership and following and its importance comes from the fact that it seems gradually to be evolving an American drama and a typically American art of the theatre. Moreover, within itself, the movement has had its ultimate source in three fairly distinct native impulses—economic, artistic, educational—and these usually have been reflected in the types of theatres they developed.

Sources of Three Main Types of Little Theatres.—For purposes of identification, these three types can be distinguished as community theatres, art theatres and college theatres or workshops, although their aims and results overlap so much that they should not be considered separately. The community theatre has come as a result of the break-up of the touring system which, controlled by an organized trade theatre in New York, for many years provided dramatic entertainment to the cities of the entire country. The high price of rents, railroading and publicity, added to a growing lack of faith in their offerings, gradually ruined the business of "the road," as it was called, closed most of the large playhouses or turned them into cinemas, and left the cities of the country largely dependent upon their own resources to supply some form of spoken drama.

The art theatre is the direct result of the desire of many young

American artists to express themselves creatively in terms of the theatre arts—play-writing, acting, directing, designing, etc.—even more alluring perhaps because a participation in them had so long been denied by Puritan tradition.

The college theatre is the most native and in many ways the most influential of the three forms. It grew out of a fusion of modern educational impulses: an appreciation of the value of the dramatic method in instruction, a desire to stimulate an understanding of the world's great dramas through a differentiation between literature intended to be read and plays intended to be acted; the need in modern psychological drama for playwrights and players with enough education to interpret life in the aspects that are more complex than mere situation; the necessity for giving students intending to work professionally in the theatre the advantage of workshop training in association with workers in the related arts, so as to enable them to save years of effort and error in a profession in which waste is disastrously expensive; and finally the desire to stimulate the theatre intelligence of the American audience, so long theatre-starved. Although any idea of such breadth and complexity is always a product of its hour rather than the invention of a single mind, the giant's share in the inception and realization of the college theatre and workshop is generally credited to George Pierce Baker, for years from 1905 professor of English at Harvard university, who started the course in playwriting known as "English 47" which, under his leadership grew to be the "47 Workshop."

College Theatres and Workshops.—The college theatre in 1928 extended from amateur dramatic groups, through the Elizabethan clubs and dramatic societies, which act as interpreters to the literary and historical courses in drama, to the drama departments and theatre workshops, many of which provided their own completely equipped playhouses. Among the courses they include are: general history of the theatre, playwriting, acting, rehearsal and performance, English pronunciation and stage speech, stagecraft, scene design, costume, the puppet theatre, stage lighting, dramatic production, etc. In many cases, and increasingly, work done in these courses is counted toward an academic degree. In some cases, as at Yale, where the department of drama is almost entirely devoted to post-graduate work, a special "certificate of proficiency" is issued. In spite of the age-old theory that the only school of the theatre is the theatre, the entire trend in America is toward a training wherever possible in one of these laboratories. Among the most complete and successful are the departments of drama at Yale university, at the Carnegie Institute of Technology at Pittsburgh, at Cornell, Vassar, Dartmouth, Wellesley, Smith, Southern California, the State universities of Iowa, Washington, California, Montana. Graduates of these institutions are in evidence all over America to-day in every branch of the little theatre, at the head of other college theatres or departments of drama, as directors, actors, designers and as successful artists in the professional theatre in New York. For example, among the men and women who have achieved success after working with Professor Baker either at the 47 Workshop or at the Yale department of drama of which he has been the head since it was founded in 1924 are Edward Sheldon, Eugene O'Neill, Sidney Howard, Philip Barry and Maurine Watkins, playwrights; Robert Edmond Jones, Lee Simonson and Donald Mitchell Oenslager, designers; Kenneth Macgowan, Theresa Helburn, Irving Pichel and Sam Hume, directors; Robert Benchley, Heywood Broun, Walter Prichard Eaton, David Carb and John Mason Brown, critics; Alexander Dean, J. A. Crafton, Esther W. Bates, Sam Eliot, Jr., and Frederick H. Koch, teachers. Each year some of these colleges add new theatres to their campuses, and the buildings are notable examples of modern theatre design and especially of stage equipment. In many important college towns these are the only theatres showing living drama today.

One special phase of dramatic work which the college workshops have developed and which offers great promise in the actual creation of an American drama and a complete American theatre is folk play-making. In the wheat fields of the Dakotas, in the sea-coast centres of the State of Washington, in the mountains of North Carolina, college groups are learning to re-create the history of their States, to interpret the character of their people, the quality and meaning of their life and labour. All the plays in these groups are written by the students on the basis of local material, to carry on a story or to establish a tradition. They are acted by student actors, and increasingly are enlarging their audiences to cover the people not only of the college town but of neighbouring towns and sometimes of neighbouring States. The Carolina Playmakers of the University of North Carolina, under the direction of Frederick Koch, have built up a large repertory of folk-plays of their own writing, a theatre company and an entire crew which travels in a large touring truck through the cities and towns of a dozen States. In North Dakota, Alfred Arvold, director of drama of the State agricultural college at Fargo, keeps the Little Country Theatre on the second floor of the administration building continually busy with productions of plays that range from Shakespeare and Ibsen to modern farce and that play to audiences of grain-growers, cattle-ranchers, miners, who come from miles around. Through the influence of Arvold's work, moreover, hardly a school-house is built in North Dakota to-day without a theatre equipment, hardly a crop is harvested without a pageant of the grain to celebrate and illuminate it, hardly an event of historical or political significance passes without its dramatic interpretation.

The Community Theatre.—The community theatre is organized to provide good entertainment for the average taste of the average family in a community, at a cost not above what the average man can afford. To be successful it must give the largest possible number of people an opportunity each to have some part in the work, not only as playwright, director, designer, actor, but as scene-painter, seamstress, electrician, business manager, play-reader, ticket taker, house manager, usher, etc., which, taken together, make the community theatre in itself a working community.

Moreover, it must be run with enough economy and economic security not to be an undue financial burden. The success of such a theatre depends on many special features. A community that is far away from the centre of theatre distribution, with an element of wealth or at least of leisure, and with a certain homogeneity, lends itself more readily to the experiment than one that is too near a metropolis, too largely industrial, too varied in its citizenship and citizen interest. The success of such a theatre depends, moreover, on certain important and rare qualities in the director, who must be at once a competent artist, a good manager and a good leader; somebody who will understand the many-sided problems of securing and spending municipal funds, who can produce good plays well, gauge the popular taste well enough to satisfy and improve it, interest his workers and create an enthusiastic and responsive audience. There are good community theatres all over America, many of them unknown outside their community and yet doing important work. Several of the best known are, as might be expected, well out of range of New York production and touring companies. In California, the Pasadena Community Theatre, under the direction of Gilmor Brown, seems to have solved most of the problems of a community theatre.

The development of community art centres in American cities and towns has given an added impetus to the growth of these theatres which—on account of the many opportunities offered by a theatre stage and auditorium—are recommended by architects and city planners as a good focus for a community art building.

The Art Theatre.—The measure of the community theatre's success is the response it gets from the community. The measure of an art theatre's success is the freedom and creative quality of its production, the contribution it makes to the growth of the individual artist and to theatre progress. The art theatre that is most apt to succeed is one that starts with a director who is at once a man of aesthetic instinct and of broad sympathy, who can use the talents of other artists creatively and gain impetus from the force of a creative failure as well as from an artistic success. Because experiment in the theatre is by its nature so expensive, because a successful artist developed by an art theatre naturally turns to professional fields of larger opportunity, as well as because good directors are scarce, there are not many art theatres in the country, except in New York, which have been permanent. There are a few worthy leaders who have achieved fine theatres, good repertories and a fair permanence of cast by steadiness of purpose. The only art theatre which has come through from amateur beginnings to professional stature in its building, its direction, its repertory and its productions, is the Cleveland playhouse, under the direction of Frederic McConnell.

What is the general trend of the little theatre movement is difficult to indicate. It is for the first time in America establishing the theatre as a force in the social life of cities large and small, it is using the dramatic impulse in education to the full, it is developing the talents of hundreds of theatre artists of various kinds, it is serving as a tributary stream to the larger stream of professional theatre life which still centres in New York. There is no end to what it can do from these beginnings.

LITTLETON or **LYTTELTON, EDWARD,** Baron (1589–1645), son of Sir Edward Littleton (d. 1621) chief-justice of North Wales, was born at Munslow in Shropshire; he was educated at Oxford and succeeded his father as chief-justice of North Wales. In 1625 he became a member of parliament and acted in 1628 as chairman of the committee of grievances upon whose report the Petition of Right was based. In 1631 he became recorder of London, and in 1634 the king attached him to his own side by appointing him solicitor-general. In the famous case about ship-money Sir Edward argued against Hampden. In 1640 he was made chief-justice of the common pleas and in 1641 lord keeper of the great seal, being created a peer as Baron Lyttelton. In Jan. 1642 he refused to put the great seal to the proclamation for the arrest of the five members and he voted for the militia ordinance. He returned the great seal to Charles, but recovered it after joining the king at York. Littleton died at Oxford on Aug. 27, 1645; he left no sons and his barony became extinct.

LITTLETON, SIR THOMAS DE (*c.* 1407–1481), English judge and legal author, was born, it is supposed, at Frankley Manor House, Worcestershire, about 1407. He is said by Sir E. Coke to have "attended one of the universities," but there is no corroboration of this statement. He was probably a member of the Inner Temple, and lectured there on the statute of Westminster II., *De Donis Conditionalibus.* His name occurs in the Paston Letters (ed. J. Gairdner, i. 60) about 1445 as that of a well-known counsel and in 1481–42 he received a grant of the manor of Sheriff Hales, Shropshire, from a Sir William Trussel as a reward for his services as counsel. He appears to have been recorder of Coventry in 1450; he became serjeant-at-law in 1453 and was afterwards a justice of assize on the northern circuit. In 1466 he was made a judge of the common pleas, and in 1475 a knight of the Bath. He died, according to the inscription on his tomb in Worcester Cathedral, on Aug. 23, 1481. He married, about 1444, Joan, widow of Sir Philip Chetwind of Ingestrie in Staffordshire, and by her had three sons.

His *Treatise on Tenures* was probably written after he had been appointed to the bench. It is addressed to his second son Richard, who went to the bar, and whose name occurs in the year books of the reign of Henry VII. It was printed in 1481 or 1482, was one of ten earliest books published in London, and the earliest treatise on English law ever printed. There are two mss. of it written when he was alive. The book was written in law French, which was still in use for law books, though proceedings in the courts had to be in English. The essential element of English law at that time was land law, and it is of this that Littleton treats. Unlike the preceding writers on English law, Glanville, Bracton and the authors of the treatises known by the names of Britton and Fleta, Littleton borrows nothing from the sources of Roman law or the commentators. He deals exclusively with English law.

The book is written on a definite system, and is the first attempt at a scientific classification of rights over land. Littleton's method is to begin with a definition, usually clearly and briefly expressed, of the class of rights with which he is dealing. He then proceeds to illustrate the various characteristics and incidents of the class by stating particular instances, some of which refer to decisions which had actually occurred, but more commonly they are hypothetical cases put by way of illustration of his principles. He occasionally refers to reported cases. His book is thus much more than a mere digest of judicial decisions; to some extent he pursues the method which gave to Roman law its breadth and consistency of principle. In Roman law this result was attained through the practice of putting to jurisconsults hypothetical cases to be solved by them. Littleton, in like manner, is constantly stating and solving by reference to principles of law cases which may or may not have occurred in actual practice.

One may summarize the scope of the book by saying that it affords a complete view of the English land-law (that is to say, substantially, of the English law) of the middle ages, before it had become affected by the recognition of equitable rights in land. Not that Littleton was personally unaware of these, as his will shows. The first book of Coke's *Institutes* is in the form of a commentary on Littleton's *Tenures.*

Bibliography.—There are three early mss. of Littleton at Cambridge. The *editio princeps* is by Letton and Machlinia (1481–82). There were many editions in the 16th century. The first English translation is by Rastell (between 1514 and 1533). There are many commentaries, one earlier than Coke. The existing division into sections dates from the edition of West (1581).

See E. Wambaugh, *Littleton's Tenures in English* (Washington, D.C., 1903).

LITTLETON, town of Grafton county, New Hampshire, U.S.A., beautifully situated on the Ammonoosuc and the Connecticut rivers, at an altitude of 1,100 ft., 11 mi. N.W. of the Franconia notch. It is served by the Boston and Maine railroad. The population in 1930 was 4,558; in 1940, 4,571. It is a summer and winter resort and the business centre for the White mountain region. Its manufactures include whetstones, razor strops, shoes, furniture, caskets, and over 1,000,000 pairs a year of buckskin gloves and mittens. The town was at first called Apthorp, and later Chiswick. In 1874 it was incorporated under the name of Littleton, in honour of one of the first settlers.

LITTRÉ, MAXIMILIEN PAUL ÉMILE (1801–1881), French lexicographer and philosopher, was born in Paris on Feb. 1, 1801. He was educated at the Lycée Louis-le-Grand, where he had for friends Hachette and Eugène Burnouf. He then studied the English and German languages, and classical and Sanskrit literature and philology. He intended to become a doctor, and had completed his studies when his father's death (1827) made it necessary for him to begin earning money. He began to teach classics, and in 1835 became a regular contributor to the *National,* and eventually director of the paper. In 1839 appeared the first volume of his edition (completed 1862) of the works of Hippocrates, which secured his election the same year into the Académie des Inscriptions et Belles-Lettres. He also became a friend of Comte, and popularized his ideas in numerous works on the positivist philosophy.

About 1844 he started working on his great *Dictionnaire de la langue française.* In the revolution of July 1848 he took part in the repression of the extreme republican party in June 1849. His essays, contributed during this period to the *National,* were collected together and published under the title of *Conservation, révolution et positivisme* in 1852, and show a thorough acceptance of all the doctrines propounded by Comte. During the later years of Comte's life, he found himself out of sympathy with the more mystic ideas of his friend and master, but he concealed his differences of opinion, and Comte failed to perceive that his pupil had outgrown him, as he himself had outgrown his master Saint-Simon. After Comte's death in 1858 he felt free to publish his own ideas in his *Paroles de la philosophie positive* (1859), and at still greater length in his work in *Auguste Comte et la philosophie positive* (1863).

About 1863, after completing his Hippocrates and his Pliny, he set to work in earnest on his French dictionary. In the same year he was proposed for the Académie Française, but rejected, owing to the opposition of Mgr. Dupanloup, bishop of Orleans, who denounced him in his *Avertissement aux pères de famille* as the chief of the French materialists. He also at this time started with G. Wyrouboff the *Philosophie Positive*, a review which was to embody the views of modern positivists. His life was thus absorbed in literary work till the overthrow of the empire called on him to take a part in politics. He felt himself too old to undergo the privations of the siege of Paris, and retired with his family to Brittany, whence he was summoned by Gambetta to Bordeaux, to lecture on history, and thence to Versailles to take his seat in the senate to which he had been chosen by the department of the Seine. In Dec. 1871 he was elected a member of the Académie Française in spite of the renewed opposition of Dupanloup, who resigned his seat rather than receive him When he was on the point of death, his wife had him baptized, and his funeral was conducted with the rites of the Catholic Church. He died on June 2, 1881.

Littré's *Dictionary* was completed in 1873. An authoritative interpretation is given of the use of each word, based on the various meanings it had held in the past.

For his life consult C. A. Sainte-Beuve, *Notice sur M. Littré, sa vie et ses travaux* (1863); and *Nouveaux Lundis*, vol. v.; also the notice by M. Durand-Gréville in the *Nouvelle Revue* of Aug. 1881; E. Caro, *Littré et le positivisme* (1883), Pasteur, *Discours de réception* at the Academy, where he succeeded Littré, and a reply by E. Renan.

LITURGY, in the technical language of the Christian Church, the order for the celebration and administration of the Eucharist. The word (from Gr. λειτουργία, public service) has come to be used in a more general sense to denote any or all of the various prescribed forms of public worship. In this article the liturgy is treated in the stricter sense.

There are nine main families or groups of liturgies, four of them being of Eastern and five of them of Western origin and use. They are known either by the names of the apostles with whom they are traditionally connected, or by the names of the countries or cities in which they have been or are still in use.

The Syrian Rite (St. James).—The principal liturgies to be enumerated under this group are the Clementine liturgy, so called from being found in the eighth book of the Apostolic Constitutions, which claim in their title, though erroneously, to have been compiled by St. Clement, the 1st-century bishop of Rome; the Greek liturgy of St. James; the Syriac liturgy of St. James. Sixty-four more liturgies of this group have existed, the majority being still in existence. Their titles are given in F E. Brightman's *Liturgies, Eastern and Western* (1896), pp. lviii.-lxi

The Egyptian Rite (St. Mark).—This group includes the Greek liturgies of St. Mark, St. Basil and St. Gregory, and the Coptic liturgies of St. Basil, St. Gregory, St. Cyril or St. Mark; together with certain less known liturgies the titles of which are enumerated by Brightman (*op. cit.* pp. lxxiii. lxxiv.). The liturgy of the Ethiopian church ordinances and the liturgy of the Abyssinian Jacobites, known as that of the Apostles, fall under this group.

The Persian Rite (SS. Adaeus and Maris).—This Nestorian rite is represented by the liturgy which bears the names of SS. Adaeus and Maris together with two others named after Theodore of Mopsuestia and Nestorius. This group has sometimes been called "East-Syrian." The titles of three more of its now lost liturgies have been preserved, namely those of Narses, Barsumas and Diodorus of Tarsus. The liturgy of the Christians of St. Thomas, on the Malabar coast of India, formerly belonged to this group, but it was almost completely assimilated to the Roman liturgy by Portuguese Jesuits at the synod of Diamper in 1599.

The Byzantine Rite.—The Greek liturgies of St. Chrysostom, St. Basil and St. Gregory Dialogus, or The Presanctified, also extant in other languages, are the living representatives of this rite. The Greek liturgy of St. Peter is classified under this group, but it is merely the Roman canon of the Mass, etc., inserted in a Byzantine framework, and seems to have been used at one time by some Greek communities in Italy. To this group also belongs the Armenian liturgy, of which ten different forms have existed in addition to the liturgy now in general use named after St. Athanasius.

The Hispano-Gallican Rite (St. John).—This group of Latin liturgies, which once prevailed very widely in Western Europe, has been almost universally superseded by the liturgy of the Church of Rome. Where it survives, it has been more or less assimilated to the Roman pattern It prevailed once throughout Spain, France, northern Italy, Great Britain and Ireland The term "Ephesine" has been applied to this group or family of liturgies, chiefly by English liturgiologists, and the names of St. John and of Ephesus, his place of residence, have been pressed into service in support of a theory of Ephesine origin, which, however, lacks proof and may now be regarded as a discarded hypothesis. Other theories represent the Gallican to be a survival of the original Roman liturgy, or an importation into Western Europe from the East through a Milanese channel.

The Mozarabic Liturgy.—This was the national liturgy of the Spanish church till the close of the 11th century, when the Roman liturgy was forced upon it. Its use, however, lingered on, till in the 16th century Cardinal Ximenes, anxious to prevent its becoming quite obsolete, had its books restored and printed, and founded a college of priests at Toledo to perpetuate its use. It survives now only in several churches in Toledo and in a chapel at Salamanca, and even there not without certain Roman modifications of its original text and ritual.

Gallican Liturgy.—This was the ancient and national liturgy of the church in France till the commencement of the 9th century, when it was suppressed by order of Charlemagne, who directed the Roman missal to be everywhere substituted in its place. All traces of it seemed for some time to have been lost until three Gallican sacramentaries were discovered and published by Thomasius in 1680 under the titles of *Missale Gothicum, Missale Gallicum* and *Missale Francorum*, and a fourth was discovered and published by Mabillon in 1687 under the title of *Missale Gallicanum.* Fragmentary discoveries have been made since. Mone discovered fragments of eleven Gallican masses and published them at Carlsruhe in 1850. Other fragments from the library at St. Gall have been published by Bunsen (*Analecta Ante-Nicaena,* iii. 263–266), and from the Ambrosian library at Milan by Cardinal Mai (*Scriptt. Vet. Vat. Coll.* iii. 2. 247). A single page was discovered in Gonville and Caius College, Cambridge, published in *Zeitschrift für Kath. Theologie,* vi. 370.

Ambrosian Liturgy.—Considerable variety of opinion has existed among liturgical writers as to the proper classification of the "Ambrosian" or "Milanese" liturgy. If we are to accept it in its present form and to make the present position of the great intercession for quick and dead the test of its *genus,* then we must classify it as "Petrine" and consider it as a branch of the Roman family If, on the other hand, we consider the important variations from the Roman liturgy which yet exist, and the traces of still more marked variation which confront us in the older printed and ms. copies of the Ambrosian rite, we shall detect in it an original member of the Hispano-Gallican group of liturgies, which for centuries underwent a gradual but ever-increasing assimilation to Rome. We know this as a matter of history, as well as a matter of inference from changes in the text itself. Charlemagne adopted the same policy towards the Milanese as towards the Gallican church. He carried off all the Ambrosian church books which he could obtain, with the view of putting Roman books in their place, but the completion of his intentions failed, partly through the attachment of the Lombards to their own rites, partly through the intercession of a Gallican bishop named Eugenius (Mabillon, *Mus. Ital.* tom. i. Pars. ii. p. 106). It has been asserted by Joseph Vicecomes that this is an originally independent liturgy drawn up by St. Barnabas, who first preached the Gospel at Milan (*De Missae* Rit. 1 capp. xi. xii.), and this tradition is preserved in the title and proper preface for St. Barnabas Day in the Ambrosian missal (Pamelius, *Liturgicon,* i. 385, 386), but it has never been proved.

The Roman Rite (St. Peter).—There is only one liturgy to be enumerated under this group, viz. the present liturgy of the Church of Rome, which, though originally local in character and circumscribed in use, has come to be nearly co-extensive with the Roman Catholic Church, sometimes superseding earlier national liturgies, as in Gaul and Spain, sometimes incorporating more or less of the ancient ritual of a country into itself and producing from such incorporation a sub-class of distinct Uses, as in England, France and elsewhere. Even these subordinate Uses have for the most part become, or are rapidly becoming, obsolete.

The date, origin and early history of the Roman liturgy are obscure. The first Christians at Rome were a Greek-speaking community and their liturgy must have been Greek, and is possibly represented in the so-called Clementine liturgy. But the date when such a state of things ceased, when and by whom the present Latin liturgy was composed, whether it is an original composition, or, as its structure seems to imply, a survival of some intermediate form of liturgy—all these are questions which are waiting for solution.

The Roman liturgy seems to have been introduced into England in the 7th, into France in the 9th and into Spain in the 11th century, though no doubt it was known in both France and Spain to some extent before these dates. In France certain features of the service and certain points in the ritual of the ancient national liturgy became interwoven with its text and formed those many varying mediaeval Gallican Uses which are associated with the names of different French sees.

The chief distinguishing characteristics of the Roman rite are these: (*a*) the position of the great intercession for quick and dead within the canon, the commemoration of the living being placed just before and the commemoration of the departed just after the words of institution; (*b*) the absence of an "Epiklesis" or invocation of the Holy Ghost upon the elements; (*c*) the position of the *Pax* or "Kiss of Peace after the consecration" and before the communion, whereas in other liturgies it occurs at a much earlier point in the service.

LITURGIES OF THE BRITISH ISLES

Period I. The Celtic Church.—Until recently almost nothing was known of the character of the liturgical service of the Celtic church which existed in these islands before the Anglo-Saxon conquest, and continued to exist in Ireland, Scotland, Wales and Cornwall for considerable though varying periods of time after that event. But in recent times a good deal of light has been thrown on the subject, partly by the publication or republication of the few genuine works of Patrick, Columba, Columbanus, Adamnan and other Celtic saints; partly by the discovery of liturgical remains in the Scottish *Book of Deer* and in the Irish *Books of Dimma and Mulling* and the *Stowe Missal*, etc.; partly by the publication of mediaeval Irish compilations, such as the *Lebar Brecc, Liber Hymnorum, Martyrology of Oengus*, etc., which contain ecclesiastical kalendars, legends, treatises, etc., of considerable but very varying antiquity. The evidence collected from these sources is sufficient to prove that the liturgy of the Celtic church was of the Gallican type. In central England the churches, with everything belonging to them, were destroyed by the heathen invaders at the close of the 5th century; but the Celtic church in the remoter parts of England, as well as in the neighbouring kingdoms of Scotland and Ireland, retained its independence for centuries afterwards.

An examination of its few extant service-books and fragments of service-books yields the following evidence of the Gallican origin and character of the Celtic liturgy: (*a*) the presence of collects and anthems which occur in the Gallican or Mozarabic but not in the Roman liturgy; (*b*) various formulae of thanksgiving after communion; (*c*) frequent biddings or addresses to the people in the form of Gallican *Praefationes;* (*d*) the Gallican form of consecration, being a prayer called *Post-Sanctus* leading up to the words of institution; (*e*) the complicated rite of "fraction" or "the breaking of bread," as described in the Irish treatise at the end of the *Stowe Missal,* finds its only counterpart in the elaborate ceremonial of the Mozarabic church; (*f*) the presence of the Gallican ceremonial of *Pedilavium* or "Washing of feet" in the earliest Irish baptismal office. (*See* F. E. Warren, *Liturgy and Ritual of the Celtic Church,* 1881.)

Period II. The Anglo-Saxon Church.—We find ourselves here on firmer ground, and can speak with certainty as to the nature of the liturgy of the English church after the beginning of the 7th century. Information is drawn from liturgical allusions in the extant canons of numerous councils, from the voluminous writings of Bede, Alcuin and many other ecclesiastical authors of the Anglo-Saxon period, and above all from a considerable number of service-books written in England before the Norman Conquest. Three of these books are missals of more or less completeness: (1) the *Leofric Missal,* a composite 10th- to 11th-century ms. presented to the cathedral of Exeter by Leofric, the first bishop of that see (1046–1072), now in the Bodleian library at Oxford; edited by F. E. Warren (Oxford, 1883); (2) the missal of Robert of Jumièges, archbishop of Canterbury (1051–1052), written probably at Winchester and presented by Archbishop Robert to his old monastery of Jumièges in the neighbourhood of Rouen, in the public library of which it now lies; edited by H. A. Wilson (1896); (3) the *Red Book of Derby,* a ms. missal of the second half of the 11th century, now in the library of Corpus Christi College, Cambridge.

The Anglo-Saxon church owed its foundation to a Roman pontiff, and to Roman missionaries, who brought, as we are told by Bede, their native liturgical codices with them (*Hist. Eccles.* lib. ii. cap. 28). Accordingly, when we speak of an Anglo-Saxon missal, we mean a Roman missal.

Period III. Anglo-Norman Church.—The influx of numerous foreigners, especially from Normandy and Lorraine, which preceded, accompanied and followed the Conquest, and the occupation by them of the highest posts in church as well as state had a distinct effect on the liturgy of the English church. These foreign ecclesiastics brought over with them a preference for and a habit of using certain features of the Gallican liturgy and ritual, which they succeeded in incorporating into the service-books of the church of England. One of the Norman prelates, Osmund, count of Séez, earl of Dorset, chancellor of England, and bishop of Salisbury (1078–1099), is credited with having undertaken the revision of the English service-books; and the missal which we know as the *Sarum Missal,* or the *Missal according to the Use of Sarum,* practically became the liturgy of the English church. It was not only received into use in the province of Canterbury, but was largely adopted beyond those limits—in Ireland in the 12th and in various Scottish dioceses in the 12th and 13th centuries.

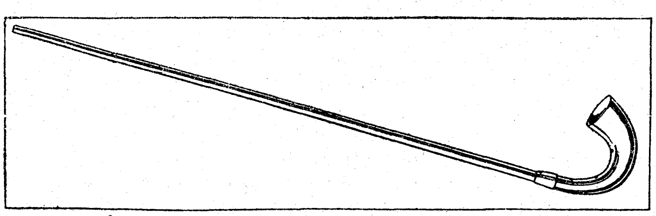
Besides the famous and far-spreading Use of Sarum, other Uses, more local and less known, grew up in various English dioceses. In virtue of a recognized diocesan independence, bishops were able to regulate or alter their ritual, and to add special masses or commemorations for use within the limits of their jurisdiction. The better known and the more distinctive of these Uses were those of York and Hereford, but we also find traces of or allusions to the Uses of Bangor, Lichfield, Lincoln, Ripon, St. Asaph, St. Paul's, Wells and Winchester. The Eucharistic service was contained in the volume called the Missal (*q.v.*), as the ordinary choir offices were contained in the volume known as the Breviary (*q.v.*).

Period IV. The Reformed Church.—The Anglican liturgy of Reformation and post-Reformation times is described under the heading of PRAYER, BOOK OF COMMON, but a brief description may be added here of the liturgies of other reformed churches. The liturgy of the Scottish Episcopal Church in nearly its present form was compiled by Scottish bishops in 1636 and imposed—or, to speak more accurately, attempted to be imposed—upon the Scottish people by the royal authority of Charles I. in 1637. The prelates chiefly concerned in it were Spottiswood, bishop of Glasgow; Maxwell, bishop of Ross; Wedderburn, bishop of Dunblane; and Forbes, bishop of Edinburgh. Their work was approved and revised by certain members of the English episcopate, especially Laud, archbishop of Canterbury; Juxon, bishop of London; and Wren, bishop of Ely. This liturgy has met with varied fortune and has passed through several editions. The present Scottish office dates from 1764. It is now used as an alternative form with the English communion office in the Scottish Episcopal Church. The general arrangement of its parts approximates more closely to that of the first book of Edward VI. than to the present Anglican Book of Common Prayer. (*See* Bishop J. Dowden, *The Annotated Scottish Communion Service*, 1884.)

American Liturgy.—The Prayer Book of "the Protestant Episcopal Church" in America was adopted by the general convention of the American church in 1789. It is substantially the same as the English Book of Common Prayer, but among important variations we may name the following: (*a*) The arrangement and wording of the order for Holy Communion rather resembles that of the Scottish than that of the English liturgy, especially in the position of the oblation and invocation immediately after the words of institution. (*b*) The Magnificat, Nunc dimittis and greater part of Benedictus were disused; but these were reinstated among the changes made in the Prayer Book in 1892. (*c*) Ten selections of Psalms are appointed for use as alternatives for the Psalms of the day. (*d*) *Gloria in excelsis* is allowed as a substitute for *Gloria Patri* at the end of the Psalms at morning and evening prayer. In addition to these there are many more both important and unimportant variations from the English Book of Common Prayer.

The Irish Prayer Book.—The Prayer Book in use in the Irish portion of the United Church of England and Ireland was the Anglican Book of Common Prayer, but after the disestablishment of the Irish church several changes were introduced into it by a synod held at Dublin in 1870. These changes included such important points as: (*a*) the excision of all lessons from the Apocrypha, (*b*) of the rubric ordering the recitation of the Athanasian Creed, (*c*) of the rubric ordering the vestments of the second year of Edward VI., (*d*) of the form of absolution in the office for the visitation of the sick, (*e*) the addition to the Catechism of a question and answer bringing out more clearly the spiritual character of the real presence.

The Presbyterian Church.—The Presbyterian churches of Scotland at present possess no liturgy properly so called. Certain general rules for the conduct of divine service are contained in the *Directory for the Public Worship of God* agreed upon by the assembly of divines at Westminster, with the assistance of commissioners from the Church of Scotland, approved and established by an act of the general assembly, and by an act of parliament, both in 1645. In 1554 John Knox had drawn up an order of liturgy closely modelled on the Genevan pattern for the use of the English congregation to which he was then ministering at Frankfort. On his return to Scotland this form of liturgy was adopted by an act of the general assembly in 1560 and became the established form of worship in the Presbyterian church until the year 1645, when the Directory of Public Worship took its place. Herein regulations are laid down for the conduct of public worship, for the reading of Scripture and for extempore prayer before and after the sermon, and in the administration of the sacrament of baptism and the Lord's Supper, for the solemnization of marriage, visitation of the sick and burial of the dead, for the observance of days of public fasting and public thanksgiving, together with a form of ordination and a directory for family worship.



LITUUS, THE CAVALRY TRUMPET OF THE ROMANS

LITUUS, the cavalry trumpet of the Romans, said by Macrobius (*Saturn.* lib. vi.) to have resembled the crooked staff borne by the Augurs. It consisted of a cylindrical tube 4ft. or 5ft. long, having a narrow bore, and shaped like the letter J.

LITVINOV, MAXIM MAXIMOVICH (1876–), Russian politician, was born at Bielostok. When 17 he entered military service as a volunteer and while in the army became interested in Marxism. When his service was completed, he became a member of the Kiev committee of the Social Democratic party. One of the members of that committee proved to be a police agent and the committee was arrested. After a year and a half in prison Litvinov with 11 companions escaped, went abroad and took an active part in the *Iskra,* the Social Democratic newspaper. Litvinov joined the Bolshevik section of the party, returned to Russia illegally in 1903, and worked there as a member of the central committee until the revolution of 1905. In that year he attended the London Congress as a delegate from the Riga Committee, and took part with Gorky in founding *Novaya Zhizn* (*The New Life*).

After the failure of the attempted revolution of 1905 Litvinov lived abroad, and organized the sending of weapons to the revolutionaries in the Caucasus. After the November revolution (1917) in Russia he was appointed diplomatic agent of the Soviet government in England. He was subsequently arrested as a hostage for Mr. Lockhart, for whom he was exchanged. As assistant commissar for foreign affairs he took part in the initiation of peace negotiations with Estonia, in negotiations at Copenhagen with England, in the Genoa conference and, as president of the Russian delegation, in the subsequent conference at The Hague. Litvinov continued to take a leading part in disarmament conferences, both in Moscow and Geneva. From 1930 to 1939 he was people's commissar for foreign affairs.

LIUDPRAND (LIUTPRAND, LUITPRAND) (*c.* 922–972), Italian historian and author, bishop of Cremona, came of a noble Lombard family. In 931 he entered the service of King Hugo of Italy as page; he became chancellor under Berengar, and was sent (949) on an embassy to the Byzantine court. On his return he fell into disgrace with Berengar. He then attached himself to the emperor Otto I., who made him bishop of Cremona (961). He was frequently employed in missions to the pope, and in 968 to Constantinople to demand for the younger Otto (afterwards Otto II.) the hand of Theophano, daughter of the emperor Nicephorus Phocas. His account of this embassy in the *Relatio de Legatione Constantinopolitana* (Eng. trans. in Henderson's *Select Documents of the Middle Ages,* 1896) gives a graphic and lively description of Constantinople and the Byzantine court.

Liudprand wrote (1) *Antapodoseos, seu rerum per Europam gestarum, Libri VI.,* an historical narrative, relating to the events from 887 to 949, directed against Berengar and Willa his queen; (2) *Historia Ottonis,* covering the years 960 to 964; and (3) the *Relatio de Legatione Constantinopolitana* (968–969). All are to be found in the *Monum. Germ. Hist.* of Pertz, and in the *Rer. Ital. Script.* of Muratori; there is an edition by E. Dümmler (1877), and a partial translation into German in *Geschichtsschreiber der deutschen Vorzeit* (vol. ii., 1853).

See L. M. Hartmann, *Geschichte Italiens im Mittelalter,* vol. ii. (1903).

LIVER, ANATOMY OF. The liver is a large reddish-brown gland situated in the upper and right part of the abdominal cavity. When hardened *in situ* its shape is that of a right-angled, triangular prism showing five surfaces—superior, anterior, inferior, posterior and right lateral which represents the base of the prism. It weighs about three pounds or one-fortieth of the body weight. The liver is plastic, and moulds itself to neighbouring viscera. The superior surface is in contact with the diaphragm, but has peritoneum between (*see* COELOM AND SEROUS MEMBRANES). At its posterior margin the peritoneum of the great sac is reflected on to the diaphragm to form the anterior layer of the *coronary ligament.* Near the mid line of the body, and at right angles to the last, another reflection, the *falciform ligament,* runs forward, and the line of attachment of this indicates the junction of the *right* and *left lobes* of the liver. The anterior surface is in contact with the diaphragm and the anterior abdominal wall. The attachment of the falciform ligament is continued down it. The posterior surface is more complicated (fig. 1); starting from the right and working toward the left, a large triangular area, uncovered by peritoneum and in direct contact with the diaphragm, is seen. This is bounded on the left by the inferior vena cava, which is sunk into a deep groove in the liver, and into the upper part of this the *hepatic veins* open. Just to the right of this and at the lower part of the bare area is a triangular depression for the right suprarenal body. To the left of the vena cava is the *Spigelian lobe,* which lies in front of the bodies of the tenth and

FIG. 1.—THE LIVER VIEWED FROM BELOW AND BEHIND
The visceral surface and posterior area of parietal surface are seen. The portal fissure has been opened to show passage of portal vein and other vessels

eleventh thoracic vertebrae, the lesser sac of peritoneum, diaphragm and thoracic aorta intervening. To the left of this is the fissure for the *ductus venosus,* and to the left of this again, the left lobe, in which a broad shallow groove for the oesophagus may usually be seen. Sometimes the left lobe stretches as far as the left abdominal wall, but more often it ends below the apex of the heart, which is $3\frac{1}{2}$in. to the left of the mid line of the body. The relations of the lower surface can only be understood if it is realized that it looks backward and to the left as well as downward (fig. 1). Again starting from the right side, two impressions are seen; the anterior one is for the hepatic flexure of the colon, and the posterior for the upper part of the right kidney. To the left of the colic impression is a smaller one for the second part of the duodenum. Next comes the *gall bladder,* a pear-shaped bag, the fundus of which is in front and below, the neck behind and above. From the neck passes the *cystic duct,* which is often twisted into the form of an S. To the left of the gall bladder is the *quadrate lobe,* which is in contact with the pylorus of the stomach. To the

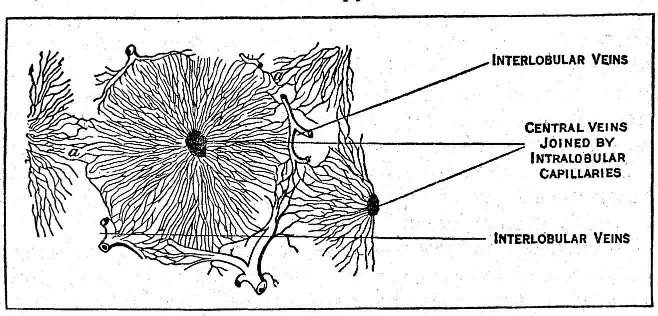

FIG. 2.—TRANSVERSE SECTION THROUGH LOBULES SHOWING VENOUS ARRANGEMENT. AT *a* THE CAPILLARIES OF ONE LOBULE ANASTOMOSE WITH THOSE OF THE ADJACENT LOBULE

left of this is the left lobe of the liver, separated from the quadrate lobe by the umbilical fissure in which lies the *round ligament* of the liver, the remains of the umbilical vein of the foetus. The under surface of the left lobe is concave for the anterior surface of the stomach (*see* ALIMENTARY CANAL), while on the other hand a convexity (*tuber omentale*) fits into the lesser curvature of that organ. The posterior boundary of the quadrate lobe is the *transverse fissure,* which is little more than an inch long and more than half an inch wide. This fissure represents the hilum of the liver, and contains the right and left hepatic ducts and the right and left branches of the hepatic artery and portal vein, together with nerves and lymphatics, the whole being enclosed in condensed subperitoneal tissue known as *Glisson's capsule.* Behind the transverse fissure the lower end of the Spigelian lobe is seen as a knob, and from the right of this a narrow bridge runs forward and to the right to join the Spigelian lobe to the right lobe and to shut off the transverse fissure from that for the vena cava. This is the *caudate lobe.* The right surface of the liver is covered with peritoneum and is in contact with the diaphragm, outside which are the pleura and lower ribs. From its lower margin the *right lateral ligament* is reflected on to the diaphragm. A similar fold passes from the tip of the left lobe as the *left lateral ligament,* and both these are the lateral margins of the coronary ligament. Sometimes, especially in women, a tongue-shaped projection downward of the right lobe is found, known as *Riedel's lobe;* it is of clinical interest as it may be mistaken for a tumour or floating kidney. The right and left *hepatic ducts,* while still in the transverse fissure, unite into a single duct which joins the cystic duct from the gall bladder at an acute angle. When these have united the duct is known as the *common bile duct,* and runs down to the second part of the duodenum (*see* ALIMENTARY CANAL).

Minute Structure of the Liver.—The liver is made up of an enormous number of conical *lobules* (fig. 3). If the portal vein is followed from the transverse fissure, it will be seen to branch and rebranch until minute twigs called *interlobular veins* (fig. 2), ramify around the lobules. From these *intralobular capillaries* run toward the centre of the lobule, forming a network among the polygonal hepatic cells. On reaching the core of the conical lobule they are collected into a central or *intralobular vein* (fig. 2) which unites with other similar ones to form a *sublobular vein* (fig. 3). These eventually reach the hepatic radicles, and so the blood is conducted into the vena cava. In man the lobules are not distinctly separated one from the other, but in some animals, *e.g.,* the pig, each has a fibrous sheath derived from Glisson's capsule (fig. 3).

Embryology.—The liver first appears as an entodermal hollow longitudinal outgrowth from the duodenum into the ventral mesentery. The upper part of this forms the future liver, and grows up into the *septum transversum* from which the central part

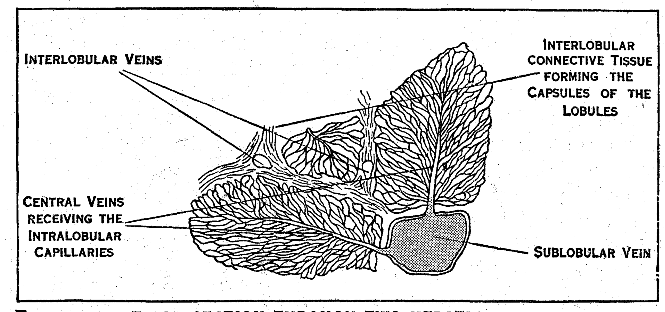

FIG. 3.—VERTICAL SECTION THROUGH TWO HEPATIC LOBULES OF A PIG

of the diaphragm is formed (*see* DIAPHRAGM). From the cephalic part of this primary diverticulum solid rods of cells called the *hepatic cylinders* grow out, and these branch repeatedly until a cellular network is formed surrounding and breaking up the umbilical and vitelline veins. The liver cells, therefore, are entodermal, but the supporting connective tissue mesodermal from the septum transversum. The lower (caudal) part of the furrow-like outgrowth remains hollow and forms the gall bladder. At first the liver is embedded in the septum transversum, but later the diaphragm and it are constricted off one from the other, and soon the liver becomes very large and fills the greater part of the abdomen. At birth it is proportionately much larger than in the adult, and forms one-eighteenth instead of one-fortieth of the body weight, the right and left lobes being nearly equal in size.

Comparative Anatomy.—In the Acrania (*Amphioxus*) the liver is probably represented by a single ventral diverticulum from the anterior end of the intestine, which has a hepatic portal circulation and secretes digestive fluid. In all the Craniata a solid liver is developed. In the adult lamprey among the Cyclostomata the liver undergoes retrogression, and the bile ducts and gall bladder disappear, though they are present in the larval form (ammocoetes). In fishes and amphibians the organ consists of right and left lobes, and a gall-bladder is present. The same description applies to the reptiles, but a curious network of cystic ducts is found in snakes and to a less extent in crocodiles. In the Varanidae (monitors) the hepatic duct is also retiform. In birds two lobes are present, but in some, *e.g.*, the pigeon, there is no gall-bladder.

In mammals Sir William Flower pointed out that a generalized type of liver exists, from which that of any mammal may be derived by suppression or fusion of lobes. The accompanying diagram of Flower (fig. 4) represents an ideal mammalian liver. It will be seen that the umbilical fissure divides the organ into right and left halves, as in the lower vertebrates, but that the ventral part of each half is divided into a central and lateral lobe. The gall-bladder when present, is always situated on the caudal surface or in the substance of the right central lobe. The Spigelian and caudate lobes belong to the right half of the liver, the latter being usually a leaf-shaped lobe attached by its stalk to the Spigelian, and having its blade flattened between the right lateral lobe and the right kidney. The vena cava is always found to the right of the Spigelian lobe and dorsal to the stalk of the caudate. In tracing the lobulation of man's liver back to this generalized type, it is evident that his quadrate lobe does not correspond to any one generalized lobe, but is merely that part of the right central which lies between the gall bladder and the umbilical fissure. From a study of human variations compared with an Anthropoid liver, such as that of the gorilla, it is fairly clear that the human liver is formed, not by a suppression of any of the lobes of the generalized type, but by a fusion of those lobes and obliteration of certain fissures. This fusion is attributed by Sir A. Keith to the effect of pressure following the assumption of the erect position. The accompanying diagram (fig. 5) shows an abnormal human liver in the anatomical department of St. Thomas's hospital which reproduces the generalized type.

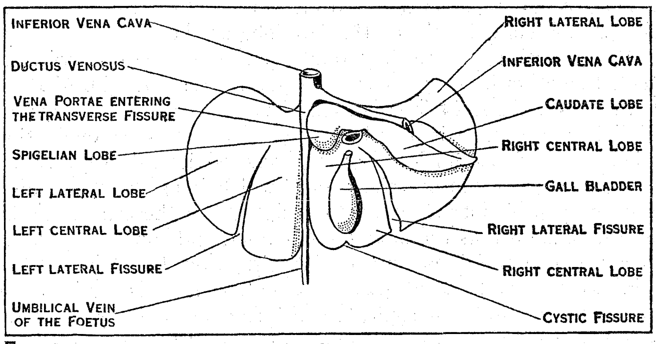

FIG. 4.—DIAGRAMMATIC PLAN OF INFERIOR SURFACE OF A MULTILOBED MAMMALIAN LIVER. THE POSTERIOR OR ATTACHED BORDER IS UPPERMOST

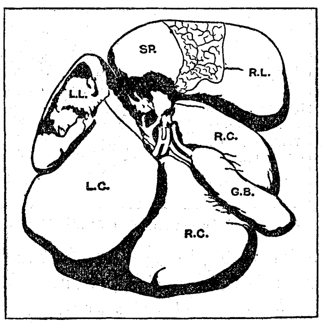

FIG. 5.—HUMAN LIVER, SHOWING A REVERSION TO THE GENERALIZED MAMMALIAN TYPE

SP, Spigelian Lobe; R.L., right lateral lobe; R.C., right central lobe; G.B., gall bladder; L.C., left central lobe; L.L., left lateral lobe

The gall-bladder is usually present in mammals, but is wanting in the odd-toed ungulates (*Perissodactyla*) and *Hyrax*. In the giraffe it may be absent or present. The Cetacea and a few rodents are also without it. In the otter the same curious network of bile ducts already recorded in the reptiles is seen. (F. G. P.)

LIVER AND GALL-BLADDER, DISEASES OF. Being somewhat friable, the human liver is often torn or ruptured by blows or kicks, and, the large blood-vessels being thus laid open, fatal haemorrhage into the belly-cavity may take place. The individual becomes increasingly collapsed, and there are pain and tenderness in the liver region. The right thing to do is to open the belly in the middle line, search for a wound in the liver, and treat it by deep sutures, or by plugging it with gauze.

Cirrhosis of the Liver.—This is a chronic fibrosis not obviously dependent upon inflammation in the majority of cases. According to the distribution of the adventitious fibrous tissue, multilobular (atrophic), uni-lobular (hypertrophic), and intercellular varieties are recognized. The commonest causes are alcohol and syphilis, but probably bacterial toxins are effective in certain cases. As the fibrous tissue undergoes the gradual contraction to which it is liable, liver cells are destroyed by pressure atrophy, thus inducing digestive disorder; bile ducts are obstructed, leading to jaundice; and the flow of blood through the liver is impeded leading to dropsy in the belly (ascites) and, secondarily, to other morbid conditions.

Inflammation of the Liver (hepatitis).—In a strict sense this disease is rare and usually septic and secondary. Thus blood passing from an inflamed appendix to the liver by the portal vein may carry pyogenic organisms and lead to a widespread and suppurative thrombosis in the liver (pyle-phlebitis), or the liver may be affected along with other parts in pyaemia or suppurative blood-poisoning. In tertiary syphilis the specific inflammation may manifest itself by the formation of a gummatous mass in the liver. Under treatment with potassium iodide the gumma may be absorbed, leaving merely a puckered scar.

Hepatic Abscess.—Apart from that form of suppuration mentioned in the last paragraph, hepatic abscess is especially common in persons from the East who have suffered from amoebic dysentery, and is usually single and large. In addition to local pain and tenderness, there is a high temperature, accompanied with shiverings or occasional rigors, the patient becoming daily more thin and miserable. Sometimes the abscess declares itself by a bulging at the surface, but if not, an incision should be made through the belly-wall over the most tender spot and a direct examination of the surface of the liver made. A bulging having been found, that part of the liver which apparently overlies the abscess should be stitched up to the sides of the opening made in the belly-wall, and should then be explored by a hollow needle. Pus being found, the abscess should be freely opened and drained. It is inadvisable to explore for a suspected abscess with a hollow needle without first opening the abdomen, as septic fluid might thus leak out and infect the general peritoneal cavity. If a hepatic abscess is injudiciously left to itself it may eventually discharge into the chest, lungs or belly, or it may establish a communication with a piece of intestine. The only safe way for an abscess to evacuate itself is on to the surface of the body.

Hydatid Cysts.—These growths are often met with in the liver, particularly in Australia. They are due to a development of the eggs of the tape-worm of the dog, which have been received into the alimentary canal with infected water or uncooked vegetables, such as watercress. The embryo of *Taenia echinococcus* finds its way from the stomach or intestine into a vein passing to the liver and, lodging there, becomes surrounded by a capsule of fibrous tissue. Inside this wall is the special covering of the embryo, which shortly becomes distended with clear hydatid fluid. The cyst should be treated like a liver-abscess, by incision through the abdominal or thoracic wall, by circumferential suturing, and by exploration and drainage.

Tumours of the Liver.—These may be innocent or malignant. The commonest innocent variety is naevus. The commonest form of malignant tumour is the result of the growth of cancerous elements from the breast along the round ligament, or brought to the liver by the veins coming from a primary focus of the stomach or large intestine. Occasionally cancer is primary in the liver. Active surgical treatment of such a tumour is out of the question. Fortunately it is, as a rule, painless.

Gall-bladder.—The gall-bladder may be ruptured by external violence and then should be removed surgically or peritonitis will be set up.

Biliary concretions, known as *gall-stones,* are apt to form in the gall-bladder. They may be composed of cholesterin or of bile pigments combined with calcium and are deposited from an organic basis such as a collection of epithelial cells or of bacilli in a slightly abnormal gall-bladder. Sometimes, in the course of a post-mortem examination a gall-bladder is found full of gall-stones, which during life had caused no inconvenience and had given rise to no suspicion of their presence. In other cases gall-stones set up inflammation (cholecystitis), which may go on to abscess. As the result of long-continued irritation the gall-bladder may become the seat of cancer.

Cholecystitis or abscess gives rise to a painful, tender swelling near the cartilage of the ninth rib of the right side. If allowed to take its course, adhesions may form around it and it may burst into the intestine or on to the surface of the abdomen, a *biliary fistula* remaining. Either condition being suspected, an incision should be made, and, its covering having been stitched to the abdominal wall, the gall-bladder should be opened and drained, or, which is still more preferable, the gall-bladder should be removed unopened.

Stones in the gall-bladder should be removed by operation, as, if left, there is a great risk of their trying to escape with the bile into the intestine and thus causing a blockage of the common bile-duct, and perhaps a fatal leakage of bile into the peritoneum through a perforating ulcer of the duct. Whether the gall-bladder should be removed along with the calculi depends upon circumstances. Other treatment than surgery is useless if not positively harmful. "Biliary colic" is the name given to the distressing symptoms associated with the passage of a stone through the narrow bile-duct. The individual is doubled up with acute pains, which, starting from the hepatic region, spread through the abdomen and radiate to the right shoulder-blade. Inasmuch as the stone is blocking the duct it gives rise to jaundice, which becomes obvious a day or two after the colic has occurred. The distress is due to spasmodic muscular contraction and comes on at intervals, each attack increasing the patient's misery. He breaks out into profuse sweats and may vomit. If the stone happily finds its way into the intestine the distress suddenly ceases. In the meanwhile, relief may be afforded by fomentations, and by morphia or chloroform, but if no prospect of the stone escaping into the intestine appears likely it must be removed surgically.

LIVERMORE, MARY ASHTON [RICE] (1821–1905), American reformer, was born in Boston, Mass., on Dec. 19, 1821. She joined the abolitionists, and took an active part in the Washingtonian temperance movement. In 1845 she married Daniel Parker Livermore (1819–99), a Universalist clergyman. During the Civil War, as an associate member of the U.S. sanitary commission, and as an agent of its northwestern branch, she organized many aid societies, contributed to the success of the Northwestern Sanitary fair in Chicago in 1863 and visited army posts and hospitals. After the war she devoted herself to the promotion of woman suffrage and to temperance reform, founding in Chicago in 1869 *The Agitator,* which in 1870 was merged into the *Woman's Journal* (Boston), of which she was an associate editor until 1872. She served as president of the Illinois, the Massachusetts and the American woman suffrage associations. She lectured in the United States, England and Scotland, and contributed to magazines. Her writings include *The Children's Army,* temperance stories (1844); *Thirty Years Too Late,* a temperance story (1848); *A Mental Transformation* (1848); *Pen Pictures,* short stories (1863); *What Shall We Do With Our Daughters? and Other Lectures* (1883); *My Story of the War* (1888); and *The Story of My Life* (1897). With Frances E. Willard she edited *A Woman of the Century: Biographical Sketches of Leading American Women* (1893). She died at Melrose, Mass., on May 23, 1905.

LIVERPOOL, EARLS OF. Charles Jenkinson, 1st earl of Liverpool (1729–1808), English statesman, eldest son of Colonel Charles Jenkinson (d. 1750) and grandson of Sir Robert Jenkinson, Bart., of Walcot, Oxfordshire, was born at Winchester on the 16th of May 1729. The family was descended from Anthony Jenkinson (d. 1611), sea-captain, merchant and traveller, the first Englishman to penetrate into Central Asia. Charles was educated at Charterhouse school and University college, Oxford, where he graduated M.A. in 1752. In 1761 he entered parliament as member for Cockermouth and was made undersecretary of state by Lord Bute; he won the favour of George III, and when Bute retired Jenkinson became the leader of the "king's friends" in the house of commons. In 1763 George Grenville appointed him joint secretary to the treasury; in 1766, after a short retirement, he became a lord of the admiralty and then a lord of the treasury in the Grafton administration; and from 1778 until the close of Lord North's ministry in 1782 he was secretary-at-war. From 1786 to 1801 he was president of the board of trade and chancellor of the duchy of Lancaster, and he was popularly regarded as enjoying the confidence of the king to a special degree. In 1772 Jenkinson became a privy councillor and vice-treasurer of Ireland, and in 1775 he purchased the lucrative sinecure of clerk of the pells in Ireland and became master of the mint. In 1786 he was created Baron Hawkesbury, and ten years later earl of Liverpool. He died in London on the 17th of December, 1808. His best known work is *Coins of the Realm;* reprinted by the Bank of England in 1880.

His son, Robert Banks Jenkinson, 2nd earl (1770–1828), was educated at Charterhouse and at Christ Church, Oxford, where he had George Canning, afterwards his close political associate, for a contemporary. In 1790 he entered parliament as member for Appleby; he became master of the mint in 1799 and foreign secretary in Addington's administration in 1801, when he conducted the negotiations for the abortive treaty of Amiens. On the accession of Pitt to power in 1804, he obtained the home office, having in the previous year been elevated as Baron Hawkesbury to the house of lords, where he acted as leader of the government. He declined the premiership on the death of Pitt in 1806, and remained out of office until Portland became prime minister in 1807, when he again became secretary of state for home affairs. In 1808 he succeeded his father as earl of Liverpool. In the ministry of Spencer Perceval (1809–1812) he was secretary for war and the colonies. After the assassination of Perceval in May 1812 he became prime minister, and retained office till compelled in February 1827 to resign by the illness (paralysis) which terminated his life on the 4th of December 1828.

The political career of the 2nd Lord Liverpool was of a negative character so far as legislation was concerned. The energy of Castlereagh and Canning secured the success of the foreign policy of his cabinet, but in his home policy he was always retrograde. The introduction of the bill of pains and penalties against Queen Caroline greatly increased his unpopularity, originated by the severe measures of repression employed to quell the general distress, which had been created by the excessive taxation which followed the Napoleonic wars. Lord Liverpool was destitute of wide sympathies and of true political insight, and his resignation of office was followed almost immediately by the complete and permanent reversal of his domestic policy.

See *Memoirs of the Public Life and Administration of Liverpool* (1827); C. D. Yonge, *Life and Administration of the 2nd Earl of Liverpool* (1868); and references *s.v.* Londonderry, Robert Stewart; Canning, George.

The 2nd earl of Liverpool was twice married but had no children, and was succeeded by his half-brother, Charles Cecil Cope Jenkinson (1784–1851), who was lord steward, 1841–46. He left three daughters, and the earldom and barony became extinct; but in 1893 his grandson (son of his 2nd daughter and co-heiress), Cecil George Savile Foljambe (1846–1907), who had been a Liberal member of parliament from 1880 to 1892, was created Baron Hawkesbury, and in 1905 the earldom of Liverpool was revived in his person. He was lord-in-waiting to Queen Victoria 1894–95, and lord steward of King Edward VII's household from 1905 till his death in 1907, when he was succeeded by his eldest son, Arthur William de Brito Savile Foljambe (1870–1941). The 2nd earl of the 1905 creation was appointed governor of the dominion of New Zealand in 1912, and retired as governor-general (the title having been changed in 1917) in 1920.

LIVERPOOL, city; county and parliamentary borough;

seaport; Lancashire, England; 201 mi. northwest of London by rail; situated on the right bank of the estuary of the Mersey, the centre of the city being about 3 mi. from the open sea. The form of the city is that of an irregular semicircle, having the base-line formed by the docks and quays extending about 9 mi., along the northeast bank of the estuary, which varies in breadth from 1 to 2 mi. On the north the city is partly bounded by the borough of Bootle, along the shore of which the line of docks is continued. Pop. (1938) 827,400. Area 42.7 sq.mi.

The city lies on a continuous slope of varying gradient, in some districts very steep. The old borough, lying between the pool, now completely obliterated, and the river, was a conglomeration of narrow alleys, and during the 16th and 17th centuries it was several times visited by plague. When the town expanded beyond its original limits and spread up the slopes beyond the pool, conditions improved. The commercial part of the city is remarkable for the number of palatial offices built chiefly of stone, among which the banks and insurance offices stand pre-eminent. From the beginning of the 20th century, slum clearance and the improvement of sanitary arrangements and roads were vigorously carried out, though during the two World Wars work had to be curtailed. In the period 1900–18 nearly 27,500 houses were built, but between 1919 and 1931 about 30,000 were erected, 74.8% by the corporation, which in the previous period had been responsible for only 8.7%. By 1943 the corporation owned over 30,000 dwellings, etc. The principal municipal housing estate is Norris Green with 7,000 houses and a population of over 30,000. The city suffered badly in World War II; at the end of 1941 about 150,000 houses on Merseyside had been damaged.

Public Buildings.—The city is rich in buildings of architectural interest but there is practically no work in the town earlier than 18th century. The earliest important work is the Old Blue Coat hospital (built 1717) at the back of Church St., which is a Queen Anne group built round a courtyard. The town hall (opened 1754), designed by John Wood of Bath, is a rectangular stone building in the Corinthian style. It has been altered and added to and the inside remodelled since a fire in 1795. There are a large number of fine 19th-century houses in Rodney street and Abercromby square, which houses were the former residences of Liverpool merchants. Liverpool contains a fine piece of modern Graeco-Roman architecture in St. George's hall. Designed by Harvey Lonsdale Elmes and completed in 1854, it stands in the centre of the city and is surrounded by an area sufficiently extensive to exhibit its proportions. Externally the east front is faced with a fine portico of sixteen Corinthian columns, 60 ft. in height. Owing to the death of Elmes in 1847 the work was completed by Prof. C. R. Cockerell, R. A.

To the north of St. George's hall are the law courts, the Walker Art gallery, the Picton library and the museum and Technical school, which forms an impressive row of buildings. Of the public buildings, the exchange, adjoining the town hall, is worthy of note. It is built around three sides of a quadrangle and replaces an earlier structure on the same site, which had become inadequate to the needs of the city. The Customs House is an impressive building of the mid-19th century. Of modern buildings three imposing structures overlook the river at the Pier Head. These comprise the Dock Offices, the Liver buildings and the Cunard building but, although some of the buildings have distinct architectural merit, the group as a whole is very unbalanced.

Liverpool cathedral, of which the foundation stone was laid by Edward VII in 1904, will be when completed the largest Anglican church in the country. The architect, Sir Giles Gilbert Scott, planned an impressive mass of buildings in a new and romantic Gothic style, most distinctive of the architect himself. The site is an excellent one and overlooks the whole city. The building is of red sandstone, the roof of copper. The Lady chapel, full of wealth of detail and with an atrium decorated with windows commemorating noble women, was consecrated in 1910, and the choir, east transepts and chapter house in 1924. The organ, dedicated in 1926, is the largest in the country (5 manuals, 10,925 pipes). The great square tower is to be buttressed by transepts, northeast and northwest, southeast and southwest, and there is here a large "central space" for seating accommodation without trenching upon either nave or choir. Work on the "central space" and west transepts was begun in 1926. The Lady chapel is almost a separate church, and on a different level. The cathedral is oriented N. and S. The ultimate length will be 619 feet. The interior height is 116 feet. Westminster abbey is 102 ft.

The air raids of World War II took their toll of Liverpool's buildings. Of the churches, St. Michael's, Pitt St., was completely destroyed, and those of St. Nicholas, St. Catherine and St. Luke were burned out. The Derby memorial transept of the cathedral was damaged, but injury to the building as a whole was slight. Among other buildings, Blue Coat Chambers, until the outbreak of war the headquarters of the Liverpool Architectural society, was damaged; an engineering laboratory of the university received a direct hit and others were damaged, while injuries more or less serious were inflicted on the Customs House, St. George's hall, the cotton and commercial exchanges and the fine Gorce warehouses.

Railways.—There are three terminal passenger stations in Liverpool, all on the L.M.S. railway. They are:—Lime Street, Exchange and Central. The L.N.E. railway also has running powers into Central station. Connection with the Wirral is effected by the old Mersey tunnel (opened 1886), and by the new road tunnel completed in 1928. (*See* BIRKENHEAD.) The Liverpool electric overhead railway running along the line of docks from Seaforth to Dingle was opened in 1893, and in 1905 a junction was made with the L.M.S. railway by which through passenger traffic between Southport and the Dingle was established. In 1895 the Riverside station at the Prince's dock was completed, giving direct access from the landing stage to the L.M.S. system.

Water Supply.—The original supply of water was from wells in the Triassic sandstone, but in 1847 an act was passed under which extensive works were constructed and extended later at Rivington, about 25 mi. distant. The vast increase of population led to further requirements, and in 1880 another act gave power to impound the waters of the Vyrnwy, one of the affluents of the Severn. These works were completed in 1892, when one pipe line was laid. A second pipe line was opened in 1905. The catchment area was increased in 1910 by the diversion into the lake of two other rivers, the Conway and the Marchnant. Further pipe lines were completed in 1938, after which the supply area was about 118 sq.mi.

Ecclesiastical.—The see of Liverpool was created in 1880, an endowment fund of about £100,000 having been subscribed for the purpose. The parish, which was separated from Walton-on-the-Hill in 1699, contained two churches, St. Nicholas, the ancient chapel, and St. Peter's. There were two rectors, the living being held in medieties. The living is now held by a single incumbent, and a large number of the churches which have since been built have been formed into parishes by the ecclesiastical commissioners. St. Peter's was constituted the pro-cathedral, pending the erection of the cathedral. The Roman Catholics form a very numerous and powerful body in the city. Many are of Irish descent; but this district has always been a stronghold of Roman Catholicism, some of the landed gentry belonging to old Roman Catholic families. The new cathedral, designed by Sir Edwin Lutyens in the Roman style, is intended to be the largest in the world after St. Peter's, Rome. It is to be of brick, dressed with Cornish granite. The foundation stone was laid in 1933, after which the crypt, 300 ft. by 193 ft., was finished. The church will be 670 ft. long and will have the largest dome in the world.

Charities.—The earliest charitable foundation was the Blue Coat hospital, established in 1708, for orphans and fatherless children born within the borough. The original building was opened in 1718, and the hospital now maintains 200 boys and 100 girls. In 1906 the school was removed to new buildings at Wavertree. The Liverpool dispensaries (founded 1778) were among the pioneers of medical charity. The Royal infirmary now situated in Pembroke place (opened 1749), had a school of medicine attached which has become world famous and is now merged in the university. The sailors' home (opened 1850), designed to provide board, lodging and medical attendance for the seamen frequenting the port, is one of Liverpool's best-known charities. Numerous other charities, homes, clubs and institutions have arisen.

ARTS, EDUCATION AND UNIVERSITY

The free library, museum and gallery of arts, established and managed by the city council, was originated in 1850. The first library building was erected by Sir William Brown. The Derby museum, containing the collections of Edward, the 13th earl, was presented by his son. The Mayer museum of historical antiquities and art was contributed by Joseph Mayer, F.S.A. (1803–86), who presented his collections to Liverpool in 1867. The museum contains an unrivalled collection of Wedgwood and Liverpool ware. Sir Andrew Walker (1824–93) erected in 1877 the art gallery which bears his name. Large additions were made in 1884, the cost being again defrayed by Sir Andrew Walker. The valuable permanent collection of paintings includes the Roscoe collection of old masters and the bequest (1923) of James Smith of Blundellsands of 18 pictures of Watts, 4 sculptures by Rodin, many etchings and engravings by Dürer, Seymour Haden and Whistler, together with a large number of modern works, British and foreign. The annual loan exhibition held in the autumn is the most important in the provinces. The Picton circular reading room was built by the corporation and opened in 1879. Adjoining it is the Hornby library of fine art books. The Literary and Philosophical society was established in 1812. The Royal institution, established in 1817, is the centre of the literary institutions of the town. The Philharmonic society was instituted in 1840. Its new hall, replacing one that had burned, was opened in 1939.

Education.—Sunday schools were founded in 1784, as the result of a town's meeting. These were soon followed by day schools. Semi-private schools were founded by public subscription—the Royal Institution school (1819), the Liverpool institute (1825) and the Liverpool college (1840). The first has ceased to exist. The institute, a development of the Mechanics' institute, was divided into a high school and a commercial school. This school, and the Blackburne House high school for girls which was attached to it, became public secondary schools and were transferred to the corporation in 1903 and 1905 respectively. Liverpool college was formerly divided into three schools, upper, middle and lower, for different classes of the community. The middle and lower schools (Liverpool collegiate) were transferred to the corporation in 1907. Since 1902 all new secondary schools on Merseyside, apart from two Catholic schools, have been provided by the local authorities. In 1930 there were all together 20 secondary schools in Liverpool with 8,427 pupils. A cadet ship, the "Conway," for the training of boys for the mercantile marine, is moored in the Mersey. The training ship "Indefatigable," moored in the Mersey, was replaced by the H.M.S. "Phaeton," presented in 1914 to the Liverpool Sea Training homes, mainly for the sons and orphans of sailors. There are many other educational institutions, including a large technical college.

The University.—Liverpool university, as a university college, received its charter in 1881, and in 1884 was admitted as a college of the Victoria university. In the same year the medical school of the Royal infirmary became part of the University college. A supplemental charter (1900) brought the college into closer relations with the city authorities. In 1903 a charter of incorporation constituted it as the University of Liverpool. The large group of buildings is situated on Brownlow hill.

The university developed rapidly, particularly after World War I. After 1920 chairs were established in tropical diseases of Africa (1921), social science (1922), industrial chemistry—oils, fats and waxes (1923), care of animals—causation and prevention of disease—(1924), pharmacology (1930), tropical hygiene (1934), and orthopaedic surgery (1938). There are schools of tropical medicine, architecture, local history and records, social sciences and Russian studies, besides an institute of archaeology and departments of education and civic design. A tidal institute (1919) and, in connection with the department of oceanography, a sea fisheries laboratory at Port Erin are specialities. Extensive researches are carried on in the local sea fisheries in regard to fish disease and kindred subjects. The University Extension board has greatly extended its influence. With the growth of the university many new buildings and extensions were constructed, including the chemistry research building (1923), the Jane Herdman geology laboratories (1929), the veterinary hospital (1929), the social sciences building (1931), the Liverhulme building of the school of architecture (1933), an extension to the students' union (1935) and the men's hall of residence at Mossley hill (1938). A new library building was begun in 1935 and work started on further engineering laboratories just before the outbreak of World War II. A laboratory for research in tropical diseases was set up in Sierra Leone, while residential buildings, including a number of the fine merchants' houses in Abercromby square, were altered and equipped for the purposes of the various departments. There were 2,521 students in the year 1938–39.

Trade and Commerce.—In 1800 the tonnage of ships entering the port was 450,000; in 1938 it was 17,600,000. The commerce of Liverpool extends to every part of the world, but probably the intercourse with North America stands pre-eminent, there being lines of steamers to New York, Philadelphia, Boston, Baltimore, Galveston, New Orleans and the Canadian ports. Cotton is the great staple import. Meat comes next, with a large fleet of refrigerated vessels sailing from Argentina and Australia. Grain is third, though Liverpool is the greatest grain marketing centre outside the U.S., and Merseyside is the second milling centre after Minneapolis-St. Paul. The fruit trade, which comes fourth, has grown very largely on account of the post-World War I habit of eating more fruit. Other important imports are wool, sugar and timber. The port has long been a tobacco importing and re-exporting centre, and petroleum arrives in large quantities. In regard to exports, Liverpool is excellently situated. Lying so near the great manufacturing districts of Lancashire and the West Riding of Yorkshire, this port is the natural channel of transmission for their goods, although the Manchester ship canal diverts a certain proportion of the traffic. The chief exports are cotton yarns and manufactures, metal goods, machinery, vehicles (bicycles and parts, motor cars, railway engines and rolling stock) and woollen goods. Liverpool is a great centre of passenger traffic, but in this it has given way somewhat to Southampton. In general, it may be said that Liverpool's share in the trade of the United Kingdom has declined, more in share of imports than of exports and slightly more in share of trade than of total shipping. Imports measured by value increased after 1930 relative to exports, so that imports subsequently came to exceed exports.

The manufactures of Liverpool are not extensive. Unsuccessful attempts have been repeatedly made to establish cotton mills in and near the city. Engineering works, especially connected with marine navigation, have grown up on a large scale. Shipbuilding in the early part of the 19th century was active and prosperous, and although it had practically ceased, it revived somewhat after World War I. There is a considerable industry in ship-repairing, but this has shown some decline. During the latter half of the 18th century and the beginning of the 19th, pottery and china manufacture flourished in Liverpool. A large establishment, called the Herculaneum pottery, was founded in a suburb on the bank of the Mersey, but the trade long ago disappeared. Litherland, the inventor of the lever watch, was a Liverpool manufacturer, and Liverpool-made watches have always been held in high esteem. There are extensive sugar refineries and important corn mills. Sugar refining grew rapidly after World War I and the confectionery trade also developed, several large biscuit works having been built, induced by the prospect of obtaining cheap sugar directly from the Liverpool quays. Oilseed crushing is an important industry, with which is associated the manufacture of oil-cake and soap and candles. The cutting, blending and preparing of crude tobacco led to the erection of factories employing some thousands of hands, but the tobacco trade showed a substantial decline in the 15 years before World War II. Many firms are engaged in various branches of the chemical industry. Among other industries for which the city and its environs are celebrated are glass factories, bobbin works, match factories; cable, electrical and telephone engineering works; rope, sack and bag factories, cement works, and salt works. Merseyside is the most important single centre in Great Britain for sole-leather tanning. The making of compound foods for animal feeding is a new industry.

Docks.—The docks of the port of Liverpool on both sides of the Mersey are owned and managed by the Mersey Docks and Harbour board. On the Liverpool side they extend along the estuary 6½ mi., of which 1¼ mi. is in the borough of Bootle. The Garston docks, 6 mi. above Liverpool, are also within the city boundary. The Birkenhead docks have not such a frontage, but extend a long way backward. The water area of the Liverpool docks and basins is 477 ac. with a lineal quayage of nearly 29 mi. Birkenhead docks contain a water area of about 181¼ ac., with a lineal quayage of 9¾ mi. The system of enclosed docks was begun by the corporation in 1709. The Gladstone Docks, opened 1927, are among the best equipped in the world. The sill is 20 ft. below datum level and the entrance is 130 ft. wide and the area with branch docks is nearly 54 ac. A fine graving dock is part of the system. Down to 1843 the docks were confined to the Liverpool side of the Mersey. In 1843 a scheme for docks in Birkenhead was carried through, proved unsuccessful, and was acquired in 1855 by Liverpool. The Birkenhead docks were for many years only partially used, but are now an important centre for corn-milling and oil-cake making, the importation of foreign cattle and export trade to the east.

The first portion of the great landing stage, known as the Georges' stage, was constructed in 1847. This was 500 ft. long. In 1857 the Prince's stage, 1,000 ft. long, was built to the north of the Georges' stage and distant from it 500 ft. In 1874 the intervening space was filled up and the Georges' stage reconstructed, but being destroyed by fire, was reconstructed a second time. In 1896 it was extended farther north, and its length is now 2,534 ft. and its breadth 80 feet. It is supported on floating pontoons (about 200), connected with the river wall by 10 bridges, besides a floating bridge for heavy traffic 550 ft. in length and 35 ft. in width. The southern half is devoted to the traffic of the Mersey ferries, of which there are six—New Brighton, Egremont, Seacombe, Birkenhead, Rock Ferry and Eastham. The northern half is used by ocean-going steamers and their tenders. The warehouses for storing produce form a prominent feature in the commercial part of the city. In addition to general produce warehouses, grain warehouses have been constructed by the dock board at Liverpool and Birkenhead, with machinery for discharging, elevating, distributing, drying and delivering. Warehouses for the storage of tobacco and wool have also been built by the board. The Stanley tobacco warehouse is the largest of its kind in the world, the area of its fourteen floors being some 36 ac.

MUNICIPALITY AND HISTORY

Under the Municipal Reform Act of 1835, the boundaries of the original borough were extended, and there were several extensions afterward. In 1932 was added the township of Speke, where the municipal airport was established. Though opened to aircraft in 1933 it was unfinished in 1943. In 1918 the number of members of parliament was increased to eleven. The corporation of Liverpool has possessed from a very early period considerable landed property, the first grant having been made by Thomas, earl of Lancaster, in 1309. This land was originally of value only as a source of supply of turf for firing, but in modern times it has become profitable building land. A large proportion of the southern district is held in freehold by the corporation and leased to tenants for terms of seventy-five years, renewable on a fixed scale of fines. The fee farm rents and town dues originally belonging to the crown were purchased from the Molyneux family in 1672 on a long lease, and in 1777 converted into a perpetuity. With the growth of commerce these dues enormously increased, and became a cause of great complaint by the shipping interest. In 1856, by act of parliament, the town dues were transferred to the Mersey Docks and Harbour Board on payment of £1,500,000. which was applied in part to the liquidation of the bonded debt of the corporation, amounting to £1,150,000.

History.—During the 8th century colonies of Norsemen settled on both sides of the Mersey. After the Conquest the site of Liverpool formed part of the fief granted by the Conqueror to Roger de Poictou. Although Liverpool is not named in Domesday it is believed to have been one of the six berewicks, or subordinate manors, dependent on the manor of West Derby therein mentioned, and cultivated by 53 villeins, 62 bordarii or day-labourers, 3 ploughmen, 6 herdsmen, a horseman, 2 bondmen and 3 bondwomen. After various forfeitures and regrants from the crown, it was handed over by Henry II. to his falconer Warine. In a deed executed about 1191 by John, earl of Morton, afterwards King John, who was then Lord of the Honour of Lancaster, in which he confirms Henry Fitzwarine in the possession of Liverpool, the name of the town first occurs. Probably its most plausible derivation is from the Norse *Hlithar-pollr,* "the pool of the slopes." Another possible derivation is from the Prov. E. *lever,* the yellow flag or rush, O.E. *laefer,* any rush-like or sword-bladed plant. (*See* the *New English Dict., s.v.* "Levers.")

Owing to the decline of Chester as a port, due to the silting up of the river Dee, another site for a port for Ireland had to be found. Into the tidal waters of the Mersey a small stream ran, forming an open pool or sea lake at its mouth, and this was chosen as the site for the new port. The pool was admirably adapted as a harbour for vessels, being well protected, and the tide rising from 15 to 21 ft. King John repurchased the manor from Henry Fitzwarine, giving him other lands in exchange. Here he founded a borough, and by letters patent dated 1207 granted Liverpool the same status as any other free borough upon the sea and invited his subjects to take up "burgages," or allotments, in the new town, which was built along the brow of the hill on which Castle street and the Town Hall are erected. The High Cross stood near the present Town Hall, and here the main line of street was intersected by another line extending from the riverside to the Townsend bridge, which crossed the pool where the end of Dale street now is. Considerable use was made of Liverpool in the 13th century for shipping stores and reinforcements to Ireland and Wales. In 1229 a charter was granted by Henry III. confirming in detail that previously granted by his father, making Liverpool a free borough for ever, and authorizing the formation of a merchants' gild. Several charters were granted until the reign of William and Mary, whose charter was that under which the town was governed until the Municipal Reform Act of 1835. In 1880 when the diocese of Liverpool was created, the borough was transformed into a city by royal charter, in 1888 it became a county borough, and in 1892 the style and dignity of "Lord Mayor" was conferred on its chief magistrate.

The crown revenues from rents and the royal customs were leased from time to time, sometimes to the corporation, at other times to private persons. The first lease was from Henry III., in 1229, and in the same year the borough, with all its appurtenances, was bestowed with other lands on Ranulf, earl of Chester, from whom it passed to the earl of Derby, who seems to have built Liverpool castle between 1232 and 1237. The lands of his grandson, Robert de Ferrers were confiscated in 1266 when Liverpool passed into the hands of Edmund, earl of Lancaster. Liverpool again became the property of the crown, when Henry IV. inherited it from his father John of Gaunt. In 1628 Charles I. sold Liverpool to certain merchants of London, who, in 1635, reconveyed the crown rights, including the fee-farm rent of £14, 6s. 8d., to Sir Richard Molyneux, then Viscount Molyneux of Maryborough, for the sum of £450. In 1672 all these rights and interests were acquired by the corporation.

Liverpool's trade developed slowly. From £10 per annum, in the beginning of the 13th century, the crown revenues had increased towards the end of the 14th century to £38; but then they underwent a decline. The black death, about 1360, carried off a large part of the population. The Wars of the Roses in the 15th century retarded progress for at least a century, during which period the crown revenues diminished from £38 and were finally leased at £14, 6s. 8d., at which they continued until the sale by Charles I. It is, however, not safe to conclude that the reduced fee-farm rent represents an equivalent decline in prosperity; the privileges conferred by the various leases differed widely and may account for much of the apparent discrepancy.

Liverpool sent no representatives to parliament in 1264, but in 1296 the borough sent two members, and again in 1307. The next time it sent members was in 1547. In 1588 the borough was represented by Francis Bacon. During the Civil War the town was fortified and garrisoned by the parliament. It sustained three sieges, and in 1644 fell to Prince Rupert. The true rise of the commerce of Liverpool dates from the Restoration. Down to that period its population probably never exceeded about 1,000. Its trade was chiefly with Ireland, France and Spain, exporting fish and wool to the continent, and importing wines, iron and other commodities. The rise of the manufacturing industry of south Lancashire, and the opening of the American and West Indian trade, gave the first impulse to the progress which has since continued. By the end of the century the population had increased to 5,000. In 1699 the borough was constituted a parish distinct from Walton. In 1709, the small existing harbour was found insufficient to accommodate the shipping, so a wet dock was constructed with floodgates impounding the water, so as to keep the vessels floating during the recess of the tide. This dock was the first of its kind. The name of the engineer was Thomas Steers.

About now the Liverpool merchants entered on the slave trade, into which they were led by their connection with the West Indies. In 1709 a vessel of 30 tons carried 15 slaves across the Atlantic from Liverpool; in 1730, encouraged by parliament, Liverpool went heartily into the new trade. In 1751, 53 ships sailed from Liverpool for Africa, of 5,334 tons in the aggregate. The ships sailed first to the west coast of Africa, where they shipped the slaves, and thence to the West Indies, where the slaves were sold and the proceeds brought home in cargoes of sugar and rum. In 1765 the number of Liverpool slavers had increased to 86, carrying 24,200 slaves. By the end of the century five-sixths of the African trade centred in Liverpool. Just before its abolition in 1807 the number of Liverpool ships engaged in the traffic was 185, carrying 49,213 slaves in the year. Another branch of maritime enterprise which attracted the attention of the merchants of Liverpool was privateering, which, during the latter half of the 18th century, was a favourite investment. After the outbreak of the Seven Years' War with France and Spain in 1756, the commerce of Liverpool suffered severely, the French having overrun the narrow seas with privateers, and the premiums for insurance against sea risks rose to an amount almost prohibitive. The Liverpool merchants took a lesson from the enemy, and armed and sent out their ships as privateers. Some of the early expeditions proved so successful that almost the whole community rushed into privateering, with results of a very chequered character. When the War of Independence broke out in 1775, American privateers swarmed about the West Indies and, crossing the Atlantic, intercepted British commerce in the narrow seas. The Liverpool merchants again turned their attention to retaliation. Between Aug. 1778 and April 1779, 120 privateers were fitted out in Liverpool, carrying 1,986 guns and 8,745 men.

Handbook, 1923); *Official Handbook* published by the Corporation; *Survey of Merseyside* (Liverpool Univ. Press, 1934); Wilfred Smith, *Distribution of Population and the Location of Industry on Merseyside* (Liverpool Univ. Press, 1942), and other publications of the social science dept. of the Univ. of Liverpool. (W. F. I.; J. I. P.; X.)

LIVERSIDGE, ARCHIBALD (1847–1927), English chemist, was born on Nov. 17, 1847 in London, and studied at the Royal School of Mines and the Royal College of Chemistry, and entered Christ's college, Cambridge. In 1867 he became instructor in chemistry at the Royal School of Naval Architecture, and three years later university demonstrator in chemistry at Cambridge. He was professor of chemistry at the University of Sydney from 1873 to 1908. In 1879 he founded the faculty of science at Sydney university, and also the school of mines (1890). Liversidge gave an impetus to technical education in Australia. He founded the Australasian Association for the Advancement of Science in 1885, acted as secretary (1888–1909) and president (1888–90). In 1902 he founded the Sydney section of the Society of Chemical Industry and served as its first chairman (1903–05). His researches were chiefly in mineralogy; he collected and analyzed meteorites. He also wrote papers on the origin of the gold nuggets in Australian alluvial deposits. His most important work is *The Minerals of New South Wales* (1888), but he was also the author of a *Report upon Technical Education and Museums* and of more than a hundred technical papers, most of which treated matters relating to chemistry and mineralogy. He died in Surrey on Sept. 26, 1927.

LIVERWORTS, the name applied to plants in the classes *Hepaticae* and *Anthocerotae* of the Bryophyta (*q.v.*); one of the commoner forms in North America is the thalloid species, *Conocephalum conicum.*

LIVERY, originally the provision of food, clothing, etc., to household servants. The word is an adaptation of the Anglo-French *livrée,* from *livrer,* to deliver, in the special sense of distributing.

In the sense of a fixed allowance of provender for horses, it survives now only in "livery-stable," *i.e.,* an establishment where horses and carriages are kept or let out for hire. From the meaning of provision of food and clothing the word is applied to a uniform worn by the retainers and servants of a household. In the 15th century in England a badge, collar or other insignia, the "livery," was worn by all those who pledged themselves to support one of the great barons in return for his promise of "maintenance," *i.e.,* of protection against enemies; thus arose the custom of "livery and maintenance," suppressed by Henry VII. The members of the London city companies (*see* Livery Companies) wore a distinctive costume or "livery," whence the term "livery companies."

In law, the term "livery" means "delivery," the legal handing of property into the possession of another; for "livery of seisin" *see* Feoffment.

LIVERY COMPANIES, the name of a class of institutions in the city of London which at one time were universal in Europe. The gild (*see* Guilds) in the 12th century "has many aspects, social, religious and economical, and it is unwise to look for any single origin for so complex an institution." The gilds assumed generally the character of corporations in the reign of Edward III. Many of them had been chartered before, but their privileges, hitherto exercised only on sufferance and by payment of their terms, were now confirmed by letters patent. Edward III himself became a member of the fraternity of Linen Armourers, or Merchant Taylors, and other distinguished persons followed his example. George VI is a freeman of the Grocers', Drapers', Fishmongers' and Merchant Taylors' companies, honorary freeman of the Needlemakers', Permanent Master of the Shipwrights', and Admiral of the Master Mariners'. From Edward III's time they are called livery companies. The charters were re-granted, generally in the original form, by successive sovereigns upon payment of a fine to the king's hanaper. In 1684, on receipt of writs *Quo warranto,* the companies surrendered their governance to the King—Charles II—who granted a charter which abolished the right of election of wardens vested by earlier charters in the liverymen of the companies, increased the number of the courts of assistants and conferred membership for life upon the persons selected for these offices. James II, just before his departure to exile, restored the ancient privileges. All proceedings were formally cancelled by Act of Parliament, 2, William and Mary session I, chapter 8. But even in cases where liverymen form an integral element in the administration of their companies' affairs, the system introduced by Charles II is followed in essentials.

The authority of the company extended to the general welfare, spiritual and temporal, of its members. In the regulation of trade they possessed extensive powers. They required every one carrying on the trade to join the company, to prevent monopoly or enhancement of prices. There was no question of a monopoly until the degeneration of the craft gilds into limited corporations of capitalists. In the regulation of trade the goldsmiths had the assay of metals, the fishmongers the oversight of fish, the vintners of the tasting of wine, etc. The companies enforced their regulations on their members by force and by fines. Many of their ordinances looked to the domestic affairs and private conduct of the members. The grocers ordain "that no man of the fraternite take his neyghbor's house y[t] is of the same fraternite, or enhaunce the rent against the will of the foresaid neyghbor." The wearing of beards was forbidden. Football was prohibited. Attempts to restrict marriage to daughters of liverymen were made and failed. Members reduced to poverty by adventures on the sea, increased price of goods, borrowing and pledging, or any other misfortune, are to be assisted "out of the common money, according to his situation, if he could not do without."

From Gild to Charitable Trust.—But the companies gradually lost their industrial character. The richer members engrossed the power and the companies tended to become hereditary and exclusive. Persons became members who had nothing to do with the craft, and the rise of great capitalists and the development of competition in trade made the regulation of industry by means of companies no longer possible. The usurpation of power on the part of the richer members encountered, still encounters, opposition. In the Goldsmiths' company in 1529 the mode of electing officers, and the system of management generally, was challenged by three members who called themselves "artificers," poor men of the craft of goldsmiths. The dispute was carried into the court of chancery and the star chamber. The artificers accused the company of changing the constitution of the society, by persons who "were but merchant goldsmiths, and had but little knowledge in the science." In 1531 the three complainants were expelled from the company, and then the dispute seems to have ended. In most cases their regulative functions have disappeared. The Fishmongers company still carries out the supervision of certain Acts with vigour and success. The Goldsmiths carry out the assay of the Pyx. Throughout the companies have been owners of property and managers of charitable trusts.

The City and the Companies.—The ordinance of Edward II. required freemen of the city to be members of one or other of the companies. By the ordinance of 49 Edw. III. (1375), the trading companies were to nominate the members of common council, and the persons so nominated alone were to attend both at common councils and at elections. An ordinance in 7 Richard II. (1383) restored the elections of common councilmen to the wards, but corporate officers and representatives in parliament were elected by a convention summoned by the lord mayor from the nominees of the companies. An act of common council in 7 Edw. IV. (1467) appointed the election of mayor, sheriffs, etc. to be in the common council, together with the masters and wardens of the companies. By 15 Edw. IV. masters and wardens were ordered to associate with themselves the honest men of their mysteries,[1] and come in their best liveries to the elections; that is to say, the franchise was restricted to the "liverymen" of the companies. At this time the corporation exercised supreme control over the companies, and the companies were still genuine associations of the traders and householders of the city. The delegation of the franchise to the liverymen was thus, in point of fact, the selection of a superior class of householders to represent the rest. By 19 Henry VII. (1504) ordinances and by-laws were required to be submitted for approval to the chancellor, chief justices of either Bench or the Justices in eyre. This act still remains in force and by-laws or ordinances which have not been thus validated are devoid of authority. The corporation lost its control over the companies, and the members of the companies ceased to be traders and householders; the liverymen were no longer a representative class, and the Reform Acts of 1832 and 1867 reformed the representation in several particulars which was practically abolished by the Representation of the People Act of 1918. The liverymen of the companies, being freemen of the city, still elect the lord mayor, sheriffs, chamberlain and other corporate officers.

Taxing the Companies.—The wealth and organization of the companies made them a most appropriate instrument for the enforcement of taxation. The loan of £21,263 6s. 8d. to Henry VIII., for his wars in Scotland, in 1544 seems to be the first instance of a pecuniary grant to the crown. The confiscation of ecclesiastical property at the time of the Reformation affected many of the trusts of the companies; and they were compelled to make returns of their property devoted to religious uses, to pay over the rents to the crown and to purchase the trusts from their corporate funds. In course of time the taxation of the companies became "a regular source of supply to government," which when money was wanted for public works, informed the lord mayor, who apportioned the sums required among the various companies, and issued precepts for its payment. Contributions towards setting the poor to work, erecting the Royal Exchange, cleansing the city ditch, discovering new countries, furnishing military and naval armaments, for men, arms and ammunition for the defence of the city, are among the purposes thus served.

The livery companies in existence in 1940 were the following:

Apothecaries	Fishmongers	Musicians
Armourers and Brasiers	Fletchers	Needlemakers
Bakers	Founders	Painter Stainers
Barbers	Framework Knitters	Pattern Makers
Basket Makers	Fruiterers	Paviors
Blacksmiths	Gardeners	Pewterers
Bowyers	Girdlers	Plasterers
Brewers	Glass Sellers	Plumbers
Broderers	Glaziers	Poulters
Butchers	Glovers	Saddlers
Carmen	Gold and Silver Wyre-drawers	Salters
Carpenters	Goldsmiths	Scriveners
Clockmakers	Grocers	Shipwrights
Clothworkers	Gunmakers	Skinners
Coach and Coach-harness Makers	Haberdashers	Spectacle Makers
Cooks	Horners	Stationers and Newspaper Makers
Coopers	Innholders	Tallow Chandlers
Cordwainers	Ironmongers	Tin Plate Workers
Curriers	Joiners	Turners
Cutlers	Leathersellers	Tylers and Bricklayers
Distillers	Loriners	Upholders
Drapers	Makers of Playing Cards	Vintners
Dyers	Masons	Wax Chandlers
Fanmakers	Master Mariners	Weavers
Farriers	Mercers	Wheelwrights
Feltmakers	Merchant Taylors	Woolmen

The Parish Clerks and the Watermen and Lightermen, though non-livery companies of the City of London, have sometimes been included.

In 1927 the Company of Master Mariners was constituted by Royal Charter and, in remembrance of the connection of the Mercer's Company, the first of all the companies, with the Merchant Adventurers and the maritime activities of earlier days, a loving cup was presented to the newly constituted company.

The following are the twelve great companies in order of civic precedence: Mercers, Grocers, Drapers, Fishmongers, Goldsmiths, Skinners, Merchant Taylors, Haberdashers, Salters, Ironmongers, Vintners, Clothworkers. The "Irish Society" was incorporated under James I. as "the governor and assistants of the new plantation in Ulster, within the realm of Ireland." The twelve companies contributed the sum of £60,000 for the scheme to settle a Protestant colony in the lands forfeited by the Irish rebels. The companies divided the settlements into twelve, under the paramount jurisdiction of the Irish Society. The charter of the society was revoked by the court of star chamber in the reign of Charles I., but a new one was granted by Charles II., under which the society still acts. The situation has been changed by the operation of the Land Purchase Act of 1903.

Livery Company Charities.—Most of the companies administer charities of large value under schemes of the Charity Commissioners, the Board of Education, the Endowed School Commissioners and the Court of Chancery. Education in particular has benefited. The Mercers' Company administers St. Paul's school under Dean Colet's will, and in 1902 built a girls' school—now of the first rank. Mercers' school is one of the oldest schools in London. The Drapers administer Bancroft's school (1727) and Howell's school for girls, Denbigh. Queen Mary College (formerly the East London college), an important centre of university education in London, was built up by the company and has received from its

[1]Properly the word should be spelled, as it was originally, "mistery"; it comes through the O.Fr. *mestier*, modern *métier*, from Lat. *ministerium*, service, employment, and meant a trade or craft, and hence the plays acted by craftsmen and members of gilds were called "mystery plays" (*see* DRAMA). For the word meaning a hidden or secret rite, with which this has so often been confused, *see* MYSTERY.

corporate funds grants approximating £400,000. This company's donations to education and charity since 1907 amount to about £1,000,000. The Merchant Taylors' company maintains their school, removed in 1933, from the City to Sandy Lodge, Northwood, Middx., with admirable results. The Skinners' school at Tonbridge is of the first order. The City and Guild of London Institute was developed from the initiative of the Cloth-workers company in 1875 by the joint action of the companies, and is now incorporated in the Imperial College. The Goldsmiths' company has given handsome sums to the Institute. In aiding science the companies have been wisely generous by founding research fellowships (Salters' company) or by grants in aid of institutions carrying on scientific investigations. By exhibitions and scholarships meritorious students are helped in their university careers. The endowment of professorial chairs and research work have also received the support of City companies.

Constitution of the Companies.—The constitution of the livery companies usually embraces (1) the court, which includes the master and wardens, and is the executive and administrative body (2) the livery or middle class, being the body from which the court is recruited; and (3) the general body of freemen, from which the livery is recruited. Some companies admit women as freemen. The freedom is obtained either by patrimony (by any person over 21 years of age born in lawful wedlock after the admission of his father to the freedom), by servitude (by *bona fide* apprenticeship to a freeman of the company) or by redemption which is in some cases wisely allowed only where an ancestor in the male line has had the freedom which his descendants have omitted to or been unable to acquire. Purchase is still regarded as rather disreputable. Admission to many of the companies is subject to the payment of considerable fees. Gift of the freedom is a recognized mode of expressing admiration for high public service. A royal commission was appointed in 1880 to inquire into all the livery companies, into the circumstances and dates of their foundation, the objects for which they were founded, and how far those objects were being carried into effect. A very valuable *Report and Appendix* (4 vols. 1884) was published, containing, *inter alia,* information on the constitution and powers of the governing bodies, the mode of admission of members of the companies, the mode of appointment, duties and salaries and other emoluments of the servants of the companies, the property of, or held in trust for the companies, its value, situation and description. The companies generally very freely made returns to the commission. The commission estimated the annual income of the companies to be from £750,000 to £800,000, about £200,000 of that amount being trust income, the balance corporate income; but these figures are now obsolete. No accounts are published, though the commission of 1880 recommended that this should be done.

Histories of the companies have in several cases been prepared for private circulation among their members.

LIVIA DRUSILLA (*c.* 55 B.C.–A.D. 29), Roman empress, was originally the wife of Tiberius Claudius Nero, by whom she had two sons, Drusus and Tiberius (afterwards emperor). In 38 Augustus compelled her husband to divorce her and married her himself, having first got rid of his own wife Scribonia. Her two sons were entrusted to the guardianship of Augustus, to whom she bore no children. Livia was suspected of committing various crimes to secure the throne for Tiberius. The premature deaths of Augustus' nephew Marcellus (whom he had at first fixed upon as his successor) and of his grandsons Gaius and Lucius Caesar, the banishment of his grandson Agrippa Postumus, and even his own death, were attributed to her. Augustus by his will declared her and Tiberius (whom he had adopted in A.D. 4) his heirs; Livia inherited a third of his property; she was adopted into the Julian gens, and henceforth assumed the name of Iulia Augusta. She had now reached the summit of her ambition, and at first acted as joint-ruler with Tiberius. Tiberius, however, soon became tired of her control; his retirement to Capreae is said to have been caused by his desire to escape from her. Livia continued to live quietly at Rome, in the full enjoyment of authority, until her death at an advanced age.

LIVINGSTON, EDWARD (1764–1836), American jurist and statesman, was born in Clermont, N.Y., on May 26, 1764. He graduated at Princeton in 1781, was admitted to the bar in 1785, and began to practise law in New York city, rapidly rising to distinction. He was a Republican representative in Congress, 1795–1801, where he was one of the leaders of the opposition to Jay's Treaty, taking the ground that Congress was not bound to appropriate money to carry out a treaty obligation. He opposed the alien and sedition laws, and introduced legislation on behalf of American seamen. In 1801 Livingston was appointed U.S. district attorney for the State of New York and while retaining that office was in August of the same year elected mayor of New York city. When, in 1803, the city was overtaken by an epidemic of yellow fever, Livingston helped to prevent the spread of the disease and relieve distress, and was himself attacked by the fever.

On his recovery he found himself indebted to the Government for public funds which had been lost through the dishonesty of a confidential clerk, and for which he was responsible as district attorney. He at once surrendered all his property, resigned his two offices in 1803, and removed early in 1804 to Louisiana. He soon acquired a large law practice in New Orleans, and in 1826 repaid the Government in full, including the interest.

Almost immediately upon his arrival in Louisiana, he was appointed by the legislature to prepare a provisional code of judicial procedure, which (in the form of an act passed in April 1805) was continued in force from 1805–25. In 1807 Livingston became involved in litigation over his claim to the Batture, Ste. Marie land, ending in a heated controversy with President Jefferson who upheld the public claim. Livingston's final victory in the courts brought him little financial profit because of the heavy expenses of the litigation. During the war with England from 1812–15 Livingston was active in rousing the mixed population of New Orleans to resistance, and acted as adviser and volunteer aide-de-camp to Gen. Jackson. In 1821, by appointment of the legislature, of which he had become a member the preceding year, Livingston began the preparation of a new code of criminal law and procedure, afterwards known in Europe and America as the "Livingston Code." Completed in 1824, it was accidentally burned, and reproduced in 1826, though not printed until 1833. It was never adopted by the State. It was at once reprinted in England, France and Germany, and studied all over the world, attaining wide influence. In referring to this code, Sir Henry Maine spoke of Livingston as "the first legal genius of modern times" (*Cambridge Essays,* 1856, p. 17). His code of reform and prison discipline was adopted by Guatemala. In 1823 he was appointed with Moreau Lislet to revise the civil code of Louisiana, which was substantially ratified.

Livingston was again a representative in Congress during 1823–29, a senator in 1829–31, and for two years (1831–33) Secretary of State under President Jackson. In this last position he was one of the most trusted advisers of the President, for whom he prepared a number of State papers, the most important being the famous anti-nullification proclamation of Dec. 1832. From 1833 to 1835 Livingston was minister plenipotentiary to France, charged with procuring the fulfilment by the French Government of the treaty negotiated in 1831. Livingston's negotiations were well conducted, but the French Chamber of Deputies refused to pay the first instalment of the adjudicated claims which, according to the treaty, was due in 1833. Relations between the two Governments became strained, and Livingston was finally instructed to close the legation and return to America. He died May 23, 1836 at Montgomery place, Dutchess county, New York. His works include: *Reports of the Plan of the Penal Code* (1822); *System of Penal Law for the State of Louisiana* (1826); *System of Penal Law for the United States* (1828); *Complete Works on Criminal Jurisprudence* (1873).

See C. H. Hunt, *Life of Edward Livingston* (1864); Louise Livingston Hunt, *Memoir of Mrs. Edward Livingston* (1886); Merrill Moore's "Edward Livingston" in the *Louisiana Historical Quarterly* (vol. 3, Jan.–Oct. 1920).

LIVINGSTON, ROBERT R. (1746–1813), American statesman, son of Robert R. Livingston (1718–75), a justice of the New York supreme court after 1763, and brother of Edward Livingston (*q.v.*), was born in New York city on Nov. 27, 1746. He graduated at King's college, New York (now Columbia university), in 1765 and was admitted to the bar in 1773. He was a member of the second, third, and fourth Provincial Congresses of New York (1775–77), was a delegate from New York to the Continental Congress in 1775–77, and again in 1779–80, and was a member of the committee which drafted the Declaration of Independence. He was prevented from signing that document by his absence at the time to attend a meeting of the fourth New York Provincial Congress, which on July 10 became the Convention of the Representatives of the State of New York, and by which at Kingston in 1777 the first State Constitution was adopted, Livingston having been a member of the committee that drafted this instrument. He was the first chancellor of the state, from 1777 to Feb. 1801, and is best known as "Chancellor" Livingston. In this capacity he administered the oath of office to Washington at his first inauguration to the presidency, in New York, on April 30, 1789. In 1788 he had been a member of the New York convention, which ratified for that state the Federal Constitution. He became an anti-Federalist and in 1798 unsuccessfully opposed John Jay in the New York gubernatorial campaign. In 1801 he became minister to France on President Jefferson's appointment and in 1803, in association with James Monroe, effected on behalf of his Government the purchase from France of what was then known as "Louisiana." In 1804 Livingston withdrew from public life and returned to New York, where he promoted various improvements in agriculture. He did much to introduce the use of gypsum as a fertilizer, and published an *Essay on Sheep* (1809). He was long interested in the problem of steam navigation; before he went to France he received from the State of New York a monopoly of steam navigation on the waters of the state and assisted in the experiments of his brother-in-law, John Stevens; in Paris he met Robert Fulton, and with him in 1802 made successful trials on the Seine of a paddle-wheel steamboat; in 1803 Livingston (jointly with Robert Fulton) received a renewal of his monopoly in New York, and the first successful steam-vessel, which operated on the Hudson in 1807, was named after Livingston's home, Clermont. He died at Clermont, N.Y., on Feb. 26, 1813.

Branch Historical Papers of Randolph-Macon College,* i. 299–324 and ii. 34–46; and J. B. Moore, "Robert R. Livingston and the Louisiana Purchase," in *Columbia University Quarterly,* vi. 221–229 (1904); D. S. Alexander, "Robert R. Livingston," *N.Y. State Hist. Assoc. Proc.,* vol. vi., pp. 100–114 (Albany, 1906); and J. L. Delafield, *Chancellor Robert R. Livingston and His Family* (Albany, 1911).

LIVINGSTON, WILLIAM (1723–1790), American political leader, was born at Albany (N.Y.), probably on Nov. 30, 1723. He was the son of Philip Livingston (1686–1749), and grandson of Robert Livingston (1654–1725), an important figure in the early life of New York State.

William Livingston graduated at Yale college in 1741, studied law in the City of New York, was admitted to the bar in 1748, and served in the New York legislature (1759–60). However, his chief political influence was exerted through pamphlets and newspaper articles. Through the *Independent Reflector,* which he established in 1752, Livingston fought the attempt to bring the projected King's college (now Columbia university) under the control of the Church of England. Upon the suspension of the *Reflector* in 1753, he edited in the New York *Mercury* the "Watch Tower" section (1754–55), which became the organ of the Presbyterian faction.

In 1772 he removed to Elizabeth, New Jersey. He represented New Jersey in the first and second Continental Congresses (1774, 1775–76), but left Philadelphia in June 1776, probably to avoid voting on the question of adopting the Declaration of Independence, which he regarded as inexpedient. He was chosen first governor of the State of New Jersey in 1778, and was regularly re-elected until his death at Elizabeth (N.J.), on July 25, 1790. Livingston was a delegate to the Federal Constitutional Convention of 1787, and supported the New Jersey small State plan. In 1754 he joined with his brother, Philip, and others in founding what is now known as the Society Library of New York. With the help of William Smith (1728–93), the New York historian, William Livingston prepared a digest of the laws of New York for the period 1691–1756, which was published in two volumes (1752 and 1762).

See Theodore Sedgwick, Jr., *Life of William Livingston* (1833); and E. B. Livingston, *The Livingston of Livingston Manor* (1910).

His brother, Peter van Brugh Livingston (1710–1792), was a merchant and a Whig political leader in New York, and one of the founders of the College of New Jersey (now Princeton university).

Another brother, Philip Livingston (1716–1778), was a member of the Continental Congress from 1774 until his death; he was a signer of the Declaration of Independence.

William's son, (Henry) Brockholst Livingston (1757–1823), was an officer in the American War of Independence. From 1807 until his death he was an associate justice of the United States Supreme Court.

LIVINGSTON, city of south central Montana, U.S.A., on the Yellowstone river, at an altitude of 4,490 ft., 56 mi. from the northern entrance to Yellowstone park; the county seat of Park county. It is on Federal highways 10 and 89 and the main line of the Northern Pacific railway. The population was 6,642 in 1940 by the federal census. It has railroad shops, and is the trading and shipping centre for a mining, farming and stock-raising region. Surrounded by high mountain ranges, it is an important recreational centre, with many fine dude ranches and summer resorts. Livingston was settled about 1879 and incorporated in 1884.

LIVINGSTONE, DAVID (1813–1873), Scottish missionary and explorer in Africa, was born on March 19, 1813, at the village of Blantyre Works, in Lanarkshire, Scotland. David was the second child of his parents, Neil Livingston (for so he spelled his name, as did his son for many years) and Agnes Hunter. At the age of ten David entered the neighbouring cotton-mill, and by strenuous efforts qualified himself at the age of twenty-three to undertake a college curriculum. He attended for two sessions the medical and the Greek classes in Anderson's College, Glasgow, and also a theological class. In September 1838 he went up to London, and was accepted by the London Missionary Society as a candidate. He took his medical degree in the Faculty of Physicians and Surgeons in Glasgow in November 1840. Livingstone had set his heart on China, and it was a great disappointment to him that the society finally decided to send him to Africa.

The Exploring Missionary.—Livingstone sailed from England on Dec. 8, 1840. From Algoa Bay he made direct for Kuruman, Bechuanaland, the mission station established by Robert Moffat twenty years before. The next two years Livingstone spent in travelling about the country to the northwards, in search of a suitable outpost for settlement. During these two years he became convinced that the success of the white missionary in a field like Africa was not to be reckoned by the tale of doubtful conversions he could send home each year—that the proper work for such men was that of pioneering, opening up and starting new ground, leaving native agents to work it out in detail. The whole of his subsequent career was a development of this idea. He selected the valley of Mabotsa, on one of the sources of the Limpopo river, 200 m. north-east of Kuruman, as his first station. Shortly after his settlement here he was attacked by a lion which crushed his left arm. The arm was imperfectly set, and it was a source of trouble to him at times throughout his life.

To a house, mainly built by himself at Mabotsa, Livingstone in 1844 brought home his wife, Mary Moffat, the daughter of Moffat of Kuruman. Here he laboured till 1846, when he removed to Chonuane, 40 m. farther north, the chief place of the Bakwain or Bakwena tribe under Sechele. In 1847 he again removed to Kolobeng, about 40 m. westwards, the whole tribe following their missionary. With two English sportsmen, William C. Oswell and Mungo Murray, he undertook a journey to Lake Ngami, which had never yet been seen by a white man. Crossing the Kalahari Desert, of which Livingstone gave the first detailed account, they reached the lake on Aug. 1, 1849. In April next year he made an attempt to reach Sebituane, who lived 200 m. beyond the lake, this time in company with his wife and children, but again got no farther than the lake, as the children were seized with fever. A year later, April 1851, Livingstone, again accompanied by his family and Oswell, set out, this time with the intention of settling among the Makololo for a period. At last he succeeded, and reached the Chobe (Kwando), a southern tributary of the Zambezi, and in the end of June reached the Zambezi itself at the town of Sesheke. Leaving the Chobe on Aug. 13, the party reached Cape Town in April 1852. Livingstone may now be said to have completed the first period of his career in Africa, the period in which the work of the missionary was predominant, but it must be remembered that he regarded himself to the last as a pioneer missionary, whose work was to open up the country to others.

Loanda and Victoria Falls.—Having seen his family off to England, Livingstone left Cape Town on June 8, 1852, and reached Linyante, the capital of the Makololo, on the Chobe on May 23, 1853, being cordially received by Sekeletu and his people. His first object was to find healthy high land for a station. Ascending the Zambezi, he found no place free from the tsetse fly, and therefore resolved to discover a route to the interior from either the west or east coast. He started, with 27 natives, from Linyante on Nov. 11, 1853, and, by ascending the Liba, Lake Dilolo was reached on Feb. 20, 1854. On May 31 the expedition reached Loanda, Livingstone, however, being all but dead from fever, semi-starvation and dysentery. From Loanda Livingstone sent his astronomical observations to Sir Thomas Maclear at the Cape, and an account of his journey to the Royal Geographical Society, which in May 1855 awarded him its patron's medal. Loanda was left on Sept. 20, 1854, but Livingstone lingered long about the Portuguese settlements. Making a slight détour to the north to Kabango, the party reached Lake Dilolo on June 13, 1855. Here Livingstone made a careful study of the hydrography of the country. He "now for the first time apprehended the true form of the river systems and the continent," and his conclusions have been essentially confirmed. The party returned to Linyante in the beginning of September.

For Livingstone's purposes the route to the west was unavailable, and he decided to follow the Zambezi to its mouth. With a numerous following, he left Linyante on Nov. 8, 1855. A fortnight afterwards he discovered the famous "Victoria" falls of the Zambezi. Livingstone reached the Portuguese settlement of Tete on March 2, 1856, in a very emaciated condition. Here he left his men and proceeded to Quilimane, where he arrived on May 20, thus having completed in two years and six months one of the most remarkable and fruitful journeys on record. The results in geography and in natural science in all its departments were abundant and accurate; his observations necessitated a reconstruction of the map of Central Africa. When Livingstone began his work in Africa the map was virtually a blank from Kuruman to Timbuktu, and nothing but envy or ignorance can throw any doubt on the originality of his discoveries.

The Zambezi Expedition.—On Dec. 12 he arrived in England, after an absence of sixteen years. He told his story in his *Missionary Travels and Researches in South Africa* (1857) with straightforward simplicity, and with no effort after literary style, and no apparent consciousness that he had done anything extraordinary. In 1857 he left the London Missionary Society, with which, however, he remained on the best of terms, and in February 1858 he accepted the appointment of "Her Majesty's consul at Quilimane for the eastern coast and the independent districts in the interior, and commander of an expedition for exploring eastern and central Africa." The Zambezi expedition, of which Livingstone thus became commander, sailed from Liverpool in H.M.S. "Pearl" on March 10, 1858, and reached the mouth of the Zambezi on May 14. The party, which included Dr. (afterwards Sir) John Kirk and Livingstone's brother Charles, ascended the river from the Kongone mouth in a steam launch, the "Ma-Robert"; reaching Tete on Sept. 8. Livingstone then explored the river above Tete, and especially the Kebrabasa rapids. The year 1859 was spent in exploring the river Shire and Lake Nyasa, which was discovered in September; and during a great part of the year 1860 Livingstone was engaged in repatriating such of the Makololo as cared to go home. In January of next year arrived Bishop C. F. Mackenzie and a party of missionaries sent out by the Universities Mission to establish a station on the upper Shiré.

After exploring the river Rovuma for 30 m. in his new vessel the "Pioneer," Livingstone and the missionaries proceeded up the Shiré to Chibisa's; there they found the slave trade rampant. On July 15 Livingstone, accompanied by several native carriers, started to show the bishop the country, and after seeing the missionary party settled in the highlands to the south of Lake Chilwa (Shirwa) Livingstone explored (Aug.–Nov.) Lake Nyasa. While the boat sailed up the west side of the lake to near the north end, the explorer marched along the shore. He returned more resolved than ever to rouse the civilized world to put down the desolating slave-trade. On Jan. 30, 1862, at the Zambezi mouth, Livingstone welcomed his wife and the ladies of the mission, with whom were the sections of the "Lady Nyassa," a river steamer which Livingstone had had built at his own expense. When the mission ladies reached the mouth of the Ruo tributary of the Shiré, they were stunned to hear of the death of the bishop and one of his companions. This was a blow to Livingstone, seeming to have rendered all his efforts to establish a mission futile. A still greater loss to him was that of his wife at Shupanga, on April 27, 1862.

The "Lady Nyassa" was taken to the Rovuma. Up this river Livingstone managed to steam 156 m., but farther progress was arrested by rocks. Returning to the Zambezi in the beginning of 1863, he found that the desolation caused by the slave trade was more horrible and widespread than ever. It was clear that the Portuguese officials were themselves at the bottom of the traffic. Kirk and Charles Livingstone being compelled to return to England on account of their health, the doctor resolved once more to visit the lake, and proceeded some distance up the west side and then north-west as far as the watershed that separates the Loangwa from the rivers that run into the lake. Meanwhile a letter was received from Earl Russell recalling the expedition by the end of the year. In the end of April 1864 Livingstone reached Zanzibar in the "Lady Nyassa." He reached England on July 23. The geographical results of this expedition, though not comparable in extent to those of his first and his final expeditions, were of high importance, as were those in various departments of science, and he had unknowingly laid the foundations of the British protectorate of Nyasaland Details will be found in his *Narrative of an Expedition to the Zambesi and its Tributaries* (1865).

The Slavers in Lualaka.—By Sir Roderick Murchison and his other staunch friends Livingstone was as warmly welcomed as ever. When Murchison proposed to him that he should go out again, although he seems to have had a desire to spend the remainder of his days at home, the prospect was too tempting to be rejected. He was appointed British consul to Central Africa without a salary, and government contributed only £500 to the expedition. The chief help came from private friends. During the latter part of the expedition government granted him £1,000, but that, when he learned of it, was devoted to his great undertaking. The Geographical Society contributed £500. The two main objects of the expedition were the suppression of slavery by means of civilizing influences, and the ascertainment of the watershed in the region between Nyasa and Tanganyika. At first Livingstone thought the Nile problem had been all but solved by Speke, Baker and Burton, but the idea grew upon him that the Nile sources must be sought farther south, and his last journey became in the end a forlorn hope in search of the "fountains" of Herodotus.

Leaving England in the middle of August 1865, via Bombay, Livingstone arrived at Zanzibar on Jan. 20, 1866. He was landed at the mouth of the Rovuma on March 22, and started for the interior on April 4. His company consisted of thirteen sepoys, ten Johanna men, nine African boys from Nasik school, Bombay, and four boys from the Shiré region, besides camels, buffaloes, mules and donkeys. This imposing outfit soon melted away to four or five boys. Rounding the south end of Lake Nyasa, Livingstone struck in a north-northwest direction for the south end of Lake Tanganyika, over country much of which had not previously been explored. The Loangwa was crossed on Dec. 14, 1866. On Christmas day Livingstone lost his four goats, a loss which he felt very keenly, and the medicine chest was stolen in January 1867. Fever came upon him, and for a time was his almost constant companion; this, and other serious ailments, which he had no medicine to counteract, told on even his iron frame. The Zambezi was crossed on Jan. 28, and the south end of Tanganyika reached on March 31. Here, much to his vexation, he got into the company of Arab slave dealers (among them being Tippoo-Tib) by whom his movements were hampered; but he succeeded in reaching Lake Mweru (Nov. 1867). After visiting Lake Mofwa and the Lualaba, which he believed was the upper part of the Nile, he, on July 18, 1868, discovered Lake Bangweulu. Proceeding up the west coast of Tanganyika, he reached Ujiji on March 14, 1869, "a ruckle of bones."

Livingstone recrossed Tanganyika in July, and passed through the country of the Manyema, but baffled partly by the natives, partly by the slave hunters, and partly by his long illnesses it was not till March 29, 1871 that he succeeded in reaching the Lualaba, at the town of Nyangwe, where he stayed four months, vainly trying to get a canoe to take him across. It was here that a party of Arab slavers, without warning or provocation, assembled one day when the market was busiest and commenced shooting the women, hundreds being killed or drowned in trying to escape. Livingstone had "the impression that he was in hell," but was helpless, though his "first impulse was to pistol the murderers." The account of this scene which he sent home roused indignation in England to such a degree as to lead to determined and partially successful efforts to get the sultan of Zanzibar to suppress the trade. In sickened disgust the weary traveller made his way back to Ujiji, which he reached on Oct. 13.

Stanley.—Not long after his arrival in Ujiji he was inspired with new life by the timely arrival of H. M. Stanley, the richly laden almoner of Gordon Bennett, of the *New York Herald.* With Stanley, Livingstone explored the north end of Tanganyika, and proved conclusively that the Rusizi runs into and not out of it. In the end of the year the two started eastward for Unyamwezi, where Stanley provided Livingstone with an ample supply of goods, and bade him farewell. Stanley left on March 15, 1872, and after Livingstone had waited wearily in Unyamwezi for five months, a troop of fifty-seven men and boys arrived, good and faithful fellows on the whole, selected by Stanley himself. Thus attended, he started on Aug. 15 for Lake Bangweulu, proceeding along the east side of Tanganyika. His old enemy dysentery soon found him out. In January 1873 the party got among the endless spongy jungle on the east of Lake Bangweulu, Livingstone's object being to go round by the south and away west to find the "fountains." The doctor got worse and worse, and in the middle of April he had to be carried in a rude litter. On April 29 Chitambo's village on the Lulimala, in Ilala, on the south shore of the lake, was reached.

The last entry in the journal is on April 27. "Knocked up quite, and remain—recover—sent to buy milch goats. We are on the banks of the Molilamo." On April 30 he with difficulty wound up his watch, and early on the morning of May 1 the boys found "the great master," as they called him, kneeling by the side of his bed, dead. His faithful men preserved the body in the sun as well as they could, and, wrapping it carefully up, carried it and all his papers, instruments and other things across Africa to Zanzibar. It was borne to England with all honour, and on April 18, 1874, was laid to rest in Westminster Abbey. His faithfully kept journals during these seven years' wanderings were published under the title of the *Last Journals of David Livingstone in Central Africa,* in 1874, edited by his old friend Horace Waller. In Old Chitambo's the time and place of his death are commemorated by a permanent monument, which replaced in 1902 the tree on which his native followers had recorded the event.

Estimate.—In spite of his sufferings and the many compulsory delays, Livingstone's discoveries during these last years were of prime importance as leading to a solution of African hydrography. No single African explorer has ever done so much for African geography as Livingstone during his thirty years' work. His travels covered one-third of the continent, extending from the Cape to near the equator, and from the Atlantic to the Indian Ocean. Livingstone was no hurried traveller; he did his journeying leisurely, carefully observing and recording all that was worthy of note, with rare geographical instinct and the eye of a trained scientific observer, studying the ways of the people, eating their food, living in their huts, and sympathizing with their joys and sorrows. In all the countries through which he travelled his memory is cherished by the native tribes who, almost without exception, treated Livingstone as a superior being; his treatment of them was always tender, gentle and gentlemanly. By the Arab slavers whom he opposed he was also greatly admired, and was by them styled "the very great doctor." "In the annals of exploration of the Dark Continent," wrote Stanley many years after the death of the missionary explorer, "we look in vain among other nationalities for a name such as Livingstone's. He stands pre-eminent above all; he unites in himself all the best qualities of other explorers . . . Britain . . . excelled herself even when she produced the strong and perseverant Scotchman, Livingstone."

But the direct gains to geography and science are perhaps not the greatest results of Livingstone's journeys. His example and his death acted like an inspiration, filling Africa with an army of explorers and missionaries, and raising in Europe so powerful a feeling against the slave trade that through him it may be considered as having received its death-blow. Personally Livingstone was a pure and tender-hearted man, full of humanity and sympathy, simple-minded as a child. The motto of his life was the advice he gave to some school children in Scotland—"Fear God, and work hard." (J. S. K.)

Finger, *David Livingstone, Explorer and Prophet* (1928); the *Proceedings* of the London Missionary Society, from 1840, the *Journal* and *Proceedings* of the Royal Geographical Society; the Despatches to the Foreign Office sent home by Livingstone during his last two expeditions; and H. M. Stanley, *How I found Livingstone* (1872) and *Autobiography* (1909).

LIVINGSTONE MOUNTAINS, a range of highlands in Tanganyika Territory, forming the eastern border of the rift-valley of Lake Nyasa, at the northern end of the lake. In parts these highlands, known also under their native name of Kinga, are more a plateau in character than a true mountain range. The northern end is well marked by an escarpment facing the Ruaha valley, which is regarded as the continuation of the eastern rift-valley. Southwards the range terminates in the deep valley of the Ruhuhu. The mountains are formed of Archaean granites, gneisses and schists and are overlain in the east by sandstones with thin coal seams. (Karroo System, Permo-Carboniferous.) The gneisses form a series of north to south ridges, the one nearest the lake (which in Mount Jamimbi or Chamembe, rises to a height of 7,870ft.), falls almost sheer to the water, the same steep slope being continued beneath the surface. Only 20m. wide in the south, the range widens to 40 in the north where is the depression of

Buanyi and the highest known summit of the range (9,600ft.). North and east of Buanyi, as in the east of the range, table-topped mountains occur, composed above of the horizontally bedded quartzites, sandstones and conglomerates of the Karroo System. There is rich grass on the uplands, forests in the hollows and poor scrub near the lake. Native settlements are scattered over the whole range. The climate is healthy, and night frosts occur in the cold season. European crops are raised with success. On the lake side are the ports of Manda and Lumbira.

LIVING WAGE: *see* POVERTY LINE.

LIVIUS ANDRONICUS (*c.* 284–204 B.C.), the founder of Roman epic poetry and drama. His name indicates that he was a Greek, a manumitted slave of the Livian family, and thus typical of the early influences in Latin literature, and of the interest of the enlightened aristocracy in Greek culture. He is supposed to have been a native of Tarentum, and to have been brought, while still a boy, after the capture of that town in 272, as a slave to Rome. He lived in the household of a member of the *gens Livia,* probably M. Livius Salinator. He determined the course which Roman literature followed for more than a century after his time. To judge, however, from the insignificant remains of his writings, and from the opinions of Cicero and Horace, he can have had no pretension to original genius. His real claim to distinction was that he was the first great schoolmaster of the Roman people. We learn from Suetonius that, like Ennius after him, he obtained his living by teaching Greek and Latin; his translation of the *Odyssey* into Saturnian verse was probably always intended as a school-book and was still used as such in Horace's time; although faultily executed, it satisfied a real want by introducing the Romans to a knowledge of Greek. The Romans and Italians had an indigenous drama of their own, known by the name of *Satura.* This, however, lacked a definite plot. In 240 Andronicus produced at the *ludi Romani* a translation of a Greek play (it is uncertain whether a comedy or tragedy or both), and this representation marks the beginning of Roman dramatic literature (Livy vii. 2).

Livius himself took part in his plays, and introduced the custom of having the solos (*cantica*) sung by a boy, while he himself represented the action of the song by dumb show. In his translation he discarded the native Saturnian metre, and adopted the iambic, trochaic and cretic metres. He continued to produce plays on Greek mythical subjects (*Achilles, Equus Troianus,* etc.). In the year 207, when he must have been of a great age, he was appointed to compose a hymn of thanksgiving, sung by maidens, for the victory of the Metaurus and an intercessory hymn to the Aventine Juno. As a further tribute of national recognition the "college" or "gild" of poets and actors was granted a place of meeting in the temple of Minerva on the Aventine.

See fragments in L. Müller, *Livi Andronici et Cn. Naevi Fabularum Reliquiae* (1885); also J. Wordsworth, *Fragments and Specimens of Early Latin* (1874); Mommsen, *Hist. of Rome,* bk. iii. ch. 14.

LIVNO, a town of Bosnia, Yugoslavia, in the fertile plain of Livno, at the foot of Mt. Krug (6,581 ft.); occupied by Italy in World War II. Pop. (1931) 4,331. There are cement works and a model farm for cattle rearing, and the town has some trade in grain, livestock and silver filigree work. In 1904 a fire destroyed more than 500 of the old Turkish houses, together with the Roman citadel. Remains prove that Livno occupies the site of a Roman settlement, the name of which is uncertain.

LIVONIA, a former province of Russia, now partly in Latvia (*q.v.*) and partly in Estonia (*q.v.*).

History.—Coins of the time of Alexander the Great, found in Oesel, show that the coasts of the Baltic were at an early period in commercial relation with the civilized world. The chronicle of Nestor mentions as inhabitants of the Baltic coast the Chudes, the Livs, the Narova, Letgola, Semigallians and Kors. It was probably about the 9th century that the Chudes became tributary to the Varangian-Russian states. As they reacquired their independence, Yaroslav I. undertook in 1030 a campaign against them, and founded Yuriev (Dorpat). The Germans first penetrated into Livonia in the 11th century. In 1186 the emissaries of the archbishop of Bremen began to preach Christianity among the Ehsts and Letts, and in 1201 the bishop of Livonia established his residence at Riga. In 1202 or 1204 Innocent III. recognized the order of Brothers of the Sword, the residence of its grand master being at Wenden; and the order, spreading the Christian religion by the sword among the natives, carried on from that time a series of uninterrupted wars against the Russian republics and Lithuania. The first active interference of Lithuania in the affairs of Livonia took place immediately after the great outbreak of the peasants on Oesel; Olgierd then devastated all southern Livonia. The war of the order with Ivan IV. of Russia in 1558 led to a division of Livonia, its northern part, Dorpat included, being taken by Russia, and the southern part falling under the dominion of Poland. From that time (1561) Livonia formed a subject of dispute between Poland and Russia, the latter only formally abdicating its rights to the country in 1582. In 1621 it was the theatre of a war between Poland and Sweden, and being conquered by Sweden enjoyed twenty-five years of milder rule. In 1654, and again at the beginning of the 18th century, it was the scene of war between Poland, Russia and Sweden. It was finally conquered by Russia, the official concession being confirmed by the treaty of Nystad in 1721. From this time Livonia formed, with Courland and Estonia, the Baltic provinces, a part of the old Russian Empire. On the conclusion of the World War a German army occupied these provinces and, although required by the Armistice Convention to evacuate the territory, it did not altogether withdraw until Dec. 1919. Livonia lost its individuality in the formation (1918) of the two republics of Latvia and Estonia (*qq.v.*), which divided between them the territory of the former Baltic provinces.

See E. Seraphim, *Geschichte Liv-, Esth-, und Kurlands* (2nd ed., Revel, 1897–1904) and *Geschichte von Livland* (Gotha, 1905, etc.); H. M. Stationery Office, Peace Handbooks No. 50. Courland, Livonia, Esthonia (1920).

LIVRE. The livre is an obsolete French monetary unit and weight, the word being derived from the Latin "libra," a pound used as money; it was called the livre (Tournois) and was divided into 20 "sous" of 12 "deniers" each. This corresponds to the present English system of pounds, shillings and pence, each containing that weight of silver. Originally equal to the English pound, it early depreciated to a far greater extent. Thus the franc, whose name dates from the middle ages, circulated before the Revolution by the side of the livre, and the legal rate of conversion was that of 81 livres to 80 francs.

After the Revolution the franc became the official monetary unit, but the livre continued to circulate until 1834, when it was withdrawn.

As a measure of weight, the livre was of an indefinite character, each town having its own standard.

LIVY (TITUS LIVIUS) (59 B.C.–A.D. 17), Roman historian, was born at Patavium (Padua) in Cisalpine Gaul, some 22 m. S.W. of Venice. His mature years were doubtless spent mostly in Rome, where he enjoyed the friendship of Augustus—a friendship that was not impaired by the fact that Livy eulogized Pompey so highly that Augustus called him "a Pompeian" (Tac., *Ann.* iv. 34). Of his domestic relations we know only that he had a son (Quintil. x. 1.39), who may have been the writer referred to as one of his authorities by Pliny (*N.H.* i. 5 Livio filio, *ibid.* 6 T. Livio filio), and a daughter (Seneca, *Controv.* x. 29.2). He died in A.D. 17 at his native Padua, of which he constituted the chief title to fame (Mart. i. 61.3 *Censetur Apona Livio sua tellus*).

We have some testimony to Livy's studies in rhetoric (Quintil. x. 1.39 "that brevity which is found in Livy in a letter written to his son: Read Demosthenes and Cicero, then other authors as each is likest to Demosthenes and Cicero," *cf.* ii. 5.20, viii. 2,18) and philosophy (Seneca, *Ep.* 100.9 "You may add the name of Titus Livius: for he wrote both dialogues assignable as well to history as to philosophy, and other books avowedly containing philosophy"). But his life-work was history.

His *History of Rome* (*Ab urbe condita libri*) was in 142 books, and told the story of Rome from the arrival of Aeneas in Italy down to the death of Drusus, younger brother of the emperor Tiberius, in A.D. 9. There are indications that the work was published in parts: thus, while Bk. I. opens with a formal preface to the whole work, prefaces of a less formal nature introduce Bks. VI., XXI. and XXXI. The division into *decades* is a late one and is not heard of before the end of the 5th century, though some scholars have seen what they consider to be traces of an original decadic division, *e.g.*, Bk. LXXX. contained the death of Marius, Bk. XC. the death of Sulla.

Of the 142 books only 35 are extant, viz., I.–X., carrying the story down to 293 B.C.; XXI.–XLV. (with some *lacunae* in XLI.–XLIV.), covering the years 218–167 B.C. We have, further, a fragment of Bk. XCI. which was discovered in the Vatican in 1772. The lost books are to some extent replaced by the *Periochae* (or summaries of contents), dating perhaps from the 4th century, which we possess for all the books with the exception of CXXXVI. and CXXXVII. Further, the *Prodigia* of Iulius Obsequens (4th century A.D.) which gives a list of prodigies from 190–12 B.C., is directly taken from (probably an epitome of) Livy. The same applies to the *fasti* in the *Chronica* of Cassiodorus (6th century). An Oxyrhynchus papyrus (for which *see* J. S. Reid, *Classical Review,* July 1904) contains fragments of an epitome—excerpts from Bks. XXXVII.–XL. and XLVIII.–LV. Lastly, the substance of much of Livy's history is no doubt to be found in later writers, who made use of his work.

His Conception of History.—To understand the ideas with which Livy undertook his great work, we turn to the general preface prefixed to Bk. I.: "Whether I shall perform a work worth the doing if I write the history of the Roman people from the foundation of the city, I do not well know, nor, if I knew, would I dare to say, inasmuch as I perceive that the subject is both old and trite, new writers ever believing either that they will contribute some greater certainty in matters of fact, or that in the art of writing they will surpass the rudeness of antiquity. However that may be, it will be at least a pleasant thought that I myself also should have done my duty to the memory of the deeds of the chiefest people in the world; and if in so great a company of writers my fame should be obscured, I would comfort myself with the nobility and greatness of those who shall darken my name. My theme, moreover, is one of immense labour—an empire whose story goes back beyond 700 years, and which, starting from small beginnings, has grown to a point where it labours under its own magnitude. To the greater number of my readers, I doubt not, the story of the first beginnings and of the times nearest to the beginning will afford less pleasure, eager as they will be to reach these latter times when the powers of a long puissant people are working their own decay. I, on the contrary, will seek this reward also of my labour—to avert a little while my eyes from the contemplation of the evils which our age has seen during so many years, while with my whole mind I recall those ancient things, free from every care which might distract the mind of the writer, even if it did not deflect it from the truth.

"With regard to the traditions of times before the city was founded or its foundation contemplated—traditions adorned by the fables of the poet rather than based upon the incorruptible monuments of history—I have no intention either to affirm them or to refute. Antiquity is allowed the privilege of mingling human things with divine in order to render the first beginnings of cities more august. And, if it should be permitted to any people to hallow their origins and refer them to the authorship of the gods, such is the warlike glory of the Roman people that, though they chiefly avow Mars to be their parent and the parent of their founder, even this vaunt the nations of mankind tolerate with the same equanimity with which they tolerate the Roman rule.

"But these and such-like matters, however they may be regarded or esteemed, I shall hold of small moment. The things to which I would have everyone for himself bend his keen attention are these: what Roman life and character have been; through what men and by what arts, at home or in the field, the empire was won and extended; then let him follow with attention how, as discipline gradually relaxed, character first, as it were, declined, then lapsed more and more, then began to go headlong, until we reached these last days when we can endure neither our vices nor their remedies. Here is that supremely salutary and fruitful thing in the study of history—that you should behold examples of every pattern placed upon a conspicuous monument and therefrom, for yourself and for your country, take what you should imitate, and therefrom see what—foul in inception and foul in issue—you should avoid.

"For the rest, either my love for the task which I have undertaken deceives me, or there has never been a state either greater or holier or richer in good examples; no state into which avarice and luxury made their entrance so late; none where poverty and thrift were honoured so much and so long—nay, the less wealth, the less cupidity. Of late riches have introduced avarice, abundance of pleasures has brought to men the desire by way of luxury and lust to ruin themselves and to ruin all.

"But complaints will never be pleasing, not even when they are perhaps necessary: from the beginning at least of this great business on which I am embarking, let them be absent. Rather would I commence—were it the custom for historians as it is for poets—with good omens and vows and prayers to gods and goddesses to grant a happy issue to the great task now begun."

Livy thus had two main purposes in writing his history—apart from the personal solace which it afforded him by diverting his mind from the troubles of his own time—(1) to preserve the memory of the great deeds of the Roman people; and (2), which he regards as still more important, to teach by conspicuous examples what is worthy of imitation and what is to be avoided. His first purpose is thus identical with that of Herodotus (i. 1) who wrote his history in order that the story of the past might not be obliterated by lapse of time, and that the great and marvellous deeds performed by Greeks and barbarians might not lose their fame. His second purpose reminds us of Thucydides (i. 22) who, writing in the belief that history tends more or less to repeat itself, aims at making his work a true record of the past and thus a safe guide to the future. The only difference is that Livy's educational purpose is more ethical than political. The same sort of two-fold object is indicated also by Polybius (i. 1) as having been the purpose of almost all his predecessors (and, apparently, he adopts it as his own purpose), who declare that "the knowledge of history is the truest education and gymnastic for political affairs, and the clearest and, indeed, the only teacher of the power to support the changes of fortune nobly is the memory of the vicissitudes of others."

Sources.—The question of the literary sources used by Livy has been the subject of much discussion and research. The chief difficulty arises from the somewhat haphazard way in which he refers to his authorities. Explicit reference to his authority for specific statements is rare: xxii. 7 "The number of the slain on both sides is multiplied by other authorities. For myself, apart from the fact that I would have nothing drawn from idle rumour, I have taken as my authority, Fabius, a contemporary of this war." xxxiii. 10 "On that day there were slain 8,000 of the enemy, 5,000 taken captive. . . . If one were to believe Valerius, who extravagantly exaggerates the number of everything, 40,000 of the enemy were slain, the captives—a more modest falsehood—were 5,700. . . . Claudius, too, writes that 32,000 of the enemy were slain, while the captured were 4,300. We have not accepted the smaller numbers by preference, but have followed Polybius, no uncertain authority for all Roman affairs, but especially for those carried out in Greece." More often the reference is quite vague: x. 25 "whether of his own will . . . or summoned by decree of the senate: for there are authorities for both statements" (*in utrumque auctores sunt*). Often we have no reference to authorities at all. So far, however, as can be ascertained, his chief authorities in the different *decades* may be enumerated as follow: In the first *decade* he depended chiefly on the earlier and later annalists. Q. Fabius Pictor, the earliest of all, who served in the Second Punic War, is referred to in i. 44 (*scriptorum antiquissimus*); i. 55 "I would, therefore, rather believe Fabius, apart from his greater antiquity . . . than Piso"; ii. 40, Coriolanus "is said to have perished, but authorities differ as to the manner of his death. In Fabius, by far the most ancient authority, I find that he lived to old age"; also in viii. 30, x. 57. L. Calpurnius

Piso, consul in 133 B.C., who *"reliquit . . . annales sane exiliter scriptos"* (Cic. *Brut.* 27), is cited in i. 55, ii. 58, ix. 44, x. 9; Q. Valerius Antias (early in 1st century B.C.) in iii. 5; C. Licinius Macer (born *circ.* 110 B.C.) in iv. 7, iv. 20, iv. 23, vii. 9, x. 9; Q. Claudius Quadrigarius (about the same date), whose *Annales* (Aul. Gell. i. 25, etc.) began from the sacking of Rome by the Gauls (390 B.C.), in viii. 19, ix. 5; Q. Aelius Tubero (1st cent. B.C.) in iv. 23, x. 29. There is a single reference to L. Cincius Alimentus (who served in the Second Punic War), the celebrated annalist and antiquary (vii. 3, *diligens talium monumentorum auctor Cincius*).

In the third *decade* (Bks. XXI.–XXX.), in addition to Fabius Pictor (xx. 7), Piso (xxv. 39), Valerius Antias (xxv. 39, xxvi. 49, xxix. 35, xxx. 19 and 29), Claudius Quadrigarius (xxv. 39 *auctor est Claudius qui annales Acilianos* [*i.e.*, of C. Acilius Glabrio, 2nd century B.C., Cic. *De Off*, iii. 115, Aul. Gell. vii. 14, 9, Plut. *Cat.* 22, Macrob. *Sat.* i. 5] *ex Graeco in Latinum sermonem vertit*), Cincius Alimentus (xxi. 38), we have some new names. L. Coelius Antipater, a contemporary of C. Gracchus, who wrote a history of the Second Punic War (Cic., *De Div* i. 24, *De Or.* ii. 12, *De Legg.* i. 2, *Brut.* 26, *Ad. Att.* xiii. 8, Gell. x. 24, Valer. Max. i. 7), is cited in xxi. 38, xxii. 31, xxiii. 6, xxvi. 11. xxvii. 27, xxviii. 46, xxix. 27. Silenus (*cf.* H. Dessau, *Über die Quellen unseres Wissens vom zweiten punischen Kriegs*, Hermes 51 [1916] p. 364 *seq.*), of Calé Acté in Sicily, who was in the camp of Hannibal for part of the campaign (Corn. Nep. xxiii. 13,3: "The events of this war have been recounted by many writers, but of these, two were with him in his camp and lived with him as long as fortune permitted, Silenus and Sosilus of Lacedaemon"), and whose work was used by Coelius Antipater (Cic., *De Div.* i. 24: "This is also in the Greek history of Silenus whom Coelius follows: he was a most careful follower of the affairs of Hannibal"), is referred to in xxvi. 49. Lastly, Polybius is cited once (xxx. 45 *Polybius, haudquaquam spernendus auctor*).

In the fourth and fifth *decades* (Bks. XXXI.–XLV.) the authorities cited are Claudius Quadrigarius (xxxiii. 10, xxxv. 14), Valerius Antias (xxxii. 6, xxxiii. 10, xxxiv. 15, xxxv. 2, xxxvi. 19 and 38, xxxviii. 50, xxxix. 22, xl. 29, xli. 32, xlii. 11, xliv. 13, xlv. 40), and Polybius (xxxiii. 10, xxxiv. 50, xxxvi. 19, xxxix. 52, xlv. 45). The principle on which he proceeds is to use Polybius for matters concerning Greece and the East, the Roman writers for those concerning Italy and Western Europe. In this way is explained the comparatively small use made of Polybius in the third *decade* which is occupied mainly with Rome and Roman affairs, for which Roman authorities were naturally more abundant.

Livy's Use of His Authorities.—Livy had the reputation in antiquity of conspicuous honesty and impartiality (Tac., *Ann.* iv. 34 *Titus Livius, eloquentiae ac fidei praeclarus in primis;* Senec. *Suas.* vi. 22 *candidissimus omnium magnorum ingeniorum aestimator*), and probably no competent historian would accuse him of deliberately falsifying or misrepresenting his authorities. Macaulay, in his essay on history, says that "no historian with whom we are acquainted has shown so complete an indifference to truth," but this characteristic extravagance is somewhat discounted by the fact that in his next paragraph he proceeds to speak of Livy's attitude to the past in terms so grotesquely erroneous as to suggest that Macaulay had either never read, or had forgotten the memorable language of Livy's preface. The charges which modern scholarship brings against Livy in regard to the use of his literary authorities are mainly these: That in his selection of authorities, and in his discrimination between them, he does not proceed on adequate critical grounds; that, following now one authority, now another, he has involved himself in inconsistent accounts of the same events; that by omission in some cases, in others by addition, he has, however unintentionally misrepresented his authorities; and, lastly, that in some cases he has failed to understand the meaning of the text before him.

A few examples will illustrate his method of dealing with his authorities. Mere vague rumour is always to be neglected in favour of written evidence: vi. 1, the history of Rome down to the capture of the city by the Gauls (390 B.C.) is obscure, "first through its antiquity and then because in those times letters, the one faithful guardian of the memory of things (*litterae, una custodia fidelis memoriae rerum gestarum*), were few and rare, and because such as existed in the journals (*commentarii*) of the *pontifices* or in other public or private memorials perished when Rome was burnt." When his authorities agree, he usually accepts them without comment. When they differ, he is sometimes content to state the different accounts without deciding between them, *e.g.*, xxv. 39. More often he indicates his preference and the grounds on which it is based. In general, preference is given to the older and, if available, contemporary authority: viii. 40 "Nor is there extant any writer contemporary with those times on whom one could take one's stand as a sufficiently sure authority," *cf.* xxii. 7. Sometimes the ground is merely general probability: xxvii. 7 "The storming of Carthage I have put in this year, with many authorities, although I am not unaware that some put the capture of the city in the following year, because it seemed to me less likely that Scipio would have spent a whole year in Spain doing nothing," *cf.* vi. 21. "In the case of things so ancient I should be content if what looks like the truth were taken for true." Where the number of the slain and captured, or the amount of booty, is variously given, he prefers the middle estimate: xxvi. 49 "If we must agree with some authority, the middle estimate is likest the truth." Sometimes he admits that he can discover no ground for a decision: vii. 40 "It is not easy to prefer one account to another or one authority to another" (*aut rem rei aut auctorem auctori praeferre*). Sometimes, if he sees reason, he does not hesitate to reject all his authorities: xxii. 31 "Almost all the annalists say that Fabius was dictator when he fought against Hannibal. Coelius (Antipater) also writes that he was the first dictator created by the people. But it has escaped Coelius and the rest that only the consul Gnaeus Servilius, who was then far away in the province of Gaul, had the power to appoint a dictator. As the State, already terror-stricken by disaster, could not await the delay thus occasioned, recourse was had to the appointment by the people of a pro-dictator. The general's subsequent exploits, his eminent fame, and the exaggeration by his descendants in the title attached to his portrait, easily brought it about that he should be styled dictator instead of pro-dictator." For mere invention he has no place (xxii. 7 *nihil haustum ex vano velim, quo nimis inclinant ferme scribentium animi*), and the exaggerations of Valerius Antias (xxxiii., 10 *Si Valerio quis credat omnium rerum immodice numerum augenti*) are stigmatized with the utmost candour (xxvi. 49 *adeo nullus mentiendi modus est*).

That his somewhat haphazard use of different authorities involved him sometimes in inconsistencies (*e.g.*, xxvii. 7. 1, compared with xxvi. 51. 2), sometimes in duplications which represent a single event as two (*e.g.*, xxiii. 46 compared with xxv. 18; xxvii. 18 compared with xxviii. 13), seems undeniable. As to mistaking the meaning of his authorities, one of the best known examples is xxxiii. 35 "Cornelius came to Thermopylae, where a full convention of Greece—called the Pylaic convention—takes place on fixed days." This appears to represent Polybius xviii. 31. 6 ἧκον ἐπὶ τὴν τῶν Θερμικῶν σύνοδον: that is to say, Livy appears to have confused a convention at Thermum in Aetolia with the amphictyonic convention at Thermopylae. The slip is a very natural one, and, of course, Livy may here be following some other authority than Polybius.

It is further charged against Livy that he does not appear to have made any attempt to check his literary authorities by personal examination of official records and monumental evidence. His discussion of the inscription on the linen breastplate of A. Cornelius Cossus in the temple of Iupiter Feretrius (iv. 20) and his references to the *"magistratuum libri lintei"* (iv. 7 and 20), which he cites on the authority of Licinius Macer, appear to imply that he had not personally inspected them. We have, indeed, some phrases which suggest such personal examination (*e.g.*, ix. 18 *Paginas in annalibus magistratuum fastisque percurrere licet, etc.*), but there is certainly no sign of anything like a critical examination of all available records. And, lastly, there is no evidence that he made any study of the topography of the places in which the scenes which he described were enacted.

But whatever may be his defects as a scientific historian, there can be no doubt that in regard to the two chief aims which Livy proposed to himself—to preserve the memory of the great deeds of the Roman people and to set upon a pedestal, for imitation or avoidance, conspicuous examples of good and evil—the history is a triumphant success. Nor is it altogether too bold to hazard the conjecture that if Livy had shown more meticulous accuracy in the verification of his facts, he might have—comparatively at least—failed of his principal purpose. It is, unhappily, too often true of historians, that accuracy is a synonym for dullness which, for the end which Livy had in view, would have been the most fatal of all faults. "Never let us speak disrespectfully," says a modern critic, "of accuracy, of research, of stern veracity, of unbiassed judgments, or lightly confer the grave title of historian upon hasty rhetoricians who have refused to take pains; but the fact remains that, for the ordinary thinking man who has taken his degree, an ounce of mother-wit is often worth a pound of clergy, and that even the so-called history of an inaccurate genius may be not only more amusing, but more profitable reading than the blameless work of a duller nature."

In addition to enthusiasm for his subject—a prime, if not an indispensable, requisite in a historian,—Livy was the happy possessor of two other supreme endowments. The first is his gift of sympathetic imagination which enables him so to identify himself with the past that he becomes not so much the critical spectator of events as an interested participant. "I am not unaware," he writes (xliii. 13), "that, owing to the same indifference (*negligentia*) which nowadays leads the generality of men to disbelieve that the gods give warning of anything by portents, no prodigies are now reported publicly or recorded in our annals; but, on the one hand, when I am writing ancient history, my mind, I know not how, takes on an antique tinge (*antiquus fit animus*), and, on the other hand, a certain feeling of reverence (*quaedam religio*) constrains me to consider those things worthy of being recorded in my annals which the wisest men considered deserving of the attention of the State." It is this imaginative sympathy which lends vivacity and verisimilitude to his descriptions, whether his theme be a warlike scene, such as the sack of Rome by the Gauls (v. 41 *seq.*), the siege of Saguntum (xxi. 7. *seq.*), the battle of the Metaurus (xxvii. 47 *seq.*), or a scene of a domestic character, such as the death of Lucretia (i. 58) or the death of Philopoemen (xxxix. 50). To the same gift are largely to be attributed the brilliance of his pen-portraits, such as those of M. Porcius Cato (xxxix. 40), Hannibal (xxi. 4), and the vivid quality of the set speeches which, following established precedent, he puts into the mouth of his characters (*e.g.,* Cato xxxiv. 2.); Q. Fabius (xxii. 39), Hannibal (xxx. 30). And since nothing is so potent as imagination to stir the imagination, one may suppose that it was this quality which chiefly moved the man of Gades "who came from the ends of the earth to look upon Livy, and, having seen him, immediately departed" (Plin., *Ep.* ii. 3.).

The other great endowment which Livy possessed was a gift of style such as very few historians have boasted. Asinius Pollio, indeed, is said to have found in Livy a certain provincialism (*Patavinitas*), but it is quite clear from Quintilian (i. 5. 56; viii. 1. 3), who reports the fact, that the criticism referred merely to some peculiarity in vocabulary or, at most, of idiom, which we can no longer detect. Quintilian himself in x. 1. 101, where he sums up the characteristics of Livy ("Nor let Herodotus be indignant if we claim an equal rank for T. Livius—in narrative marvellously pleasant and eminently lucid; in speeches eloquent beyond all telling—so appropriate are the sentiments both to the situation and to the speaker; the emotions, and particularly the softer emotions, no historian, to speak with the utmost reserve, has commended more"), hardly touches on the question of style, and the elusive phrase which he uses in x. 1. 32 "the milky richness of Livy" (*Livi lactea ubertas*), has produced more controversy than illumination. Macaulay, in his essay on History, supposes it to refer to his "exuberance of thought and language, always fresh, always sweet, always pure, no sooner yielded than repaired." If one remembers that the *uber* (= ἁδρόν) *genus dicendi* is the rich and ornate style, the qualities of which are "dignity and amplitude," and that the bad style which apes the ornate is the "turgid and inflated" (Aul. Gell. vi. 14), the translation of Quintilian's phrase which suggests itself is "unaffected richness" or "rich simplicity." In any case, Livy's style is a happy medium between the austerity of the republican age and the preciosity of the imperial. And by virtue of those two gifts of imagination and style her loyal and devoted son has succeeded in fashioning for the vanished republic "a winding-sheet"—to use the language of Simonides—"such as neither mould nor all-conquering Time shall destroy."

Bibliography.—*Editio princeps,* Rome (1469); Drakenborch, Leyden (1738–46); Weissenborn (1858–62), new ed. by Müller, Weidmann, Berlin (1875–94). There are numerous editions of single books. There is no worthy translation, but that of Philemon Holland (1600), has an interest of its own. (A. W. Ma.)

LIXIVIATION is equivalent to leaching and is the process of removing a soluble substance from one that is insoluble in the solvent employed. Potash was originally obtained by the lixiviation of wood ashes. In the crude industry the ashes were simply stirred with successive lots of water, allowed to settle and the solution decanted. In modern industry lixiviation is carried on in vessels which permit either batch treatment or continuous lixiviation. A typical example is percolation in the pharmaceutical industry, where liquid is permitted to pass slowly through a mass from which it dissolves out the active principles desired.

LI YUAN-HUNG (1864–1928), President of the Chinese Republic, was born in the province of Hupeh, and educated at the Pei-yang naval college at Tientsin. He served in a cruiser during the war with Japan, and later was in charge of fortifications at Nanking. He accompanied the Viceroy Chang Chih-tung to Wuchang, and twice visited Japan to study her educational system and army organisation. In 1911 he had risen to the rank of Divisional Commander and was among the first military officials to realise the force of the revolutionary movement. In consequence he was empowered to negotiate peace at Shanghai, and upon the foundation of the Republic became its first vice-president. Upon the death of Yuan Shi-kai he succeeded as president and held office until the temporary restoration of the boy Emperor in July, 1917, when he resigned, remaining for the next five years in Tientsin. In 1922 he was prevailed upon to resume the presidency, but in September of the following year he was compelled to resign in favour of Tsao Kun. Li Yuan-hung at an early date opposed "Tuchunism," *i.e.,* the system of military governorships, and advocated divesting the tuchuns of administrative duties; he worked for the reunification of the country by negotiation instead of by force, but in this he was unsuccessful and he died in retirement in Tientsin on June 5, 1928.

LIZARD. Any member of the reptilian order Sauria. These animals differ from turtles in the absence of carapace and plastron and from crocodiles and the tuatara in never having more than one bony arch across the temporal region of the skull. As a rule they may be distinguished from snakes by the presence of limbs, but there are limbless lizards that resemble snakes in so many respects that no single character or group of simple external characters serves to differentiate them; the two orders are undoubtedly closely allied and they are the two dominant groups of reptiles of the present day. Lizards, of which about 2,500 species are at present known, are a cosmopolitan group, their northern and southern limits approaching those regions where the subsoil is permanently frozen; it is in the tropics, however, that the greatest number, both of individuals and species, is to be found. None of the living forms are thoroughly aquatic though many take readily to water, and none are efficient fliers, but they have invaded almost every other type of environment. Correlated with the environmental conditions and with their habits they exhibit great variety in size, shape and structure, the structural modifications occurring chiefly in the skin, limbs, tail, tongue, teeth and digestive tract. The skin is usually beset with horny scales, which are sometimes underlain with bony plates (osteoderms), and this horny outer covering is shed at irregular intervals, not in one piece as is usual among snakes, but piecemeal; the scales themselves may be small and granular, flattened and overlapping or irregularly enlarged to form tubercles or spines. Limbs may be well-developed with five separate clawed digits on each, or entirely absent, and an uninterrupted transition from one condition to the other can be traced; in addition, the digits may have fringes of scales or be webbed in desert-dwelling species, be equipped with adhesive pads in climbing forms or be bound together to form opposable bundles. The tail varies considerably in shape and relative size and is often extremely fragile; fracture occurs in definite cleavage planes which pass through the middle of the vertebrae and the lost portion is regenerated, but on a simpler plan, without true vertebrae and usually with a more primitive type of scalation. If the fracture is incomplete a new tail is often produced from the wound and in this way double, and sometimes triple tails may be produced. The ability to shed the tail has a definite value since the detached member retains its muscular irritability for a short time and its wriggling movements may distract the pursuer's attention for the short time necessary to enable the lizard to make its escape. The tongue is usually covered with papillae which may be scale-like or arranged in parallel rows; in the majority of lizards it is flattened and only slightly notched in front but in some it is rounded, bifid and retractile into a basal sheath, like that of a snake. Teeth are generally all alike, conical and pointed but rarely they are flattened, grooved or serrated; occasionally they are differentiated into "incisors," "canines," and "molars" though the teeth so named are not homologous with the same teeth in mammals.

RESTORATION OF A MOSASAUR, THE GREAT MARINE LIZARD TYLOSAURUS
The extinct Mosasaurs flourished in the age of reptiles

Most lizards reproduce by means of eggs which are left to hatch where they are deposited; they are elliptical, pointed at both ends and enclosed in a leathery or calcareous shell. In different families the practice of retaining the eggs within the body of the mother until the young are ready to be hatched (ovo-viviparity) has been developed but in one or two skinks the egg-shell is entirely lost and the developing embryo receives nourishment directly from the mother through a placenta-like structure (viviparity).

The species existing at the present day (a few fossil forms are known) are grouped into 21 families, based chiefly on features of the skeleton which are discussed in the general article on REPTILES.

1. *Gekkonidae.*—Geckoes, *q.v.* Small, soft-skinned lizards with the eye covered by a transparent watch glass-like covering and often with adhesive lamellae beneath the digits; cosmopolitan in distribution; all reproducing by means of hard-shelled eggs.

2. *Uroplatidae.*—A single genus in Madagascar, the best known species being *Uroplates fimbriatus;* this is a gecko-like creature with large eyes covered by a transparent membrane and with adhesive lamellae on the digits. The body is depressed and its lateral edges are produced into a fimbriated fold of skin which also borders the edges of the limbs; the tail is much flattened, leaf-like, with its outline broken by numerous indentations and the colouring so closely imitates a patch of lichen that when the animal is at rest on a tree trunk the broken outline and cryptic colouring render it very inconspicuous.

3. *Xantusiidae.*—A small Central and Western American family with well-developed limbs, no adhesive lamellae on the fingers or toes but without movable eyelids. *Xantusia* occurs in the desert regions of California and Nevada, *Lepidophyma* in Central America and *Cricosaura* in Cuba.

4. *Dibamidae.*—A single genus of burrowing forms in the Malayan region from New Guinea to S. Annam and the Nicobar Islands. Limbs are entirely absent in females but the hind ones persist in males as a pair of stylets which are probably used as claspers. The body is serpentiform, covered with small imbricating scales and the eyes are entirely covered by the skin.

5. *Feyliniidae.*—Another small family of degenerate, burrowing forms without any external rudiments of limbs and with the eyes completely covered over by the skin; *Typhlosaurus* in Madagascar and *Feylinia* in West and South Africa.

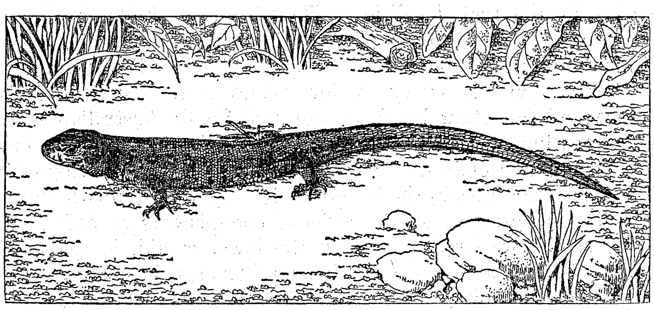
6. *Anelytropsidae.*—A single species only is known of this family, *Anelytropsis papillosus,* a burrowing creature found in the humus of the forests of Mexico; in all outward respects it resembles the members of the preceding family in which it was formerly included.

7. *Scincidae.*—This is one of the largest families of lizards and is cosmopolitan in its distribution; in America it is comparatively poorly represented but the tropical parts of the Old World possess a bewildering variety of forms. All have hard, overlapping scales beneath each of which is a bony plate embedded in the skin; limbs may be well-developed with five fingers and toes, or completely absent and every intermediate condition can be found; in some the forelimbs show greater reduction than the hinder pair but in others the converse is true and limb reduction appears to have taken place, not once, but many times within the family. The largest species is the blue tongued lizard (*Tiliqua scincoides*) of Australia, a heavy-bodied creature which may reach a length of two feet and which has relatively short pentadactyle limbs; other well-known Australian forms are the stump-tailed skink (*Trachysaurus rugosus*), with large rough scales and a short, broad tail and *Egernia stokesii* also with a short tail whose scales are enlarged to form thorn-like spines. *Lygosoma* is circumtropical in its distribution and its numerous species show every stage of limb reduction; this reduction is correlated with burrowing or cryptozoic habits and occurs in widely separated groups of species in different localities. Though most skinks are ovo-viviparous a few species in this genus lay eggs, among them the widespread blue-tailed skink (*L. cyanurum*) which occurs in large numbers on almost every Pacific Island from Tahiti to New Guinea; on the other hand, one or two South Australian lygosomas are known to be truly viviparous. Another modification, of which gradational stages can be traced, is the development of a transparent disc in the lower eyelid, apparently in correlation with life in desert or sandy regions; commencing as a few enlarged semi-transparent scales on the lower eyelid, in the more advanced forms almost the whole eyelid has lost its scaly character and become quite transparent. The same modification has also occurred in other genera and reaches its highest development in such forms as *Ablepharus* and *Ophiseps,* in which the transparent lower lid is fused with the edge of the upper and thus superficially resembles the transparent eyecovering of the geckoes and their allies. *Mabuya,* another large circumtropical genus, closely resembles *Lygosoma* and has undergone almost all the same modifications; the limbs are not, however, completely lost and no species are as yet known to be viviparous. The skink, the species which has given its name to the whole family, is a small North African and Syrian desert-dwelling form, *Scincus scincus,* with a peculiar wedge-shaped head, small eyes and very short limbs; the edges of the fingers and toes have a fringe of short, broad scales which render the hands and feet paddle-like, and by

means of these, assisted by the wedge-shaped head, the animal can dive into, and literally swim through, loose sand. *Chalcides,* a genus of southern Europe, North Africa and western Asia, shows again various stages of limb reduction and the development of a transparent disc in the lower eyelid, and one species, *C. tridactylus,* is viviparous.

8. *Gerrhosauridae.*—A small family confined to southern Africa and Madagascar. As in the skinks, the scales are large and imbricating with osteoderms beneath them but there is often a band of small scales between the armour of the belly and the back and, when the body is not distended, this region has the form of an inturned fold. *Gerrhosaurus* of South Africa and *Zonosaurus* of Madagascar have well-developed limbs but the African *Tetradactylus* shows various stages of limb reduction, the most degenerate form, *T. africanus,* having mere stumps.

9. *Lacertidae.*—The true lizards of the old world, but not found in Madagascar or the Australian region; their northern limits coincide almost with the edge of the area of permanently frozen subsoil but they are most numerous in the African region. All are terrestrial with well-developed pentadactyle limbs and long, fragile tails; the scales of the body as a rule are small, but the head is covered with large, regularly arranged shields beneath which are osteoderms. The majority of the European lizards belong to this family and to the genus *Lacerta* of which two species occur in the British Isles. The common lizard (*L. vivipara*) has a wide range through northern Europe and is fairly plentiful on heaths and commons throughout Great Britain; in Ireland its distribution is irregular. It is a small creature, rarely more than 5 or 6 in. in total length, brown or olive in colour with darker streaks and small lighter round spots on the flanks; like the majority of lizards it feeds chiefly on insects and normally it is ovo-viviparous though there are records of specimens having laid eggs. The other British lizard is the sand lizard (*L. agilis*) which, despite its scientific name, is a more heavily built, larger and less nimble species than the preceding; it is rare in England, being confined to a few isolated localities in Lancashire and the south, though common on the continent. Females are brown with rows of darker and lighter spots and patches but the ground colour of the males is a brilliant emerald green with an irregular dark stripe down the middle of the back and small, ocellar, whitish spots. The green lizard (*L. viridis*) is a much larger species, usually of a vivid green colour with or without small black dots, and is fairly common throughout France and central Europe. The commonest and most variable species in Europe is the wall lizard (*L. muralis*); it abounds throughout the centre and south and on the islands of the Mediterranean, where almost every tiny islet has it own peculiar colour variety, often endowed with the rank



BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

THE SAND LIZARD OF ENGLAND AND THE CONTINENT, A SPOTTED SPECIES, NEVER ATTAINING TO A LENGTH OF MORE THAN NINE INCHES

of a separate species. On the mainland, too, the colour varieties are almost endless but all intergradations are known and it is impossible to tell whether we have to deal with a number of species which freely hybridize or with one or two which are very variable. Another very beautiful southern European species is the eyed lizard (*L. ocellata*) which reaches a length of 18 to 20 in.; the colour is brilliant green with rows of blue, black-bordered, eye-like spots along the flanks.

Acanthodactylus of southwest Europe and north Africa has the fingers and toes edged with a fringe of elongate scales, a modification which enables the animals to run over the surface of soft sands. *Cabrita* in India has a transparent disc in the lower eyelid and *Ophisops* which ranges from North Africa to India has a similar modification but has the lower eyelid fused to the upper as in the skink *Ablepharus.*

10. *Teiidae.*—An American family whose typical members superficially resemble the old world lacertids; the tongue is always narrow, deeply bifid and often retractile into a basal sheath like that of a snake; the majority are South American but a few have established themselves as far north as the southern United States. Some are arboreal, others strictly terrestrial and a number of small forms have the limbs reduced in correlation with burrowing or semi-burrowing habits. The teju or teguexin (*Tupinambis teguixin*) of the tropical parts of America is the largest species and in size and general habitus as well as habits resembles the monitors; it reaches a length of 3 to 4 ft. most of which, however, belongs to the whip-like tail. *Callopistes* of Peru and Chile is another large monitor-like creature that digs branching burrows often several yards long. *Crocodilurus* of the Amazon basin is characterized by a double, crocodile-like crest along the tail and *Dracaena,* another large species of the same region, has the lateral teeth modified to form large oval crushers in correlation with a herbivorous diet. More lacerta-like are the numerous species and varieties of *Ameiva* and *Cnemidophorus* which extend throughout tropical America, the former reaching the West Indies and the latter extending into the southern United States where they are known as the race runners. Frequenting dry and sandy localities they move with prodigious speed and are usually characterized by a number of longitudinal yellow stripes on a dark background; *Ameiva ameiva* exhibits almost as many local races and intermediates as the European wall lizard. In the smaller forms there is progressive reduction of the limbs and development of a window in the lower eyelid; *Alopoglossus* of Ecuador and Peru has a few enlarged semi-transparent scales on the lower eyelid; *Pantodactylus* of southern Brazil and northern Argentina is a rather elongate form with an undivided transparent disc and *Gymnophthalmus* and *Micrablepharus* have, like some skinks and lacertids, the transparent lower eyelid fused with the upper. *Anadia* of Central America and Ecuador is very elongate but with the limbs pentadactyle; *Scolecosaurus* is serpentiform with three or four clawed fingers and toes and burrows in humus and rotten wood, feeding principally on termites. *Bachia* of northern South America exhibits the greatest degree of degeneration in the family; the body is elongate and serpentiform, the eye minute but still equipped with functional eyelids, the scales no longer granular or overlapping but squarish and arranged in regular longitudinal and transverse rows like those of the amphisbaenids, the fingers reduced to clawless tubercles or quite absent and the hind limbs having perhaps but a single toe.

11. *Amphisbaenidae.*—Worm-like forms with soft skin divided into squarish segments arranged to form annuli, mere vestiges of scales, no visible eyes or ears, and a very short, bluntly rounded tail; all are pinkish, sometimes more or less dusted with tiny black specks and living in moist, sandy localities where they construct subterranean galleries, never appearing on the surface; they inhabit America, the Mediterranean countries and Africa. *Chirotes* of Western Mexico and lower California is the only genus with external limbs; the hind pair are absent and the forelimbs reduced to short paddles with five, four or three clawed fingers. Some of the genera; *e.g., Amphisbaena,* occur both in South America and Africa and this would appear to indicate that the species living at the present day are but the isolated remnants of a formerly widely distributed group. (*See* AMPHISBAENA.)

12. *Varanidae.*—Monitors; an old world family of large lizards with small scales, a long protrusible tongue and always with powerful clawed, pentadactyle limbs. This family contains but a single genus, *Varanus,* with about 30 species in Africa, Arabia, Southern Asia and Australia. Some of the species are semiaquatic with laterally flattened tails, others inhabit dry sandy districts but almost all are equally at home on land, in water or among trees. The largest species is the comparatively recently discovered *V. komodoensis,* the so-called "Dragon" of the East Indian islands

of Komodo, Rinja and Flores. This species differs from the majority of monitors in being heavily built with a relatively short tail, so that, although its total length probably never exceeds 10 ft., a specimen of this size is a very bulky powerful animal; they are diurnal creatures, hiding at night in dens among rocks and active during the day, and like all the other species are strictly carnivorous, eating meat of any kind whether freshly killed or not. The Nile monitor (*V. niloticus*), an agile wary animal hiding often in burrows on the banks of streams, is one of the commonest African species. *V. exanthematicus* of West Africa is more sluggish and fearless than the Nile monitor and, unlike that species, relies for defense largely on the use of its powerful whip-like tail; if, however, it does bite, the grip may be maintained for as long as half an hour. A peculiarity of this species is its habit, when frightened, of rolling over on its back, taking one hind foot in its mouth and remaining absolutely motionless until the supposed danger has passed. The kabara goya of India and the Malayan region (*V. salvator*) is a large slender species equally at home on land or in the water where it swims by means of the flattened tail, the limbs being closely pressed against the sides. Another Indian species is the bis-cobra (*V. bengalensis*) which, in common with all the other monitors, is erroneously regarded by the natives as poisonous. Australia possesses a large number of species, the largest being *V. giganteus,* a rare species from N. Queensland, and the commonest the lace monitor (*V. varius*). The whole group exhibits great uniformity both as regards structure and colouring; the latter is usually brown, gray or black with dull yellow markings taking the form of transverse bars or rows of rounded ocellar spots.

13. *Pygopodidae.*—Degenerate serpentiform lizards of Australia, Tasmania and New Guinea, with very long fragile tails, without movable eyelids or forelimbs, and with the hindlimbs reduced to a flap on either side of the vent. These lizards are not burrowers but appear to live in thick grass or similar vegetation where limbs are of little use and a snake-like method of progression is possible. Movement is accomplished by a series of side to side, wave-like movements which travel from head to tail, a system essentially similar to that of eels and sea snakes; as each undulation travels backwards it presses against the surrounding medium, water or grass, and so drives the animal forwards. *Pygopus,* distributed over almost the whole of Australia, may reach a length of 2 ft. of which two-thirds belongs to the tail.

14. *Helodermatidae.*—Lizards with small, tubercle-like scales and sometimes with recurved, grooved teeth. This family contains only two species, the Gila monster (*Heloderma*) of the deserts of Texas, Arizona and Mexico and *Lanthanotus* of Borneo. The Gila monsters are the only known poisonous lizards; they are sluggish, heavy-bodied creatures with weak limbs, short stumpy tails and a "warning" colouration of alternating rings of blackish-brown and yellow or pinkish-orange. The poison apparatus consists of a row of glands along the inside of the lower lip (contrast with snakes in which the poison glands and fangs are always in the upper jaw) whose openings lie near the bases of the grooved teeth. When the animals bite they deliberately chew the object and in this way a considerable amount of venom is worked into the wounds through the channels of the teeth. The food consists chiefly of small lizards on which the poison acts fairly rapidly, but the bite is not, as a rule, fatal to man. *Lanthanotus* known only from a few specimens from the interior of Borneo is uniformly dull brown in colour and has regular rows of enlarged tubercles; the teeth are not grooved.

15. *Anniellidae.*—Worm-like degraded forms with no external traces of limbs, eyes or ears, but with soft overlapping scales. Only two species are known from California and both are referred to the genus *Anniella.*

16. *Anguidae.*—A small family, chiefly American, but with a few species in Europe and the Indian region; all the species have large, overlapping scales with osteoderms beneath them and the tongue is retractile into a basal sheath. *Gerrhonotus* of North and Central America and *Diploglossus* of the West Indies, Central and South America are genera with well-developed, pentadactyle limbs; *Ophisaurus* has the limbs reduced to a pair of small stylets on each side of the vent and has a peculiar distribution, one species occurring in the United States, another in India and Burma, and the third in Southern Europe and Morocco. The European species (*O. apus*) is the "scheltopusik" or "glass snake," the latter name bestowed on account of the extreme fragility of its tail, which, if the creature is roughly handled, breaks into several fragments. The American species has a similar habit and the same vernacular name. *Anguis,* another genus, has no external rudiments of limbs; its sole species, *A. fragilis,* known in England as the slow-worm or blind worm, is a snake-like creature frequenting grassy banks and ditches and is remarkable as one of the few animals which preys almost exclusively on slugs.

17. *Xenosauridae.*—With but a single species, *Xenosaurus grandis* from the mountains of Mexico has four well-developed limbs, the body covered with small granules and tubercles and a distinct fold of skin along the flanks.

18. *Zonuridae.*—African and Malagasy lizards usually with rather large rough scales, regular plates on the head and often with osteoderms. *Zonurus* of East and South Africa and Madagascar has strong, hard scales which are often enlarged to form large spikes arranged in regular rows round the tail; in some the back of the head is also equipped with large spines and a few have a transparent disc in the lower eyelid; *Z. giganteus* reaches a length of about 15 in. *Chamaesaura* of South Africa is a degenerate genus whose members are small and serpentiform and live among thick vegetation; *C. aenea* has two pairs of pentadactyle limbs, *C. anguina* has four short styliform rudiments and in *C. macrolepis* the forelimbs are entirely lost.

19. *Iguanidae.*—A new world family analogous with the old world *Agamidae; see* Iguana.

20. *Agamidae.*—Old world lizards with broad, thick tongues, usually with small scales, even on the head, without osteoderms, and with the teeth usually differentiated into incisors, canines and molars; the majority are insectivorous but a few are almost exclusively vegetarian. *Agama,* common throughout the drier parts of Africa, and southwest Asia is a ground-living genus, and as a rule its members are dull brown creatures with irregularly arranged patches of enlarged scales which may form tufts of spines in the neck region; the males of many species, however, exhibit brilliant patches of red and blue. *Phrynocephalus* is an Asiatic genus of desert and steppe-dwelling forms all with very depressed bodies and coloured with neutral tints of browns, grays, dull reds and yellows. The frilled lizard (*Chlamydosaurus*) of Australia is another inhabitant of dry districts and possesses a remarkable erectile collar; this is a fold of skin supported by cartilaginous rods like the ribs of an umbrella and when not in use is folded, cape-like, about the shoulders; when the lizard is disturbed, it first seeks safety in flight, running swiftly on its hind limbs with the body inclined forwards and the long tail raised as a counterpoise; but if unable to escape, it turns at bay and tries to frighten the pursuer by erecting the frill and opening the mouth; the saffron yellow interior of the mouth contrasting with the green and brown of the frill is impressive, but actually the chief means of defense lies in the powerful, whip-like tail. Another common Australian species is the bearded or jew lizard (*Amphibolurus barbatus*), a rather large species with an array of spiny scales under the throat and fringing the head behind the ears. *Physignathus* which ranges from Australia to Tonkin is largely aquatic, frequenting the banks of streams and taking readily to the water if disturbed. Arboreal forms are represented in the Indo-Malayan region by such genera as *Calotes* with very compressed bodies and long tails; the species of this genus have a crest of large, blade-like scales along the back and possess considerable powers of colour change, which, as in the chameleons, are often called into play more by psychical disturbances and physical conditions than by relationship to the background; the bloodsucker (*C. ophiomachus*) of South India and Ceylon has acquired its name from the blood red head and neck which it acquires when excited. Most remarkable of the arboreal agamids are the flying lizards (*Draco*) of the Malayan region, which, like their mammalian analogues, the flying lemurs and squirrels, have

a fold of skin along the sides of the body that functions as a "plane" and enables them to make gliding flights from branch to branch or from tree to tree; these wings, supported by five or six elongate ribs, are often so gorgeously coloured that the animals in flight resemble gaily coloured butterflies, but the body of the animal is usually of a sober hue and, when the wings are folded at the end of a flight, the change is so abrupt and deceptive that the animal itself seems to disappear. Herbivorous forms are represented by the mastigures (*Uromastix*) of the dry regions of North Africa and southwest Asia, heavily built creatures with tails armed with whorls of large spines. Another agamid of dry regions is the Australian moloch (*Moloch horridus*) a deserticolous species which, like so many desert-dwelling animals and plants, has developed an armour of large spines; it is a small, squat animal with a short tail and is covered with relatively large spines which reach their greatest size on the head above the eyes. Bizarre ornamentation is exhibited by a number of genera in the Indo Malayan region; *Ceratophora* of Ceylon has a horn-like prominence on the tip of its snout and *Lyriocephalus,* also of Ceylon, has the sides of the head raised into bony ridges like those of some chameleons and has the tip of the snout ornamented with a large, globular boss.

21. *Chamaeleontidae.*—Arboreal lizards with the fingers and toes bound together into opposable bundles: *see* CHAMELEON.

(H. W. P.; X.)

LIZARD POINT, or THE LIZARD, the southernmost point of Great Britain, Cornwall, England, in 49° 57′ 30″ N., 5° 12′ W. There are two lighthouses on it. The cliff scenery is magnificent, and attracts many visitors; the coast is fretted into small bays, such as Housel and Kynance Cove; caves pierce the cliffs and bold isolated rocks fringe the shore. The colouring of the serpentine rock is a remarkable feature. The chasm known as the Lion's Den was formed by the falling in of a sea-cave in 1847; the Stags is a dangerous reef stretching southward from the point, and at Asparagus Island, Kynance Cove, is a natural funnel in which the waves and air cause a violent ejection of foam. Lizard Town, a mere village, is 10½ mi. distant from Helston, the nearest railway station.

LJUBLJANA, a town of Slovenia, Yugoslavia. Pop. (1931) 59,767, mostly Slovenes. It is an episcopal see, founded in 1461, with a Renaissance cathedral, lavishly frescoed, and several beautiful churches. There is a high school, a technical school, a School of Music, a university, a museum, a chamber of commerce, several banks, a theatre and societies for the promotion of science and literature. While under Austrian rule it was the centre of the Slovene national movement, the first Slovene newspaper having been published here in 1797, while the Prince Bishop was one of the chief promoters of the Yugoslav Movement. Ljubljana is an important road centre and is a busy industrial town with eight suburbs. There are cotton, woollen, porcelain, paper, furniture, boot, tobacco, soap, pottery, firehose, match and chemical factories, a bell foundry, breweries, distilleries, leather tanneries and brickfields. There is also a State forest nursery, and horses are bred and sold at the annual fair. Since the draining of the surrounding plain, the town has become a beautiful spot, and a favourite summer resort and tourist centre.

It is dominated by the mediaeval fortress on the height of the Schlossberg, from which a magnificent view is obtained.

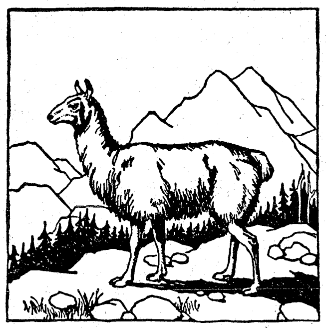
Ljubljana lies on the trade route from east to west, and legend says that it was founded by Jason. It is supposed to occupy the site of the ancient Emona or Aemona, founded by the emperor Augustus in 34 B.C. It was besieged by Alaric in 400 and desolated by the Huns in 451. In 900 it suffered much from the Magyars, who were, however, defeated there in 914. In the 12th century the town passed into the hands of the dukes of Carinthia; in 1270 it was taken by Ottokar of Bohemia; and in 1277 it came under the Habsburgs. In 1809 the town was twice taken by the French, and from 1809 to 1813 it became the seat of their general government of the Illyrian provinces. From 1816–49 Ljubljana was the capital of the kingdom of Illyria. It is historically known from the Congress of Laibach. In 1895 it suffered severely from an earthquake. In 1941 Ljubljana became the capital of the part of Slovenia annexed by Italy, and the centre of resistance to Italian occupation.

LJUNGGREN, GUSTAF HAKAN JORDAN (1823–1905), Swedish man of letters, born at Lund on March 6, 1823, was educated at Lund university, where he was professor of German (1850–1859), of aesthetics (1859–1889) and rector (1875–1885). He had been a member of the Swedish academy for twenty years at the time of his death in September 1905. His most important work, *Svenska vitterhetens häfder efter Gustav III.'s död* (5 vols., Lund, 1873–1895), is a comprehensive study of Swedish literature in the 19th century.

His other works include: *Framställning af de förniämste estetiska systemerna* (an exposition of the principal system of aesthetics; 2 vols., 1856–60); *Svenska dramat intill slutet af 17 århundradet* (a history of the Swedish drama down to the end of the 17th century, Lund, 1864); an edition (1864) of the *Epistlar* of Bellman and Fredman, and a history of the Swedish academy in the year of its centenary (1886).

His scattered writings were collected as *Smärre Skrifter* (3 vols., 1872–81).

LLAMA, the larger of the two domesticated members of the camel-tribe indigenous to South America. The llama (*Lama guanicoe glama*) is a domesticated derivative of the wild guanaco, which has been bred from time immemorial as a beast of burden, its sure-footedness and endurance rendering it almost the equal of the mule. Chiefly found in southern Peru, it attains a larger size than the guanaco and is usually white, spotted with brown or black, or sometimes altogether black. The following account was given by Augustin de Zarate in 1544:



THE LLAMA, USED IN PERU FOR CENTURIES AS A BEAST OF BURDEN

"These sheep of Peru are large enough to serve as beasts of burden. They can carry about 100 lb. or more, and the Spaniards used to ride them, and they would go four or five leagues a day. When there is a man on one of them, if the beast is tired and urged to go on, he turns his head round and discharges his saliva, which has an unpleasant odour, into the rider's face. These animals are of great use and profit to their masters, for their wool is very good and fine, particularly that of the species called pacas; and the expense of their food is trifling, as a handful of maize suffices them, and they can go four or five days without water. Their flesh is as good as that of the fat sheep of Castile."

The disagreeable habit of spitting is common to all the group.

In a wide sense the term "llama" is used to designate all the South American Camelidae. (*See* TYLOPODA.)

LLANBERIS, a village and civil parish of Caernarvonshire, Wales, 9 mi. S.E. of Caernarvon, by a branch of the L.M.S.R. Pop. (1931) 2,370. It is finely situated in a valley near the foot of Snowdon. The valley has two lakes, Llyn Paris and Llyn Padarn, formed chiefly behind moraines. From Padarn rises the Seint, called Rothell in its upper part. Dolbadarn castle is at the foot of Lake Peris. The Vaenol slate quarries are here, and hence is the easiest ascent of Snowdon, with a railway to the summit. From the road over the fine Llanberis pass (1,169 ft.) toward Capel Curig, a turn to the right leads to Beddgelert, through Nant Gwynnant. Gwynnant Lake is about 1 mi. long by ¼ mi. broad, and below it is the smaller Llyn Dinas. About 2 mi. S.E. of Lake Peris and at the foot of the Llanberis pass is the picturesque village of Old Llanberis or Nant Peris.

LLANDAFF, a ward in the county borough of Cardiff, Glamorganshire, Wales, on the G.W.R. 149 mi. from London. Pop. (1931) 27,762. It is situated on high ground sloping toward the southern bank of the Taff. The first two bishops of Llandaff, St. Dubricius and St. Teilo, flourished during the latter half of the 6th century. By the 12th century, when Urban was bishop, the see had acquired great wealth (as may be seen from the *Book of Llandaff,* a mediaeval inventory of its land), but after the reign of Henry VIII, Llandaff became impoverished, and its cathedral was left to decay. In the 18th century a new church, in debased Italian style, was planted amid the ruins. This was demolished and the old cathedral was restored, 1844–69. The oldest remaining portion was the chancel arch of Bishop Urban's building, opened in 1120. The restored cathedral was, however, very badly damaged in an air raid on Cardiff in 1941, and St. Michael's Theological college, removed to Llandaff from Aberdare in 1907, also suffered. The palace or castle built by Urban was destroyed about 1402, and only a gateway with flanking towers and some fragments of wall remain. After this, Mathern near Chepstow became the episcopal residence until about 1690, when it fell into decay, leaving the diocese without a residence until Llandaff Court was acquired during Bishop Ollivant's time (1849–82). Money bequeathed by Thomas Howell, a merchant, who died in Spain in 1540, maintains an intermediate school for girls, managed by the Drapers' company, Howell's trustees. Llandaff has been included in Cardiff since 1922.

LLANDILO or **LLANDEILO FAWR,** a town and urban district, Carmarthenshire, Wales, on the Towy. Pop. (est. 1938) 1,902. It was a natural centre for S.W. Wales during the early middle ages. The defensible site known as Dinefawr, west of Llandilo, was the capital of Rhodri Mawr (*c.* 876) and still remains in the hands of the descendants of the family. The church is dedicated to St. Teilo, a famous Celtic saint. The dedication argues the importance of this valley site in the days of Celtic Christianity. The Normans rebuilt Dinefawr castle, and under its protection a market town grew up, but remoteness both from the south coastal road and the coal valleys has limited modern development. Its market, however, has much increased in recent years owing to the rise of industrial towns within a short distance. The L.M.S.R. and G.W.R. give it railway communication and it has become an important station for motor traffic. Area, .5 sq.mi.

LLANDOVERY (*Llan-ym-ddyffri*), a municipal borough of Carmarthenshire, Wales, on the Towy, 35 mi. from its mouth. Pop. (est. 1938) 2,006. Area, 2 sq.mi. The place probably owes its Welsh name of Llan-ym-ddyffri (the church amid the waters) to the proximity of Llandingat church to the streams of the Towy, Bran and Gwydderig. Being at the head of the fertile vale of Towy, Llandovery was a strategic site in the middle ages. The 12th-century castle frequently changed hands and was partly burned by Gruffydd ap Rhys in 1115. In 1485 the borough of Llandovery, or Llanymtheverye, was incorporated by a charter from Richard III, a privilege confirmed by Henry VIII and Queen Elizabeth. Her charter is still held by the corporation. In the 17th century the vicarage of Llandingat was held by the celebrated Vicar Pritchard (1579–1644) whose book *Canwyll y Cymry* (*The Welshman's Candle,* a paraphrase of the Gospels in Welsh verse) was the most famous book produced during the Renaissance in Wales. In the early 19th century Llandovery was famous for its printing press. Many well-known books concerning Wales were published from there. A small school was founded at Llandovery by Sir Thomas Phillips in 1848. Llandovery is a small market, fair and cattle mart centre.

LLANDRINDOD WELLS, a town, urban district and health resort of Radnorshire, Wales, in a rugged district near the river Ithon, a tributary of the Wye. Pop. (est. 1938) 2,610. Area, 2.4 sq.mi. Llandrindod is on the Mid-Wales section of the L.M.S. There are evidences of early settlement, *e.g.,* the hilltop camp of Castell Collen, $1\frac{1}{2}$ mi. N. of Llandrindod, and the Norman motte and bailey of Cefn Llys. Llandrindod became known for its mineral springs as early as 1696 but it was only during the 19th century that it became a spa with tourist traffic. It is the seat of the county council.

LLANDUDNO, a seaside resort and urban district of Caernarvonshire, Wales, in a detached portion of the county east of the Conwy, on a strip of sandy soil ending in the massive limestone of Great Orme's head. Pop. (est. 1938) 15,110. Area, 7.7 sq.mi. The town is on the L.M.S.R., 48 mi. N.W. of Chester. The Great Orme has evidences of early settlement, with hut circles, a camp (probably of Romano-British age) and a 7th-century church of St. Tudno, restored in 1885. At Aeganwy, 2 mi. from Llandudno, is a mediaeval castle, Dinas Gonwy. A village in 1850, Llandudno is one of the most flourishing watering places in north Wales. Sheltered by the Great Orme on the N.W. and by the Little Orme on the E., it faces a wide bay of the Irish sea, and is backed by low sandhills. There is a promenade $1\frac{1}{4}$ mi. long.

LLANELLY, municipal borough and seaport, Carmarthenshire, Wales, on the Lliedi, a stream at the estuary of the Burry river, and on the G.W.R. main line from Paddington to Fishguard. Pop. (est. 1938) 36,890. Area, 3.2 sq.mi. The town derives its name from the dedication of the parish church to the Celtic saint Elliw or Elli. With the beginning of the industrial revolution Llanelly became important for its lead smelting works, its shipbuilding and flannel industries. In 1804 copper works were established but gradually the older industries were superseded by the manufacture of tin plates. The first tin works opened in 1847 and others followed in 1852–53 until in 1888, 92 mills were in operation. The town became a colliery centre and a collecting ground for the rich anthracite coalfield of the Gwendraeth valley. With the growth of the town, secondary industries grew up, including potteries, iron foundries and chemical works. The construction of the old L.N.W.R. (now L.M.S.) line from Llandilo via Pontardawe to Swansea seriously cut down Llanelly's coal exporting trade, as many of the coal trains from these valleys could be run direct to the larger docks at Swansea. The silting up of the Burry river seriously handicapped the Llanelly docks, but the deflection of the river to a deeper channel improved matters. Llanelly was an ancient parish and a borough by prescription under a portreeve and burgesses in the old lordship of Kidwelly. In 1918 it was merged in the east Carmarthenshire parliamentary division.

LLANES, a seaport of northern Spain, in the province of Oviedo, on the river Carrocedo and the Bay of Biscay. Pop. (1940) 2,953 (mun., 20,421). The principal buildings are a fine Gothic church and an old Augustinian monastery. It is a summer resort. Llanes is a second-class port for light-draught vessels; but the entrance is narrow, and difficult in rough weather. Trade is chiefly in agricultural produce, timber, butter and fish.

LLANFYLLIN, the only municipal borough in the whole of north Montgomeryshire, Wales, a market town in the pleasantly wooded tributary valley of river Vyrnwy (*see* MONTGOMERYSHIRE). Pop. (est. 1938) 1,319 (of which less than 1,000 dwell within the town). Area, 12.7 sq.mi. The early Llan of Saint Myllin had by the 13th century grown sufficiently to receive a municipal charter. The town was formerly the commercial and social capital of a large area of hill country, comprising much of north Montgomeryshire and several Denbighshire parishes. With the opening of a branch railway from Llanymynech (1863), the town declined, as trade drifted eastward.

LLANGOLLEN, urban district, picturesque market town and summer resort of Denbighshire, Wales, in the Dee (*Dyfrdwy*) valley, on a branch of the G.W.R., 9 mi. S.W. of Wrexham. Pop. (est. 1938) 2,893. Area, 4.9 sq.mi. Castell Dinas Brân, 1 mi. from the town, is a hilltop camp. The Dee is here crossed by a 14th-century bridge. The church of St. Collen is Norman and Early English in style. Valle Crucis abbey (*Llan Egwest*) is a Cistercian ruin at the foot of Bronfawr hill, some 2 mi. N.W. of Llangollen, founded about 1200 by Madoc ab Gruffydd Maelor, lord of Dinas Brân. Llan Egwest, dissolved in 1535, was given by James I to Edward, Lord Wotton. Llangollen manufactures flannel. Within the parish, an aqueduct carries the Ellesmere canal across the Dee.

LLANIDLOES, market town and municipal borough, Montgomeryshire, Wales, in the upper Severn valley, where the Clywedog stream joins the Severn which there turns E.N.E. towards Caersws after its torrent course from Plynlymon. Pop. (est. 1938) 2,324. Area, 1 sq.mi. The history of the settlement commences with the local saint (Idloes) and the Llan (church) which he founded. The fine old parish church dedicated to him is the successor to his original foundation. The belfry is of a type widespread in the county and the English border. In 1286 the prince of Powys (Owen of Arwystli) obtained a charter establishing the fairs and markets of Llanidloes, and from the 13th century, or perhaps earlier, the town has retained its civic privileges. A link with the past is the half-timbered market-house at the town centre. For many years Llanidloes was an important publishing centre for the Welsh language, doubtless owing to its central position. The development of industrial life in the 19th century (lead mining and flannel making) led to an increase of population from 2,500 in 1830 to 3,400 in 1870. Shawls and tweeds were still made until 1918, but the industry then declined. The best years of lead mining were from 1860 to 1880, when 16 companies were conducting operations in the Plynlymon district. At the Van mine alone 700 men were employed, and the town flourished as an industrial and intellectual centre. Llanidloes has a station on the Mid-Wales railway (G.W.R.). Its interests are now mainly agricultural. A museum of local history and industry was opened in 1933.

LLANQUIHUE, a province of southern Chile bordering on the northern shores of the Golfo de Ancud, bounded on the north by Osorno and extending from the Pacific to the Argentine frontier. Area, 7,107 sq.mi.; pop. (1940) 117,225. It is a region of forests, rivers and lakes, and the eastern part is mountainous. The rainfall is excessive, the average at Puerto Montt being 104 in. a year, and the temperature is singularly uniform, the average for the summer being 58½°, for the winter 47½° and for the year 53° F. There are several large lakes in the eastern part of the province, chief among which is Llanquihue, the largest body of fresh water in Chile, having an extreme length from north to south of about 33 mi. and an extreme breadth of nearly the same. The southern coast of the province is indented by a number of inlets and bays affording good fishing, but the mouths of the rivers flowing into the Pacific are more or less obstructed by sand-bars. Apart from the lumber industry, which is the most important, the productions of Llanquihue include wheat, barley, potatoes, cattle and sheep. The white population is composed in great part of German colonists and their descendants, who have turned large areas of forest lands in the northern districts into productive agricultural land. Puerto Montt, the capital of the province, is on a nearly land-locked bay called Seno Reloncaví and is the southern terminus of the longitudinal railway, 670 mi. south of Santiago. Pop. (1940) 21,552.

LLANTRISANT, a town and civil parish of Glamorganshire, Wales, situated where the hill lands of the county abut on to the vale. It is served by the G. W. R. though the station is 2 mi. S. of the town (Cross Inn station ½ mi.). Pop. (1931) 22,276. The castle dates from Henry III or Edward I. Of the original building nothing remains, and of a later building only slight ruins. It was the head of the lordship of Miskin, a great part of which was in the hands of native owners until Howel ap Meredith was expelled by Richard de Clare (1222–62). Since then it has been in the hands of the lord of Glamorgan. The church was dedicated to three saints (Illtyd, Gwyno and Tyfodwg), whence the name Llantrisant. Originally a Norman building, most of the present fabric belongs to the 15th century. The mediaeval records show evidences of intensive agriculture and the use of the three-field rotation system. In 1426 the lord of Glamorgan granted a charter confirming grants made by his predecessors in 1346, 1397 and 1424. The corporation was abolished in 1883, and its property (including 284 ac. of common land) is administered by a town trust under a scheme of the charity commissioners. The "freemen" of the borough, however, still hold a court leet in the town hall. The great increase in the surrounding population was due to the numerous collieries, but the area suffered the general depression of the Rhondda valley.

LLANTWIT MAJOR, a village and civil parish on the south coast of Glamorganshire, Wales, on the G.W.R., 5 mi. S. of Cowbridge. Pop. 1,541. About 1 mi. N.N.W. there were discovered in 1888 the remains of a large Roman villa which was identified as part of a settlement mentioned in Welsh writings as Caer Wrgan. On the sea coast are two camps, one known as Castle Ditches, commanding the entrance to the creek of Colhugh, once the port of Llantwit. In the time of Henry I a small colony of Flemings settled in the district. The town and church derive their name from St. Illtyd or Iltutus, a native of Brittany and a great-nephew of Germanus of Auxerre. Having come under the influence of St. Cadoc, abbot of Llancarvan, 6 mi. E.N.E. of Llantwit, Illtyd established at Llantwit in the 6th century a monastic college which became famous as a seat of learning. The place had associations with Brittany and the Celtic Saint movement in Wales. After the Norman conquest Llanilltyd Fawr passed to the abbey to Tewkesbury. The present church of St. Illtyd is the result of a sequence of churches which have sprung from a pre-Norman edifice, almost entirely rebuilt and greatly extended in the 13th century and again partially rebuilt in the 14th century. It consists of an "eastern" church—the only part now used for worship, a western one used before the dissolution, and still farther west a chantry, now in ruins. In the church and churchyard are preserved some early monuments of Celtic Christianity. They include two cross-shafts and one cross with inscriptions in debased Latin (one being to the memory of St. Illtyd) and two cylindrical pillars, most of them being decorated with interlaced work. The town is situated in a fertile district and its people depend mainly on agriculture.

LLANWRTYD WELLS (ɫahn-ōōr'tĭd), urban district, Breconshire, South Wales, on the L.M.S. Pop. (est. 1938) 662. Area, 2.6 sq.mi. It is in the midst of mountain scenery on the Irfon, a branch of the Wye, and is noted for its sulphur and chalybeate springs. The importance of these was emphasized in 1732 and since then they have formed the nucleus of the settlement. The old village with the parish church lies higher up the valley.

Lower down the Irfon valley, at the junction of the Cammarch and Irfon, is Llangammarch village, noted for its barium springs. The ancient parish of Llangammarch consists of the townships of Penbuallt and Treflis. The region was a centre of early puritanism and has had associations with John Penry and Charles Wesley.

LLEWELLYN, SIR WILLIAM (1863–1941), British painter, was born in Dec. 1863, and studied at South Kensington, and in Paris under Cormon, Lefebre and Ferrier. He became A.R.A. in 1912, R.A. in 1920, and was president of the Royal Academy from 1928 to 1938.

In 1918 he was created K.C.V.O., and in 1931 G.C.V.O. His many portraits include the State portrait of Queen Mary, and the United Services Club portrait of her.

LLEWELYN, the name of two Welsh princes.

Llewelyn I, Ap Iorwerth (d. 1240), prince of North Wales, was born after the expulsion of his father, Iorwerth, from the principality. In 1194, Llewelyn recovered the paternal inheritance. In 1201 he was the greatest prince in Wales. At first he was a friend of King John, whose illegitimate daughter, Joanna, he married (1201); but the alliance soon fell through, and in 1211 John reduced Llewelyn to submission. In the next year Llewelyn recovered all his losses in North Wales. In 1215 he took Shrewsbury. His rising had been encouraged by the pope, by France, and by the English barons. His rights were secured by special clauses in Magna Carta. But he never desisted from his wars with the Marchers of South Wales, and in the early years of Henry III he was several times attacked by English armies. In 1239 he retired into a Cistercian monastery.

See the lists of English chronicles for the reigns of John and Henry III.; also the Welsh chronicle *Brut y Tywysogion* (ed. Rolls Series); O. M. Edwards, *History of Wales* (1901); T. F. Tout in the *Political History of England,* iii. (1905).

Llewelyn II, Ap Gruffydd (d. 1282), prince of North Wales, succeeded his uncle David in 1246, but was compelled by Henry III to confine himself to Snowdon and Anglesey. In 1254 Henry granted Prince Edward the royal lands in Wales. The steady encroachment of royal officers on Llewelyn's land began immediately, and in 1256 Llewelyn declared war. The Baron's War engaged all the forces of England, and he was able to make himself lord of south and north Wales. Llewelyn also assisted the barons. By the treaty of Shrewsbury (1265) he was recognized as overlord of Wales; and in return Simon de Montfort was supplied with Welsh troops for his last campaign. Llewelyn refused to do homage to Edward I, who therefore attacked him in 1276. He was besieged in the Snowdon mountains till hunger made him surrender and conclude the humiliating treaty of Conway (1277). He was released, but in 1282 he revolted again, and was killed in a skirmish with the Mortimers, near Builth in central Wales.

See C. Bémont, *Simon de Montfort* (1884); T. F. Tout in the *Political History of England,* iii. (1905); J. E. Morris in *The Welsh Wars of Edward I.* (1901).

LLOYD, EDWARD (1845–1927), English tenor singer, was born in London on March 7, 1845, his father, Richard Lloyd, being vicar choralist at Westminster Abbey. From 1852 to 1860 he sang in the abbey choir, and was thoroughly trained in music, eventually becoming solo tenor at the Chapel Royal. His voice never broke, but developed gradually from treble to tenor. He began singing at concerts in 1867, and in 1871 appeared at the Gloucester Musical Festival. His fine, evenly-produced voice and pure style at once brought him into notice, and he gradually took the place of Sims Reeves as the leading English tenor of the day, his singing of classical music, and especially of Handel, being particularly admired. At the Handel Festivals after 1888 he was the principal tenor, and even in the vast auditorium at the Crystal Palace he triumphed over acoustic difficulties. He was one of the greatest Wagner platform-singers. In 1888, 1890 and 1892 he paid successful visits to the United States; but by degrees he appeared less frequently in public, and in 1900 he formally retired from the platform. Lloyd died at Worthing on March 31, 1927.

LLOYD, MARIE (1870–1922), English music-hall artist, was born on Feb. 12, 1870, the daughter of John and Matilda Wood. She first appeared at the Eagle music-hall in 1885 under the stage name of Bella Delmore. Six weeks later she adopted the stage name of Marie Lloyd, which she afterwards retained to the end of her career. After a series of engagements at various East End music-halls, during which she made her first real success with "The boy I love sits up in the gallery," she was engaged for twelve months at the Oxford music-hall, and in 1891–92–93 appeared in pantomime at Drury Lane theatre. From this time on until her death, she was responsible for a series of music-hall entertainments, songs, sketches, etc., which placed her in the front rank among the music-hall artistes of her generation. In particular she introduced to the British public a remarkable series of studies in cockney humour, chief among which may be mentioned "Everything in the garden's lovely," "I do like to be beside the seaside," "Oh, Mr. Porter, whatever shall I do" and "One of the Ruins that Cromwell knocked about a bit." She was married three times (1) to Percy Courtney, (2) to Alec Hurley, a singer of coster songs (d. 1913), and (3) to Bernard Dillon, a well-known jockey. She died, practically "in harness," on Oct. 7, 1922.

Marie Lloyd may be said without exaggeration to have been the incarnation of the London, or cockney genius for low comedy, which grew to its height in the 19th century. (E. I. J.)

LLOYD, WILLIAM (1627–1717), English divine, successively bishop of St. Asaph (1680), of Lichfield and Coventry (1692), and of Worcester (1699), was born at Tilehurst, Berks., and was educated at Oriel and Jesus colleges, Oxford. Lloyd was an indefatigable opponent of the Roman Catholic tendencies of James II., and was one of the seven bishops who were arrested and tried for refusing to have the Declaration of Indulgence read in their dioceses. Lloyd was a stanch supporter of the revolution. His chief publication was *An Historical Account of Church Government as it was in Great Britain and Ireland when they first received the Christian Religion* (London, 1684, reprinted Oxford, 1842). He died at Hartlebury castle on Aug. 30, 1717.

LLOYD GEORGE, DAVID (1863–1945), British statesman, was born at Manchester on Jan. 17, 1863. His father, William George, a Welshman of yeoman stock, had left Pembrokeshire and lived in Liverpool and Haverfordwest, and then was headmaster of an elementary school at Pwllheli, Carnarvonshire, where he married the daughter of David Lloyd, a neighbouring Baptist minister. Soon afterwards William George became headmaster of an elementary school in Manchester, but after the birth of his eldest son David his health failed, and he gave up his post and took a small farm near Haverfordwest. Two years later he died, leaving his widow in poor circumstances; a second child, another son, was posthumously born. Mrs. George's brother, Richard Lloyd, a shoemaker at Llanystumdwy, and pastor of the Campbellite Baptists there, now became her chief support; it was from him that young David obtained his earliest views of practical and political life, and also the means of starting, at the age of fourteen, on the career of a solicitor.

Having passed his law preliminary, he was articled to a firm in Portmadoc, and in 1884 obtained his final qualifications. In 1888 he married Margaret, daughter of Richard Owen of Criccieth. From the first he managed to combine his solicitor's work with politics, becoming secretary of the South Carnarvonshire Anti-tithe League; and his local reputation was made by a successful fight, carried to the High Court, in defence of the right of Nonconformists to burial in the parish churchyard. In the first county council elections for Carnarvonshire he played a strenuous part on the radical side, and was chosen an alderman; and in 1890, at a by-election for Carnarvon Boroughs, he was returned to parliament by a majority of 18 over a strong conservative opponent. He held his seat successfully at the contests in 1892, 1895 and 1900, his reputation as a champion of Welsh nationalism, Welsh nonconformity and extreme radicalism becoming thoroughly established both in parliament and in the country. In the House of Commons he was one of the most prominent guerrilla fighters, conspicuous for his audacity and pungency of utterance, and his capacity for obstruction while the conservatives were in office. During the South African crisis of 1899–1902 he was specially vehement in opposition to Chamberlain, and took the "pro-Boer" side so fiercely that he was mobbed in Birmingham during the 1900 election when he attempted to address a meeting at the town hall. But he was again returned for Carnarvon Boroughs; and in the ensuing parliament he came still more to the front by his resistance to the Education Act of 1902.

As the leader of the Welsh party, and one of the most dashing parliamentarians on the radical side, his appointment to office when Sir H. Campbell-Bannerman became premier at the end of 1905 was generally expected; but his elevation direct to the cabinet as president of the board of trade was somewhat of a surprise. The responsibilities of administration have, however, often converted a political free-lance into a steady-going official. His settlement of the railway dispute in 1906 was universally applauded; and the bills he introduced and passed for reorganizing the port of London, dealing with merchant shipping, and enforcing the working in England of patents granted there, and so increasing the employment of British labour, were greeted with satisfaction by the tariff-reformers, who congratulated themselves that a radical free-trader should thus throw over the policy of *laisser faire.* The president of the board of trade was the chief success of the ministry, and when Asquith became premier in 1908 and promoted Lloyd George to the chancellorship of the exchequer, the appointment was well received even in the City of London. For that year the budget was already settled, and it was introduced by Asquith himself, the ex-chancellor; but the provision of the finance for old age pensions was left to Lloyd George. The money was raised by the new taxation provided for in the budget of 1909–10.

Chancellor of the Exchequer.—For 1909–1910 a considerable deficit, of about £16,000,000, was in prospect. Lloyd George and Winston Churchill were conspicuously in alliance in advocating the use of the budget for introducing drastic reforms in regard to licensing and land, which the resistance of the House of Lords prevented the radical party from effecting by ordinary legislation. When Lloyd George, on April 29, introduced his budget, its trenchant character, however, created widespread dismay in the City and among the propertied classes. In a very lengthy speech, which had to be interrupted for half an hour while he recovered his voice, he ended by describing it as a "war budget" against poverty, which he hoped, in the result, would become "as remote to the people of this country as the wolves which once infested its forests." The excitement over the budget entirely monopolized public attention for the year, and while the measure was defended by Lloyd George in parliament with much suavity, and by Asquith, Grey and Haldane outside the House of Commons with tact and moderation, the feelings of its opponents were exasperated by a series of denunciatory public speeches at Limehouse and elsewhere from the chancellor of the exchequer, who kindled the passions of the working-classes against the landed classes and the peers. When the Finance Bill went up to the House of Lords, Lord Lansdowne gave notice that on the second reading he would move "that this House is not justified in giving its consent to this bill until it has been submitted to the judgment of the country," and on the last day of November this motion was carried by an overwhelming majority of peers. The government passed a solemn resolution of protest in the House of Commons and appealed to the country; and the general election of January 1910 took place amid unexampled excitement. The Unionists gained a hundred seats over their previous numbers, but the constitutional issue undoubtedly helped the government to victory, won indeed the votes of the labour members and Irish nationalists.

Events had now made Lloyd George and his financial policy the centre of the liberal party programme; but party tactics for the moment prevented the ministry, who remained in office, from simply sending the budget up again to the Lords and allowing them to pass it. There was no majority in the Commons for the budget as such, since the Irish nationalists only supported it as an engine for destroying the veto of the Lords and thus preparing the way for Irish Home Rule. Instead, therefore, of proceeding with the budget, the government allowed the financial year to end without one, and brought forward resolutions for curtailing the powers of the Lords, on which, if rejected by them, another appeal could be made to the people. (*See* PARLIAMENT.) Hardly, however, had the battle been arrayed when the King's death in May upset all calculations. An immediate continuance of hostilities between the two Houses was impossible. A truce was called, and a conference arranged between four leaders from each side—Lloyd George being one—to consider whether compromise on the constitutional question was not feasible. The budget for 1909–10 went quietly through, and before the August adjournment the chancellor introduced his budget for 1910–11, discussion being postponed till the autumn. It imposed no new taxation, and left matters precisely as they were. (X.)

The 1910 conference of British party leaders lasted from June till November. The conferring leaders nearly arrived at a very comprehensive and far-reaching scheme of agreement, affecting all the disputed issues—the House of Lords, Home Rule, tariffs and conscription. But the six months of secrecy ended in detaching the leaders from their followers. While the leaders had passed into a mood of conciliation, the followers were still living in an atmosphere of party warfare. On both sides the proposals put forward were regarded as surrenders.

It is a fit reflection now that, but for the World War, this conference presented to Great Britain at that moment the last solid alternative to Irish civil war. Lloyd George was ready to come to very bold settlements if they would save the country from civil strife. He and Balfour agreed in this attitude, but party tides still ran too strong.

SCHEMES OF SOCIAL REFORM

National Insurance.—In December there took place the second of the two 1910 general elections. The Liberal Government had refused to go to the polls until they obtained the promise of the King that, if they were successful, he would consent to employ his prerogative of peer-making in order to carry the Parliament bill. That promise was reluctantly given by King George V. Lloyd George was returned for Carnarvon Boroughs for the seventh time with an enhanced majority (1,208). But a second national campaign within one year proved too much for his strength, and he was struck down by serious throat trouble for some months. During this compulsory retirement he prepared the National Insurance bill of 1911. This was the first of a series of measures for improving the condition of the British working class by the method of social insurance. The idea was first applied by Bismarck, and Lloyd George had made a study of the German insurance system during a holiday visit to Central Europe in the autumn of 1908. Old age pensions had been already passed into law before that visit; and thus it was that the British system of old age pensions originally took a non-contributory form.

Lloyd George's first general application of the contributory insurance principle was to sickness and invalidity, and the proposal produced a formidable social and political crisis in the autumn of 1911. Lloyd George was proposing a new habit to the British people, and at the first shock it was profoundly unpopular. All classes rose against it. There followed a succession of political revolts; and it seemed as if the combination of forces—of the conservatives—of the press and the public—opposed to the bill would be sufficient to swamp it. By-election after by-election was lost by the Liberal Government. The party managers were in favour of postponement; but Lloyd George held on. He eased the passage of the bill by a series of conferences with all the disturbed parties, and achieved its third reading early in December 1911. This was followed by Lloyd George with an Unemployment Insurance bill which broke new ground. It was extended in subsequent years over the whole working class, and did much to carry the country through the dark years of unemployment which followed the World War.

The "Marconi Affair."—In 1912 Lloyd George approached the reform of the English land system by way of a land committee. He sketched the main lines of his policy in a series of speeches throughout 1912 and 1913. But just as he approached this venture his way was barred by two events—one personal and the other national. The first was known as the "Marconi Affair," which produced a grave crisis in Lloyd George's career. He had been persuaded by his friend Sir Rufus Isaacs (later Lord Reading) to take £1,000 worth of shares in the American branch of the great Marconi company at a moment when the British Post Office was discussing the terms of a contract with the British company. The two companies were separate, and there could in fairness be no accusation of anything beyond carelessness. But Lloyd George—at that moment chancellor of the exchequer—was too formidable a political figure to be let off lightly. The proceedings became the subject of an inquiry by a committee of the House of Commons, and he was gravely censured in the report of the chairman, Sir Albert Spicer, a prominent Liberal member of Parliament, although the majority of the committee acquitted him of serious blame. A majority of the House of Commons replied to the opposition attacks by a vote of confidence in Lloyd George. But for the moment his position was shaken.

The Curragh Revolt.—Already overshadowed by these events, the land proposals were now effectively blocked by the far greater crisis of Irish civil war. Ulster, organized by Sir Edward Carson (later Lord Carson), threatened an armed defiance of the Government. This defiance had now its first effect in the revolt of the officers at the Curragh against the orders issued for carrying out the prospective Home Rule policy. Faced with the possibility of a military revolt both at the Curragh and at Aldershot, Lloyd George took a very grave view of the situation and devoted all his energies to preserving civil peace. But at this moment, at the very heart of this Irish crisis, there came the vaster and more momentous challenge of the World War.

THE FIRST WAR YEARS

Lloyd George's Position.—Lord Grey of Fallodon in his memoir, *Twenty-Five Years, 1892–1916* (1925), gives a vivid account of the state of division that prevailed in the liberal cabinet in the fortnight before the outbreak of war. During that period the attitude of Lloyd George was deeply affected by his position as chancellor of the exchequer. On the Saturday before the declaration of war—Aug. 1, 1914—the governor of the Bank of England headed a deputation to 11, Downing Street, urging the policy of neutrality upon the Government. The same governor on Monday, Aug. 3, when the Germans invaded Belgium, telephoned to Downing street withdrawing the opposition of the City, and declaring that they were now in favour of war. This change of opinion in the City was highly dramatic, but it reflected the attitude of the chancellor of the exchequer. Lloyd George at first was not in favour of Great Britain being drawn into a contest between the two great warring groups of Europe unless some British interest or some British obligation were clearly involved. Accordingly during the previous week he did not take up the decisive attitude against Germany which he adopted in 1911, when he held the view that the claim of Germany to go to war with France over Morocco clearly involved a British guarantee (under the Entente). Once Belgium was invaded, however, and the neutrality treaty of 1839 defied, all hesitation left him; and never from that moment forward did he doubt that the military machine of the Central European Powers must be destroyed. Thus it was that Lloyd George entered upon a new phase of his career—that of war statesman.

The first great civilian duty of the war fell on Lloyd George. As chancellor of the exchequer, he had to secure the finances of the country. While Lord Kitchener at the war office was organizing the armies, Lloyd George had to see that the credit of the country did not collapse. At the very opening of the war he called together the governors of the leading banks and arranged a moratorium which prevented a panic. All the gloomy forecasts of the breakdown of finance so freely indulged in by the opponents of the war were in a moment dissolved into thin air. During the first 10 months of the war he remained chancellor of the exchequer; and thus on him fell the main financial responsibility. By common agreement of all parties he placed British finance on an impregnable foundation.

The Ministry of Munitions.—The insufficient supply of shells and guns at the front was exposing British armies to an intolerable inequality of loss. The crisis which followed on the general realisation of this fact in England broke up the liberal government, May 19, 1915, and substituted for it the first coalition administration, of Asquith and Bonar Law. The government was entirely reconstituted. Perhaps the most important change was the creation of a ministry of munitions—offered to and accepted by Lloyd George. This ministry was boldly entrusted with the whole function of providing war armaments, hitherto part and parcel of the duties of the war office. It was natural that the war office should resent this subtraction from their powers. But it was now quite clear that, in so great a war, the supply of munitions would be a function on a scale so large as to require a separate department. The new enterprise was rather a national movement than an ordinary office of state. The government workshops at Woolwich and elsewhere had been modelled to supply arms for a small peace army. Now that Kitchener was calling forth from the nation by his magnetic appeal an army of 2,000,000 there had to be a corresponding effort to supply them with weapons. In order to achieve this, Lloyd George put forth all his powers as a democratic orator and organizer. He first called on the private armament firms to make a new and gigantic combined effort; and they gave him splendid support. But this was not enough. He was compelled to create a vast network of new factories and workshops, and to rally to his effort a huge army of workers, both men and women. He set out to supply the army not only with sufficient shells, but also with the great guns and explosives rendered necessary by Germany's extensive preparations. Above all, he had to create the machine-guns, hand grenades, trench mortars, and other equipments which were now absolutely necessary for the efficient conduct of a war which was from day to day taking on new types and forms.

It was one thing to raise so gigantic an army. It was another thing to apply it to its full use and value. On all these questions Lloyd George in 1915–16 held vigorous views. He was not content to confine himself to the function of creating guns and shells. In the beginning of 1915 he began to pour out to the cabinet a succession of memoranda, in which he endeavoured to put before them the full seriousness of the military situation following upon the collapse of the Russian attack in the spring and summer of 1915.

Lloyd George and the Eastern Front.—The policy and strategy laid before the cabinet in the Lloyd George memoranda in the year 1915 were never fully adopted. In the language of the time, the cabinet was divided between "Westerners" and "Easterners"—those who looked for a decision only on the Western Front, and those who believed that victory could be quickened by transferring part of the British effort to the Near East. It ended in a compromise which resulted in the expedition to Salonika. But Lloyd George aimed at something far larger—nothing less than a considerable diversion of armies from the West to the East of Europe. He proposed and contemplated the diversion of an army of at least 1,000,000 from the Western to the Eastern Front. With the development of the German submarine warfare Lloyd George's Eastern idea became less and less practicable; and with the increase of the German armies the danger of a German break-through on the West finally held the British armies to their task. But in early 1915 these facts had not been fully disclosed.

As the year 1915 advanced, Lloyd George's general discontent with the conduct of the war grew stronger with every month. It extended to home policy as well as foreign. The war required a continual supply of vast armies. Such armies, Lloyd George now began to perceive, could not be secured by the voluntary principle alone. Having once made up his mind on that point, he became a vehement advocate of conscription in the autumn of 1915. But liberal sentiment was against it, and Asquith hesitated. At last Lloyd George swung the cabinet into conscription; and only one minister—Sir John Simon—resigned. Everything possible had now been done to supply the generals both with men and with munitions. But the question of policy remained, and there Lloyd George's discontent continued to grow. The tragic death of Kitchener by the sinking of the cruiser H.M.S. "Hampshire" on June 5, 1916, created a vacancy at the war office which could only be filled in one way. So in that month Lloyd George passed from the ministry of munitions to the war office. In this new position of power he obtained a firmer grip on the military machine at the front, and in particular he carried out a drastic reform of communications in France.

From these lesser tasks his mind was diverted to the main issue of victory or defeat by the tremendous tragedy that befell the Allied cause in the autumn of 1916. Rumania, tempted by Russia into the War on the side of the Allies at an unseasonable moment, was violently attacked by General Mackensen and dramatically crushed before the eyes of her distant and helpless Allies. In vain Lloyd George appealed to the cabinet to make some effort to save Rumania. Italy had entered the war in the previous year, and the Russian armies were still in being—could nothing be done? Nothing was done; and for the moment Rumania was blotted out. But the event had a profound effect on the mind of Lloyd George. It brought him to the parting of the ways. "Is it necessary," he used to say, "that a little nation should be laid on the altar of this war every Christmas? It was Serbia in 1915, now it is Rumania. What nation will come next?" Possessed with this dread, he decided to raise the issue in a definite form, and on Friday, Dec. 1, 1916, he laid his views before Asquith.

Collapse of the Asquith Government.—His main contention was that so large a war committee as then existed could not conduct the war to victory. He proposed a smaller and more efficient body of three or four men, solely devoted to this one object of winning the war. What was wanted was unified and unsleeping control. But he proposed—and here was the crux of the political situation—that the existing prime minister should not be chairman of the committee. That was where the dividing line came. For frankly and definitely Lloyd George had ceased to believe in Asquith as war leader. Asquith's pride was touched to the quick; and it was quite clear that he profoundly resented the proposal, although he himself had first named Lloyd George as chairman of the new war committee. On Saturday, Dec. 2, Lloyd George was under the impression that his proposal had been accepted. But friends intervened on both sides: the Northcliffe Press in favour of Lloyd George, and Asquith's friends in favour of a chief whose loyalty had always commanded a fit return of personal devotion. On Monday, Dec. 4, 1916, *The Times* published a leading article displaying exultation over Asquith's defeat, and immediately Asquith wrote to Lloyd George breaking off the agreement. In the afternoon of that day Asquith resigned office. He received authority from the king to form a new ministry. He wrote to Lloyd George asking him to join on condition that he—Asquith—as prime minister should be chairman of the new War

Committee. Lloyd George refused that condition and placed his office at Asquith's disposal.

Already, on Sunday, Dec. 3, the conservative rank and file had met. They had decided at first against following Lloyd George, whereupon Bonar Law had emphatically said that, in that case, they could not count on his leadership. He and his friends refused to join the new ministry and so Asquith's efforts to reform his coalition without Lloyd George broke down. The king then sent for Bonar Law. But as some of the Liberals and the Labour party refused to support him, he too failed to form a government, although Lloyd George offered to serve under him. The king then called a conference at Buckingham Palace and tried to form a new coalition ministry under Bonar Law, with the offer of the Woolsack to Asquith. Asquith refused. Thereupon the king sent for Lloyd George, as he was clearly the only possible premier.

LLOYD GEORGE AS PREMIER

The New War Policy.—There was nothing left for Lloyd George but to accept the call. He attempted to rally all parties behind him. He succeeded with the conservatives and the labour party, and a certain number of liberals. But the bulk of the liberal ex-ministers stood aside and began to form a group known as the Independent Liberal party. Lloyd George was now in sole command of his own war policy. The small war committee which he instantly appointed fully carried out the hopes of its founders. It sat from day to day, and very often twice a day. It practically took the place of the cabinet. Records were kept of its meetings, and Lloyd George formed a small Downing Street secretariat in order to keep in close touch with the various ministries. The result was a general quickening up of war decisions and a more decisive control of the whole machine of government.

During the year 1917 Lloyd George pressed forward his idea of unified command of the Allied armies. He was now completely convinced that the war could only be won if the Allies were to face Germany with the same concentrated authority that Germany had established over her own partners. He was faced, however, with a very steady resistance from the high military command.

On Oct. 24, 1917, there occurred an event which finally decided him to force the matter of unified control to a decision. On that day the Austro-German armies under Von Bülow broke through the lines of the Italian armies and drove them back to the line of the Tagliamento with the loss of 300,000 men and 2,000 guns. Italy stood for the moment in peril of a defeat equal to that of Serbia and Rumania in the preceding years. Lloyd George was determined that this defeat should not take place. He compelled the Western commands to send an army of infantry and artillery, English and French, under General Plumer through the Mont Cenis tunnel to northern Italy. These reinforcements arrived in the nick of time.

The End of the War.—Having achieved this task, Lloyd George, with characteristic swiftness, determined to press on with the matter of unified control. On his journey back to England he stopped in Paris on Nov. 12, 1917, to make a speech in which he plainly announced that divided control meant defeat. But that speech for the moment only aroused fresh opposition. Full unity of control was not really achieved until the terrible events of March 1918 brought home to all parties in England the nearness of the peril. During the winter the Germans brought across Europe a fresh army of 2,000,000 men released by the collapse of Russia after the Bolshevik revolution of November 1917. This gigantic new army created a fresh situation in the West, and the first blow fell on March 21, when 40 German divisions attacked and broke through the British line west of St. Quentin. On the following days the British line withdrew 15 miles, and the military struggle that followed lasted through five terrible months. Lloyd George was indomitable in this supreme crisis and met it by two principal steps. One was the assertion of full unity of control, and the other was the bringing over of the American armies.

President Wilson had not contemplated sending his armies to Europe until they were fully trained. In that case the American armies would be too late. Lloyd George therefore made a definite appeal to President Wilson to send all he could immediately, and the President instantly responded by a promise to do so on condition that Great Britain provided the transport. Thus with the combined effort of the American command and the British Navy and Marine no less than 2,000,000 American soldiers were carried across the Atlantic, in spite of the submarines, during the months of April and May 1918. But mere numbers were still useless without unity. Visiting France in the first week of May 1918, Lloyd George held a decisive combined meeting of the military and civil powers, in which, supported by Lord Milner and Clemenceau, he was at last able to persuade the British generals to accept the supreme command of the great French soldier Marshal Foch. During the final months of the War the British armies fought loyally under that command. It was by the combined attacks of British and French troops, storming the German lines east of Amiens, that the tide was turned on Aug. 8, 1918. Seven great battles were fought after this event, but from August until November the German armies were steadily driven back. Finally, on Nov. 11, came the collapse of the German resistance and the acceptance of armistice terms of defeat by the new German Government. "Germany is doomed," cried Lloyd George, speaking at the Mansion House on Nov. 9, 1918, and he proved a true prophet. The Allies had won the war.

The Peace Conference.—Victory having been achieved, it now remained to make peace. There were inevitable delays. Lloyd George deemed it necessary first to strengthen his position by an appeal to the country. The polls took place on Dec. 14, 1918, and the results were declared on Dec. 28. The effect was an overwhelming victory for Lloyd George, he being returned to power by a majority of 249 over all the independent groups. He himself was returned for the eighth time as member for Carnarvon Boroughs with a majority of 12,898. These events filled up the pause rendered inevitable by the waiting of Europe for the arrival of President Wilson, who had decided to attend the Peace Conference as American representative. The first meeting of the conference took place on Jan. 18, 1919, at the Palace of Versailles, and it proved an impressive gathering of the representatives of all the 30 countries who had taken part in the defeat of the Central Powers. The whole British empire was represented at Paris among the colleagues of Lloyd George.

It soon became obvious that so big an assembly could not really arrive at peace. There were too many conflicting views, there was no possibility of secrecy. The allied negotiators gradually narrowed to an inner council of ten, which was soon reduced to five; then from five to four; and finally from four to three—Lloyd George, Wilson and Clemenceau. What happened behind the scenes was this: roughly speaking, the position was that Lloyd George and Wilson worked for a peace of conciliation, while Clemenceau worked for a peace of victory. The French started with a claim to extend their frontier up to the left bank of the Rhine. Wilson and Lloyd George together succeeded in moderating this claim. But they were compelled to hand over the Saar Valley for 15 years as part of the compromise. Other compromises took place in regard to Silesia and the Polish corridor. No one was completely satisfied, but every country had its say. Wilson's unique contribution to the settlement was the League of Nations Covenant. When the crisis came and President Wilson threatened to leave the conference unless the Covenant was placed first in the treaty, Lloyd George supported the view of President Wilson.

The Treaty of Versailles.—Lloyd George's freedom was much hampered by Press attacks from home, and at one moment Lord Northcliffe organized a mandatory telegram from over 200 members of Parliament rebuking him for a tendency to weaken on the demands to Germany. Lloyd George returned to London to face his critics in parliament and secured a huge majority. There can be no doubt, however, that these symptoms of discontent at home diminished his authority and weakened his resistance to the military policy of France. At this point, for instance, he agreed, (as he found Wilson had already done) to the French claim to occupy the left bank of the Rhine for 15 years, which he had hitherto attempted to limit to a much shorter period. On May 6 a draft of the treaty was completed, and was presented to the German foreign minister, Count Brockdorff-Rantzau on the following day. Germany instantly pleaded for various important modifications. During the six weeks of parley with Germany that followed Lloyd George played the part of conciliator. Wilson hardened against Germany, and took the view that he was pledged to the treaty as it stood. On June 22 the National assembly authorized the signing of the treaty, and on June 28 it was signed at Versailles by the German envoys. Lloyd George returned to England and defended the treaty before parliament, which unanimously ratified it on July 3. Shortly after he was awarded the Order of Merit.

Domestic Discontents.—Having made peace abroad, Lloyd George returned to restore peace at home, which was just as much in peril. The long strain of the World War and the terrible losses of men and material had left Great Britain gravely wounded and weakened. The impulse of patriotism passed away; and the idea seemed to spread that every class was to be enabled to "get rich quickly" by the achievement of victory. The result was a series of industrial struggles, beginning with the London railway strike in February 1919, followed a few weeks later by the first of the coal crises. Lloyd George averted a strike on the coalfields by appointing a royal commission with Mr. Justice Sankey as chairman, with a promise that the commission should report on wages and hours by March 20. The Sankey commission reported on that day, recommending a two-shillings' increase in wage and an immediate seven-hours' day. The concessions were granted and a strike was averted. But when the majority of the commission went on to recommend nationalization of the mines, Lloyd George refused to adopt the suggestion. In October 1919 the railwaymen precipitated a national strike; and once more Lloyd George had to play the part of national conciliator. He brought the strike to an end by a compromise settlement fixing wages according to the scale of living.

During the next two years the Lloyd George coalition government passed a series of agreed measures on housing, suffrage and land. But as time went on it became clear that the country was financially more exhausted than had been supposed. The first after-War "boom" gradually passed into a "slump," and there arose from the whole country a cry for economy which expressed itself in an "Anti-Waste" campaign of the utmost vigour. By-election after by-election was lost to the government, and the country was swept by financial panic. Lloyd George met it by a drastic measure. He appointed a small committee, with Sir Eric Geddes as chairman, to revise the whole of Britain's national finance. As a result of its sweeping report—the "Geddes Axe"—widespread economies were effected in all departments. The agricultural subsidy was withdrawn and the agricultural wages boards were suspended. A halt was called in housing, pending a fall in prices, and progress involving expenditures on other matters (including education) was checked.

Fall of the Ministry.—Those concessions weakened the radical support of the coalition. In the autumn of 1922 a similar weakening occurred on the unionist wing of the Conservative party owing to the policy to which Lloyd George was driven in Ireland by the course of events. The Sinn Fein trouble which had broken out in the later period of the war worked up in 1920–21 to an actual rebellion. All Lloyd George's efforts to effect a compromise between Northern and Southern Ireland proved vain. In the spring and summer of 1921 the condition of Ireland grew rapidly worse. Murder and outrage were rampant. The coalition government initiated a special force, who received the nickname "Black and Tans," to deal with the violent methods of the Sinn Feiners by vigorous reprisals. This produced in England a divided feeling as to the equity of the struggle. In the autumn of 1921 peace overtures began to pass from one side to the other. Lloyd George decided to make a real effort after a settlement. A truce was declared, and the picked leaders of Sinn Fein came to Downing street, where, after several weeks of discussion, a settlement was reached, at midnight, Dec. 6, 1921. This great concession to Ireland was followed by resistance to the Turks at Chanak on the Dardanelles (September 1922), and the two events produced the downfall of the Lloyd George coalition. The Unionist party, created on the principle of resistance to Home Rule, was riven asunder by so great a concession as that of Dominion Home Rule to Southern Ireland. The threat of renewed war with Turkey was profoundly unpopular, and presented the enemies of the government with an opportunity. Bonar Law, who had retired from the government, returned to a meeting of the Conservative party at the Carlton Club on Oct. 19, 1922, at which it was decided that the conservative party should leave the coalition. Lloyd George instantly resigned, and in the election that followed (1922) Baldwin—who succeeded on the death of Bonar Law—obtained a majority. (*See* ENGLISH HISTORY.)

AN OPPOSITION LEADER

Throughout the vicissitudes of the general elections which followed in the autumns of the following years (1923 and 1924) Lloyd George remained a leader of opposition. He reunited his followers with the independent Liberals after the election of 1922, and devoted his energies to identifying the Liberal party with a policy of economic reconstruction. In 1924 he published *Coal and Power,* which outlined a comprehensive scheme for the more efficient utilization of the natural resources of the country. Nevertheless the reunited Liberal party failed to gain strength and in the general election of 1924 its numbers in the House of Commons, controlled by Asquith and Lloyd George, sank to 40 members. Lloyd George continued his active efforts to rouse the country to the need of further domestic reform to meet the home crisis: and in the early autumn of 1925 he issued a big land programme which he proceeded to advocate throughout the country.

By the elevation of Asquith to the peerage as the Earl of Oxford and Asquith (1925) Lloyd George earned the succession to the Liberal leadership in the House of Commons, and was elected to that office in the sessions of 1925 and 1926, and in subsequent sessions. In February 1926 he carried his land proposals, with few modifications, through a Liberal convention assembled at the Kingsway Hall in London. But the Liberal party still showed no signs of revival in the country. His national and parliamentary position was in strange contrast to the size of his following; and that created a strange diversity of opinion in the forecasts of his future. In May, during the course of the general strike, Lloyd George expressed opinions that were not in accord with those of Lord Oxford and the other Liberal leaders. His idea was that the government should negotiate with the strike leaders without delay, instead of declining to do so until the strike had been called off. He ridiculed the view that the general strike was aimed at the constitution. A somewhat acrimonious correspondence between him and Lord Oxford followed, and the party, both in and out of the House of Commons, was acutely divided upon the question. At last in October 1926, Lord Oxford resigned the liberal leadership. For a time worse dissensions followed. Lord Grey's very small but weighty group reprobated Lloyd George. The latter, however, was soon recognized by almost the whole of Liberalism as the indispensable man and he secured its enthusiastic allegiance. He provided a fighting fund out of the large resources placed under his personal trusteeship by his supporters when prime minister. From the spring of 1927 onwards he threw himself with ceaseless energy into the task of stirring up his party throughout the country. An important committee working in the same spirit proposed in the "Yellow Book" an elaborate industrial policy. For some time the by-elections seemed to show signs of a real "Liberal Revival," but at length the Labour party resumed its old rate of progress chiefly at Liberal expense. The position of Lloyd George in the late autumn of 1928 was unprecedented and enigmatical. In the general election of 1929 the Liberal party (*q.v.*) under his leadership returned 59 members.

After the formation of the National Government, and the general election of 1931, Lloyd George remained in opposition, but held aloof from party politics. His *War Memoirs* were published in six volumes (1933–36). On Dec. 31, 1944, he was elevated to the peerage as Earl Lloyd George of Dwyfor. He died March 26, 1945. (*See* LIBERAL PARTY.)

Mills, *David Lloyd George, War Minister* (1924). (H. Spe.; X.)

LLOYD OF DOLOBRAN, GEORGE AMBROSE LLOYD, 1st Baron, cr. 1925 (1879–1941), British politician and administrator, was born on Sept. 19, 1879, at Dolobran, Montgomeryshire, and was educated at Eton and Cambridge. He travelled widely in Burma, India, Little Tibet, the Himalayas, Egypt, Morocco and Asia Minor. In 1905 he was appointed attaché to the British embassy at Constantinople. During the World War of 1914–18 he saw service in Egypt, Gallipoli, Russia, Mesopotamia and with the sherif of Mecca's forces in the Hejaz, gaining the D.S.O. in 1917. He was Conservative M.P. for West Staffordshire from 1910 until 1918, governor of Bombay from 1918 until 1923, and M.P. for Eastbourne from 1924 to 1925. From May 1925 until 1929 he was high commissioner of Egypt and the Sudan. He was created G.C.I.E. in 1918 and G.C.S.I. in 1924. In 1940 he entered the Churchill cabinet as colonial secretary. He was appointed leader of the House of Lords shortly before his death Feb. 4, 1941.

LLOYD'S. The corporation of Lloyd's, which in March 1928 entered into possession of a fine building erected for it from the designs of Sir Edwin Cooper, F.R.I.B.A., upon the site of the East India House, is an old London institution in which all forms of insurance, except long term life insurance, can be effected. Its constitution and methods are unique because the corporation as such does not subscribe policies, the risks being accepted by individuals each signing for a specified sum for which he alone is responsible. Policies can be subscribed only by underwriting members each of whom has before election to place with the corporation securities to an amount fixed by the committee, in no case less than £5,000 and in most cases much more, the amounts required being proportionate to the business underwritten. In 1938 the total amount of securities deposited was £18,960,382, and the number of underwriting members was 1,883. Elaborate precautions have been taken to render the security of Lloyd's policy unimpeachable. The liability of each individual is unlimited. Each underwriter's accounts are subjected to an annual audit, when the auditor must certify that the underwriting assets of each underwriter are sufficient to meet his underwriting liabilities calculated in accordance with stringent regulations laid down by the committee.

Lloyd's has for two centuries been a centre for the collection and diffusion of maritime information. At every seaport of any importance and at many inland towns throughout the world Lloyd's agents are established to collect information, to give assistance in casualties and to survey and assess damaged cargo. There were in 1938 approximately 1,500 such agencies and subagencies. Lloyd's has also established signal stations of which in 1938 there were 21 in Great Britain and 115 abroad.

Lloyd's Coffee House.—The present institution has had a remarkable and indeed a romantic history. A certain Edward Lloyd, the oldest record of whom is in the year 1689, kept a coffee house first in Tower street and afterwards in Lombard street which, with other similar houses, became the resort of business men, some of whom were willing to subscribe policies insuring against sea risks. It thus became convenient for those seeking insurance, instead of going from office to office in search of insurers, to go to a coffee house where, instead of only one, several insurers might be found. At this time this was the only means of placing marine risks, but in 1720 charters were granted to the London and the Royal Exchange Assurance Corporations, but no other companies nor partnerships were allowed to insure marine risks. The grant of these charters was strenuously opposed by private underwriters but it had the effect of conferring a monopoly, and, as the Corporations transacted a comparatively small amount of marine insurance, the virtual monopoly thus created became a powerful factor in stimulating the growth of insurance by individuals. As Lloyd's coffee house gradually became the centre for such insurance its power and importance developed during the early 18th century. In 1696 Lloyd printed a news sheet called *Lloyd's News* which, however, was soon dropped owing to its publication of an erroneous statement of no importance in a report of the proceedings of the House of Lords. *Lloyd's News* was not a specialized shipping paper and it was not until 1734 that *Lloyd's List* was established. This was devoted mainly to shipping news and as it has appeared continuously ever since it is the oldest London newspaper excepting the *London Gazette*. In the meantime, Lloyd had died in 1713 but the coffee house in Lombard street (on part of the site now occupied by Coutts' Bank) was carried on under the same name, a name which has survived all the vicissitudes of the institution which bears it and which has been adopted all over the world as that of a sort of tutelary genius of shipping. It is for example curious to note that an air fleet in Germany, the "German Aero Lloyd," bears the name of an English coffee house keeper of the 17th century.

In 1774 Lloyd's, under the guidance of John Julius Angerstein, perhaps the most outstanding personality who has appeared in its history, took up its abode in the Royal Exchange where it remained for more than a century and a half during a tenancy broken only by the period of rebuilding after the fire of 1838. The move to the Royal Exchange was signalized by a departure from the status of a proprietary coffee house, the "Masters" as they were called becoming tenants at will to the subscribers. The outbreak of the French war in 1793 led to a period of remarkable expansion during which Lloyd's advanced in wealth and importance although the underwriters were at times subjected to losses which strained their resources; in 1794–95 one underwriter, Robert Sheddon, paid out losses of £190,000. During 1793–1815 Lloyd's became an institution which exerted a salutary influence on the direction of naval operations in relation to sea-borne trade. It carried an insurance of over £600,000 on bullion and specie from Vera Cruz. It is found constantly influencing the Admiralty in regard to convoys. At a time when the State made no provision for war victims, Lloyd's inaugurated many subscriptions for that purpose, culminating in the "Patriotic Fund" established in 1803, which still exists and which received a great augmentation during the World War. Gifts of plate were made to Nelson and to the captains at Trafalgar. A portion of the Nelson plate and a Trafalgar cup designed by Flaxman are now in the possession of Lloyd's.

In 1811 under the influence of Joseph Marryat, M.P., father of the novelist, and himself a man of unusual ability, Lloyd's prepared the way for incorporation by the curious expedient of inducing the subscribers to sign a trust deed vesting the corporate funds in the "committee of treasury" and imposing by-laws on the subscribers. It was moreover at this period that the system of Lloyd's agencies was initiated, and the duties defined.

Incorporation, 1871.—After the destruction by fire of the Royal Exchange, and the return to improved premises, business was continued under the old system until 1870 when the control of the society over its members was found wanting. This led to the Act of Incorporation (Lloyd's Act 1871) which formed the constitution of Lloyd's as it exists to-day. The society was given power to make its own by-laws, to acquire real and personal property, and to do all acts in its corporate name. By the Act of Incorporation the society was restricted to marine insurance but by Lloyd's Act 1911 the power was given to carry on insurance of every description. Although individual initiative is still a most striking characteristic of Lloyd's the powers and activities of the corporate body have increased. The measures designed to make the security of a Lloyd's policy unquestionable have been taken almost entirely since the Act of 1871. Under the Assurance Companies Act 1909 special provisions are included with which Lloyd's underwriters comply.

There is no more striking illustration of the practical conservatism characteristic of Lloyd's, than the Lloyd's policy of marine insurance. Its germ is found in a Florentine policy of 1523. Its substance goes back to the 17th century, when a common printed form was gradually evolved. One of the first acts of Lloyd's, as a society, was to revise this form, with a view to resisting certain attempted innovations, and the policy "revised and confirmed" on Jan. 12, 1779, is still in use, with practically no alterations and only three additions, the "Waiver Clause" (1874), the clause excluding War Risks (1898) and the "Frustration Clause" (1919). In many respects the old form is inadequate to the requirements of modern commerce; but almost every phrase has been judicially interpreted and it is felt that revision would lead to much litigation.

Its inadequacy has been rectified by the use of clauses devised to meet the special requirements of each class of insurance, which are printed separately and then affixed to the policy.

See Chas. Wright and C. Ernest Fayle, *History of Lloyd's* (1928), the leading authority; and F. Martin, *History of Lloyd's and Marine Insurance* (1875). (C. W.; X.)

LLOYDS BANK LIMITED, one of the great British joint-stock banking companies familiarly known as the "big five." It was established as Taylor and Lloyd in 1765 by Sampson Lloyd II and John Taylor and in 1853 the name was changed to Lloyds and Company. The Bank was incorporated in 1865 as a joint stock company under the name of Lloyds Banking Company, Limited upon the amalgamation of Lloyds and Company with Moilliet and Sons. This was a direct outcome of the passing of the Limited Liability Act of 1862. The two firms which founded the new business had a high reputation, and a few months after its formation the private banking firm of P. and H. Williams, of Wednesbury, became amalgamated with it. During the whole of the bank's history there has been a continuous increase in its resources from natural growth, but the policy of amalgamation has had a great deal to do with its expansion. In the early days of its history, the bank absorbed, among others, the Warwick and Leamington Banking Company, the Shropshire Banking Company and the Coventry and Warwickshire Banking Company, and had spread its operations well over the counties of Warwickshire, Staffordshire and Shropshire. In 1884 the businesses of Barnetts, Hoares and Co. and Bosanquet, Salt and Co. were taken over.

After four years, during which the combination of town and country business was thoroughly organized, the bank in 1888 recommenced the process of absorption, and hardly a year passed for a long period which did not bring the announcement that Lloyds had absorbed one or more banks. Altogether about 38 private and 15 joint stock banks were taken over, amongst the most important of them since 1888 being the Birmingham Joint Stock, the Worcester City and County, the Burton Union, the Liverpool Union, Hodgkin Barnett and Co., Lambton and Co., the Devon and Cornwall, the Wilts and Dorset, and more recently the Capital and Counties. The most recent amalgamation took place in 1923, when the businesses of Cox and Co., the well-known army bankers, and H. S. King and Co. were acquired. As a consequence Lloyds Bank has several branches in India and Burmah. After the amalgamation with the two Lombard Street firms, the bank was known for a few years as Lloyds, Barnetts and Bosanquets Bank, Ltd., but in 1889 this name was cut down to the present short title Lloyds Bank Limited.

The growth of the bank has been remarkable. At the end of 1865 the offices numbered 14, its staff 50, and its shareholders 865; the authorized capital was £2,000,000, the deposits amounted to £1,166,000, and the total of the balance sheet to just over £1,346,000. In 1938, the bank had over 1,900 offices, a staff of nearly 14,000, and the shareholders numbered 72,000. The authorized capital was £74,000,000, the paid-up capital £15,810,252, and the reserve fund £9,500,000. Deposits amounted to over £398,000,000, advances to customers to about £164,000,000, and the total of the balance sheet to over £464,000,000. The head office is in London.

In 1918 Lloyds Bank effected a union of interests with the National Bank of Scotland Limited by a purchase of its stock, and with the London & River Plate Bank (now the Bank of London and South America Limited) by a purchase of shares. Each of these two banks, however, preserves its separate existence.

Lloyds Bank and the National Provincial Bank of England (*q.v.*) are joint proprietors of Lloyds and National Provincial Foreign Bank Ltd., which has 9 offices in France, 2 in Belgium, and 1 in Switzerland, as well as its head offices in London. In addition Lloyds Bank has agents and correspondents throughout the British Empire and all over the world. (*See* also BANKS, HISTORY OF.) (L. C. M.; X.)

LLOYD'S REGISTER OF SHIPPING. A society with head office in London, for the survey and classification of mercantile shipping and which may be said to have set the recognized standard for the construction of vessels throughout the world during the last century. In all essentials it is a public body having no pecuniary or commercial purpose to serve other than those of the shipping interests in general.

The society had its origin, like the parent institution of Lloyd's, in the coffee house of Edward Lloyd in the reign of Charles II. For the assistance of the underwriters and merchants frequenting the coffee house, a list became necessary of the vessels offered for insurance of hulls and cargo. These lists, at first in manuscript, attained the dignity of a printed volume in 1760, and were strictly limited in circulation. The Register for 1775–76 is interesting as being the earliest book containing the familiar class of A1, which has been replaced in modern times by the class 100A1 for steel and iron vessels.

Differences arose regarding the standards adopted for classification, and in 1800 the shipowners published a book of their own. The two registers continued in independent circulation until 1833, when a reorganization took place, and Lloyd's Register of Shipping became an independent institution, and for the first time standard rules for shipbuilding were issued. In the reconstituted society the management was vested in a committee elected by the merchants, underwriters and shipowners of London, and from time to time representatives have been added of shipping centres in the country, and of shipbuilders, engineers, and steelmakers, so that it now numbers 81 members. There are in addition local committees at Liverpool and Glasgow, together with committees abroad; viz., in the United States of America, France, Sweden, Holland, Denmark and Japan.

The register book, containing all particulars of all sea-going merchant ships afloat of 100 tons and upwards, is published annually in two editions. One consists of two volumes, and the other, known as the "posted" edition, is bound in three volumes. This posted edition is remarkable for the fact that the books are collected weekly for the purpose of being corrected up to date, in type, by hand at the society's printing house. Lists of shipowners, shipbuilders, telegraphic addresses and docks and harbours of the world are included, together with much statistical information relating to shipping. A register of yachts is also being published; the society compiles and issues to the press and shipping public periodical statistics regarding vessels under construction and of merchant vessels totally lost, broken up, etc. The society's activities comprise the supervision of the construction of a vessel and her machinery from the submission of plans and the testing of the steel material, through the various stages of building up to the trial trip, and surveys are continued throughout the vessel's life if the society's class is to be retained. The society issues very comprehensive rules relating to the construction of ships and machinery, steel testing, etc. For the purpose of carrying out its numerous and highly specialized duties, the society employs a large staff of surveyors of both ships and engines, steel testing surveyors, forging inspectors and electrical engineers; and its representatives are stationed at all the principal ports throughout the world. Some idea of the magnitude of the operations of Lloyd's Register may be gathered from the fact that of 29,763 steam and motor vessels of 100 tons and upwards—of a total tonnage of 68½ millions—afloat in the world in 1939, 13,694 vessels of more than 42 million tons were built under the survey of the surveyors to the society with a view to classification in the register book. (M. K. S.)

LLOYD TRIESTINO LINE. The Lloyd Triestino Steamship Company started its activities in 1833. The capital of the Company amounting to one million florins was gradually raised to four millions in 1851, and to 15,750,000 florins in 1855. The rapid increase of the fleet made it desirable to build a shipyard, that has since been transformed into an arsenal for the repair of ships.

The opening of the Suez canal gave scope to the Lloyd Triestino for organizing services further afield and in 1873 the company's vessels were calling regularly at Colombo, in 1879 they were going as far as Calcutta and in 1880 to the ports of the far east. At the outbreak of World War I the Lloyd Triestino had a fleet of 66 vessels. The war checked its expansion but immediately after the war a new impulse was given to the company under Italian government. In 1937 the Italian mercantile services were reorganized and the Lloyd Triestino company was allotted all the services to India and the far east; Australia; East, West and South Africa. The company had in 1939, 73 vessels with gross tonnage of 603,682. (W. Sto.; X.)

LOACH. The loaches (Cobitidae) are cyprinoid fishes, elongate in form, naked or with very small scales, with three to six pairs of barbels, with the air-bladder reduced and wholly or partly enclosed in a bony capsule, and with the pharyngeal teeth in a single series. More than 200 species are known, mostly from mountain streams in central and southern Asia; three species occur in Europe, and one in Abyssinia. They are small fishes, few species attaining a length of 12 in. In low and stagnant ponds, loaches come to the surface and swallow air, the intestine serving as an organ of respiration. The British species, both of which extend through Europe and northern Asia to Japan, are the stone loach (*Nemachilus barbatula*) and the spined loach (*Cobitis taenia*); the latter has a movable lateral ethmoid, forming a bifid spine, which at rest lies in a groove below the eye.

LOAD LINE. A line (or rather the combination of a circular disc with horizontal line passing through its centre) which is placed on the side of a vessel, to indicate the limit of loading when going into the open sea. The disc is 12 in. in diameter, and the upper edge of the line passes through the centre of the disc. The distance between this centre of disc and the edge of the uppermost continuous deck of an ordinary ship at the middle of the length is termed the "freeboard" (*q.v.*). The centre of the disc indicates the appropriate freeboard for the summer season; other lines give the loading for the Indian summer, winter and winter North Atlantic seasons. (*See* SHIPPING: REGISTRATION, CLASSIFICATION AND STATE REGULATION.)

LOAM, a fertile soil composed of sand, clay and decomposed vegetable matter, the quantity of sand being sufficient to prevent the clay massing together; also, a mixture of sand, clay and straw used for making casting-moulds and bricks and for plastering walls, etc. (*See* SOIL.)

LOANDA (LUANDA): *see* ANGOLA.

LOANGO, a region of the west coast of Africa, extending from the mouth of the Congo to the mouth of the Ogowe. Prior to Africa's partition by European powers, it formed a kingdom by that name (also known as Brama) but now is divided between French Equatorial Africa, the Portuguese district of Kabinda and the Belgian Congo. The roadstead of Loango, an insignificant coastal place, is the only testimony of former grandeur. The inhabitants belong to the Bantu groups of Mayombe and Bakongo; older reports refer to the Loango inhabitants as Bafiote.

The early history of Loango is unknown. During the 15th and 16th centuries Portuguese merchants visited the kingdom which appears to have been founded by the king of the kingdom of Congo, located south of the river Congo. Although a vassal state as late as 1570, it achieved independence toward the end of that century and began to conquer some of the adjacent kingdoms. In the 17th century Loango became divided into many small, politically ineffective states. During this time the country was an important source of slaves for the new world. It was largely under Portuguese control, except for a brief period (1641–48) when the Dutch assumed control of the country's lucrative slave trade. By the middle of the 19th century the kingdom had been reduced in influence. In 1883 the king of Loango signed a treaty placing his country under the protection of France; it became part of the middle Congo territory. (H. A. Wf.)

LOATUKO, the name by which a tribe formerly variously known as Latuko, Lotuko, Latouka, Latuka, etc., is known. The language known by this name is spoken over an area to the east of Bahr-el-Jebel, between 5° and 4° N. latitude. The language is one of a group of 26 designated the Nilo-Equatorial group containing such well-known tongues as Bari, Nandi, Masai and Turkana. These languages have an interesting feature in the use of tones whose object is the fixation of the meaning of a word in cases where its position in the sentence is not sufficient to show this. In some of the allied languages the rôle of the tones is definite and fixed, for example, in Masai, the high tone indicates that the word is the subject of the sentence, while the low tone shows that the word is the complement of the next.

The Loatuko-speaking tribes, so far as they are known, comprise the Loatuko, the Lokoiya and the Lango (*q.v.*), the last named apparently a northern section of the originally Shilluk-speaking Lango of Uganda, who have been dominated by the Loatuko and come to speak their language. All are dolichocephalic, but the Loatuko, with an average stature of about 70 in., are taller by about 2 in. than the Lokoiya and Lango.

The social organization of the Loatuko, by far the best known of the group, has been described by Somerset ("The Lotuko," *Sudan Notes and Records,* vol. i, 1918) and by C. G. and B. Z. Seligman ("Social Organization of the Lotuko," *Sudan Notes and Records,* vol. viii, 1925). Each of a number of independent territorial groups, often at enmity, has at its head a rain-maker, who is its supreme chief. There is a clan organization with descent in the male line, and at death everyone becomes the animal associated with his clan. In spite of a certain feeling of sympathy or friendliness between the clan and its animal it is not unusual for the clan animal to be killed, though it will not generally be eaten. Besides the rain-maker, there are a number of "fathers of the land," of very real power in the magico-religious sphere. There are large stockaded villages, such as Tirangore (Tirangole), as well as hill villages, such as Logurun, with its homesteads scattered irregularly about the hillside. In some hill villages there are megalithic stone circles, with stones up to 5 or 6 ft. high, built up to the present day and used as squatting places for the men, though they seem to be of relatively little social importance. The Loatuko have initiation ceremonies into manhood, in which the lighting of a new fire by friction is one of the essential features, and a system of age classes, which probably are of relatively little importance apart from military organization.

There is a cult of the dead, concerning which not very much is yet known, while the nature of Naijok, perhaps associated with the firmament, is even less understood. The remains of near relatives are dug up some months after burial and the bones exposed in pots under trees and in rock shelters, the reason as stated being the promotion of the fertility of their women. The bones of rain-makers are treated with considerably more ceremony and form the chief contents of the rain shrines at which the great rain ceremonies take place. The Loatuko occupy the mountainous country east of Gondokoro on the upper Nile. (C. G. S.; X.)

LOBACHEVSKI, NIKOLAI IVANOVICH (1793–1856), Russian mathematician, was born at Makariev, Nizhni-Novgorod, on Nov. 2 (N.S.), 1793. He studied at Kazan university, and began teaching there in 1812. In 1823 he succeeded to the ordinary professorship of mathematics, and retained the chair until about 1846. Lobachevski was one of the first thinkers to apply a critical treatment to the fundamental axioms of geometry, and he became a pioneer of the modern geometries which deal with space other than as treated by Euclid. The subject of non-Euclidean geometry is treated in his *Geometrische Untersuchungen zur Theorie der Parallellinien* (Berlin, 1840; new edition, 1887), and *Pangéométrie* in which he summarized the results of his geometrical studies, and is described in the subtitle as a précis of geometry founded on a general and rigorous theory of parallels. (*See* GEOMETRY: *Non-Euclidean.*) He died at Kazan on Feb. 24 (N.S.), 1856.

Pangéométrie was translated into German by H. Liebmann, 1902; and *Geometrische Untersuchungen* was translated into English by Halsted, 1891. *See* F. Engel, *N. I. Lobatchewsky* (Leipzig, 1899).

LOBANOV-ROSTOVSKI, ALEXIS BORISOVICH, PRINCE (1824–1896), Russian statesman, was born on Dec. 30, 1824, and educated at the lyceum of Tsarskoe Selo. At the age of 20 he entered the diplomatic service, and became minister at Constantinople in 1859. In 1863 he retired but at the close of the Russo-Turkish war in 1878 he was sent as ambassador to Constantinople. In 1879 he was transferred to London, and in 1882 to Vienna; and in March 1895 he succeeded de Giers as foreign minister. In this position he showed much of the caution of de Giers, but adopted a more energetic policy in European affairs generally. Russian influence in the Balkan peninsula suddenly revived, and Russia's Balkan policy in the next years seemed to foreshadow the creation of a Balkan confederation hostile to Turkey; in reality Lobanov was merely trying to establish a strong Russian hegemony among these nationalities, and he did not desire a new crisis in the Eastern Question until such time as Russia could act independently of foreign powers. Accordingly, when Lord Salisbury proposed energetic action to protect the Armenians, Russia assumed the rôle of protector of the sultan and vetoed the proposal. At the same time efforts were made to weaken the Triple Alliance, the principal instrument employed being the *entente* with France, which Lobanov helped to convert into a formal alliance. In the far east he became the protector of China. Japan was compelled to give up her conquests on the Chinese mainland, so as not to interfere with the future action of Russia in Manchuria.

Lobanov died on Aug. 30, 1896.

LÖBAU, a town of Germany, in the *Land* of Saxony, on the Löbau water, 12 mi. S.E. of the town of Bautzen, on the Dresden-Görlitz railway. Pop. (1939) 13,763. Löbau is first mentioned as a town in 1221; it received civic rights early in the 14th century and, in 1346, became one of the six allied towns of Lusatia. It suffered severely during the Hussite war and was deprived of its rights in 1547. There is a spa, largely frequented during the summer. The town has agricultural implement, pianoforte, sugar, machine-building and button works, and trade in grain, yarn and stockings. Other industries are spinning, weaving, dyeing, bleaching and brewing.

LOBBY, a corridor or passage, an ante-room, or entrance hall in a building. The two corridors into which the members of the house of commons and other legislative bodies pass on a division are known as "division lobbies," their votes being recorded according to which "lobby," "aye" or "no," they enter. The entrance lobby to a legislative building is open to the public, and thus is a convenient place for interviews between members and the public. The pressure thus brought to bear upon members of legislative bodies has given rise to the expressions "lobbying," "lobbyist." *See* below.

LOBBYING, in the United States, is the practice by non-members of influencing members of legislative bodies either for or against proposed legislation. Such influence may be exerted by entirely open and desirable methods, as giving testimony before congressional committees or bringing printed literature to the attention of congressmen, by debatable methods such as personal interviews with members, which are usually secret and therefore cannot be checked or controlled, or by definitely undesirable methods such as bribery. Lobbying is usually thought of as being conducted chiefly by business corporations and private interests, but it may be carried on as well by chambers of commerce, boards of trade, labour organizations, farmers' alliances, philanthropic agencies and welfare organizations. Indeed, the work of such organizations has in recent years assumed larger importance, and their influence is perhaps greater than private corporations were ever able to exercise. Examples of such powerful organizations after World War I were the various peace societies, soldier associations, prohibition and anti-prohibition interests. Lobbying in so far as it helps to place first-hand facts and reliable arguments before congressmen may be of great assistance and is indispensable. However, to the extent that biased information is given which may unduly influence congressmen who do not verify its claims, such lobbying is also decidedly pernicious. The type of lobbying most dangerous to public interests is the secret work of agents of powerful corporations which seek to institute or influence legislation in their favour regardless of the general welfare. These agents are usually attorneys, or former congressmen who are well versed in legislative procedure and keep in close touch with the passage of business in both houses, so that by a little pressure and manipulation at favourable times they exert an undue influence, even when their methods are honest.

The lobbying evil became serious by the end of the 19th and beginning of the 20th century when trusts and corporations were at the zenith of their power and largely uncontrolled. A number of investigations with startling disclosures resulted in a movement to curb undesirable features. All states have laws severely punishing the actual giving and taking of bribes. Most states have constitutional provisions prohibiting the legislature from passing acts of a local or private nature. The Massachusetts Anti-Lobbying Act of 1890, which served as a model for legislation in other states, provided that lobbyists must register with the sergeant-at-arms, giving the names and addresses of their employers and the terms of their employment. Most states have anti-lobbying laws, but they are difficult to enforce and in many states there is little attempt to enforce them. Senator R. M. LaFollette (*q.v.*) a leader in the anti-lobbying movement, argued that "every legal argument which any lobbyist has to offer, and which any legislator ought to hear, can be presented before committees, before the legislature as a body, through the press, from the public platform, and through printed briefs and arguments placed in the hands of all members and accessible to the public." On the other hand, hearing testimony before committees is possible for only a small number of the members of any legislative body, while few congressmen have time to read a tithe of the literature submitted to them or of the information contained in the public press. Little is left but uncontrolled contact with men directly interested.

Lobbying by private interests has become a potent factor in both federal and state legislation. So incriminating were the disclosures revealed in an investigation of certain company activities in 1928, and so active were other organizations, that the U.S. senate was moved to pass an anti-lobbying bill without a dissenting vote, only to see it die in the house. Renewed investigation in 1930 and again in 1935 disclosed the undercover activity of pressure groups seeking favourable legislation on tariffs, utilities, armaments and what not. Senator Black's bill providing for the registration and regulation of lobbyists passed the senate in May 1935 but stopped in the house judiciary committee.

See P. S. Reinsch, *American Legislatures and Legislative Methods* (1907); R. Luce, *Legislative Assemblies* (1921). The activities of a typical lobby, that of the power companies, can be followed in the *Congressional Record,* vol. lxix, pp. 10,229–10,254.

LOBE, any round projecting part, specifically the lower part of the external ear, one of the parts into which the liver or lung is divided, also one of several parts of the brain, divided by marked fissures. (*See* LIVER, ANATOMY OF; RESPIRATORY SYSTEM, ANATOMY OF; BRAIN: *Anatomy of the Brain.*) The diminutive "lobule" is applied to a similarly shaped portion of a gland, *e.g.,* breast, liver, when of microscopic size.

In architecture a lobe is a curve-sided projection; also a hollow form of similar shape, as, in tracery, the curved segments or foils separated by cusps. Technically, in ornament, lobe is sometimes used synonymously with leaf.

LOBELIA, the typical genus of the family Lobeliaceae, named after Matthias de Lobel, a native of Lille, botanist and physician to James I. It numbers about 250 species, natives of nearly all the temperate and warmer regions of the world, excepting central and eastern Europe as well as western Asia. They are annual or perennial herbs or under-shrubs, rarely shrubby; remarkable arborescent forms are the tree-lobelias found at high elevations on the mountains of tropical Africa. The water lobelia (*L. dortmanna*) (named by Linnaeus after Dortmann, a Dutch druggist), occurs throughout the north temperate zone. *L. urens* is only found in England, on heaths, etc., in Dorset and Cornwall. The genus is distinguished from *Campanula* by the irregular corolla and completely united anthers, and by the excessive acridity of the milky juice. The species earliest described and figured appears to be *L. cardinalis,* under the name *Trachelium americanum sive cardinalis planta,* "the rich crimson cardinal's flower"; Parkinson (*Paradisus,* 1629, p. 357) says, "it groweth neere the riuer of Canada, where the French plantation in America is seated." It is a native of the eastern United States. This and several other species are in cultivation as ornamental garden plants, *e.g.,* the dwarf blue *L. erinus,* from the Cape, which, with its numerous varieties, forms a familiar bedding plant. *L. splendens* and *L. fulgens,* growing from 1 to 2 ft. high, from Texas and Mexico, have scarlet flowers; *L. tupa,* a Chilean perennial 6 to 8 ft. high, has reddish or scarlet flowers; *L. tenuior* with blue flowers is Australian and grown in the greenhouse, while *L. amoena,* from North America, as well as *L. siphilitica* and its hybrids, have also blue flowers. The last-named was introduced in 1665. The hybrids raised by crossing *cardinalis, fulgens, splendens* and *siphilitica,* constitute a fine group of fairly hardy and showy garden plants, little known in America.

The species *Lobelia inflata,* the Indian tobacco of North America, was used in medicine, the entire herb, dried and in flower, being employed. The species derives its specific name from its characteristic inflated capsules. It is somewhat irritant to the nostrils, and is possessed of a burning, acrid taste. The chief constituent is a volatile liquid alkaloid (*cf.* nicotine) named lobeline, which occurs to the extent of about 30%. This is a very pungent body, with a tobacco-like odour. It occurs in combination with lobelic acid and forms solid crystalline salts.

LOBENSTEIN, a town of Germany, in the *Land* of Thuringia, on the Lemnitz, 25 m. N.W. from Hof by railway. Pop. (1933) 3,391. The town is grouped round a rock, upon which stands the ruins of the old castle. It contains a palace, until 1824 the residence of the princes of Reuss-Lobenstein-Elersdorf, and a hydropathic establishment. The manufactures include metal wares, brewing and cigar-making.

LOBI, a long-headed, light-complexioned and well-proportioned people living in the Gaoua district of Upper Volta. There are traces of exogamy. They live in scattered groups of one or more united households without social organization, and there are no considerable villages. Descent is matrilineal. Inheritance goes to the brother and then to the son. The Lobi practise private vendetta, and use poisoned arrows (stropanthus). They are cultivators and cattle-raisers, and animists in religion.

See H. Labouret, "La terre, la chasse et la guerre parmi les populations du Lobi," *Annuaires et Mémoires, Comité Études Hist. et Scient., Dakar* (1916–17).

LOBITO: *see* ANGOLA.

LOBO, FRANCISCO RODRIGUEZ (*c.* 1580–1622), Portuguese bucolic writer, was born of rich and noble parents at Leiria, and wrote of shepherds and shepherdesses by the rivers Liz and Lena. He studied at the university of Coimbra, took the degree of licentiate about 1600, and entered the service of Theodosio, duke of Braganza. He died some time before the end of 1622 by drowning on his way to Lisbon as he was descending the Tagus from Santarem. Though his first book, a little volume of verses (Romances) published in 1596, and his last, a rhymed welcome to King Philip III., published in 1623, are written in Spanish, he composed his eclogues and prose pastorals entirely in Portuguese, at a time when Castilian was the language preferred by polite society and by men of letters. His *Primavera,* a book that may be compared to the *Diana* of Jorge de Montemôr (Montemayor), appeared in 1601, its second part, the *Pastor Peregrino,* in 1608, and its third, the *Desenganado,* in 1614. The dullness of these pastoral romances is relieved by charming and ingenious songs named *serranilhas.* His eclogues in endecasyllables are an echo of those of Camoens, but like his other verses they are inferior to his *redondilhas,* which show the traditional fount of his inspiration. In his *Corte na Aldeia* or *Noites de Inverno* (1619), a man of letters, a young nobleman, a student and an old man of easy means, beguile the winter evenings at Cintra by a series of philosophic and literary discussions in admirable prose dialogue. Lobo also wrote an epic in twenty cantos in *ottava rima* on the Constable D. Nuno Alvares Pereira, a volume of *Eglogas* (1605), and of *Romances* (1596), the latter in Spanish. His descriptions of natural scenery are unsurpassed in the Portuguese language, and generally his writings strike a true note and show a sincerity that was rare at the time. An edition of his collected works was published in one volume in Lisbon in 1723, and another in four volumes, but less complete, appeared there in 1774.

LOBO, JERONIMO (1593–1678), Jesuit missionary, was born in Lisbon, and entered the Order of Jesus at the age of 16. In 1621 he was ordered as a missionary to India, and in 1622 he arrived at Goa. With the intention of proceeding to Abyssinia, whose negus (emperor) Segued had been converted to Roman Catholicism by Pedro Paez, he left India in 1624. He disembarked on the coast of Mombasa, and attempted to reach his destination through the Galla country, but was forced to return. In 1625 he set out again, accompanied by Mendez, the patriarch of Ethiopia, and eight missionaries. The party landed on the coast of the Red sea, and Lobo settled in Abyssinia as superintendent of the missions in Tigré. He remained there until the death of Segued. Forced by persecution to leave the kingdom, in 1634 Lobo and his companions fell into the hands of the Turks at Massawa, who sent him to India to procure a ransom for his imprisoned fellow-missionaries. He obtained the ransom, but could not induce the Portuguese viceroy to send an armament against Abyssinia. He embarked for Portugal, and after he had been shipwrecked on the coast of Natal, and captured by pirates, arrived at Lisbon. He obtained no support, and in 1640 he returned to India, and was elected rector, and afterwards provincial, of the Jesuits at Goa. He died in Lisbon on Jan. 29, 1678.

Lobo wrote an account of his travels in Portuguese, which appears never to have been printed, but is deposited in the monastery of St. Roque, Lisbon. Balthazar Telles made large use of the information therein in his *Historia geral da Ethiopia a Alta* (Coimbra, 1660), often erroneously attributed to Lobo (*see* Machado's *Bibliotheca Lusitana*). Lobo's own narrative was translated from a ms. copy into French in 1728 by the Abbé Joachim le Grand, under the title of *Voyage historique d'Abissinie.* In 1669 a translation by Sir Peter Wyche of several passages from a ms. account of Lobo's travels was published by the Royal Society (translated in M. Thévenot's *Relation des voyages* in 1673). An English abridgment of Le Grand's edition by Dr. Johnson was published in 1735 (reprinted 1789). In a *Mémoire justificatif en réhabilitation des pères Pierre Paez et Jérôme Lobo,* Dr. C. T. Beke maintains against Bruce the accuracy of Lobo's statements as to the source of the Abai branch of the Nile. *See* A. de Backer, *Bibliothèque de la Compagnie de Jésus* (ed. C. Sommervogel, iv., 1893).

LOBSTER, an edible crustacean found on the coasts of the north Atlantic and Mediterranean. The name is sometimes loosely applied to any of the larger Crustacea of the shrimplike or macrurous Decapoda, especially to such as are used for food.

The true lobsters, forming the family Homaridae, are distinguished by having the first three pairs of legs terminating in chelae or pincers. The first pair are large and massive. The common lobster (*Homarus gammarus*) is found on the European coasts from Norway to the Mediterranean. The American lobster (*H. americanus*), which should perhaps be ranked as a variety rather than as a distinct species, is found on the Atlantic coast of North America from Labrador to Cape Hatteras. A third species, found at the Cape of Good Hope, is of small size and of no economic importance.

Both in Europe and in America the lobster is the object of an important fishery. It lives in shallow water, in rocky places and is usually captured in lobster-pots, or creels, made of wickerwork or of hoops covered with netting, and having funnel-shaped openings permitting entrance but preventing escape. These traps are baited with pieces of fish, preferably stale, and are sunk on ground frequented by lobsters, the place of each being marked by a buoy. In Europe the lobsters are generally sent to market in the fresh state, but in America, especially in the northern New England States and in the maritime provinces of Canada, the canning of lobsters is an important industry. The European lobster rarely reaches 10 lb. in weight, though individuals of 15 lb. have been found, and in America there are authentic records of lobsters weighing from 30 to 34 lb. The latter specimen was just about 2 ft. long and had a crushing claw (the larger) measuring 15 in. in length and 20½ in girth.

Nearly 2,000,000 lobsters are taken yearly in European waters. Three-fourths of the United States catch comes from Maine, where 14,500,000 lb. were marketed by the fishermen in 1944 at a record average price of 28 cents per lb., the largest catch in more than 50 years. In 1942 Canada produced 28,025,000 lb. as compared with 12,299,000 lb. for the United States.

The Norway lobster (*Nephrops norvegicus*) is found, like the common lobster, from Norway to the Mediterranean. It is a smaller species, found in deeper water and is generally captured by trawling.

The names rock lobster, spiny lobster, sea-crawfish and "langouste" refer to members of the family Palinuridae, readily distinguished from the Homaridae by the fact that the first legs are not provided with chelae or pincers. The European rock lobster (*Palinurus vulgaris*) ranges from southern Britain to the Mediterranean. All species are taken for food wherever they occur, especially in Florida and the West Indies, the Pacific coast of North America, Juan Fernandez, Australia, New Zealand and South Africa. Spears, traps and hoop-nets are used in their capture. Available European Atlantic statistics lump Norway and rock lobsters together, the annual prewar catch averaging nearly 3,000,000 lb. The spiny lobster catch of Florida (*Panulirus argus*) totalled nearly 500,000 lb. in 1940 as compared with more than 1,000,000 lb. for California (*P. interruptus*), but all spiny lobster fisheries are dwarfed by South Africa (*Jasus lalandii*) which produces (1939) upward of 18,000,000 lb., of which the greater part was exported in the shape of frozen tails, or canned.

The "Murray lobster" of Melbourne and Sydney is a large species of crayfish (*Euastacus armatus*), much used for food. (*See* CRUSTACEA; MALACOSTRACA; CRAYFISH.) (W. L. ST.)

LOCAL GOVERNMENT. Some degree of local government characterizes every state in the world: the degree is all-significant. Local government means authority to determine and execute measures within an area inside and smaller than the whole state. Local means a restricted area. The variant, local self-government, is important for its emphasis upon the freedom of the locality to decide and act. Local self-government has been traditionally used of local government in Great Britain. The Weimar constitution of 1919–33, art. 127, prescribed self-government to accentuate the principle of free self-government in the great tradition of German liberal jurists like Heinrich Rudolf H. F. von Gneist and Otto von Gierke, admirers of British practice.

There is more than a technical importance in the difference between the two terms, because they are related to the distinction sometimes drawn between decentralization and deconcentration. Local government is often, but not necessarily related to the former; local self-government to the latter. That distinctions have been made is important, even if they are blurred. By deconcentration some have meant that for the mere convenience of a congested central government some functions have been devolved to administration on the spot, rather than from the centre, but through officials appointed by and responsible to the centre. Authority and discretion are vested in the centre. On the other hand, decentralization represents local government in areas where the authority to decide has been devolved to a council of locally elected persons, acting in their own discretion, with their own officials. This is almost synonymous with the British and German traditional forms of local self-government. There are in actual fact examples of simple deconcentration—for example, the placement offices of the United States employment service or the tractor stations of the soviet republics. However tightly bound to the central office's authority and regulations, a degree of discretion in its local officials is unavoidable. Often, again, the fairly pure organs of local self-government, for example, a British county borough council or a French *commune*, are obliged to execute the purposes of the central government. Primarily units of local government, they are simultaneously units of local obligation acting as ordered.

Thus, modern local government has a twofold aspect—it is a mixture of both deconcentration and decentralization, of central convenience and an acknowledgment that not all authority ought to be exerted by the centre. The mixture is revealed by the extent to which some of the powers exercised by local government units are exercised compulsorily and under fairly strict control by central authority with financial assistance, and others not. This mixture produces the high complexity of modern local government. Further, local government is a departmentalization of the state's work, based on the territorial distribution of services, as contrasted with (a) division into departments at the centre, or, (b) as in the Italian corporate state, the decentralization of functions to authorized economic groupings. In local government, territorial distribution of power is the essence.

The importance of local government in the modern state can hardly be overestimated. The sheer weight of its functions recommends it. The possibility of the abuse of powers through usurping tendencies, the need for lively political opinion throughout a democratic nation, the significance of a plurality of political experience and confidence—and even vested interests—dictate decentralization.

The history of local government in western Europe, Great Britain, the United States and Russia, exhibits the growing awareness of its significance. This awareness is a product and not the origin of a development of parochial and town life beginning centuries before the modern state emerged between the 15th and 17th centuries. Any central control over these and other areas was, until the 18th century, rather exiguous, though sometimes, as under Jean Baptiste Colbert in France, or Frederick the Great in Prussia, liable to spurts of centralizing zeal. Many Germanic states were nothing but cities: the Hanse towns are examples. In England and New England, especially in the latter, the local units, parishes, towns, cities emerged from their origins as spontaneous self-governing units; so, also, in Russia, although in this instance the state colonized some cities *ab initio*. The various local units were gradually integrated by the state which exacted obligations from them—peace, crime and police duties, taxes, military supplies, assistance to the poor, highways. By ordinances or statutes or judicial decisions they were subordinated, so that the idea of an inherent right to self-government was extinguished. By the 19th century all local units were legal creatures of the state, subsidiary in authority and acting independently by sufferance alone.

Indeed, the battle for the continuance of local self-government is desperate though not hopeless. The local freedoms of the 19th century have been challenged by (1) speed of communications which has reduced administrative space-time; (2) demands for economy; (3) growth of nation-wide parties with social service programs uniform for all parts of the nation; (4) the growth of a consciousness favouring a national minimum of services; (5) realization that best technical administration of modern utilities requires areas different from the traditional, knitted together by a central plan. These are powerful forces working against claims to purely self-regarding government. But on the other hand, local freedom is supported by need for (1) intimate local knowledge and variation; (2) intensity of local interest and enlistment of loyalty and co-operation; (3) small areas for easy impact of the citizen-consumers upon officials-producers; (4) an accessible area of political education. Planning ideas force a reconsideration of all aspects of local government. In all plans, decentralization, whether to a regional corporation like the Tennessee Valley authority, or to reformed traditional units, is exigent, necessary and fruitful.

COMPARATIVE STUDY OF CHARACTERISTICS

The chief characteristics of local government, which may be studied by comparison of Great Britain, France, Germany, the U.S.A. and the U.S.S.R. are (1) constitutional status; (2) areas and authorities; (3) powers; (4) finance; (5) organization; (6) central controls.

Constitutional Status.—In Great Britain, the local authorities are subordinate corporations formed by acts of parliament or charters. Their powers and immunities derive from statute and judicial interpretation. They have many obligatory duties; a vast field of permissive powers. Each authority is independent within the sphere of power authorized by the central government: there is no hierarchy of layers of authorities. Slight tutelary control over the health and roads services of the urban and rural districts has been given to the counties. Local councillors are freely elected and constitute the local executive as well as the legislature. There is no appointment or ratification of local executives by the central government, though certain important local officials require qualifications stipulated thereby. The local authorities are compendious, *i.e.*, combine many functions, and are not, like the school committees so frequent in the U.S.; single function or *ad hoc* authorities. The local finances—rates—are locally raised and appropriated with practically no interference by the centre. Though they have considerable freedom to use their permissive powers, and even the obligatory, they operate within judicial controls lest they act *ultra vires* or are negligent, and under continuous central administrative controls. A condition of local central partnership characterizes the system. Though the central controls have increased markedly in the last 30 years, local powers have also greatly increased. The local units are very virile. They exercise an important influence over the central administration through their M.P.'s, and through their increasingly large representation on advisory councils and committees officially attached to the several departments. The nation-wide associations of the different classes of local authorities exercise an advisory and representative influence on the centre and keep up the standard of local administration.

French local government differs from the English in being both hierarchical and centralized. Though the municipal code of 1884 gives the municipalities a wide general scope of activity, these *communes* and *départements* are limited by strong controls over their budgets, modified for the bigger cities by political influence. The inspectorial system, strong in the English system, because the relationship of government to the localities is direct, is of less consequence in the French, where hierarchical control seeps down through the *préfet* of the *département.* Obligatory functions which must be carried out by the municipalities can be inscribed by both the *maire* and the *préfet.* The *préfet* may be removed by the central authority at its discretion—he is appointed by it; the mayor, until 1884 appointed by the central government, since elected by the local council, is removable by the central government for default in acting as the law requires, and is suspendible by order of the *préfet* for similar cause for from one to three months. Judicial control over the activities of local government is very heavy, culminating in the supreme administrative court, the *conseil d'état.* The rather severe centralization of French local government, a legacy of the *ancien régime* hardly affected by the Revolution, is considerably criticized, but decentralization is very unlikely. The rural nature of France, despite many cities, retards change.

German local government (omitting the nazi interlude) attempted to unite the age-long pride in free and enterprising civic life with the full popular enfranchisement of 1919. Its hierarchical system reaching back to the 18th century, with strong central surveillance, was a little eased during the Weimar period. The position of the local executives, *burgermeister* or *magistrat,* ratifiable by the central government, was much troubled by the universal suffrage of 1919 which replaced the oligarchic three class system. A very wide scope of authority was accorded to the *gemeinde,* whether rural or urban, by the basic laws, such as the Prussian *städteordnung* of 1808, the *kreisordnung* of 1872 and the *provinzialordnung* of 1873. But this came to be limited by the financial stringency induced by World War I, so that local revenues were subordinated almost completely to state and reich. But local government flourished: German cities showed great enterprise and developed many utilities. The nazi system was fortunately destroyed, for this had in general kept the framework of areas and authorities, but abolished all elections, and substituted appointed councillors and executives. The future in 1946 was promising for the revival of local government.

In the U.S. the main features of the constitutional status of local authorities are the variety of arrangements in the various states, the large degree of freedom of the local units deriving from early English township forms and reinforced by migration into new lands. Nevertheless, that freedom is subordinate and defined by state statutes and charters giving corporate status. The special charter, referring to individual cities; the general charter, which is a state-wide municipal code; the charter which confers status by classifying the local units for privileges—these are varieties of the attempt to give the local units a status which relieves them of the need for repeated application to the legislature, while subjecting them to a firm pattern of permissions and limits. Amendments, however, still require suppliancy to the legislature; and growth requires powers in addition to the general grant. In more than 20 states home rule charters, granted by the legislature, allow the city to draft its own charter by a local convention, sometimes requiring legislative ratification, sometimes not. Another system allows the local units to choose from among several forms of charter provided in a state general law. There is much independence and vigour, no hierarchy, little central administrative control, much judicial control to hold the units within their charter and statutory position. There are growing direct relations between federal government and local units.

The local government system of tsarist Russia was one of strict centralized hierarchy, executed through the governors of the 78 *guberniya,* with police, military and taxation powers and the scantiest recognition of rights of local government. Provincial and village governments were dominated by the landlords, who had an *ex officio* right to chairmanship of local administration, especially of the *zemstvo,* set up in 1864, to govern the provinces under strict control of the imperial governors. The *zemstvo,* nevertheless, made progress in educational, health, welfare and agricultural development. The soviet constitution of 1936 and the decree on the city soviets (1933) together introduce extraordinarily wide specified powers for the local units, and simultaneously rigorous submission to hierarchical control of the next higher authorities upwards to the central government of the various republics, and in some cases to the union itself. Authority and direction are heavily centralized and animated in the last resort by the all-union supervisory commission. All units from lowest to highest are linked by the ubiquitous activities of the Communist party.

Generally speaking, then, local government as local self-government, is discernible more fully in the British and American environment than elsewhere, and more in the German than in the French. Yet *post hoc* centralization and control are not inconsistent with virile first-line activity by the local units in the matters entrusted to them.

Areas and Authorities.—Local authorities in England and Wales are (from smaller units upwards): 13,000 parishes (of minimal importance even in rural areas); 1047 rural districts and urban districts (mainly health and minor roads authorities and some water supply and other utilities where large); 309 non-county boroughs (similar to the districts but some have police forces and elementary school duties—both about to disappear); 83 county boroughs, being great towns of 50,000 population and above, with the greatest scope of local services including the public utilities; and 62 county councils, being mixed urban and rural areas. The county boroughs are independent of the counties; all other units have some of the services in their area rendered by the county council in whose area they fall. In addition to these authorities, there are 2,000 joint authorities, councils, committees or boards, established to administer burials, water and electricity, and sewerage and hospitals. There is a tendency to rely more upon such unions where the services are of a large-scale nature compared with the traditional units having responsibility. Local authorities are mutually independent: unanimity is required for joint schemes of large-scale administration, for which ample permissive provision is contained in the statutes. Even some counties are far too small for large-scale administration, while extremes of size in area and population may be encountered in each of the above-named classes of authorities. Under the Local Government acts of 1888, 1926, 1929 and 1933, areas could be reformed after a procedure of local inquiry conducted by the ministry of health (the central supervising department over local government), followed in the case of the creation and extension of county boroughs by legislation, and in the other cases by central administrative sanction. For the districts a maximum decennial review of areas is called for. In 1926 the creation of county boroughs was set back by the stipulation that the minimum population must be 75,000 in place of 50,000, as the counties suffered from the subtraction of area and taxable capacity. Civil resistance all through the system prevents more serious change. The movement for regions is strong, but cannot prevail against local inertia and the claim that small areas are needed to activate democratic vitality.

The French local government units are, in a downward order: 90 *départements;* 279 *arrondissements;* 3027 *cantons;* and more than 38,000 *communes.* The first and the last are genuine units of local governments; the middle two are only lower judicial, electoral, tax and *gendarmerie* districts. The *départements* vary in size from 185 to more than 4,000 sq.mi., with average population of 500,000. This framework, which serves the centralizing authority of the state, was established in 1790 to unify France by abolishing the traditional 35 *généralités* which partly coincided with and partly cut across the ancient provinces, for symmetry and centralization. The *communes* are the basic roots of local government. The name comprises the smallest village up to the capital. The span is from several acres to 400 sq.mi.; and less than 100 people to Paris with 3,000,000. There are only 7,000 having more than 1,000 inhabitants. Naturally the range of powers and practical hierarchical control vary accordingly, within the uniform pattern of the law. Until 1938, area alterations could be made only by parliamentary statute, preceded by local vote, inquiry and acceptance by the *département* and *conseil d'état.* Practically no changes occurred. Not even after an easier form was introduced in June 1938 did changes occur. As in England there is a movement for regions; and its fate is similar.

The German areas of local government are (proceeding upward): more than 50,000 *gemeinden* (like the *communes*) divisible into *stadt* and *land,* urban and rural (one-third of the population live in the latter). Then, upwards, the *kreis* (equivalent roughly to county in England and the U.S.A.); above this again, the *regierungsbezirk* (government district), a unit of central government control and police authority; and, above, the *provinz.* There are also 15,000 joint authorities for special purposes—roads, schools, health, fire, agriculture, water, gas, electricity. The *gemeinden* exhibit an enormous diversity of area and population. Increasing urban concentration after World War I was highly marked. The *kreis* is notable for the distinction between *stadtkreis* and *landkreis,* the former where the population is above 25,000 is a city-county (like the English county borough): the next higher level of hierarchy is the *bezirk* and *provinz.* There is a rather special kind of holding company local authority—the *amt,* to administer the common affairs of some contiguous villages while they still remain separate *gemeinden. Gemeinden* can be raised to be cities by the ministry of the interior (the local government supervisory authority) after neighbouring areas have stated their case. More important area changes require parliamentary statute. Free agreement among the local authorities is practically unobtainable. The impetus toward city-countyship is enormous, for the same reasons as toward county boroughship in England. In 1929, the rural authorities were allowed to assume any functions desirable in the public interest. Many joint authorities were formed by agreement and administrative approval, the Frankfort-Höchst experiment being of special interest. The nazi municipal order of 1935 gave wide powers of areal change to the national cabinet. In 1937 followed the creation of the greater Hamburg area. Here also the struggle of the traditional with the rational area is obvious.

The area structure of local government in the U.S. has a different foundation according to the historic settlement of the part of the nation. In the south and south central region the chief unit is the county; in the north central, the combined county and township; in New England, the town. In some states, the people of each county may vote to divide the county into townships. There are, altogether, 3,050 counties. There are nearly 19,000 towns and townships; 16,220 municipalities or cities; nearly 109,000 school districts, and about 8,300 other special function districts—in all, 155,000 local government units. Change is in store around the traditional area of the county, for in their midst townships and cities grew apace after 1860, while the nation suffered great rural depopulation. As in the other nations, wealth and people have left for the towns. Only one in five of the counties contain urban communities with more than 10,000 population. The area varies from 22 to 20,000 sq.mi.—most generally, 400 to 600 sq.mi. The smallest has 42 inhabitants, the largest (Cook county, Illinois, with Chicago) more than 4,000,000. The median is 17,000. Some of the functions are those of modern central rather than local authorities: taxation, judicial registrations and records, first instance judicial action through the county court and justices of the peace, elections. Others like education, highways and bridges, social welfare, poor law, hospitals, pensions, health, defectives and delinquents are serious burdens on nonpopulous areas. Either the services remain inefficient or the state takes them over in whole or in part. The consolidation of counties is difficult: reduction to one-third the number has been recommended. Here and there unions of counties have been formed for hospital and poorhouse purposes.

Inset in the county is the city, with its own powers, and in direct relationship with the state government. Sometimes both conduct for two concentric areas many similar services with substantial duplication of staff and organization. The cities are the areas of the heaviest integration of local government services. As elsewhere, there is antagonism between city and county, and the federal authority, after the '30s, became an important direct supporter of city unemployment, public works, municipal utility and housing schemes. Towns, mostly, but not exclusively, semirural communities, some fairly populous, in New England, New York, Pennsylvania and the north central states, play the part of the counties elsewhere and have city functions and sometimes city status also. As a part of a township or a county, there are habited centres, called villages or boroughs, a minimum of population usually being demanded by the state legislature before such a subdivision may become self-governing. Area problems in the U.S. revolve round the adjustment of county and city, and the problem of metropolitan areas. Here also, political vested interests and simple inertia obstruct modernization. The legislatures are slow in enacting reforms.

In Russia the tsarist 78 *guberniyas,* 21 *oblast* (or regions), the many *uyezd* (districts) within the *guberniya,* and the *volost* (counties) within these again, have been replaced by a soviet pattern traced in the constitution of May 1925, the municipal decree of 1925 and the constitution of 1936. Upward from the 75,000 village or city soviets of the most varied size, are the *raion* (or circuit), the *oblast* or *krai* (region). At the top of the pyramid is the republic soviet. Their upward relationship may be expressed in Lenin's phrase, "centralized supervision with decentralized activity." Within the cities of 100,000 there are ward soviets, of which Moscow has 24; they are subordinate as to budget and action to the city soviet. Cities of more than 50,000 and specially important places of lesser population receive a status independent of the *raion* hierarchy and are directly subordinate to the republics. Attached to these cities are surrounding rural settlements which fully participate in the city government, but possess village soviets also. The republics decree these connections. An experimental process led, by 1930, to the areal pattern which prevailed in 1946, and produced a reduction of the provincial units of government from 13,000 before the revolution to less than 2,500. With an urbanization which had increased nearly ten-fold to 30,000,000 by 1946, the problem of soviet areas is not one of solution by flux.

The problem of modernizing areas has nowhere been tackled radically. A process of slow boundary adjustment is accompanied by the creation of joint authorities for special purposes. The maintenance of small areas, locally elected, and therefore locally minded, is a not negligible ingredient of a robust and animated democracy which may give a long run efficiency superior to that offered by unwieldy large-scale organization.

Powers.—Broadly speaking, the big authorities in the level of the hierarchy are concerned with financial and administrative supervision of the primary units, the provision of environmental and institutional and police services, and supplements and assistance to the smaller authorities.

Authority to act is set down as already suggested: it is always a combination of specific grant and general grant by the central authority sometimes with limited additions made by the administrative supervisory authorities and the decisions of the courts on common law principles. In Great Britain, the specific grant of power is supreme. This is effectuated by grants of power to the various classes of local authorities by general statutes, and in special addition to individual local authorities by private or local acts. The powers granted by general statute are either permissive (*e.g.,* libraries) or compulsory (*e.g.,* education or hospitals for infectious disease) and they appear in the great statutes like the Municipal Corporations act, 1835, or the Local Government act, 1933, which may be termed constitutive, or in acts like those on education or police, which may be called functional. The permissive powers offer remarkably wide opportunities of initiative. Where local authorities petition parliament for private acts, they may obtain the opportunity to pioneer, if they prove desirability and financial capacity, and successful administration is sometimes followed by grant to all authorities of these novel ones. The merit of the system of specific grant is the addition of the good sense of the central authority to that of the local electorate in determining new services, which also means control over local citizens and power to raise taxes. All the bigger authorities have a rather restricted by-law making power, heavily controlled by the courts.

In France and Germany, the municipalities are given by the constituent statutes a general or universal power to act for the good proper to the municipality. But what is proper is legally challengeable by citizens, and administratively by the state departments. Initiative is limited by the claims of other communities, private enterprise and the state organs. Also there are functions obligatory on the local units—from 50 to 80% measured in expenditures—prior to the discretionary ones. Even the decree of 1926 in France, which aimed to free the power of the communes to undertake utilities without hindrance from the courts at the instance of private enterprise, still required the approval of the higher administrative authorities, so that very little was accomplished. In Germany from 1890 on, the cities proceeded remarkably with municipal enterprise, because it suited the genius of the nation. Despite general powers in France, there was small municipal enterprise; despite specific grant in Great Britain, that country is probably unmatched in the extent of municipal management of utilities.

The powers of United States counties have come by a series of specific grants. The cities receive their powers in the charters as earlier suggested—these are stated specifically, but in broad outline, while additional powers are granted specifically from time to time. The general limitations of not encroaching on state functions as defined in the state constitution, must be remembered. Though unchartered the towns have a like freedom of action.

The Russian republic constitution (sect. 79) grants to all local authorities the power to "direct the cultural, political and economic construction of their respective territories," and the power to make decrees within the laws of the union and the republic, and then specifies further by its directive (sect. 92) regarding the departments to be set up by the municipalities. The local soviets are generically unbounded in their powers: but in almost all are subject to superior political plans or trust plans.

The powers actually exercised by modern local authorities are immensely in advance of anything known in the early 19th century. Then the main services were highways, police, public assistance, the removal of health nuisances, perhaps fire-fighting, perhaps infectious diseases, here and there public education. In Great Britain something like 80% of the work of the local authorities is the modern social services and municipal enterprise: in other countries the situation is or grows similar. We may list the powers usually exercised by local authorities: education up to high school and technical schools (in the U.S. sometimes colleges and universities); public health in a variety of environmental and personal services; mental diseases; housing provision and management; town planning, zoning, building regulation; poor relief, and in the U.S., local administration of social security services; small holdings, allotments; parks and open spaces and playgrounds; agricultural improvement and land drainage, agricultural education; roads and bridges; streets; public lighting; fire-fighting; police (larger authorities only except in the U.S.); lower instance justice; foods and drugs, and weights and measures inspection; enterprises of gas, electric power, transport by trams and bus, water supply (and in the German cities, laundries, milk supply, bakeries, theatres, concerts); land purchase in relationship to specific municipal powers, but as a general power in Germany. In the soviet system, where special decentralized units of the big enterprises under the state planning commissions are in charge of the utilities, there is some participation by the local soviet.

The tendency is towards more local powers, but also to more integration with the higher authorities, with emphasis on large-scale organization. The development of planned economy, social security and public medical care, must take the task of higher direction to the bigger authorities, though not excluding the smaller from direct execution with much latitude therein.

Finance and Local Freedom.—The finances of local authorities have a bearing upon their administrative freedom. The crucial points are (a) their authority to raise revenue; (b) freedom of budget making; (c) the revenue basis; (d) the magnitude of their expenditures. Only (a) and (b) are discussed.

(a) Revenue may be raised by authority of the general codes or the special statutes conferring powers. In France, tax freedom is limited by the need of superior authorization for the budget. In the soviet union the planned economy limits tax freedom, especially as there is much sharing of taxes between the higher and the municipal authorities.

In Great Britain and the United States, the principal financial limitations are on loans. In the former, previous administrative authority is required; in some states of the latter, limitations of total indebtedness are prescribed. The former permits higher technical examination of the projects. The latter is not infallible against default. Before Hitler, German cities had wide financial freedom, though loans required provincial sanction.

(b) Local budgets need no superior approval, either in Great Britain or the U.S.A. In France, the *préfet's* approval is required and he may require balancing and inscribe mandatory or invalidate optional expenditures. The German system requires compulsory appropriations when higher authorities consider that provision is inadequate. In soviet government, the strictest control is exercised by the higher authorities over revenue raising, appropriations and budget.

In Great Britain grants-in-aid from the central authority play a very important financial and administrative role; in the U.S. rather less so, but with growing importance in 1946. In France and Germany the sharing of taxes with the central government was more important relatively than the grant-in-aid. The subject is of the highest importance because a grant, and the form it takes, is an instrument of superior control, regulation and stimulation administratively.

Organization.—Local councils are elected by practically universal franchise for terms of three or four years, soviets for two. The nazis suspended that freedom. Soviet local elections are organized by the Communist party; but nonparty members nominate and are nominated and nearly 80% are members of the village soviets, and 44% of the city soviets; but only four out of ten chairmen of the village soviets and practically none of the city soviets are nonparty. The local government statutes of all the countries concerned prescribe certain kinds of internal organization—mayor, chairman, alderman, committees, commissions. Everywhere the councils establish committees for executive and preparatory legislative operations and to keep contact with the central authority and their own permanent staffs.

Some significant differences deserve notice. The English form of internal organization is that of all-party committees, each in touch with the technical or expert directors of departments. The only coordinator is the town or county clerk, in collaboration with the mayor or chairman who is annually elected from the council. The committees are virtually subcouncils, with a very large degree of delegated authority, subject to ratification by the council, but not to tax, raise a loan or make a contract. Some committees are prescribed by statute. The French system has the centrally appointed *préfet* dominating the *département* council; in the municipalities, the council elects the mayor. The former works with a secretary-general appointed by the central government. A small standing committee of the council, called the *commission départementale* controls and cooperates with the *préfet* as regards the budget, the audit of expenditures, civic property. It has further delegated powers from the council, but not to tax or spend. The *maire* is served by a number of *adjoints,* chosen from the council by seniority and value of services to the commune. They supervise the various departments of municipal activity, and jointly act as advisory body to the *maire* and draw up the budget. In the German system, the *provinz* is headed by a centrally appointed *oberpräsident,* for central government purposes, and a *landesdirektor* selected by the provinzial diet for local purposes, and he acts with an executive committee thereof. In the county, the chief executive is the *landrat,* appointed by the central government and cooperating with a small executive committee of the county council. In the rural communes, a chairman or bürgermeister is elected by the council, and works with assistants or aldermen chosen by the councillors. In the cities of East Prussia, the *magistrat* system prevails; in West Prussia, the *bürgermeister* system. In the former the elected council and its own chairman collaborate with the *magistrat,* which is an administrative board of professional officials and some laymen chosen by the council, organized and led by the *bürgermeister.* It is a kind of bicameral system, and on the decline. Neither of the bodies could separately decide an issue; agreement is necessary. The *magistrat* members headed the departmental offices, and were paid, subject to confirmation by the central authority. Municipal ordinances and the budget are introduced by the *magistrat.* Where the *bürgermeister* operates, this officer, a career official, is rather in the position of the whole *magistrat.* The advent of full responsible government and universal suffrage in 1919 opened an era of deadlock between the councils and the executives, broken by the central government's assumption of powers.

In the U.S. system there are four conspicuous forms of organization: the town meeting, the commission system, the council and mayor system, the city manager system. In the first, the meeting of taxpayers settles main lines of policy, chooses select men and officials, accepts the budget, controls administration and checks expenditures. It is unwieldy for large cities. These then may be administered by a small number of commissioners elected simultaneously as severally heads of the executive departments and collectively the general government of the city. It encourages disintegration of leadership, and is on the decline. Elsewhere council and some officials and the mayor are elected at the same time, and there is a separation of legislative and executive authority—at enormous cost of energy which produces some but not all the desirable progress. In the 30 years from 1916 to 1946 the city manager system developed strongly, until it applied to 572 cities. The elected council appoints an executive, a career official, to energize, manage, appoint the officials, to co-ordinate and make the budget—this, side by side with its elected mayor. The city manager is no czar; he serves the council and the local statutes give him a strong status, but it cannot be stronger than the authority of the council. His indefinite tenure may be cut short. Yet on the whole this is an improvement on other United States forms of local government organization. In general, the United States system is distinguished by its use of the initiative and referendum, especially necessary in the commission form.

In the soviet system, the local soviet elects a presidium or executive committee from its members. A small number of this body together with the president form a working inner cabinet. In the larger cities the technical officers must work under the direction of the presidium, and some may be actual members of it. This body is the formulator of policy as well as the executive—the council discusses, and ratifies. The municipal code prescribes committees of the council, called sections. Councillors may be recalled by dissatisfied constituents, but this happens very rarely.

During the 19th century, local administration, having small power, could be a field of much unpaid service, patronage and spoils. The merit and career system has advanced. Appointments are made by the chief executive officials in the French and German systems, but according to statutory qualifications and tests. In England the central government by law prescribes the basic qualifications of some officials—the medical officer of health, the sanitary inspector, the police, teachers, etc., but appointment and management are fully by the local authorities. Other appointments are entirely in their discretion. Some officers have the right of appeal to the central authority against dismissal—*e.g.*, medical officers of health. The purpose is obvious. In practically all large authorities and most small, a career service prevails. In the U.S. it has been estimated that civil service appointments total about 60% in the cities, and about 15% in the counties.

Central Control.—The intensity and techniques of administrative control by the central authorities are indexes of the limitation of local self-government. General tutelage is characteristic of France, Germany and Russia. It operates through continuous organized hierarchical vigilance and intervention downward from the appropriate central department through the higher to the lower levels of local authorities. As far as tutelage in Great Britain is concerned, it is exhibited in the form of the statutory rules and orders made by the designated central department in the course of administering the provisions of statutes relating to local functions, as well as advice, admonition, exhortation, preparation of scientific memoranda, reports of experience.

The sanction of administrative schemes is a more severe and specific form of central control: it is strong though not fully comprehensive in England, rather the same in France, less coverage in Germany and more comprehensive in the soviet than in any other country. In the U.S., sanction is rare, and applies to welfare and public works schemes assisted by the federal authority, and occasionally to highways, education and hospitals, financially assisted by the states.

Submission of periodic reports, when functions are financial or otherwise capable of statistical tabulation according to centrally designed forms is universal, but applies in the U.S. mainly to the services already mentioned, and in some states to the local accounts. The growth of standards, scientific definition, forms and statistical analysis after the middle of the 19th century has been a powerful instrument of centralization, since both local and central officials can be of one mind in reporting and deciding answers to governmental problems.

Audit of local accounts by central officials is severe and important in England; in France and Germany it is hierarchical, going finally in each case to the special courts of accounts. In the U.S., though accounting and fiscal practices are in some cases state regulated, and the election of local auditors required, external and compulsory audit hardly exists. Inspection by central officers is the most distinctive feature of the English system, having been carried to a highly comprehensive and efficient stage, in which the inspectors are not only investigating and enforcement-assisting agents, but counsellors on good practices, and flexible intermediaries between the capital and the localities. There is also inspection in the French and German systems, but it is overshadowed by the centralist quality of the system. In the U.S. the small amount of inspection is related only to the services already mentioned: in the counties, because of the nature of county services, it is hardly distinguishable from central action. Action in default is very limited and rare in England; practically nonexistent in the U.S.; has been practiced in Germany; in France, it is unnecessary because the power of supervision coupled with the inscription of obligatory expenditures prevents the rise of conditions needing action by the centre on local default; higher pressure in the soviet system obviates it. The power to remove the French mayor or the *préfet* may be borne in mind.

Finally, personnel rules are laid down by the English central authority for some key officials; *préfet* and *maire* are auxiliaries of the central authority in France; a few states in the U.S. exert some small influence on the civil service conditions of the localities; in Germany, local appointments were free except, as in France, state laws regulated general conditions of appointment and service; in Russia, the local soviets have little formal limits on their appointing power. It should be remembered that where the central authority makes regular financial grants to the local authorities, the payment or withholding of these constitutes a sanction of these various instruments of its control. This is especially strong though flexible in England; much less so in France and Germany; firm over its small field in the U.S.; while the soviet system relies on other incentives. But the grant-in-aid as sanction is replaced by other exertions of authority in France and Germany.

Variety and development are marks of contemporary local government. Larger areas are on the way as is more central direction. Many new functions are impending. The feeling of attachment to the old areas is a retarding factor; the recognition that the small area has continuous nontechnical values, and certain long run technical advantages in assisting consumer control over administrators will force centralization to assume accommodating forms. The great associations of municipalities and the professional officials already contribute considerably to the efficiency of the localities, and their services are destined to be even more valuable still.

LOCAL OPTION. In its application to the drink trade, local option may be described as a policy of decentralization which transfers the question of the continuance or non-continuance of the common sale of alcoholic beverages from the central authority to the registered electors in each local area. It is local self-government with a difference. In ordinary matters of local government the self-determination of local communities is achieved indirectly through a popularly-elected local authority. In the case of local option the action of public opinion is direct. Initiative rests with the local electors and decision is reached by a popular vote.

Under local option the power to grant or not grant licences for the sale of alcoholic liquors is transferred from the licensing justices (acting as the statutory representatives of the central authority) to the electors of the local area, who register their decision at a poll taken for the purpose. Local option laws differ in character and in scope in different countries. In most cases they are purely suppressive in character and the options offered are restricted to the two alternatives of licence or no-licence. In a few cases a third option of limitation is offered, while in one or two instances (*e.g.*, in South Australia) a right to increase the number of licences is conceded. This latter right is rarely exercised. The three-fold form of local option (*i.e.*, no-licence, limitation and no-change) was at one time generally favoured in Great Britain and in certain of the British dominions, but in recent years the "limitation" option has declined in favour and local option policy has tended more and more to revert to its original form of a direct veto upon the grant of licences.

The history of local option is in large part one of American experience. It was in the United States that the policy originated and it was there that it made its widest appeal. It grew up in the United States "as a kind of natural fungus upon the licence system stock." The original licensing laws were State laws applicable to the whole of the territory of the State, but the actual administration and use of the State law was left to the local authorities who not only granted the licences, but in many cases fixed (or supplemented) the amount of the licence fee, the proceeds from which went in whole or in part to the city or county revenue. In these local autonomous powers lay the germ of the modern local option policy. The development of the policy was at first indirect. In 1833 the State legislature in Georgia gave to the local courts in two counties the right to grant or to withhold retail licences. As the members of the courts were popularly elected the right constituted a form of indirect local option. A few years later (in 1838) two other States (Rhode Island and Connecticut) transferred the power to grant or not grant licences to the towns. Another State (Illinois) followed by empowering both counties and towns to suppress the liquor trade on the petition of a majority of the male inhabitants. And so the movement spread, developing rapidly from its initial form of an indirect restraint to its modern plebiscitary form of direct popular veto. Local option in the United States, although in its earliest stages a regulative system, quickly became in intention and effect a purely prohibitionist policy. It prepared the way for State prohibition into which it at first slowly and then rapidly developed. National prohibition superseded both of these devices for a time; since repeal state control appears to be favoured over local option in most states.

In the British Isles local option as a political issue dates back to 1857, when the United Kingdom Alliance first launched its "Permissive Bill." The only statutory recognition that the policy has received in the United Kingdom so far is contained in the local option sections of the Scottish Temperance Act of 1913, which came into force in 1920 with results which, if useful, have been inconsiderable. Local option has found a large place in the liquor laws of the British dominions, especially in Canada, where, however, it has since been largely superceded by provincial-wide experiments in prohibition (now for the most part replaced by provincial schemes of public management and control, in some of which the principle of local option is recognized).

In Europe generally, with the exception of Norway and Sweden, local option has made little progress. In Norway and Sweden it has operated chiefly in restraint of the grant of licences in rural communes, in which licences were always few and in many cases non-existent, and in an indirect and non-plebiscitary way (*i.e.*, by use of the ordinary machinery of parochial government). In 1894 a direct power to veto the retail sale of spirits was for the first time conceded to the Norwegian towns, with the result that when, during the later years of the World War, national prohibition was resorted to, there remained only 13 towns in which the retail sale of spirits was still allowed. Following the recent repeal of prohibition of spirits in Norway, the right of local option has been restored.

LOCAL TAXATION: *see* TAXATION, LOCAL.

LOCARNO (Ger. *Luggarus*), a town in the Swiss canton of Ticino (Tessin), of which until 1881 it was one of the three capitals (the others being Bellinzona and Lugano, *qq.v.*). It is a health resort (population 6,575) built at the north end of Lago Maggiore. It is 14 m. S.W. of Bellinzona by rail. An electric railway, opened in 1923, connects it with Domodossola and the Simplon via the Centovalli; another electric railway runs from Locarno along the Maggia valley. It was taken from the Milanese by the Swiss in 1512 and was subject to them until 1798, when it became a part of the canton Lugano in the Helvetic republic. In 1803 it became part of the new canton of Ticino. In its Palace of Justice in 1925 were held the sittings of the Locarno conference. (*See* LOCARNO, PACT OF.)

LOCARNO, PACT OF, a series of diplomatic instruments for peace and arbitration drawn up at Locarno in 1925, whereby (1) Germany, Belgium, France, Great Britain and Italy mutually guaranteed the peace in Western Europe and (2) Germany undertook to arbitrate about disputes with France, Belgium, Poland and Czechoslovakia.

The ceremony which took place at Locarno on Oct. 16, 1925 (Austen Chamberlain's birthday) was the initialling of the instruments by the delegates, namely Dr. Luther and Herr Stresemann (Germany), M. Emile Vandervelde (Belgium), M. Aristide Briand (France), Mr. Austen Chamberlain (Great Britain), Signor Benito Mussolini (Italy)—who arrived at Locarno by boat on Oct. 16 and left again the same day—Count A. Skrzynski (Poland) and Dr. Edouard Beneš (Czechoslovakia). The treaties were signed in the Foreign Office, London, on Dec. 1, 1925.

That achievement made an impression on popular opinion in all the countries concerned because it marked a definite break from the war atmosphere; the words "allies" and "enemies" were never uttered by any delegate throughout the conference; and the chief countries concerned in the World War committed themselves to a pacifist policy, as between themselves, for the future. For the first time in history great powers surrendered their absolute "right to make war." The surrender was localized to one particular storm centre, namely the Rhine, but it started a diplomatic fashion in Europe.

Although the technical origin of the Locarno idea was contained in a memorandum communicated on Feb. 9, 1925, by the German Ambassador in Paris to M. Herriot, yet it was recognized that Austen Chamberlain personally had played the decisive part in leading up to it. Lord D'Abernon, British Ambassador in Berlin, had prepared the ground. Lloyd George in 1922, Dr. Cuno in 1923, Ramsay MacDonald in 1924, had conceived essentially similar ideas, and the Dawes Conference of 1924 created the propitious atmosphere for what fructified in 1925; but Chamberlain forced the issue. Sir Austen Chamberlain (as he now became) had the Order of the Garter specially conferred on him in Dec. 1925 for the part he had played. During the spring and summer of 1925 difficult and brittle preliminary diplomacy had had to be faced. Chamberlain sustained his faith in success, and at Locarno it was generally agreed that he had supplied the main motive spirit. Upon Great Britain fell a special responsibility under the treaties. There were those who held the importance of the treaties to be psychological rather than technical; but realistically the kernel was implicit in article 4 of the Security Pact, by which Great Britain and Italy were committed to declare war on Germany if Germany attacked France, and to declare war on France if France attacked Germany.

Content of Treaties.—The instruments consisted of (1) a treaty of mutual guarantee between Germany, Belgium, France, Great Britain and Italy; (2) two arbitration conventions between Germany on the one side and Belgium and France severally on the other, and two arbitration treaties between Germany on one side and Poland and Czechoslovakia severally on the other; (3) a collective note of the "Allies" to Germany explaining the implications of article 16 of the League Covenant; and (4) two treaties of guarantee between France on the one side and Poland and Czechoslovakia severally on the other.

The treaty of mutual guarantee, or Security Pact, provided in its main purport (1) that the parties guaranteed the inviolability of the German-Belgian and the German-French frontiers as fixed by the Treaty of Versailles (article 1); (2) that Germany, Belgium and France undertook never to attack, invade or wage war against each other except in "legitimate defence" or as a result of a League of Nations obligation (article 2); (3) those three countries undertook to settle their disputes by pacific means (article 3); (4) in case of an alleged breach of article 2 above each of the five contracting parties undertook to come to the defence of the party adjudged by the League of Nations to be the party attacked, or in the case of a "flagrant" violation, to come immediately to the defence of the party attacked (article 4). The particular treaties between France and her eastern associates provided for mutual support against unprovoked attack resulting from a failure of the Security Pact.

In the year following the signing of the treaties the two main practical consequences that logically were to be expected were (1) the evacuation of the occupied Rhinelands and (2) Germany's entry into the League of Nations. Both those contingencies were connoted by the restoration of equal status between Germany and her former enemies. Germany duly entered the League of Nations in Sept. 1926.

Early in March, 1936, Germany broke the Pact of Locarno by marching troops into the Rhineland as a preliminary to fortifying the demilitarised zone. Germany sought to justify her action by arguing that France had changed the situation, including the Pact, by entering into an alliance with Soviet Russia. No restraining action was taken against Germany which, in effect, meant the acceptance by the Council of the League meeting in London.

LOCH, HENRY BROUGHAM LOCH, 1st Baron (1827–1900) M.P., of Drylaw, Midlothian, was born May 23, 1827. After two years' naval service, he entered the East India company's military service, and in 1842 was commissioned in the Bengal light cavalry. In the Sikh war in 1845 he served on the staff of Sir Hugh Gough. In 1852 he became second in command of Skinner's Horse. At the outbreak of the Crimean war in 1854, Loch left India, and raised a body of irregular Bulgarian cavalry, which he commanded throughout the war. In 1857 he was appointed attaché to Lord Elgin's mission to the East, was present at the taking of Canton, and in 1858 brought home the treaty of Yedo. In April 1860 he again accompanied Lord Elgin to China, as secretary of the new embassy sent to secure the execution by China of her treaty engagements. The embassy was backed up by an allied Anglo-French force. With H. S. Parkes he negotiated the surrender of the Taku forts. During the advance on Peking Loch was chosen with Parkes to complete the preliminary negotiations for peace at Tungchow. They were accompanied by a small party of officers and Sikhs. On the discovery that the Chinese were planning a treacherous attack on the British force, Loch rode back and warned the outposts. He then returned to Parkes and his party under a flag of truce. All were made prisoners and taken to Peking, where the majority died from torture or disease. Parkes and Loch were at first put in irons, but were afterwards more leniently treated. After three weeks their release was agreed, but they had only been liberated ten minutes when orders were received from the Chinese emperor, then a fugitive in Mongolia, for their immediate execution. Loch never entirely recovered his health after his experience in a Chinese dungeon. Returning home he was made C.B., and for a while was private secretary to Sir George Grey, then at the Home Office. In 1863 he was appointed lieutenant-governor of the Isle of Man. In 1882 Loch accepted a commissionership of woods and forests, and two years later was made governor of Victoria. In June 1889 he succeeded Sir Hercules Robinson as governor of Cape Colony and high commissioner of South Africa.

As high commissioner his duties called for the exercise of great judgment and firmness. The Boers were at the same time striving to frustate Cecil Rhodes's schemes of northern expansion and planning to occupy Mashonaland, to secure control of Swaziland and Zululand and to acquire the adjacent lands up to the ocean. Loch firmly supported Rhodes, and, by informing President Kruger that troops would be sent to prevent any invasion of territory under British protection, he effectually crushed the "Banyailand trek" across the Limpopo (1890–91). Loch, however, with the approval of the imperial government, concluded in July–August 1890 a convention with President Kruger respecting Swaziland, by which, while the Boers withdrew all claims to territory north of the Transvaal, they were granted an outlet to the sea at Kosi bay on condition that the republic enter the South African Customs union. This convention was concluded after negotiations conducted with Kruger by J. H. Hofmeyr on behalf of the high commissioner, and was made at a time when the British and Bond parties in Cape Colony were working in harmony. The Transvaal did not, however, fulfil the necessary condition, and in view of the increasingly hostile attitude of the Pretoria administration to Great Britain Loch advocated the annexation by Britain of the territory east of Swaziland, through which the Boer railway to the sea would have passed. He induced the British government to adopt his view and on March 15, 1895, it was announced that these territories (Amatongaland, etc.), would be annexed by Britain. Meantime Loch had travelled to Pretoria to use his personal influence with President Kruger on behalf of the Uitlanders, and obtained the withdrawal of the obnoxious commandeering regulations. In the following year he entered a strong protest against the new Transvaal franchise law. In 1895 he returned home and was raised to the peerage. He died in London on June 20, 1900.

LOCHABER, a district of southern Inverness-shire, Scotland, to the east of Loch Linnhe. The scenery is wild and beautiful, Ben Nevis being the chief mountain. The Lochaber hydro-electric scheme is designed to make use of a catchment area of 303 sq.m. extending from the head of Loch Linnhe north-eastward to Laggan, with a power-house close to Fort William.

LOCHES, a town in France, capital of an arrondissement of Tours, in the department of Indre-et-Loire, 29 mi. S.E. of Tours by rail, on the left bank of the Indre. Pop. (1936) 3,585. Loches (the Roman *Leucae*) grew up round a monastery founded about 500 by St. Ours and belonged to the counts of Anjou from 886 until 1205, when it was seized from King John of England by Philip Augustus, and from the middle of the 13th century until after the time of Charles IX the castle was a residence of the kings of France. The picturesque town lies at the foot of the rock on which stands the castle of the Anjou family, surrounded by an outer wall and consisting of the old collegiate church of St. Ours, the royal lodge and the donjon. The church of St. Ours (10th, 12th centuries) has huge stone pyramids surmounting the nave and a beautifully carved west door. The royal lodge, built by Charles VII and used as the subprefecture, contains the tomb of Agnès Sorel and the oratory of Anne of Brittany. The donjon includes, besides the ruined keep (12th cent.), the Martelet, celebrated as the prison of Lodovico Sforza, duke of Milan, who died there in 1508, and the Tour Ronde, built by Louis XI and containing the famous iron cages in which state prisoners were confined.

Beaulieu ès-Loches, suburb of Loches, contains the remains of the 11th century abbey church of the Holy Sepulchre. The chancel is of the 15th century. The Romanesque nave is in ruins, but one tower is intact.

LOCHGELLY, a small burgh, Fifeshire, Scotland, 7½ mi. N.E. of Dunfermline by the L.N.E. railway. Pop. (1938) 9,238. The town is modern and owes its prosperity to the iron works and collieries in its immediate vicinity. Loch Gelly, from which the town takes its name, is situated ½ mi. S.E., and has on its west bank Lochgelly House, a seat of the earl of Minto. To the N.E. rises the hill of Benarty (1,131 ft.). Hallyards, about 2 mi. S.E. of Lochgelly, is a ruined house that once belonged to Sir William Kirkaldy of Grange, who held Edinburgh castle for Queen Mary. Here James V was received after his defeat at Solway Moss in 1542.

LOCHGILPHEAD, a small burgh of Argyllshire, Scotland, at the head of Loch Gilp, a small arm on the western side of Loch Fyne. Pop. (est. 1938) 1,082. The herring-fishery is the chief industry, but there is some weaving of woollens and, in summer, a considerable influx of visitors.

LOCHMABEN, a royal and small burgh in Dumfriesshire, Scotland, 8 mi. N.E. of Dumfries, with a station on the L.M.S. railway company's branch from Dumfries to Locherbie. Pop. (1938) 1,045. It is delightfully situated as a holiday resort, with several lakes, the river Annan and the Waters of Ae, Kinnel and Dryfe in the neighbourhood. In the parish church is a bell said to have been presented to Robert Bruce by the pope after reconciliation with him. A statue of the king stands in front of the town hall and at the south end of Castle Loch are the ruins of Lochmaben castle, dating from the 13th century, where local tradition declares that Bruce was born. In any case Bruce was closely associated with Lochmaben. He exempted his followers in the district from feudal service and their descendants—the "kindly tenants of Lochmaben"—were confirmed in their tenure by the court of session in 1824. The Castle Loch is the only fresh water in Scotland, and possibly in the British Isles, where the vendace occurs. This fish is netted in August, and esteemed as a delicacy. Lochmaben is famous for curling, and a team entirely composed of shoemakers (souters) who held their own against all comers once added the phrase "to souter" to the vocabulary of the sport, the word indicating a match in which the winners scored "game" to their opponents' "love."

LOCHNER, STEPHAN (*c.* 1400–1451), German painter, the most distinguished representative of the Cologne school. He came to Cologne from Meersburg on the Lake of Constance about 1430. Archives prove that he bought houses in Cologne in 1442 and 1444, that in 1447 and 1450 he was elected a councillor by his gild and that he died in 1451. The painter's name has been preserved to us by an entry in the diary of Dürer, who, on his way to the Netherlands, stopped at Cologne and paid two *weisspfennige* to see the famous altarpiece which Lochner had painted for the chapel of the town hall. This triptych is now in Cologne cathedral. The Virgin, friendly and majestic, sits in the midst with the Child. Around are the three kings, patrons of Cologne, and their followers. On the wings are the saints of Cologne, on one side Ursula with her company of English maidens, on the other Gereon with his fellows of the Theban Legion. The outside wings, now in the Cologne museum, show an Annunciation, beautifully spaced. The background is diapered gold, and a florid arcade of carved wood runs across the top of the panels. Compared with the earlier work of the Cologne school, this altarpiece constitutes a step towards naturalism and plasticity. The old Cologne ideal of graceful line and pattern design are sacrificed to truth of form. The heads are lifelike; the men wear the steel and chain armour of Burgundian knights, and the ladies are in the costly costumes of a 15th century court. It is suggested that the artist received his early training in the same school, which under Burgundian influence, produced his contemporary, the strong and realistic Conrad Witz, on the Lake Constance. Moreover, between 1414 and 1418 the famous Council met at Constance which elected Pope Martin V., the art loving patron of Fra Angelico. Constance was then a great gathering place of famous people, and young Lochner must have witnessed many a court display and seen many a fine work of art. On the other hand, the realistic tendency in his art may have been a reflection from the Netherlands. Cologne stood in close relation with the Low Countries, where the Van Eycks were carrying everything before them, and where Campin was founding his school.

To the Cologne school Lochner owed his love for rich colour, for grace and splendour. He was so completely absorbed that he became Cologne's most famous artist. Other works by the artist are "the Virgin and Child in the Rose Bower surrounded by Angels Playing Music," and "the Virgin Crowned by Angels in the Garden of Paradise," both in the Wallraf-Richartz museum of Cologne. "The Virgin handing a Violet to the Child with a small Kneeling Figure of Elsa von Reicherstein" is now in the Archiepiscopal museum at Cologne. He is at his best in these representations of the Virgin as a fair and gentle maiden seated in rose gardens with saints and angels playing music, an interpretation reminiscent of the Minnesinger's worship, which was favoured by the Rhineland mystics. The Museum of Darmstadt has a "Presentation of Christ in the Temple" (1447) of very fine quality. There are small panels with "standing saints" at the Munich, London and Cologne museums. "The Last Judgment," also at the Cologne museum, is most succesful in the part which depicts the procession of saints passing through a late Gothic portal leading to heaven—while his interpretation of hell is unconvincing and burlesque.

His work forms the transition from the Gothic to naturalism. He was a lyric poet, and he preserved some of the old grace of sentiment and line of the old school. His school continued to about 1466. To it are ascribed the paintings of the legend of St. Ursula in the church of that saint at Cologne, and a Crucifix dated 1458 in the Cologne museum. His style can be traced also in several stained glass windows of the city.

See Ludwig Scheibler and Carl Aldenhoven, *Geschichte der Kölner Malerschule* (Lübeck, 1902).

LOCK, MATTHIAS, English 18th-century furniture designer and cabinet-maker. The dates of his birth and death are unknown. He was a clever craftsman, a disciple of Chippendale, and was possibly in partnership with Henry Copeland (*q.v.*). He belonged to that flamboyant school which derived its inspiration from Louis XV. models, until he fell under the classical influence of Robert Adam so completely that it is often difficult to distinguish between them. Many of his original drawings are preserved in the Victoria and Albert Museum, South Kensington, while the pieces themselves are often bolder and more solid than is suggested by the author's representations of them.

Among his works, some of which were issued in conjunction with Copeland, are: *A New Drawing Book of Ornaments* (n. d.); *A New Book of Ornaments* (1768); *A New Book of Pier Frames, Ovals, Girandoles, Tables, etc.* (1769); and *A New Book of Foliage* (1769).

LOCK. A mechanical device for securely fastening a door or lid, usually including a sliding bolt which may be shot by a removable key.

The Egyptian locksmith was probably the first whose products have been preserved. One of his locks was found in the ruins of Nineveh, and was apparently used to secure the door of a room in the Palace of Khorsabad. Isaiah probably referred to a similar lock when he said "and the key of the house of David will I lay upon his shoulder" (xx. 22). Fig. 1 shows an Egyptian lock dismantled. Both the lock and the key are constructed entirely of wood.

The vertical piece of wood, the staple, is fixed to the door post and contains in the upper part movable pins, in this case six in number; the cross piece is the bolt. The pins in the staple fall into corresponding holes in the bolt and so prevent the latter moving until they are raised to the level of the top of the bolt by pins fixed on the key. Only the key made specially to fit the lock could operate it and quite a reasonable degree of security was achieved. This lock, the earliest of which the construction is known, is as will be seen later, the prototype of the modern cylinder lock.

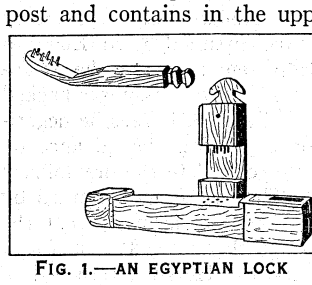

FIG. 1.—AN EGYPTIAN LOCK

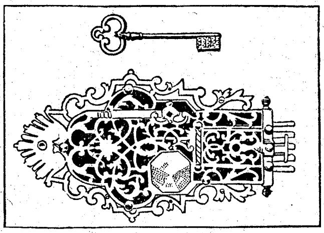
Next in order came the fabricator of the "doore fastenings of dyverse colours made of brass and ivory," of ancient Rome, followed by the maker of the still more elaborate *Serrure de Tabernacle* in the mediaeval age, immortalised in early Christian missals. The Chinese locksmith also made "strange instruments "having wooden slides," the architecture of which was peculiarly adapted to the Summer House of willow pattern fame. In England, by the time of Queen Elizabeth, the operations of the craft were fully established "in the townes of Staffordshire, to wit, Wolverhampton, Willenhall and Wednesbury."

The mediaeval period up to the late 18th century produced locks of very beautiful design as regards their exterior cases, but small attention was paid to security and convenience. Fig. 2 is a 17th century lock of French origin. It measures $17\frac{1}{4}''\times 9\frac{1}{2}''$ and the key is $7\frac{3}{4}''$ long. Fig. 3 shows a lock $14''\times 8''$ which belonged to Henry VIII. It is said that wherever he went the lock went with him and was screwed to his bedroom door.



BY COURTESY OF PARKES & SONS

FIG. 2.—17TH CENTURY LOCK AND KEY FROM TOURNEY. AIX-LA-CHAPELLE

Modern Improvements and Inventions.—A study of the history of locks reveals the fact that their design has followed the various periods of art until, in the 20th century, utility has almost entirely displaced the beautiful specimens of earlier days. Until Robert Barron in 1778 invented his double acting tumbler lock, security depended on immovable obstructions fixed inside the lock. The single acting tumbler (fig. 4) gave practically no security as, so long as the tumbler was lifted high enough for the talon on the bolt to pass underneath, the bolt was free to move. Many cheap door locks are, however, still made with this single acting tumbler.

In England and America a ward is added for greater security, and on the Continent of Europe and in America the key-hole in the case of the lock is of a peculiar design. The most common wards are: (1) Sash (fig. 5) (2) Fine (3) Solid. A Sash ward is the most used on account of its adaptability in conjunction with levers. It is made of brass, and has circular steps which vary in height, so that many different combinations may be obtained. This ward is fixed on the inside of both the case and the cap of a door lock. Fine and Solid wards are fixed in the middle of the lock, the former made of steel and the latter of brass.

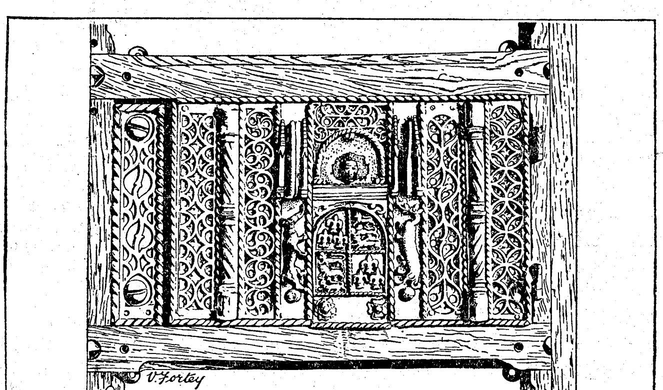


FIG. 3.—THE BEDDINGTON LOCK, OF THE EARLY 16TH CENTURY

Barron's lock could only be opened by a key which lifted both the tumblers to an exact height, so that the talon on the bolt could pass through. A modern lever works upon this same principle, and nearly all best quality locks are now made with one or more levers.

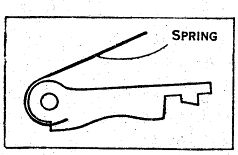

FIG. 4.—TUMBLER LOCK

English Lever Locks.—In 1818 Jeremiah Chubb patented his detector lock, since which no great improvement in the security of locks has been made. It is constructed of several levers, usually at least six, which are protected by what is termed a "detector" lever, which comes into operation if any key other than the correct one is used in an attempt to open the lock. The "detector" lever in that event is lifted too high, where it remains until the correct key is turned in the reverse direction, when the lock may again be operated. The owner of the correct key is informed by this means when some unauthorized person has tampered with his lock.

It was as a result of this invention that the modern English lever was brought into general use. Different combinations, which are almost unlimited, are obtained by raising or lowering the position of the horizontal slot, or gate, through which passes the talon on the bolt. The correct key will raise the lever (shown in its lower position in fig. 6) so that the talon (c) on the moving bolt will pass through the gate (b). An American named Hobbs invented the safety lever.

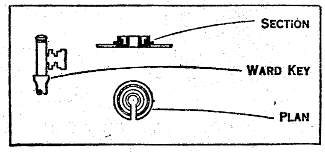

FIG. 5.—SASH WARD

Linus Yale's Cylinder Lock 1848.—The other outstanding invention is that of Linus Yale, an American, who, in the year 1848 conceived the idea of adapting the Egyptian lock to modern requirements. To do this he brought about a revolutionary change by separating the key mechanism from the lock itself, thereby making it possible for a very small key to be used, as it did not have to pass through the door. The cylinder (*see* fig. 7) or the part in which the key operates, consists of an outer barrel which is fixed to the door and a cylindrical plug which is rotated by the key and has a tongue on its back end which projects into the lock. The upper pins, five in number, in the fixed part of the cylinder, fall down into corresponding holes in the plug, which contains five similar pins which are raised to the level of the circumference of the plug by the correct key, the top pins being kept in the required position by means of phosphor bronze springs, *vide* fig. 7. If a key is inserted which does not raise the pins in the plug to the required height, the plug cannot be turned.

A further degree of security is provided by the irregular shape of the key. The notches of the average key may be cut in eight depths, so that, as there are five notches, the number of different keys possible is eight to the power of five, *i.e.*, 32,768. The notches are cut automatically in a milling machine to the required depth, and the pins in the plug are made afterwards to correspond.

Still a further number of key changes is obtained by milling grooves lengthwise on the sides of the keys to correspond with similar grooves in the keyway in the plug. By varying the shape and location of these grooves quite a large range of key changes are made possible.

The illustration (fig. 8) is of the most common form of cylinder lock, *i.e.*, the cylinder rim night latch, the term meaning a spring bolt cylinder lock operated by a key from outside and a knob from inside. This lock is almost universally accepted as a front or street door lock. The invention was therefore of great importance. It is the cheapest lock offering such a degree of security and having so many differing keys. The invention of Joseph Bramah, in 1784, of a lock also depending for its security on moving parts, has to a large extent fallen into disuse, but Bramah's name was an important one in the trade when he placed his patent on the market.

Keyless Locks.—There are several kinds of keyless locks, the two principal being those which are operated by an arrangement of letters or numbers, and special safe locks which are made to open only at a given time. In both cases the opening position in the disc or levers is achieved without the aid of a key. It is usual in the case of time locks to make use of three watch movements, in order to reduce to a minimum the possibility of failure which would be likely to occur if only one were used. The movements are wound up until the time at which the safe is to be opened is indicated on the clock faces inside the lock. When the lock is set in this manner it automatically goes off guard at the appointed hour, allowing the safe then to be opened.

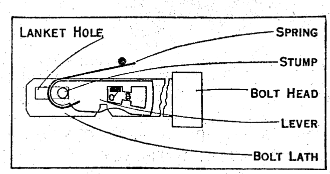

FIG. 6.—ENGLISH LEVER

The growth of safe deposits from the latter half of the 19th century has necessitated the design of special locks, one of the conditions required being that each locker should be opened only by the renter and the guardian together. These are termed duplex key action locks, a number being operated through a single keyhole and others through two. Another variety of safe deposit lock has changeable keys, *i.e.*, all the locks are identical in every respect, but all keys are different. Any lock may be set to any key by the simple action of locking out the bolt with the desired key, which then becomes the only key which will unlock until the lock is set to another key.

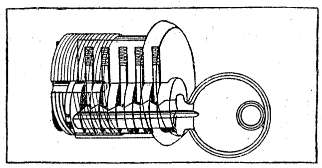

FIG. 7.—PIN TUMBLER CYLINDER WITH ITS CORRECT KEY

Construction of Modern Locks.—Most door locks are used to keep the door in a shut position besides securing it. Indeed this is one of the principal functions of a lock, and for this purpose it is provided with a bevelled spring bolt which is operated by a knob or lever handle, the dead bolt being thrown out or withdrawn by the key. The method of moving this spring bolt is called the "action" of the lock, and upon the action the easy and sweet closing of the door depends. When it is considered the different sizes, weights and types of doors that are in use, it will be understood that many different kinds of actions must be designed so that the lock may correctly perform its function.

In England, because the doors are provided with a lock rail, or style, below the middle line of the door, horizontal rim and mortice locks (usual size 6″ long$\times 3\frac{1}{2}'' \times \frac{1}{2}''$) are generally used.

The three most common actions employed in medium quality door locks are the Palace motion (fig. 9), the Easy action and the Scotch spring (fig. 10) types. The action in figure 12 is termed "Easy," because the striking plate on the door post pushes back the bolt against only one of the springs, but when the knob is turned both the feather and the coil springs come into operation. The Scotch spring in figure 10 is riveted at the end further away from its point of operation, so that the movement of the spring being very small, its life is long.

On the Continent of Europe and in South America doors are made with one large panel, and so the type of lock in use to meet this style is a high upright lock, the usual size being $3'' \times 6''$ high$\times \frac{1}{2}''$. The latch bolt is operated in this lock by spiral springs and can be made easy or hard as required.

In America the doors are made with six or more panels, and the rails, or stiles, are too small to take a lock, so that a small upright lock, usually $3'' \times 3\frac{1}{2}''$ high$\times \frac{3}{8}''$ is fitted inside the frame. The American action is as a rule of the "Easy" type, involving the use of two or more coil springs. A typical action is illustrated in figure 12.

The three principal lock producing countries of the world are England (6,000 operatives), United States of America (9,000 operatives), and Germany (7,500 operatives). Each country has her own special types of padlocks and cabinet locks, as well as of door locks.

Locks Arranged in Groups.—It has been estimated that there are upwards of 150 locks of all kinds in use in and about a 20th century house of average size. Locks are also required for many other purposes, involving a large variety of patterns. For the sake of cataloguing they are divided into four main groups.

1. *Rim locks*—all locks in this group are fixed to the surface of door.
2. *Mortice locks*—which are, as the name implies, fixed in the door.
3. *Padlocks*—the origin of this word being descriptive of their function. The word "pad" is taken from "foot-pad," as this type of hanging lock was used to secure packages being transported on the old-fashioned pack-horse, when road thieves abounded.
4. *Cabinet locks*—which term includes the whole range of locks used on household furniture.

In addition there are the safe locks referred to above which are almost a separate branch of the trade. All these groups are subdivided into many sections, the varieties of size, finish and quality in each one being very large. One English manufacturer alone offers 1,250 different kinds.

Modern Methods of Manufacture.—Great changes have taken place in the manufacture of medium quality locks in the last 25 years. These changes are not dissimilar from those which have evolved in all other metal working industries, and have been brought about by the increased use of machinery and the necessity for cheap production. To some extent manufacturers are endeavouring to standardize their products. It may be that an action is fitted into several different cases, and that one type of case may be suitable for several different actions. Costs of production are reduced in this way, fewer parts being made and a greater quantity of each part, this lending itself to mass production methods. In some locks there are as many as fifty separate parts, each of which must be accurately made, in order that it may successfully perform its function.

SEVERAL TYPES OF MODERN LOCKS
Fig. 9, Palace motion; fig. 10, Scotch spring action; fig. 11, Continental type action; fig. 12, easy action for upright locks

Until the end of the 19th century almost all locks were hand made by skilled craftsmen, whose title of "locksmith" conveys the true idea that his art is a branch of the ancient art of blacksmithing of earlier times. The skilled men of the trade are now, to a large extent, located in the toolroom, which has become the heart of the modern factory. The drawing office also plays an important part. Not only is it responsible for the design of the lock, both as regards its external and internal parts, but it is there that the charts of numbers are prepared from which the keys of a suite of locks are made, so that very little responsibility rests upon the operator of the machine making the parts, or on the assembler. Unskilled labour is employed in assembling the machined parts but there are, nevertheless, a considerable number of skilled craftsmen in the trade who make the heavier types of locks. Their labours are, however, lightened by machines which perform many operations for them which until recently were done by hand. Owing to the comparatively small sale of these heavier locks, the cost of manufacture of tools for their production would more than counter-balance the resultant saving in assemblers' wages.

The materials used in the manufacture of locks vary with the type, quality and the purpose for which the lock is required. Medium quality rim and mortice locks are of cast iron or steel cases, with brass bolts, wards and levers. Padlocks are made of steel, pressed brass, cast brass, bronze, grey iron or malleable iron, and cabinet locks of steel, pressed brass or cast brass.

Suites or sets of locks are made in several different ways, three of the most important being:—

1. All to pass, *i.e.*, all keys and locks identical.
2. All with different keys.
3. All to differ and yet controlled by a master key. A variation of this is often employed for flats, the front doors of the flats having locks with keys all different from each other but each key opening the street door lock.

There are many methods adopted in the trade for making such suites as these, depending on the types of locks used.

The selling price of a lock varies from the cheapest padlock at 2d. each, to a lock used on a Banker's strong-room door worth perhaps £100, but the price of an average household door lock is about 3/- to 4/- each. It has been estimated that there are 50,000,000 locks produced in the world every year. (A. J. Pa.)

LOCK, in canal or dock engineering, a watertight chamber, closed by gates at each end, used as a means of transferring vessels from one level or reach of a canal or canalized river to another; or at the entrance of a dock to enable vessels to be raised from a lower to a higher level, or vice versa. The largest lock in the world is that completed in 1928 to serve as a new entrance to the North Sea–Amsterdam ship canal at Ymuiden. It is 1312 feet long and 164 feet wide internally. Entrance locks are not usually embodied in the construction of dock works unless the range of tide is considerable, exceeding 14ft. or thereabouts. An analogous principle is used in compressed air working where *air-locks* are employed for the transfer of men and materials from atmospheric to higher pressures and vice versa. (*See* CANALS AND CANALIZED RIVERS; DOCKS.) (N. G. G.)

LOCKE, JOHN (1632–1704), English philosopher, was born on Aug. 29, 1632, at Wrington, Somersetshire. His father, a small landowner and attorney, was a strict but genial Puritan and fought on the parliamentary side in the Civil War. The relations between father and son were ideal, and left their mark on Locke's educational theory. In 1646 he entered Westminster school. Probably the warnings in the *Thoughts on Education* against learning by rote and against beginning the study of languages by grammar were suggested by his own experiences at school. In 1652 he entered Christ church, Oxford, then under John Owen, the Puritan dean and vice-chancellor of the university. For some years after he entered, Oxford was ruled by the Independents, who were among the first in England to advocate religious toleration. But Locke's hereditary sympathy with the Puritans was gradually lessened by the intolerance of the Presbyterians and the fanaticism of the Independents, and he had no use for the scholastic philosophy still taught at Oxford. In 1660 he was serving as tutor of Christ Church, lecturing in Greek, rhetoric and philosophy. The works of Descartes gave him a relish for philosophy, although he often differed from them. We find him experimenting in chemistry in 1663, also in meteorology, in which he was always interested. Locke's religious disposition attracted him to theology, but as there was no place for free enquiry in the Anglican Church after the Restoration, he decided on medicine as a profession. Then began his friendship with Robert Boyle and with Sydenham. Sydenham adopted empirical methods in medicine, just as Boyle did in chemistry, and Locke, during his very short experience of medicine, frequently accompanied Sydenham on his rounds.

In 1666, soon after his return from accompanying Sir Walter Vane on his mission to the elector of Brandenburg, Locke met Lord Ashley, afterwards first earl of Shaftesbury. This was the beginning of a lasting friendship, sustained by common sympathy with liberty—civil, religious and philosophical. In 1667 he moved to Exeter House, Lord Ashley's London residence, to become his confidential secretary. Although he retained his studentship at Christ church, he found a home with Shaftesbury for 15 years.

Locke's commonplace books throw welcome light on the history of his mind in early life. A paper on the "Roman Commonwealth" which belongs to this period, expresses convictions about religious liberty and the relations of religion to the State that were modified and deepened afterwards; objections to the sacerdotal conception of Christianity appear in another article; short work is made of ecclesiastical claims to infallibility in the interpretation of Scripture in a third; a scheme of utilitarian ethics, wider than that of Hobbes, is suggested in a fourth. The most significant of those early revelations is the *Essay concerning Toleration* (1666), which anticipates conclusions more fully argued nearly 30 years later.

At Exeter House Locke held informal reunions to discuss debatable questions in science and theology. One of these, in 1670, is historically memorable. "Five or six friends," he says, were discussing "principles of morality and religion. They found themselves quickly at a stand by the difficulties that arose on every side." Locke proposed to attempt some criticism of the necessary "limits of human understanding," and fancied that "one sheet of paper" might suffice. What was thus "begun by chance, was continued by entreaty, written by incoherent parcels, and, after long intervals of neglect, resumed again as humour and occasions permitted." In 1690, the issue was given to the world as the *Essay Concerning Human Understanding*.

The fall of Shaftesbury in 1675 drove Locke from English political circles to France, where he spent three years, partly at Montpellier and partly in Paris.

In Paris he met men of science and letters—Peter Guenellon, the well-known Amsterdam physician; Ole Römer, the Danish astronomer; Thoynard, the critic; Melchisédech Thévenot, the traveller; Henri Justel, the jurist; and François Bernier, the expositor of Gassendi. But there is no mention of Malebranche, whose *Recherche de la vérité* had appeared three years before, nor of Arnauld. In 1679 Locke resumed his old relations with Shaftesbury, at Thanet House in Aldersgate, London. It was a time of plots and counterplots, and in the end Shaftesbury was committed to the Tower, tried and acquitted. More insurrectionary plots followed in 1682, after which, suspected at home, the versatile statesman escaped to Holland, and died at Amsterdam in Jan. 1683. In these two years Locke was much at Oxford and in Somerset, for the later activities of Shaftesbury did not commend themselves to him. The letters of Prideaux and of John Fell show that Locke was suspected at court. Correspondence with his Somerset friend, Edward Clarke, of Chipley, describes Locke's life in those troubled years, and reveals the opening of his intimate intercourse with the Cudworth family. The letters allude to toleration in the State and comprehension in the Church, and show an indifference to theological dogma.

In 1683, Locke retired to Holland, then the asylum of exiles in search of liberty of thought. Descartes and Spinoza had speculated there; it had been the home of Erasmus and Grotius; it was now the refuge of Bayle. Locke spent more than five years there. For a time he was in danger of arrest at the instance of the English Government. After months of concealment at Amsterdam, under the assumed name of Dr. Van der Linden he escaped; but he was deprived of his studentship at Christ Church by order of the king, and Oxford was thus closed against him. In Holland he met Limborch, the successor of Episcopius as Remonstrant professor of theology, and Le Clerc, whose *Bibliothèque universelle* was then the chief organ in Europe of men of letters. Locke contributed several articles. It was his first appearance as an author, although he was now 54 years of age. The *Essay* was finished in Holland, and a French epitome appeared in 1688 in Le Clerc's journal, the forecast of the larger work. Locke was then at Rotterdam, where he was a confidant of political exiles, including Burnet and the earl of Peterborough, and he became known to William, prince of Orange. William landed in England in Nov. 1688; Locke followed in Feb. 1689, in the ship which carried the princess Mary.

WHEN HE BECAME FAMOUS

After his return to England Locke emerged into European fame. Within a month after he reached London he had declined an offer of the embassy to Brandenburg, and accepted the modest office of commissioner of appeals. His defence of religious liberty, in the *Epistola de Tolerantia,* was published at Gouda in the spring of 1685, and translated into English in autumn by William Popple, a Unitarian merchant in London. *Two Treatises on Government,* in defence of the right of ultimate sovereignty in the people, followed a few months later. The intention of the treatises was to "establish the throne of our great restorer, the present King William, to make good his title in the consent of the people." The famous *Essay concerning Human Understanding* appeared early in 1690. He received £30 for the copyright.

The course of public affairs disappointed him, for the settlement at the Revolution fell short of his ideal of toleration and civil liberty. In spring, 1691, he went to live at Oates Manor in Essex, the country seat of Sir Francis Masham. Lady Masham was the accomplished daughter of Ralph Cudworth, and was his friend before he went to Holland. At Oates he enjoyed for 14 years as much domestic peace and literary leisure as was consistent with broken health, and sometimes anxious visits to London on public affairs. In his letters and otherwise we have pleasant pictures of its domestic life and the occasional visits of his friends, among others Lord Peterborough, Lord Shaftesbury of the *Characteristics,* Sir Isaac Newton, William Molyneux and Anthony Collins.

The *Letter on Toleration* involved him in controversy. An *Answer* by Jonas Proast of Queen's college, Oxford, had drawn forth in 1690 a *Second Letter.* A rejoinder in 1691 was followed by Locke's elaborate *Third Letter on Toleration* in the following year. In 1692 he also addressed an important letter to Sir John Somers on the *Consequences of the Lowering of Interest and Raising the Value of Money.* When he was in Holland he had written letters to his friend Clarke of Chipley about the education of his children. These letters formed the substance of the little volume *Thoughts on Education* (1693), which remains an educational classic. Nor were the "principles of revealed religion" forgotten. The subtle theological controversies of the 17th century made him anxious to show the simplicity of fundamental Christianity. In the *Reasonableness of Christianity as delivered in the Scriptures* (anon., 1695), Locke sought to separate the essence of the teaching of Jesus from later accretions. This involved him in controversies that lasted for years, and his *Vindication,* followed by a *Second Vindication* in 1697, added fuel to this fire. Above all, the great *Essay* was assailed and often misinterpreted by philosophers and divines. John Norris, the metaphysical rector of Bemerton and English disciple of Malebranche, criticized it in 1690. Locke's second winter at Oates was partly employed in *An Examination of Malebranche's Opinion of Seeing all Things in God,* and in *Remarks upon some of Mr. Norris's Books,* tracts which throw light upon his own ambiguous theory of perception through the senses. These were published after his death. A second edition of the *Essay,* with a chapter added on "Personal Identity," and numerous alterations in the chapter on "Power," appeared in 1694. The third, a reprint, was published in 1695. Wynne's well-known abridgment helped to make the book known in Oxford, and his friend, William Molyneux, introduced it in Dublin. In 1695 a revival of controversy about the currency diverted Locke's attention. Events in that year occasioned his *Observations on Silver Money* and *Further Considerations on Raising the Value of Money.*

In 1696 Locke accepted a commissionership on the Board of Trade which entailed frequent visits to London. In the autumn of that year, Stillingfleet, bishop of Worcester, in his *Vindication of the Doctrine of the Trinity,* charged Locke with disallowing mystery in human knowledge, especially in his account of the metaphysical idea of "substance." Locke replied in Jan. 1697. Stillingfleet's rejoinder appeared in May, followed by a *Second Letter* from Locke, to which the bishop replied in the following year. Locke's *Third Letter* was delayed till 1699, in which year Stillingfleet died. One of the ablest of the other critics of the *Essay* was John Sergeant, a Catholic priest, in *Solid Philosophy Asserted Against the Fancies of the Ideists* (1697). He was followed by Thomas Burnet, Dean Sherlock and others. The *Essay* itself meanwhile spread over Europe, impelled by the name of its author as the chief philosophical defender of civil and religious liberty. The fourth edition appeared in 1700, with important additional chapters on "Association of Ideas" and "Enthusiasm." What was originally meant to form another chapter appeared among Locke's posthumous writings as *The Conduct of the Understanding,* one of his most characteristic works.

In 1700 Locke resigned his commission at the Board of Trade, and devoted himself to biblical studies and religious meditation. He turned to the Epistles of St. Paul, and applied the spirit of the *Essay* and the ordinary rules of critical interpretation to a literature which he venerated as infallible. The work, *A Paraphrase and Notes on the Epistles of St. Paul, etc.,* was published in 1706 and a tract on *Miracles,* written in 1702, also appeared posthumously. His last days were occupied in beginning a *Fourth Letter on Toleration,* never finished, in reply to an attack made by Jonas Proast in 1704. Locke died on Oct. 28, 1704, and was buried by the parish church of High Laver.

LOCKE'S WORKS

Locke's writings have made his intellectual and moral features familiar. Large, "round-about" common sense, intellectual strength directed by a virtuous purpose, not subtle or daring speculation, sustained by an idealizing faculty, is what we find in Locke. Defect in speculative imagination appears when he encounters the vast and complex final problem of the universe in its organic unity. He initiated criticism of human knowledge, and diffused the spirit of free enquiry and universal toleration which has since profoundly affected the civilized world. He has not bequeathed an imposing system, hardly even a striking discovery in metaphysics, but he is a signal example of the love of attainable truth for the sake of truth and goodness.

Social Economy.—Locke's works on social polity were written at a time when the principles of democracy and toleration were struggling with that of the divine right of kings, and when "the popular assertors of public liberty were the greatest engrossers of it too." "The state" with Locke was the outcome of free contract rather than a natural growth. He maintained that natural rights, among which he includes property and personal freedom, were in no way abrogated by the change from a state of nature to society. That the people, in the exercise of their sovereignty, have the right to govern themselves in the way they judge to be for the common good; and that civil government, whatever form it assumes, has no right to interfere with religious beliefs that are not inconsistent with civil society, is at the foundation of his political philosophy. He rested this sovereignty on virtual mutual contract on the part of the people themselves to be so governed. But the terms of the contract might be modified by the sovereign people themselves in accommodation to changing circumstances. He recommended harmonious co-operation with the civil magistrate in all matters of worship and government that were not expressly determined by Scripture. In the *Second Treatise on Government,* he maintained that civil rulers hold their power not absolutely but conditionally, government being essentially a moral trust, forfeited if the conditions are not fulfilled by the trustees. His *Treatises on Government* were meant to vindicate the Convention parliament and the English revolution, as well as to refute the ideas of absolute monarchy held by Hobbes and Filmer. They are classics in the library of English constitutional law and polity, and framed the principles afterwards embodied in the American War of Independence and the French Revolution.

Religious Views.—Locke's philosophical defence of religious liberty in the four *Letters of Toleration* show that a constant sense of the limits of human understanding was at the bottom of his arguments. He had no objection to a national establishment of religion, provided that it was comprehensive, and was organized to promote goodness; not to protect the metaphysical subtleties of sectarian theologians. The recall of the national religion to the simplicity of the Gospels would, he hoped, make toleration of Nonconformists unnecessary, as few would then remain. To the atheist Locke refuses full toleration, on the ground that social obligation can have no hold over him, for "the taking away of God dissolves all." He argued, too, against full toleration of the Roman Catholic Church in England, on the ground of its allegiance to a foreign sovereign. Belief is legitimately formed only by discernment of sufficient evidence; a man cannot determine arbitrarily what his neighbours must believe. Thus Locke's pleas rest upon his philosophical view of the foundation and limits of human knowledge.

Locke believed that he had established, philosophically, the existence of God and "natural" religion. Personally he added a sincere belief in revelation, and a profound reverence for Holy Writ. He sought for the original simplicity of Christianity and held that those who practically acknowledge the supremacy of Jesus as Messiah accept all that is essential. His own Christian belief, sincere and earnest, was more the outcome of the common sense which, largely through him, moulded the prudential theology of England in the 18th century, than of the nobler elements present in More, Cudworth and others of the preceding age.

Education.—Locke has his place among classic writers on education. In the *Thoughts on Education* imaginative sentiment is never allowed to weigh against utility; information is subordinate to the formation of useful character; the part which habit plays in individuals is always kept in view; the dependence of intelligence and character, which it is the purpose of education to improve, upon health of body is steadily inculcated; to make children happy in undergoing education is a favourite precept; accumulating facts without exercising thought, and without accustoming the youthful mind to look for evidence, is referred to as a cardinal vice. Wisdom more than much learning is what he requires in the teacher. The infinity of real existence, in contrast with the necessary finitude of human understanding and experience, is always in his thoughts. In his *Conduct of the Understanding* (posthumously published 1706) the pupil is invited to occupy the point at which "a full view of all that relates to a question" is to be had, and at which alone a rational discernment of truth is possible. The uneducated mass of mankind, he complains, either "seldom reason at all," or "put passion in the place of reason," or "direct their minds only to one part of the evidence." Hasty judgment, bias, absence of an *a priori* "indifference" to what the evidence may in the end require us to conclude, undue regard for authority, excessive love for custom and antiquity, indolence and sceptical despair are among the states of mind marked by him as most apt to interfere with the formation of beliefs in harmony with the Universal Reason that is active in the universe.

PHILOSOPHY

The well-known *Essay Concerning Human Understanding* embodies Locke's philosophy. It was the first extensive attempt to estimate critically the certainty and the adequacy of human knowledge when confronted with God and the universe. Excluding from his enquiry "the physical consideration of the mind," he sought to make a faithful report, based on an introspective study of consciousness, as to how far a human understanding of the universe can reach.

Locke saw that the ultimate questions about our knowledge and its extent *presuppose* questions about ideas. Without ideas knowledge is impossible. He uses the word *idea* in a peculiar way —"the term which, I think, stands best for whatsoever is the object of the understanding when a man thinks" or "whatever it is which the mind can be employed about." But ideas themselves are, he reminds us, "neither true nor false, being nothing but bare appearances," phenomena as we might call them. Truth and falsehood belong only to assertions or denials concerning ideas. That none of our ideas are "innate" is contended in book i. of the *Essay*. This means that the human mind, before any ideas are present to it, is a *tabula rasa*. This famous argument has been criticized as if it was a speculative controversy between empiricism and intellectualism, and for this, Locke himself is partly to blame; the phrase *tabula rasa* was misleading and seems to have been used to refute the Cambridge Platonists and Lord Herbert of Cherbury. What Locke really objects to is, that any of our supposed knowledge, even of the existence of God, or fundamental principles of morality, should claim immunity from free criticism. He believed that in attacking "innate principles" he was pleading for universal reasonableness instead of blind reliance on authority, and was thus, as he says, not "pulling up the foundations of knowledge," but "laying those foundations surer." When men heard that there were propositions that could not be doubted, it was a short and easy way to assume that what are only arbitrary prejudices are "innate" certainties.

Book ii. proposes that all human ideas, even the most complex and abstract and sublime, ultimately depend upon "experience." They come, either from the five senses or from reflective consciousness. He proposes to show that even those concerned with the Infinite depend at last on one or other of these two sources. To prove this, our thoughts of space, time, infinity, power, substance, personal identity, causality and others which "seem most remote from the supposed original" are shown to depend either on perception of things external, through the five senses, or on reflection upon operations of the mind within. Reflection, "though it be not sense, as having nothing to do with external objects," is yet, he says, "very like it, and might properly enough be called internal sense." But the suggestion that "sense" might designate *both* the springs of experience is misleading, when we find in the sequel how much Locke tacitly credits "reflection" with. The mind, in becoming gradually stored with its "simple ideas" is able to elaborate them in numberless modes; although it cannot invent or frame any new simple idea.

Qualities of Matter.—Chapter 8 of book ii. on "things and their qualities" looks like an interpolation in an analysis of mere "ideas." Locke here treats simple ideas of the five senses as qualities of outward things. And the sense data are, he finds, partly (*a*) revelations of external things themselves in their mathematical relations, and partly (*b*) sensations, boundless in variety, which are somehow awakened in us through contact with things relatively to their mathematical relations. Locke calls the former sort "primary, original or essential qualities of matter," and the others "secondary or derived qualities." The primary, which are quantities rather than qualities, are inseparable from matter, and virtually identical with the ideas we have of them. On the other hand, there is nothing perceived in the mathematical relations of bodies which in the least resembles their secondary qualities. If there were no sentient beings, the secondary qualities would cease to exist, "except perhaps as unknown modes of the primary, or, if not, as something still more obscure." On the other hand, "solidity, extension, figure and motion would," he assumes, "be really in the world as they are, whether there were any sensible being to perceive them or not." Thus Locke teaches that matter is something capable of being expressed in terms of mathematical quantity, and also in terms of our own sensations. A further step was to suggest the ultimate dependence of the secondary qualities of bodies upon "the bulk, figures, number, situation and motions of the solid parts of which the bodies consist," these mathematical or primary qualities "existing as we think of them whether or not they are perceived."

Chapters 13–28 of bk. ii. concern what may be called "crucial instances" in verification of its fundamental hypothesis of the dependence of human knowledge upon the simple ideas presented in our dual experience. Space, he says, appears when we use our senses of sight and touch; succession he finds "suggested" by all the changing phenomena of sense, and by "what passes in our minds"; number is "suggested by every object of our senses, and every thought of our minds, by everything that either doth exist or can be imagined." The modifications of which these are susceptible he reports to be "inexhaustible and truly infinite, extension alone affording a boundless field to the mathematicians." But the mystery latent in our ideas of space and time is, that "something in the mind" irresistibly hinders us from allowing the possibility of any limit to either. Thus Locke seems by implication to acknowledge something added by the mind to the original "simple ideas" of extension and succession; though he finds that what is added is not positively conceivable.

Substance and Causality.—Locke is too faithful to facts to overlook the ultimate mysteries in human experience. This is illustrated in his acknowledgment of the inconceivable that is at the root of our idea of Substance which he admits cannot be resolved into a mere succession of phenomena. The phenomena must be attributed to something, but he was perplexed by this "confused negative" idea. So for him the word substance means "only an uncertain supposition of we know not what." Our only positive idea is of an aggregate of phenomena.

Locke's thoughts about Causality and Active Power are especially noteworthy, for he rests our knowledge of God and of the external universe on those ultimate ideas. He is content to trace the idea of "cause and effect," to our "constant observation" that "qualities and finite substances begin to exist, and receive their existence from other beings which produce them." We find that this connection is what gives intelligibility to ceaseless and what seemed chaotic changes. Locke seems hardly to realize all that is implied in scientific prevision or expectation of change. Anything, as far as "constant observation" tells us, might *a priori* have been the natural cause of anything; and no finite number of "observed" sequences, *per se,* can guarantee universality and necessity. The idea of power, or *active* causation, on the other hand, "is got," he acknowledges, not through the senses, but "through our consciousness of our own voluntary agency, and therefore through reflection" (bk. ii. ch. 21). In bodies we observe no active agency, only a sustained natural order in the succession of passive sensuous phenomena. The true source of change in the material world must be analogous to what we are conscious of when we exert volition. Locke here unconsciously approaches the spiritual view of active power in the physical universe afterwards taken by Berkeley.

Ideas and Words.—The third book is concerned with Words, or the sensible signs of ideas. Here he analyses "abstract ideas," and instructively illustrates the confusion apt to be produced in them by the inevitable imperfection of words. He unfolds the relations between verbal signs and the several sorts of ideas; words being the means for enabling us to treat ideas as typical, abstract and general.

Fourfold Classification of Knowledge.—Bk. iv. on Knowledge proper and Probability describes knowledge as perception of relations among ideas; it is expressed in our affirmations and negations; and real knowledge is discernment of the relations of ideas to what is real. Here he is concerned with intuitive "judgment" and demonstrative "reasoning," also with judgments and reasonings about matters of fact and the narrow extent of knowledge. Knowledge is concerned either with (*a*) relations of identity and difference among ideas, as when we say that "blue is not yellow"; or (*b*) with mathematical relations, as that "two triangles upon equal bases between two parallels must be equal"; or (*c*) in assertions that one quality does or does not coexist with another in the same substance, as that "iron is susceptible of magnetical impressions, or that ice is not hot"; or (*d*) with ontological reality, independent of our perceptions, as that "God exists" or "I exist" or "the universe exists." The first sort is analytical; mathematical and ethical knowledge represents the second; physical science forms the third; real knowledge of self, God and the world constitutes the fourth.

Of these four knowable relations, which are strictly known either by mathematical demonstration or by intuition, the first is the only one in which our knowledge is coextensive with our ideas; we cannot be conscious at all without distinguishing, and every affirmation necessarily implies negation. The second sort of knowable relation is sometimes intuitively and sometimes demonstrably discernible. Morality, Locke thinks, as well as mathematical quantity, is capable of being demonstrated. Turning to concrete relations of coexistence and succession among phenomena—the third set of knowable relations—Locke finds the light of pure reason disappear; although these relations form "the greatest and most important part of what we desire to know." Man cannot attain perfect and infallible science of bodies. For natural science depends on knowledge of the relations between their secondary qualities on the one hand, and the mathematical qualities of their atoms on the other, or else "on something yet more remote from our comprehension." Now, as perception of these atoms and their relations is beyond us, we must be satisfied with inductive presumptions, for which "experimental verification" affords, after all, only conclusions that wider experience may prove inadequate.

Our knowledge under Locke's fourth category of relations—real existence—includes (*a*) intuitive perceptions of our own existence; (*b*) demonstrable certainty of the existence of God; and (*c*) actual perception of the existence of surrounding things, as long as, but only as long as the things are present to sense. "If I doubt all other things, that very doubt makes me perceive my own existence" (iv. 9. 3). Faith in the existence of God is virtually with Locke an expression of faith in the principle of active causality in its ultimate universality. Each person knows that he now exists, and is convinced that he had a beginning; with not less intuitive certainty he knows that "*nothing* can no more produce any real being than it can be equal to two right angles." His final conclusion is that there must be eternally "a most powerful and most knowing Being, in which, as the origin of all, must be contained all the perfections that can ever after exist," and out of which can come only what it has already in itself; so that as the cause of my mind, it must be Mind. There is thus causal necessity for Eternal Mind, or what we call "God." But the immanence of God in the universe is a conception foreign to Locke, whose habitual conception was of an extra-mundane deity. For Locke, nearly all that one can affirm or deny about "things external" is not knowledge but venture or presumptive trust. We have, strictly speaking, no "knowledge" of real beings beyond our own self-conscious existence, the existence of God, and the existence of objects of sense as long as they are actually present to sense. Accordingly, purely rational science of external Nature is, according to Locke, impossible. All our "interpretations of nature" are inadequate; only reasonable probabilities, not final rational certainties.

It was Locke's distinction to present to the modern world, in his own "historical plain method," perhaps the largest assortment ever made by any individual of facts characteristic of human understanding. Criticism of the presuppositions implied in those facts—by Kant and his successors, and in Britain more unpretentiously by Reid, all under the stimulus of Hume's sceptical criticism—has employed philosophers since Locke in the *Essay Concerning Human Understanding* collected materials that raised deeper philosophical problems than he tried to solve. Locke's mission was to initiate modern criticism of the foundation and limits of our knowledge. Hume negatively, and the German and Scottish schools constructively, continued what it was Locke's glory to have begun.

Bibliography.—There are numerous editions of Locke's collective works. The *Essay Concerning Human Understanding* has passed through some 40 editions (including that of A. C. Fraser, 2 vols., Oxford, 1894), besides being often translated and abridged, notably by A. S. Pringle-Pattison (1924). The two treatises *On Civil Government* were published in Everyman's Library (1924), and *The Educational Writings* were edited by J. W. Adamson (1912; 2nd ed., 1922). H. Ollion has published *Lettres Inédites de J. Locke à Nicholas Thoynard, Philip van Limborch et Edward Clarke* (1912), and B. Rand has edited *The Correspondence of Locke and Edward Clarke,* with a good biographical study (1927).

Biographies: J. Leclerc, *Éloge historique* in vol. vi. (1705), *Bibliothèque choisie,* printed in successive editions of Locke's works, based on material from personal knowledge and from Lady Masham; H. R. Fox Bourne, *The Life of John Locke* (2 vols., 1876).

Criticism and Commentaries: Leibnitz, *Nouveaux Essais sur l'entendement humain* (1765); V. Cousin, *La phil. de Locke* (1829); J. Brown, *Locke and Sydenham* (3rd ed., 1866); A. Campbell Fraser, *Locke* (in "Philos. Classics for Eng. Readers," 1890); A. Seth, "Epistemology in Locke and Kant," in *Philos. Review* (1893); C. Bastide, *John Locke* (Paris, 1907); S. Alexander, *Locke* (1908); papers on various aspects of Locke by C. Bacumker in *Archiv. für Gesch. der Philos.* (vol. xxxi., 2 pts., 1908–09), in *Philos. Jahrb.* (vol. xxi.); H. Ollion, *La phil. générale de Locke* (1909); J. Seth, *English Philosophers* (1912); E. Krakowski, *Les Sources médiévales de la phil. de Locke* (1915); J. Gibson, *Locke's Theory of Knowledge,* etc. (1917); S. P. Lamprecht, *The Moral and Political Philosophy of John Locke* (Columbia, 1918); W. R. Sorley, *Hist. of Eng. Philosophy* (1920); full bibliography in Überweg, *Gesch. der Philosophie,* vol. iii. (1914).

LOCKE, MATTHEW (*c.* 1630–1677), English musician, perhaps the earliest English writer for the stage, was born at Exeter, where he became a chorister in the cathedral. His music, written with Christopher Gibbons (son of Orlando Gibbons), for Shirley's masque *Cupid and Death,* was performed in London in 1653. He wrote some music for Davenant's *Siege of Rhodes* in 1656; and in 1661 was appointed composer in ordinary to Charles II. During the following years he wrote a number of anthems for the Chapel Royal, and excited some criticism on the score of novelty, to which he replied with considerable heat (*Modern Church Music; pre-accused, censured and obstructed in its Performance before His Majesty, April 1st, 1666, etc.;* copies in the Fitzwilliam Museum, Cambridge, and the Royal College of Music). A good deal of music for the theatre followed, the most important being for Davenant's productions of *The Tempest* (1667) and of *Macbeth* (1672), but some doubt as to this latter has arisen, Purcell Eccles or Leveridge, being also credited with it. He also composed various songs and instrumental pieces, and published some curious works on musical theory. He died in August 1677, an elegy being written by Purcell.

LOCKE, WILLIAM JOHN (1863–1930), English novelist and playwright, born on March 20, 1863 in Georgetown, Demerara, was educated at Trinidad and St. John's, Cambridge. He died at Paris on May 15, 1930.

He wrote *The Morals of Marcus Ordeyne* (1905); *The Beloved Vagabond* (1906, dramatized 1908); *Stella Maris* (1913); *The Wonderful Year* (1916); *The Rough Road* (1918); *The House of Baltazar* (1920); *The Mountebank* (1921); *The Coming of Amos* (1924); *The Great Pandolfo* (1925); *The Old Bridge* (1926); *Ancestor Jorico* (1929). His original plays include *Mr. Cynic* (1899); *The Lost Legion* (1900); and *The Man from the Sea* (1910).

LOCKERBIE, a small burgh, Dumfriesshire, Scotland, district of Annandale, 14½ mi. E.N.E. of Dumfries by the L.M.S.R. Pop. (1938) 2,640. Area, .7 sq.mi. It is famous for its sheep sales, particularly for the great August lamb fair. It contains an ancient tower, once the stronghold of the Johnstones, long the ruling family under whose protection the town grew up. At Dryfe Sands, about 2 mi. W., the Maxwells were almost exterminated by the Johnstones in 1593, hence "Lockerbie Lick" became a proverbial expression, signifying an overwhelming defeat.

LOCKER-LAMPSON, FREDERICK (1821–95), English man of letters, was born on May 29, 1821, at Greenwich hospital, son of Edward Hawke Locker, the civil commissioner of the hospital. He became deputy-reader and *précis* writer at the admiralty. In 1850 he married Lady Charlotte Bruce, daughter of Lord Elgin. After his marriage he left the Civil Service, in consequence of ill-health. He published *London Lyrics* (1857); *Lyra Elegantiarum* (1867), an anthology of light and familiar verse; and *Patchwork* (1879), a book of extracts. In 1872 Lady Charlotte Locker died. Two years later Locker married Hannah Jane Lampson, and in 1885 took his wife's surname. At Rowfant he died on May 30, 1895. Locker delighted a wide circle of friends by his gifts as a host and *raconteur*. His books are catalogued in the volume called the *Rowfant Library* (1886), to which an appendix (1900) was added by his eldest son.

See his *My Confidences* (1896), edited by his son-in-law, Augustine Birrell.

LOCKHART, GEORGE (1673–1731), of Carnwath, Scottish writer and politician, son of Sir G. Lockhart (d. 1689), lord president of the court of session, was member for the city of Edinburgh in the Scottish parliament and was appointed a commissioner for arranging the union with England in 1705. After the union he continued to represent Edinburgh, and later the Wigton burghs. His sympathies were with the Jacobites, whom he kept informed of all the negotiations for the union; in 1713 he took part in an abortive movement aiming at the repeal of the union. He was deeply implicated in the rising of 1715, the preparations for which he assisted at Carnwath and at Dryden, his Edinburgh residence. He was imprisoned in Edinburgh castle, but probably, through the favour of the duke of Argyll, he was released without being brought to trial; but his brother Philip was taken prisoner at the battle of Preston and condemned to be shot, the sentence being executed on Dec. 2, 1715. After his liberation Lockhart became a secret agent of the Pretender; but his correspondence with the prince fell into the hands of the government in 1727, compelling him to go into concealment at Durham until he was able to escape abroad. Argyll's influence was again exerted in Lockhart's behalf, and in 1728 he was permitted to return to Scotland. On Dec. 17, 1731, he was killed in a duel.

Lockhart was the author of *Memoirs of the Affairs of Scotland*, dealing with the reign of Queen Anne till the union with England, first published in 1714. These *Memoirs*, together with Lockhart's correspondence with the Pretender, and one or two papers of minor importance, were published in two volumes in 1817, forming the well-known "Lockhart Papers," a valuable authority for the history of the Jacobites.

See *The Lockhart Papers* (2 vols., 1817); Andrew Lang, *History of Scotland* (4 vols., 1900). For Sir Simon Lockhart's adventures with the heart of the Bruce, *see* Sir Walter Scott, *The Talisman*.

LOCKHART, JOHN GIBSON (1794–1854), Scottish writer and editor, was born on July 14, 1794, in the manse of Cambusnethan in Lanarkshire. At 12 he moved from the Glasgow high school to the university, and at 14 entered Balliol college, Oxford. He read French, Italian, German and Spanish, was interested in classical and British antiquities, and became versed in heraldic and genealogical lore. In 1813 he took a first class in classics in the final schools. For two years after leaving Oxford he lived chiefly in Glasgow before settling to the study of Scottish law in Edinburgh, where he was called to the bar in 1816. A tour on the Continent in 1817, when he visited Goethe at Weimar, was made possible by Blackwood, who advanced money for a promised translation of Schlegel's *Lectures on the History of Literature* (1838). In 1817 the Scottish Tories founded *Blackwood's Magazine*. After a somewhat hum-drum opening, *Blackwood* suddenly electrified the Edinburgh world by an outburst of brilliant criticism. John Wilson (Christopher North) and Lockhart had joined its staff in 1817. Lockhart no doubt took his share in the caustic and aggressive articles which marked the early years of *Blackwood;* but he was not responsible for the virulent articles on Coleridge and on "The Cockney School of Poetry," *i.e.*, on Leigh Hunt, Keats and their friends. He has been persistently accused of the later *Blackwood* article (Aug. 1818) on Keats, but he showed at any rate a real appreciation of Coleridge and Wordsworth. He contributed to *Blackwood* many spirited translations of Spanish ballads, which in 1823 were published separately. In 1818 he met Sir Walter Scott, and the acquaintance soon ripened into an intimacy which resulted in a marriage between Lockhart and Scott's eldest daughter Sophia, in April 1820. The Lockharts spent the winters in Edinburgh and the summers at a cottage at Chiefswood, near Abbotsford. In 1820 John Scott, the editor of the *London Magazine,* wrote a series of articles attacking the conduct of *Blackwood's Magazine,* and making Lockhart chiefly responsible for its extravagances. A correspondence followed, in which a meeting between Lockhart and John Scott was proposed, with Jonathan Henry Christie and Horace Smith as seconds. After complicated negotiations, a duel was fought in 1821 between Christie and Scott, in which Scott was killed.

Between 1818 and 1825 Lockhart worked indefatigably. In 1819 *Peter's Letters to his Kinsfolk* appeared, and in 1822 he edited Peter Motteux's edition of *Don Quixote,* to which he prefixed a life of Cervantes. Four novels followed, the best of which is *Adam Blair* (1822). In 1825 Lockhart became editor of the *Quarterly Review*. He contributed largely himself. He showed the old railing spirit in an amusing but violent article in the *Quarterly* on Tennyson's *Poems* of 1833, in which he failed to discover the mark of genius. He continued to write for *Blackwood;* he produced for *Constable's Miscellany* in 1828 what remains the most charming of the biographies of Burns; also he superintended *Murray's Family Library,* the opening volume being his *History of Napoleon* (1829).

But his *magnum opus* was the *Life of Sir Walter Scott* (7 vols., 1837–38; 2nd ed., 10 vols., 1839). Lockhart was taxed in some quarters with ungenerous exposure of his subject, but to most minds the impression conveyed by the biography was, and is, quite the opposite. Carlyle did justice to many of its excellencies in a criticism contributed to the *London and Westminster Review* (1837). Lockhart's account of the transactions between Scott and the Ballantynes and Constable caused great outcry; and in the discussion that followed he showed unfortunate bitterness by his pamphlet, "The Ballantyne Humbug handled." The *Life of Scott* has been called, after Boswell's *Johnson,* the most admirable biography in the English language. Lockhart resigned its proceeds for the benefit of Scott's creditors.

The close of Lockhart's life was saddened by family bereavement, resulting in his own breakdown in health and spirits. His eldest boy (the suffering "Hugh Littlejohn" of Scott's *Tales of a Grandfather*) died in 1831; Scott himself in 1832; Mrs. Lockhart in 1837; and the surviving son, Walter Lockhart, in 1852. Resigning the editorship of the *Quarterly Review* in 1853, he wintered in Rome, and being taken to Abbotsford by his daughter Charlotte (Mrs. James Robert Hope-Scott), he died there on Nov. 25, 1854. He was buried near Scott, in Dryburgh Abbey.

Lockhart's *Life* (2 vols., 1897) was written by Andrew Lang. A. W. Pollard's edition of the *Life of Scott* (1900) is the best.

LOCKHART, SIR WILLIAM, of Lee (1621–1675), eldest son of Sir James Lockhart of Lee (afterwards Lord Lee) (d.

1674), after fighting on the king's side in the Civil War attached himself to Cromwell, whose niece he married. He was appointed commissioner for the administration of Justice in Scotland in 1652, and ambassador to France in 1656.

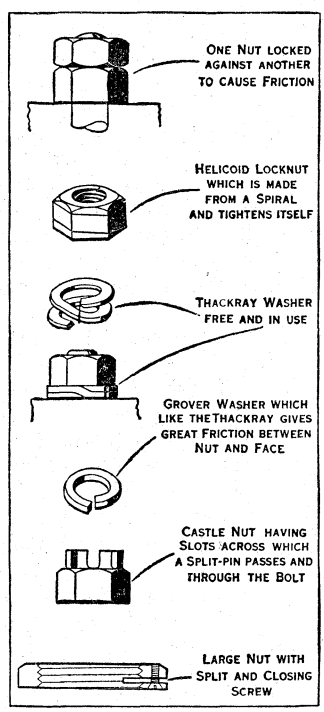
LOCKHART, SIR WILLIAM STEPHEN ALEXANDER (1841–1900), British general, was born in Scotland on Sept. 2, 1841, his father being a Lanarkshire clergyman. He entered the Indian army in 1858, in the Bengal native infantry. He served in the Indian Mutiny, the Bhutan campaign (1864–66), the Abyssinian expedition (1867–68), the Hazara Black Mountain expedition (1868–69). From 1869 to 1879 he acted as deputy-assistant and assistant quartermaster-general in Bengal. In 1877 he was military attaché with the Dutch army in Acheen. He served in the Afghan War of 1878–80, and commanded a brigade in the Third Burmese War (1886–87). An attack of fever brought him to England, where he was employed as assistant military secretary for Indian affairs; but in 1890 he returned to India to take command of the Punjab frontier force, and for five years was engaged in various campaigns including the Waziristan campaign in 1894–95. He became full general in 1896, and in 1897 he conducted the difficult Tirah campaign. In 1898 he was commander-in-chief in India. Lockhart had a great gift for dealing with the tribesmen, who called him Amir Sahib. He died on March 18, 1900.

LOCK HAVEN, a city of central Pennsylvania, U.S.A., on the west branch of the Susquehanna river, 70m. N.N.W. of Harrisburg; the county seat of Clinton county. It is on Federal highways 105, 120 and 220, and is served by the New York Central and the Pennsylvania railways. The population was 8,557 in 1920, 9,668 in 1930 and 10,810 in 1940 by the federal census. The city is surrounded by fertile cultivated valleys and beautiful mountain scenery. It is the seat of a state teachers college (opened 1877). Fireclay, shale and coal abound in the vicinity. The principal industry is the manufacture of paper for the Curtis Publishing company of Philadelphia. Other products of importance are brick, leather, silk, lumber and furniture. A town was founded there in 1833, and the name was suggested by the locks of the Pennsylvania canal (completed to this point in 1834) and the harbour, or haven, for rafts in the river. It was incorporated as a borough in 1840 and chartered as a city in 1870. It has adopted the commission form of government.

LOCKJAW: *see* TETANUS.

LOCKLAND, a city of Hamilton county, Ohio, U.S.A., 12 mi. N. of Cincinnati. It is served by the Baltimore and Ohio, the Big Four and the Erie railways. The population was 5,703 in 1930; 5,601 in 1940. Lockland has a number of manufacturing plants, making cotton goods, paper, asbestos products, steel and composition roofing. It was settled about 1800.

LOCK-NUT. Whenever a nut on a bolt or stud or shaft is subjected to vibration it is likely to work loose; therefore, in the majority of prime movers and power-driven machinery, lock-nuts are to be found. These either give a frictional grip sufficient to withstand jarring loose, or a positive lock. An expensive or delicate type is not admissible, hence the standard devices are limited in number, notwithstanding that patents for nuts are being taken out constantly. The familiar double nut device gives great friction of one face against the other and of the threads. The helicoid nut is used alone, and is made as a spiral spring, slightly small in the threaded hole. When run down with a wrench or spanner (British term) the coil is slightly sprung apart, and on touching the face of the object becomes powerfully compressed. The Dardelet creates friction between bolt and nut by a taper incorporated in the thread form. The Thackray washer gives friction under the nut, by its compression. The Grover washer has one coil. For fastenings where there must be no possible risk, either a split-pin is passed through a hole drilled through nut and bolt, or in the portion of bolt standing above the nut. Or a slotted nut is employed, giving the choice of different distances up and down the bolt, the split-pin passing through the bolt always at one place. The castle nut has the slots cut in a projecting portion above the nut proper. Other devices include a plate with corner turned up to catch against a flat of the nut and prevent rotation, a piece of wire hooked in a hole in the nut and its end caught in a slot in the bolt, or a loop sprung around into a groove in the nut and then into a hole in the bolt. Many large nuts are locked with a lateral screw passed through to press on the bolt, while another way is to partly saw through the nut and tighten the split with a screw, so causing friction of the threads on the bolt.



STANDARD LOCKNUTS USED ON MACHINERY SUBJECT TO VIBRATION

LOCKOUT: *see* STRIKES AND LOCK-OUTS.

LOCKPORT, a city of Will county, Illinois, U.S.A., 33 mi. S.W. of Chicago, on the Des Plaines river, at the end of the Chicago Sanitary and Ship canal, which has its controlling works and a hydroelectric plant there. Pop. in 1940 was 3,475. It is in a picturesque farming region, and has various manufactures. A settlement was made there about 1827. In 1837 it was chosen for the headquarters of the Illinois and Michigan canal, and a village was laid out. In 1892 work was begun on the Chicago Drainage (later renamed Sanitary and Ship) canal, which was opened in 1900. The city was incorporated in 1904.

LOCKPORT, city, western New York, U.S.A., 25 mi. N. by E. of Buffalo, on the State Barge (formerly the Erie) canal; the county seat of Niagara county. It is served by the Erie and the New York Central railways. The population was 21,308 in 1920 (84% native white) and was 24,379 in 1940 by the federal census. The city owes its name to the five double locks of the canal, which overcome the difference (66 ft.) between the level of Lake Erie and that of the Genesee river. It has abundant water power, and electric energy from Niagara. The manufactures, valued at $50,000,000, include flour, pulp and paper, wallboard, plastics, textiles, brooms, glass, steel, automobile radiators and parts and machinery; there are limestone quarries; and the district is noted for its apples, peaches and grain. The site of Lockport was in the tract bought by the Holland company (1792–93). Most of it was sold about 1816 to Esek Brown, the proprietor of a local tavern, and 14 others, but there were few settlers until after 1820. In 1822 the town was made the county seat, and in 1823 it became the temporary headquarters for construction on the Erie canal. It was incorporated as a village in 1829 and as a city in 1865.

LOCKROY, EDOUARD (1840–1913), French politician, son of Joseph Philippe Simon (1803–91), an actor and dramatist, who took the name of Lockroy, was born in Paris on July 18, 1838, and died on Nov. 22, 1913. In 1860 he enlisted as a volunteer under Garibaldi. The next three years were spent in Syria as secretary to Ernest Renan, and on his return to Paris he embarked in militant journalism against the Second empire in the *Figaro,* the *Diable à quatre,* and eventually in the *Rappel.* He commanded a battalion during the siege of Paris, and in Feb. 1871 was elected deputy to the National Assembly, where he sat on the extreme left. In March he signed the proclamation for the election of the Commune, and resigned his seat as deputy. He sat in the Chamber for various constituencies from 1873 onwards and from 1885 to 1887 he was minister of commerce. For the first ten years of his parliamentary life he voted consistently with the extreme left, but then adopted a more opportunist policy, and gave his unreserved support to the Brisson ministry of 1885. In the new Freycinet cabinet formed in January he held the portfolio of commerce and industry, which he retained in the Goblet ministry of 1886–87. In 1885 he had been returned at the head of the poll for Paris, and his inclusion in the Freycinet ministry was taken to indicate a prospect of reconciliation between Parisian Radicalism and official Republicanism. Lockroy made the preliminary arrangements for the exposition of 1889, and in a witty letter defended the erection of the Tour Eiffel against artistic Paris. After the Panama and Boulangist scandals he became one of the leading politicians of the Radical party. He was minister of marine in successive cabinets, and was a persistent and successful advocate of a strong naval policy, in defence of which he published *La Marine de Guerre* (1890), *La Défense navale* (1900) and other works. He also wrote *M. de Moltke, ses mémoires et la guerre future* (1891), *Journal d'une bourgeoise pendant la Révolution* (1881) and his reminiscences, *Au hasard de vie* (1912).

LOCKWOOD, WILTON (1861–1914), American painter, born at Wilton, Conn., on Sept. 12, 1861. He was a pupil and an assistant of John La Farge, and also studied in Paris, becoming a well-known portrait and flower painter. He became a member of the Society of American Artists (1898) and of the Copley Society, Boston, and in 1912 was elected to the National Academy of Design. He died at Brookline, Mass., on March 20, 1914.

LOCKYER, SIR JOSEPH NORMAN (1836–1920), English astronomer, was born at Rugby on May 17, 1836. After completing his education on the Continent of Europe, he obtained a clerkship in the War Office in 1857. His leisure was devoted to the study of astronomy, and he was appointed in 1870 secretary to the duke of Devonshire's royal commission on science. In 1875 he was transferred to the Science and Art Department at South Kensington, and on the foundation of the Royal College of Science he became director of the solar physics observatory and professor of astronomical physics. Eight British Government expeditions for observing total solar eclipses were conducted by him between 1870 and 1905, accounts of them being given in his *Recent and Coming Eclipses* (1897 and 1900) He was a pioneer in the application of the spectroscope to the sun and stars. He initiated in 1866 the spectroscopic observation of sunspots; announced in 1868 that the prominences were upheavals in a layer round the sun which he called the chromosphere; applied Doppler's principle to the sun in 1869; and successfully investigated the chemistry of the sun from 1872 onward. In 1868 Lockyer and Janssen, working independently, discovered a spectroscopic method whereby the solar prominences could be observed in daylight, whereas previously they could be observed only at a total eclipse. To commemorate this discovery a medal bearing the names of both astronomers was struck by the French Government in 1872. With the co-operation of Lady Lockyer he had built an observatory at Sidmouth and carried on there his photographic and spectroscopic work. After Lockyer's death this observatory was named the "Norman Lockyer Observatory." He was an enthusiast, inaugurating *Nature* in 1869, which he edited until his death on Aug. 14, 1920. He was made a F.R.S. in 1869, received the Rumford medal in 1874, and was vice-president of the Society 1892–93. He was president of the British Association in 1903, and contributed papers to the Royal Society and Royal Astronomical Society. Also, he wrote: *The Chemistry of the Sun* (1887); *The Sun's place in Nature* (1897); *The Dawn of Astronomy* (1894); *Stonehenge and other British Stone Monuments astronomically considered* (1906); *Inorganic Evolution* (1900).

See T. M. and W. L. Lockyer, *Life and Work of Sir Norman Lockyer* (1928).

LOCLE, LE, a town in the Swiss canton of Neuchâtel, 24 m. by rail W.N.W. of Neuchâtel, 5 m. S.W. of La Chaux de Fonds, and with a narrow gauge railway to Les Brenets. It is built (3,035 ft. above the sea-level) on the Bied stream in a valley of the Jura, and is about 1 m. from the French frontier. In 1681 Daniel Jean Richard introduced watch-making here, which soon drove out all other industries, and there is also a school of watch-making. In 1930 the population was 12,001, mainly Protestants and French-speaking. The church tower dates from 1521, but the old town was destroyed by fire in 1833. The valley in which the town is situated used to be subject to inundations, but in 1805 a tunnel was constructed by means of which the surplus waters of the Bied are carried into the Doubs

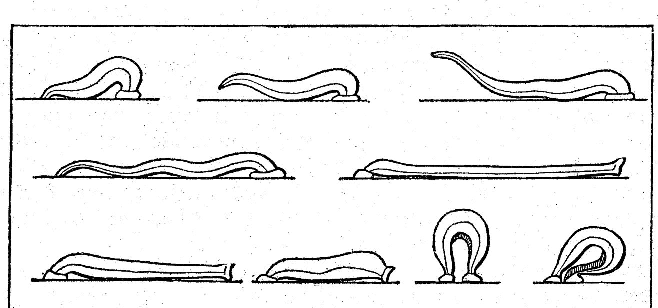
LOCMARIAQUER, a village of western France, on the west shore of the Gulf of Morbihan, in the department of Morbihan, 8½ mi. S. of Auray by road. Pop. (1936) 602. Locmariaquer has a small port, and oyster culture is carried on close to it. Roman remains are to be seen, but the place owes its fame to the very large megalithic monuments in the vicinity. A great menhir, broken into four pieces by lightning in the 18th century, measured about 67ft. in height, and from 9 to 13ft. in thickness.

LOCOMOTION OF ANIMALS. It is characteristic of animals that they can move about in search of food, foothold and mates, or away from enemies and hurtful influences; this locomotion is effected in a great variety of ways. Among multicellular animals there are four chief methods, which, following F. W. Gamble, may be illustrated by picturing a man in a boat.

Pulling.—The man may reach forward with a boathook, fasten it to some prominence like a tree-root, and pull the boat forwards. This is the pulling method, and is well illustrated by leeches and starfishes. When looping along, the leech exhibits (*see* fig.) the following order: Fixing its mouth and loosening the posterior sucker, it pulls its body forward, contracting its longitudinal muscles. At the end of this process the posterior sucker has been brought forward almost to touch the margin of the mouth, and the body is arched upwards like a croquet hoop. Then the posterior sucker being fixed, the mouth is freed, and the body is protruded forwards to a new position of oral attachment. This protrusion is effected by a contraction of circular and diagonal muscles, which squeeze the body forward. The mouth is re-attached, the posterior sucker is loosened, and the sequence re-begins.

Punting.—The man may stand up in the boat and use a pole as a lever, pressing it against the floor of the stream. This "punting" is one of the commonest modes of animal locomotion, being exhibited by all the diverse types that have firm appendages useable as levers against a base. A beetle hurrying across the roadway, a crab walking over a rock, a frog jumping among the grass, an ostrich sprinting at full speed, a man walking—all are using levers which propel the body forwards by pressing against a hard substratum. Sometimes there are complications, which do not essentially affect the principle of the method employed. Thus the freshwater mussel may make its flabby "foot" tense with blood, close a sphincter muscle which prevents backflow, and then pull the ploughshare-like organ backwards against the sand, thus pushing its body forwards. The foot has to be protracted before the next step is taken. This method approaches pulling.

The movements of snakes are somewhat intricate. A rapid dart forward may be effected by a sudden straightening of one or more of the bays of the sinuous body, but let us take the ordinary



FROM HESSE, "TIERBAU UND TIERLEBEN" (TUEBNER)

DRAWINGS SHOWING THE MOVEMENTS OF A LEECH

smoothly continuous progression. Except in burrowing snakes the ventral surface is covered by a single series of large scales, which can be raised and lowered. The posterior margins of these scales are sharp, strong and imbricating. When raised, which is effected by special muscles, they catch on roughnesses on the ground. Into the sides of these large ventral scales the lower ends of the ribs are attached by minute ligaments, and the upper ends are connected to the vertebrae by articulations which allow them ready movement forwards and backwards. Several ribs are drawn forwards by muscles and move the associated scales a minute distance headwards, a whole series of ribs and scales working simultaneously in the same direction. Then these ribs are drawn backwards, and the pressure of the raised scales against the hard ground pushes the body forwards. While one series of ribs is being drawn backwards, another series is being drawn forwards, and thus a continuous flowing movement is brought about. This case is perhaps intermediate between "punting" and "rowing."

Sculling.—The man in the boat may stand in the stern and "scull," using a single oar to displace masses of water alternately to right and left. This is a common method among swimming animals, such as fishes and whales. In most fishes the swimming organ is the post-anal body, which consists almost entirely of strong W-shaped blocks of muscle, dovetailed into one another, and centred in the flexible backbone. By alternately bending and straightening the posterior body, masses of water are displaced, and thus the fish is propelled forwards. In cetaceans locomotion is similar, but a complication is introduced by the adaptive shape of the tail-flukes. In true seals (Phocidae) the hind-limbs are permanently turned backwards and bound up with the short tail, forming a unified functional propeller. The principle is the same in cases like sea-snakes and swimming leeches, where the gripping of the water and the using of it as a resistant mass, against which to contract, extend over the whole length of the body.

Rowing.—Fourthly, the man in the boat may row, the principle being the simultaneous exertion of pressure on each side. Thus the platypus rows in the water with its webbed fore-feet, and the turtle with its paddles. Rowing in the air is the essence of flight in birds, bats and insects, though here part of the energy must be expended in keeping the body from sinking. Brittle stars or ophiuroids sometimes strike the sand with their posterior arms and may be said to row along the solid substratum, and in the mole's rapid turning in the ground the fore-limbs are used like oars as if the animal was rowing in the ground. The insect known as the water boatman (*Notonecta*) swims back-downward in the pool, using its long third pair of legs as oars. In many of the auk family the wings are used as well as the feet in swimming under water.

Other Methods.—The analogy of the man in the boat becomes somewhat forced when applied to out-of-the-way modes of animal locomotion, of which a few examples may be given. A jellyfish swims by alternately expanding and contracting the disc-like or bell-like body. The rapid contraction drives the water out from the mouth of the bell, and the medusa is propelled in the opposite direction. Cuttlefishes expand their mantle cavity, and having filled it with water proceed to close it by a hook-and-eye contrivance, so that the water cannot leave by the way it entered, but is forced, as the cavity contracts, through a narrow funnel. As the jet comes out with considerable strength, the body is driven rapidly through the water, with the head and tentacles in the wash. The same method of propulsion by a posterior outgush of water is seen in larval dragon-flies. Somewhat unusual, again, is the way in which lobsters jerk themselves tail-foremost in the water by suddenly flexing the posterior body (abdomen) forwards and downwards. This displaces a mass of water towards the head. On occasion the common scallop (*Pecten*) can jerk itself off the sea-floor with an energetic snap of its shell-valves, and continue swimming thus for some time.

In some ways the strangest mode of animal locomotion is exhibited by the common sea-urchin (*Echinus*) on a firm flat surface. This animal habitually moves by means of its tube-feet, and also utilizes its spines, which are swayed on ball-and-socket joints by basal muscles. But *Echinus* is also able to tumble along on the tips of the five teeth of Aristotle's lantern which project out of the mouth. The lantern can be swayed from side to side by powerful muscles, and the locomotion is a stumbling along on the tips of the teeth. The track shows at short intervals the indentations of the teeth, and marks of spines in between.

Mechanism of Locomotion.—The movements of most multicellular animals are effected by muscles, and there is an important distinction between the unstriped or smooth muscle of sluggish animals, such as tapeworms, and the striped or striated muscle of ordinary active animals (*see* MUSCULAR SYSTEM, ANATOMY OF). Unstriped muscle consists of homogeneous spindle-shaped cells, closely fitting, each with a single nucleus. Ordinary striped muscle is composed of elongated cross-striped cells, usually with many nuclei, which are sometimes situated peripherally, as in man; sometimes embedded in the muscle-substance, as in the frog. A striped muscle-cell is usually a single cell; but in some cases it seems to be due to longitudinal fusion of several cells. The most important general fact is that unstriped muscles contract slowly, and are therefore found in sluggish animals, and in the slowly moving parts of active animals, as the walls of the food-canal and arteries. Apart from these and similar exceptions, the muscle-fibres in active animals are cross-striped and quickly contracting. Some of the lower animals such as turbellarian and nemertean worms are aided greatly by superficial cilia. The last occurrence of these superficial cilia as locomotor structures is in newly hatched tadpoles.

Among unicellular organisms locomotion is effected by flagella, by cilia, by myonemes and in an amoeboid fashion. Each flagellum or cilium is a thread of protoplasm, sometimes with an axial filament. It is alternately flexed and straightened, as one might bend one's arm at the elbow and elongate it again. It is interesting to notice that among multicellular animals cilia are very common, from the lowest to the highest, except in nematodes and arthropods, where the abundant chitin apparently precludes their development. As has been mentioned, the turbellarian and nemertean worms are covered with cilia, which assist in locomotion; but above the level of these two classes, cilia cease to be locomotor except in larval forms, like the trochospheres of marine annelids and molluscs. Starfishes and some other echinoderms are richly provided with external cilia, but these are used for wafting food-particles, not for locomotion. Above nemerteans cilia become of great internal importance, for they may line a windpipe, an excretory tube, a female genital duct and so forth. Myonemes are contractile plasmic threads, anticipations of muscle-fibres, but intracellular. An instance of their occurrence is the axial filament inside the non-contractile sheath of the stalk of the bell-animalcule (*Vorticella*).

Amoeboid movement, probably the most primitive mode of animal locomotion, has been much studied; but it is difficult to form a clear picture of what happens. An ordinary *Amoeba*, a naked blob of living matter, protrudes blunt finger-like processes and draws others in, continually altering its shape but not its volume. It glides along at the rate of about ¾ in. an hour. It is probably in some way gripping the substratum by a very delicate external plasma-membrane, which is continually giving way anteriorly, and being re-instated posteriorly. This film is the seat of surface-tension effects, and the tension seems to increase anteriorly and decrease posteriorly. But attentive scrutiny shows that the *Amoeba* is rather rolling than gliding. For a definitely recognizable particle may be seen moving along the upper surface of the cell, in the direction in which the *Amoeba* is moving, then disappearing over the front, and, after a while, re-appearing at the posterior end; and so *da capo,* as if there were a "caterpillar-wheel"-like movement. Moreover, there is a deeper protoplasmic streaming, connected with intricate physical and chemical changes. There are indications of rapid changes of the protoplasm from "sol" to "gel" states and back again. It is very interesting to notice that this most primitive mode of locomotion is retained in varied expression even in higher animals, *e.g.,* in the outgrowing tip of embryonic nerve-cells and in the excursions of phagocytes.

AMERICAN STEAM LOCOMOTIVES—HEAVY FREIGHT TYPES

1. Consolidation, 2-8-0 type. Fast heavy freight service; fuel, anthracite and bituminous coal mixed; tractive effort, simple 84,300 lbs.; compound 70,300 lbs.; additional for tender truck booster 18,000 lbs.; boiler pressure 500 lbs.; cylinders, 2 multiple expansion, 1 high-pressure, 1 low-pressure; drivers 63″; weight on drivers 300,000 lbs.; total weight engine ex. tender 356,000 lbs.
2. Twelve-wheel 4-8-0 type. Fast heavy freight service; fuel, anthracite and bituminous coal mixed; tractive effort, simple 90,000 lbs.; triple expansion 75,000 lbs.; additional for tender truck booster 18,000 lbs.; boiler pressure 500 lbs.; cylinders, 4 triple expansion, 1 high-pressure, 1 intermediate pressure, 2 low-pressure; poppet valves and outside cam valve gear; drivers 63″; weight on drivers 313,000 lbs.; total weight engine ex. tender 382,000 lbs.
3. Sixteen-wheel 4-8-4 type. Passenger and fast freight service; fuel, bituminous coal; tractive effort 66,500 lbs.; boiler pressure 275 lbs.; cylinders, 2 single expansion; drivers 77″; weight on drivers 272,200 lbs.; total weight engine ex. tender 435,000 lbs.
4. Sixteen-wheel 2-10-4 type. Freight service; fuel, bituminous coal; tractive effort 93,000 lbs.; boiler pressure 300 lbs.; cylinders, 2 single expansion; drivers 69″; weight on drivers 349,910 lbs.; total weight engine ex. tender 502,260 lbs.
5. Eighteen-wheel 4-12-2 type. Freight service; fuel, bituminous coal; tractive effort 96,650 lbs.; boiler pressure 220 lbs.; cylinders, 3 single expansion; drivers 67″; weight on drivers 372,000 lbs.; total weight engine ex. tender 515,000 lbs.
6. Sixteen-wheel Mallet 2-6-6-2 type. Freight service; fuel, bituminous coal; tractive effort 90,000 lbs.; boiler pressure 250 lbs.; cylinders, 4 single expansion; drivers 70″; weight on drivers 372,000 lbs.; total weight engine ex. tender 465,000 lbs.
7. Eighteen-Wheel Mallet 2-8-8-0 type. Heavy freight service; fuel, powdered bituminous coal and lignite, and fuel oil; tractive effort, simple 147,220 lbs., compound 122,683 lbs.; boiler pressure 250 lbs.; firebox type superheater; cylinders, multiple expansion, 2 high-pressure, 2 low-pressure; drivers 57″; weight on drivers 466,000 lbs.; total weight engine ex. tender 495,000 lbs.
8. Twenty-two wheel 4-8-8-2 type. Passenger and freight service; fuel, fuel oil; tractive effort 123,400 lbs.; boiler pressure 250 lbs.; cylinders, 4 single expansion; drivers 63½″; weight on drivers 517,000 lbs.; total weight engine ex. tender 639,500 lbs.

BRITISH AND AMERICAN TYPES OF STEAM LOCOMOTIVES FOR PASSENGER AND FREIGHT SERVICE

1. Lord Nelson 4-6-0 type. Four-cylinder express passenger locomotive; total weight of engine and tender in working order, 140 tons, 4 cwt.; tractive effort at 85% boiler pressure 33,500 lbs. 2. Lord Baltimore, Pacific 4-6-4 type. Fast passenger service; fuel, soft coal; tractive effort 34,000 lbs.; boiler pressure, 350 lbs.; cylinders 19 in. diameter, 28 in. stroke; drivers 84″; weight on drivers 156,000 lbs.; total weight engine ex. tender 294,000 lbs. 3. Lady Baltimore, Atlantic 4-4-4 type. Fast passenger service; fuel, soft coal; tractive effort 28,000 lbs.; boiler pressure, 350 lbs.; cylinder 17½ in. diameter, 28 in. stroke; drivers 84″; weight on drivers 99,800 lbs.; total weight engine ex. tender 217,800 lbs. 4. Silver Jubilee 4-6-0 type. Fuel, bituminous coal; boiler working pressure 225 lbs. per sq. in.; three cylinders 17″ dia. x 26″ stroke; tractive effort at 85% B.P. 26,610 lbs.; weight ex. tender (light) 168,784 lbs. 5. Silver Link 4-6-2 three-cylinder engine, type A.4. Fuel, coal; boiler pressure 250 lbs.; cylinders, 18½ in. diam., 26 in. stroke; driving wheel 6 ft. 8 in.; tractive power at 85% boiler pressure 35,455 lbs.; weight of engine and tender 165 tons, 7 cwt. 6. Pacific 4-6-2 type. Fast passenger service; fuel, anthracite and bituminous coal mixed; tractive effort 59,500 lbs.; boiler pressure 325 lbs.; cylinders, 2 single expansion; poppet valves and outside rotary cam valve gear; drivers 73″; weight on drivers 191,000 lbs.; total weight of engine ex. tender 296,500 lbs. 7. Fourteen-wheel 4-8-2 type. Fast freight and passenger service; fuel, bituminous coal; tractive effort 64,550 lbs.; boiler pressure 250 lbs.; cylinders, 2 single expansion; drivers 72″; weight on drivers, 271,000 lbs.; total weight engine ex. tender 390,000 lbs. 8. Fourteen-wheel 2-10-2 type. Heavy freight service; fuel, bituminous coal; tractive effort 61,600 lbs.; boiler pressure 275 lbs.; cylinders, 2 single expansion; drivers 57″; weight on drivers 261,040 lbs.; total weight engine ex. tender, 344,170 lbs. 9. Sixteen-wheel, 2-10-4 type. Heavy freight service; fuel, bituminous coal; tractive effort 77,200 lbs.; boiler pressure 275 lbs.; cylinders, 2 single expansion; drivers 63″; weight on drivers 312,800 lbs.; total weight engine ex. tender 452,000 lbs.

MODERN LOCOMOTIVES AND TRAINS

1. "The Rebel," streamlined train designed and built by American Car and Foundry Co. for Gulf, Mobile and Northern Railroad. 2. Rear view showing observation end of "The Rebel," first streamlined train for the South. 3. Freight locomotive with new type disc driving wheels. 4. Streamlined unit of the "Bugatti" type, operated on the French State Railways. 5. "The Hiawatha" in service between Chicago, Milwaukee, St. Paul and Minneapolis. 6. "The City of Portland," Union Pacific streamliner. 7. First streamlined "Zephyr" of the Chicago, Burlington & Quincy. 8. "The Twentieth Century Limited," drawn by a Hudson type steam locomotive with 4700 horse power, in operation between New York city and Chicago

STEAM LOCOMOTIVE DEVELOPMENT

Although there were numerous predictions and suggestions of steam-propelled carriages, notably those of Sir Isaac Newton, in 1680, Cugnot's steam-driven road wagon in 1769 and Murdock's in 1784, there is little authentic information as to when actual locomotion by steam power first occurred, but there is definite record of the first success in heavy haulage, obtained on a prepared track, in England, when Richard Trevithick, a Cornish mine captain had his first locomotive built in 1801. Trevithick's next locomotive (1803), had four wheels, all drivers, 4 ft. 6 in. diameter, and the boiler was 6 ft. long and had a return flue, bringing the stack over the fire door. There was only one cylinder, which was 8 in. diameter, by 54 in. long. Trevithick found that smooth tread wheels had sufficient adhesion, and that the exhaust steam, when turned back in the stack, could be effectively utilized to promote combustion in the fire-box.

The Rocket.—Between Trevithick's steam engine of 1803, and the "Rocket" (1829), came the Blenkinsop colliery locomotive, built by Fenton, Murray and Wood of Leeds in 1812, Hedley with his "Puffing Billy" in 1813, Stephenson's "Blucher" in 1814 and various other developments. After George Stephenson produced his first locomotive his energies were devoted to the improvement of the steam locomotive by the various stages which led up to the "Rocket." The Stockton and Darlington Railway Company, the first public railway, was opened in 1825, and Stephenson was the engineer of the "Locomotive," which was built by him in that year. Several other locomotives were built, but none were entirely satisfactory. In 1829, the directors of the Liverpool and Manchester railroad offered a prize of £500 for the best locomotive engine. There were originally ten competitors, but the number was reduced on the morning of the trials to five: "The Novelty," "Sans Pareil," the "Rocket," the "Cycloped" and the "Perseverance." The trials lasted seven days, after which on Oct. 26, 1829, Stephenson's "Rocket" which was the only engine that fulfilled the conditions of the competition, was awarded the prize. When drawing a load equivalent to three times its own weight, the "Rocket" travelled at the rate of 12½ m. per hour; and with a carriage and passengers at the rate of 24 m. an hour, with the cost per mile for fuel about 3 pence. Its success was due to the combination of the tubular boiler, suggested by Henry Booth, and a suitably proportioned blast pipe, first used by Richard Trevithick, and a simple power transmission mechanism in the direct drive between the cylinder piston and the driving wheels. The principal characteristics of the "Rocket" were: boiler pressure 50 lb.; cylinders 8 by 16½ in.; one pair drivers, 3 ft. 8½ in. diameter; boiler, 3 ft. 4 in. diameter, by 6 ft. long; fire-box, 3 by 2 ft.; boiler tubes, 23 ft. 3 in.; fire-box heating surface, 63 sq.ft.; boiler tube heating surface, 7 sq.ft.; total heating surface, 138 sq.ft.; weight of engine, about 9,500 pounds.

Other Early Developments.—The early canal, quarry and coal mining engineers in the United States favoured the building of railroads as the result of their investigations in England at about the time that public opinion was being influenced in that direction there. About 1800 the American people began to realize the need of highway and other inter-communication as a means for developing the extensive unsettled districts of the country. The difficulty of constructing artificial waterways, the slowness of canal boats and the freezing of transportation channels for a considerable part of each year, gave impetus to the movement. In 1828, John B. Jervis, chief engineer of the Delaware and Hudson Canal Company, convinced of the feasibility of rail motive power, presented a plan to the management, with the result that Horatio Allen, assistant engineer, was sent to England, to study railroad operation and to contract for rails and locomotives. Jervis planned to bring the anthracite coal of the Susquehanna valley, by rail, into the valleys of the Delaware and the Hudson rivers, and on to the ocean. Allen in 1828 contracted for four locomotives. The locomotive "America," furnished by Robert Stephenson and Company, arrived in New York on Jan. 15, 1829. It was transported up the Hudson river and through the canal from Rondout and cleared Eddyville on July 16, 1829. There its record is lost, and so far as is known, it was never operated in America. The other three locomotives built by Foster, Rastrick and Company, of Stourbridge, England, were the "Stourbridge Lion," "Delaware" and "Hudson." The "Stourbridge Lion" reached New York on May 13, 1829. It was transported up the Hudson to Rondout, and by canal to Honesdale, Pa. It was set up and made a trial trip on Aug. 8, 1829, this being the first operation of a locomotive in the Western Hemisphere. The second and third locomotives from Foster, Rastrick and Company arrived in New York on Aug. 9 and Sept. 17, 1829, respectively. Their subsequent history is obscure. The "Peter Cooper," the first locomotive built in the United States, was successfully operated on the Baltimore and Ohio railroad, as early as Aug. 28, 1830. A speed of from 5 to 18 m. per hour was attained with a car and 23 persons, and the average tractive force developed represented about 1·43 h.p. or more than three times as much as the "Rocket" developed. This improvement was due to the higher pressure steam used by the "Peter Cooper."

On Jan. 4, 1831, the Baltimore and Ohio offered $4,000 for the best American engine of 3½ tons, to pull 15 tons, on level track at a speed of 15 m. an hour. Phineas Davis won the prize with the "York," a vertical engine with four 30 in. wheels. In 1832 the "Ironsides"—Matthew Baldwin's first engine—was put into service in the United States. After a trial and some imperfections had been remedied, it was put into regular service and did duty on the Philadelphia, Germantown and Norristown railroad and others for over 20 years. The Baltimore and Ohio Railroad Company was a pioneer in the United States, it having been chartered by the State of Maryland on Feb. 27, 1827, and incorporated on April 24 of the same year. Its centenary pageant and exhibit held near Baltimore, Md., during 1927, gave a graphic exhibition of transport since the first settlement of the nation. For this exhibit the "Tom Thumb," built by Peter Cooper, of New York in 1829–30, to prove the practicability of steam operation, was reproduced and operated. The original "Tom Thumb" ran successfully on the rails of the Baltimore and Ohio and was followed by the "Thomas Jefferson," 1834; "Winans Camel Back," 1848; "William Mason," 1856, and the "J. C. Davis," 1875, first passenger engine of the Mogul type used by the Baltimore and Ohio. The first Mallet type locomotive built in the United States in 1903–04, Baltimore and Ohio No. 2,400, named "John E. Muhlfeld," was exhibited, as well as numerous later steam and electric locomotive designs. The "King George V.," No. 6,000, the most powerful locomotive in Great Britain, was also sent over for the pageant. This locomotive, on its trial trip, ran from Paddington to Plymouth, a distance of 226¾ m. in 4 hours and 2 minutes, at the rate of 61·7 m. an hour, with a load of 410 tons. It is of the ten-wheel type, with four cylinders, 16¼ by 28 in.; the inside cylinders are connected to the forward pair of drivers, and the outside cylinders to the second pair of drivers. The boiler pressure is 250 lb., drivers, 78 in. diameter, weight on drivers, 151,200 pounds.

With the "King George V." was sent the "North Star," one of the first engines on the Great Western Railway of England, designed by Sir Daniel Gooch, of that company, and built by Robert Stephenson and Company. The "North Star" as well as others of the "Star" class of locomotives, of the 2-2-2 type, as designed and built by Sir Daniel Gooch, at the Swindon works of the Great Western about 1846, for fast passenger service, was adapted to a 7 ft. gauge of track; cylinders, 18 by 24 in.; one pair of driving wheels, 96 in.; heating surface, 1,952 sq.ft.; boiler tubes, 300; and was equipped with the Gooch fixed link valve motion. This locomotive had a maximum speed of 78 m. per hour, and when evaporating about 1,500 gal. of water per hour, the fuel consumption averaged about 2·5 lb. of coal per horse-power hour, which compares most favourably with present performance. The Delaware and Hudson Company high-pressure freight locomotive, No. 1,401, the "John B. Jervis," was also exhibited. The outstanding feature of this locomotive is the water tube—fire flue type of boiler carrying 400 lb. boiler pressure; one high-pressure cylinder, 22¼ in. and one low-pressure cylinder, 38½ in. diameter, by 30 in. stroke; the weight on four pairs of drivers, 295,000 lb.; driving wheels, 57 in. diameter; and the tractive power of

85,000 lb. in simple gear, 70,800 lb. in compound gear and 18,000 lb. additional tractive power in the tender truck booster for starting and accelerating trains.

Locomotive Classification.—Prior to the locomotive classification system developed by F. M. Whyte, mechanical engineer of the New York Central and Hudson River Railroad Company, the designation was by name only, as Ten-Wheel, Mogul, Consolidation and the like. Whyte's classification, which has been generally adopted, is by numerals. It consists of three divisions, the first to designate the total number of leading truck wheels; the second, the total number of coupled driving wheels and the last, the total number of trailing wheels. In some cases, the number of leading and trailing truck wheels in the tender is also added.

Capacity and Efficiency.—The capacity of a locomotive is rated in terms of—

1—Its starting tractive force and

2—The horsepower developed at speed. The latter determines the available tractive force at various speeds. The starting tractive force on the other hand is limited by the available adhesion at the driving wheels. For this reason, the starting or rated tractive force should not exceed approximately one-quarter the weight on drivers.

The tractive force is effected by the action of the steam against the pistons in the cylinders and the connecting rod mechanism, resulting in a torque applied to the driving wheels. This is resisted by the moment of the tractive force at the rim of the wheels. Friction in the mechanism, however, reduces the effective torque applied to the driving wheels, and friction in the main journal bearings further reduces the moment of the tractive force at the rail. This total friction loss reduces the actual tractive force developed at the rail and which propels the train, to a certain percentage of the cylinder tractive force. The ratio of the actual tractive force to the cylinder tractive force (*i.e.*, the tractive force developed by the cylinders without friction) is termed the machine efficiency. At low speeds, where the torque and traction force is large, the machine efficiency is relatively high, whereas at the higher speeds, it is considerably lowered and the corresponding losses materially limit the output of the locomotive. If it were not for the resistance of the locomotive and tender idle axles, the drawbar pull and tractive force at the drivers would be identical in value. Actually, the train resistance of the locomotive as a vehicle, reduces the drawbar pull below the tractive force developed at the drivers. Obviously, during acceleration, the difference may be considerable, due to inertia resistance of the locomotive.

The performance of a locomotive at speed, in fact from 50 R.P.M. or 250 ft. piston speed, and above, is dependent upon the horsepower characteristics of the locomotive as a power plant. The horsepower rating of a locomotive is essentially dependent upon the boiler evaporation rate per hour and the cylinder steam consumption rate per horsepower hour. At the lower speeds, the steam consumption of the cylinders increases over that at the higher speeds due to the inherently longer cut-offs, together with a somewhat reduced evaporation rate of the boiler. For this reason, the horsepower developed varies with the speed, increasing to a maximum value at the operating speed wherein economical cut-offs are possible.

The horsepower rating of road locomotives is, therefore, usually stated at an arbitrary piston speed at from 1000 to 1200 ft. per min. or a corresponding rotational speed of the drivers at from 200 to 750 R.P.M. In this speed range maximum horsepower is reached. It is then dependent upon the normal maximum boiler evaporation rates and the normal minimum cylinder steam consumption rate.

In heavy freight drag service, it is desirable to improve the operating efficiency in the low speed range. In this case, more economical cylinder steam consumption is obtained by early cut-offs in the low speed range. Such locomotives are frequently termed "limited cut-off" locomotives.

To increase the Rankine efficiency, high pressure locomotives have been introduced, using compound cylinders. Aside from the increased economy, the compound cylinder, properly proportioned, gives a much wider speed range for economical fuel consumption and low water rates.

To improve cylinder performance and reduce cylinder condensation, superheated steam is supplied to the cylinders by superheating the steam through superheater units in the boiler.

The thermal efficiency is the ratio of the work developed at the drivers to the heat value of the fuel, as fired, to produce its hauling capacity at the rear engine or tender drawbar. In the average steam locomotive the thermal efficiency, based on the fuel as fired during road service, will vary from 4 to 9% where high steam pressures and temperatures, multiple expansion, feed-heating and the like are utilized.

A pound of average United States coal, as used by the railways, will run about 13,500 B.T.U. as fired, and with proper combustion in the fire-box of a steam locomotive, will enable from 50 to 80% of its heat value to flow across the boiler and the superheater heating surfaces, to the water and the steam, most of the remainder of the heat passing out of the stack in the form of cinders, escaping gases with the ash, and by radiation. The steam pressure and temperature produced, in consequence of this heat transference from the furnace gas to the water and the steam, when they reach the cylinders, transform from 8 to 9% of the total heat in the steam into mechanical energy, in the conventional single expansion cylinder locomotives, the remainder passing away through the stack with the exhaust steam. By the use of feed-heating, a certain percentage of this heat in the exhaust steam may be recovered and returned to the boiler in the form of heat in the feed-water. Likewise, the waste heat in the cinders and gases passing through the smoke-box, and out of the stack, may be partially recovered, by utilization in an economizer for further heating of the boiler feed.

Locomotive Design.—The problems involved in the design, material and construction of the modern locomotive are many and complex. Of first consideration is the roadway and structures over which the locomotive is to be operated, which involves the permissible truck and driving wheel loading, both static and dynamic, on the road bed and the bridges; then the width and height of clearances as established by tunnels, overhead crossings, station platforms and other limitations; the gradient and curvature to be negotiated; the required speed; character of the local fuel and water supply; length of turn-tables and engine-houses; engine-house and shop facilities; location and general arrangement of fuel and water supply stations; length of runs between division or intermediate terminals, and other similar factors. After the design has been prepared to conform to the foregoing requirements, then the general wheel arrangement and boiler and cylinder capacities must be determined upon to best meet the gradient, curvature and train loading requirements for the different districts over which the locomotives are to operate. In these calculations, the size and capacity of the boiler and superheater, with special regard for the steam pressure and temperature, grate area, fire-box volume and fire-box and boiler evaporation surfaces are important; also the locomotive bed or frame and driving or truck wheel arrangement; the kind and size of the cylinders and the valve gear, after which the auxiliary devices and appliances to make up the assembly, as a whole, must be decided upon.

With respect to the weight and clearance limitations, the European and other foreign designers have been considerably handicapped due to the restrictions which, in the United States and Canada, have been less limited, and for which reason the American practice has reached a stage, so far as size and capacity are concerned, far in advance of other countries, and which has enabled the development of heavier motive power for the handling of longer and heavier trains. However, instead of resorting to improved combustion of fuel, maximum utilization of radiant heat, high rate of heat transfer, efficient convection, higher steam pressures and temperatures and the more economical use of the heat in the steam, the general trend, particularly during the past 20 years, has been to more extravagant methods of stoking and use of fuel, lower steam pressures in boilers and cylinders and the ejection of a greater percentage of heat from the exhaust nozzle and stack. The special appliances that have been introduced are for fuel handling, firing, combustion, superheating, boiler circulation, feed water heating and feeding, steam distribution and utilization, lubrication, insulation, lighting, heating, safety, comfort and labour saving. Those auxiliary appliances, such as trailer and tender truck auxiliary engines, stack blowers, air brake pumps, mechanical stokers, fuel oil heaters and atomizers, power reverse gears, fire door openers, feed water pumps, injectors, grate shakers, coal pushers, ashpan slide pushers, ashpan blowers, water scoops, drifting valves, electric generators, automatic train control devices, steam heat equipment, cab heaters, lubricators, wheel flange oilers, bell ringers, rail sanders, cylinder cocks, steam whistles, safety valves, blow-off cocks, snow flanges and like accessories all require live steam or heat from the boiler of the locomotive for their operation, which the boiler and firebox must generate, in addition to the steam which is actually used for overcoming heat losses.

The steam locomotive, therefore, must not only produce superheated steam for the development of draw-bar pull, but it must also supply saturated and superheated steam to various auxiliaries and for train operation. In the case of a passenger locomotive, even greater demands for power are required in connection with the train lighting, heating, air-conditioning and ventilating equipment; hot and cold water and refrigeration systems and other devices. The most modern conventional type will produce at its best, from 6 to 8% thermal efficiency at the tender drawbar in terms of the heat value in the fuel fired. In average road service this percentage will be reduced to from 4 to 6% and is being obtained in the basic design by the use of from 200 to 250 lb. boiler pressure, in combination with an average amount of superheat in from two to four single expansion cylinders, or in duplex multiple expansion types of cylinders. In the handling of heavy freight tonnage, the question of locomotives of great power as opposed to grade reduction involves, as a primary consideration, the operating cost per train mile, the train load and the resulting cost per ton mile for various kinds and capacities of locomotives on different gradients. For secondary consideration there are the factors of maintenance of way and structures and of the mechanical facilities required for the handling and upkeep. (*See* RAILWAYS for a discussion of problem.) Speed, curvature and grade are factors that largely control the loading of locomotives, as well as the cost for their operation. In view of engine and train crew wages and fuel being the governing factors in train operating expenses, it is believed that on the basis of an eight-hour day, per 100 m. run, freight train running speeds of 15, 20 and 25 m. per hour are more economical, from a transportation standpoint, than speeds of 10, 30 and 35 m. per hour. In general, freight locomotives handling low class tonnage should be loaded to haul trains at an average schedule speed between terminals, including road delays, of from 12 to 15 m. per hour on low grade, and of from 10 to 12 m. per hour on high grade lines, which is as fast as economy will allow.

During the past ten (10) years, in order for the railroads to meet the intensive competition of the highway trucks and buses, freight train speeds have been materially increased for the purpose of moving higher class freight on shorter schedules. This has made necessary a substantial increase in the sustained hauling capacity of steam locomotives, with the result that boiler capacities have been increased by greater evaporation surface, boiler water storage and higher steam pressures, in conjunction with increased total temperature of the steam admitted to the valve chests and cylinders by a combination of the higher pressure and higher superheat. (Where from 200 to 250 lb. steam pressure was formerly used, from 275 to 325 lb., is now provided in the conventional designs of locomotive boilers, and from 350 to 500 lb. in the cylindrical-drum water-tube type firebox boilers, in combination with superheated steam total temperatures of as high as 750° F., and poppet valves actuated by outside rotary cam type of valve gear.)

Boiler Pressures.—Until 1895, steam locomotive boiler pressures were generally limited to 150 or 160 lb. gauge pressure. Then there was an advance to 200 lb. and in 1903–05 the Baltimore and Ohio went to 235 lb. in its first Mallet articulated compound locomotive, Baltimore and Ohio No. 2,400; and in 1905, to 225 lb. in its first 35 Pacific type passenger locomotives. During the next 20 years there was practically no increase, the general tendency being to use 200 lb. as a maximum, due largely to the adherence to the conventional type of locomotive boiler with its flat and radial sheet stay-bolts, water-legs and other non-self-supporting surfaces. During the past five years, on account of the public service central power station boilers being installed with pressures ranging from 350 to 650 lb., and marine boiler pressures going to 350 and 400 lb., there has been a tendency to raise the locomotive steam pressures and temperatures on account of the ability to increase locomotive capacity within the established clearance and weight limitations and the possible fuel and water savings. The conventional radial and flat sheet stayed water-leg type of fire-box is in some cases now being superseded by self-sustaining cylindrical-drum water-tube type of fire-boxes. A conventional type of boiler is now carrying steam pressures as high as 325 lb., but for higher pressures, as in the case of the Delaware and Hudson Railroad 350 to 500 lb. pressure, multiple expansion, and the Baltimore and Ohio Railroad 350 lb. pressure, single expansion locomotives, the cylindrical-drum water-tube type of fire-box is being substituted.

The "Horatio Allen" (named after the engineer who ran the first locomotive in the Western Hemisphere), high-powered locomotive No. 1,400 completed in 1924, was an epochal event in steam locomotive development. It has a total loaded weight of engine and tender in working order of 273 tons, was designed by the Delaware and Hudson Company and built at the Schenectady works of the American Locomotive Company. Instead of having the usual water-leg fire-box with its undesirable flat sheets and staybolts and the sluggish circulation of water around these sheets, the fire-box is built up of self-supporting cylindrical structures in the form of drums and tubes disposed horizontally and vertically, requiring no stays, and are directly exposed to the radiant heat of combustion and split the boiler water into small streams to provide for its rapid circulation, quick absorption of heat and release of the steam bubbles. The "Horatio Allen," when operating on a 0·5% ascending grade in tonnage freight service, with 3,217 actual gross tons in the train, at an average speed of 16·5 m. per hour, with coal of about 13,500 B.T.U., can produce an equivalent evaporation of 11·35 lb. of water per pound of coal at an average high-pressure cylinder cut-off of 64%; on the basis of indicated horse-power per hour, including auxiliaries, the dry coal consumption was 2·15 lb., and the steam consumption was 17·5 lb.; on the basis of draw-bar pull, the dry coal consumption was 2·14 pounds. During this performance the efficiency of the boiler was 80·6%, the machine efficiency was 93·86%, the thermal efficiency at the tender in terms of the heat value of the coal was 8·72%. An important advantage of the higher steam pressure on the "Horatio Allen" and the "John B. Jervis" locomotives has been found to be in the ability to increase the capacity of a locomotive within the same roadway clearance and weight limitations.

The success of the "Horatio Allen" and "John B. Jervis" higher steam pressure locomotives resulted in the Delaware and Hudson Railroad building the "James Archbald," as illustrated in Plate II, Figure 1, and the "L. F. Loree" as illustrated in Plate II, Figure 2, each carrying 500 lb. boiler pressure; the first mentioned being equipped with combined cylinders, and the last mentioned being equipped with triple expansion cylinders, giving road service thermal efficiencies ranging from 10·5 to 12·5 per cent.

In Europe, the Schmidt high-pressure experimental ten-wheel passenger locomotive on the German State railways, which makes use of 855 lb. boiler pressure, is outstanding as an example of high efficiency. From the results, to date, of this locomotive, and its use of multiple pressure, super-heating and re-superheating, multiple expansion and feed-water heating and purification, it has been proven conclusively that high pressures are safe in operation, great fuel savings are effected, that the first are little more than the conventional pressure locomotive, and that the high pressure machine can be easily handled by competent locomotive engineers and engine-house and shop organizations. The German State railways built a second locomotive which makes use of

1,700 lb. steam pressure. These are, however, exceptional cases, and it is still debatable as to whether the increased weight and first cost necessary to steam pressures beyond 500 or 600 lb., in locomotive design, will be justified by the greater economy over what has already been obtained from the 350 and 400 lb. pressures in combination with multiple expansion. In 1928, for a locomotive having four pairs of coupled driving wheels, the Delaware and Hudson Company's Consolidation No. 1,401, "John B. Jervis," is the most powerful. For starting and acceleration up to 8 m. per hour, it develops a tractive power of 103,000 lb., above which speed it is reduced to about 85,000 lb., up to 10 or 12 m. per hour, when it is still further reduced to between 65,000 and 70,000 pounds.

The largest and most powerful steam locomotives in the United States are represented by the Mallet types. On the Kansas City Southern railway, Mallet articulated compounds of the 2-8-8-0 type, carrying 250 lb. boiler pressure, have a tractive power in simple gear of 147,500 lb., and in compound gear of 122,500 pounds. When the tender truck booster is cut in, this produces an additional tractive power of about 13,000 lb. for starting and acceleration, thereby bringing the total up to about 160,000 pounds. The Virginian railway has in its service some of the largest steam locomotives in the United States. These are of the Mallet articulated compound 2-10-10-2 type, having a maximum tractive power of 176,000 lb. in simple gear, 147,200 lb. in compound gear and 108,000 lb. at a speed of 15 m. per hour. The modern American steam locomotive is quite deficient in superheating, as the conventional type of superheater brings the last pass of the superheated steam before it reaches the branch pipes to the steam chests, through the coldest part, or front end, of the boiler and the smoke-box, where the prevailing temperatures are usually less than that of the superheated steam. The possibility of preventing this waste and increasing the total temperature of the steam will make it advisable to use a different type of superheater in the future. The possibilities of utilizing the waste heat in the exhaust steam from the main engines and from the auxiliaries, such as the air brake pump, turbo-generator, booster engines and other appliances, and from the smoke-box gases, offer another probability for substantial increase in capacity and reduction in fuel. Various types of open and enclosed feed-water heaters and economizers, now being used on passenger and freight locomotives in the European countries and in the United States and Canada, have demonstrated that savings of from 6% to as high as 18% in fuel can be brought about in this manner. The development of a mechanically driven pump, whereby the operating power can be obtained from the main cylinders and which will reduce the steam requirements for pumping from about 80 lb. of live steam per horse-power hour to from 16 to 20 lb., offers possibilities in this direction. The exhaust steam type of injector, as now developed, also enables substantial fuel savings, although these can be depended upon for operation with the exhaust steam only when the locomotive is running at a uniform speed of 6 m. per hour and more; when the boiler pressure does not exceed 250 lb. and when the temperature of the feed-water does not exceed about 80° F. The burning of coal and lignite in powdered form, in suspension, the same as oil or gas, has come prominently to the front during the past ten years. There were, in 1928, in the United States and Canada, in central power station and industrial use, about 650 stationary boilers, representing about 8,500 nominal boiler horse-power, that are making use of powdered coal. Boiler capacities are being obtained of from 400 to 450% of the nominal ratings, and with combined boiler, furnace, superheater and economizer efficiencies of as high as from 90 to 92%, in terms of the heat value in the coal as fired, at between 125 and 275% of boiler rating. Progress is being made in marine service through the use of powdered coal, as well as on steam locomotives in America and Europe. One great advantage on railway systems using both coal and fuel oil is that when locomotives are transferred from the coal to the oil burning districts, and vice versa, it is not necessary to change the furnace and tender equipment to adapt them to the two fuels, and the method for firing the powdered coal or lignite is practically the same. The locomotive will have as great, if not more, an evaporative and superheating capacity with the solid as with the liquid fuel. (*See* Coal and Coal Mining; Pulverized Fuel.)

Steam Cylinders.—In Europe, the use of poppet valves as a substitute for piston valves is being brought forward, particularly in Austria, France and England. A few locomotives have also been equipped in the United States, but the applications are of an experimental nature, and the use of the piston valve in com-

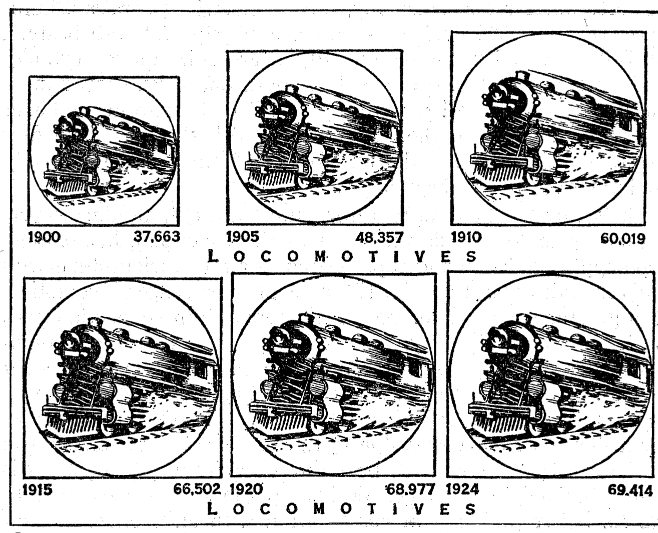

CHART SHOWING GROWTH OF LOCOMOTIVES IN SERVICE FROM 1900 TO 1924

bination with a Walschaerts or some similar outside valve gear, even in combination with pressures as high as 500 lb., will no doubt be continued until the poppet valve in combination with an angular motion gear has conclusively demonstrated its advantages, both from an operating and maintenance standpoint as compared with the linear movement. In the use of steam, the general practice in the United States and foreign countries is single expansion cylinders. Recently, by limiting the maximum cut-off in these cylinders to from 50 to 75%, an effort has been made to increase the expansion of the steam, reduce the loss of heat and produce greater economy through the use of a shorter cut-off. Reduction in the loss of heat is accomplished by the compound, triple and quadruple expansion engine by expanding the steam in several stages, which reduces the range of temperature in each cylinder and the condensation, when saturated steam is used, or waste of superheat, when superheated steam is used, but these multiple expansion engines have greatly increased the steam contacting cylinder and piston areas, and must be operated at relatively long cut-off. Furthermore, the counterflow use of the steam causes a great waste in heat. Therefore, the uniflow cylinder offers special inducements in locomotive practice. It has advantages over compounding in that the same results can be accomplished with shorter cut-off, and by the peculiarities of the flow of the steam in the cylinder. After entering the cylinder the steam does not retrace its steps, but continues to go forward from the point of entrance until it passes out, and in this way the steam in exhausting does not sweep the heat from the inlet port surfaces, nor from the cylinder heads. This method greatly reduces the cut-off, condensation and expulsion of heat with the exhaust, and enables the single cylinder non-condensing engine to excel in economy to a substantial degree the compound or any similar multiple expansion non-condensing engine.

Future Development.—The trend of the steam locomotive development is toward a wheel and running gear arrangement that will provide the maximum ratio of main engine coupled adhesive to total engine weight, and of main engine power to such adhesive weight; 500 lb. steam pressure; 850° F total temperature of the steam; a uniflow boiler, superheater and two or four outside cylinder arrangement; piston valves and outside valve gear; a 100% furnace volume, evaporation surface and

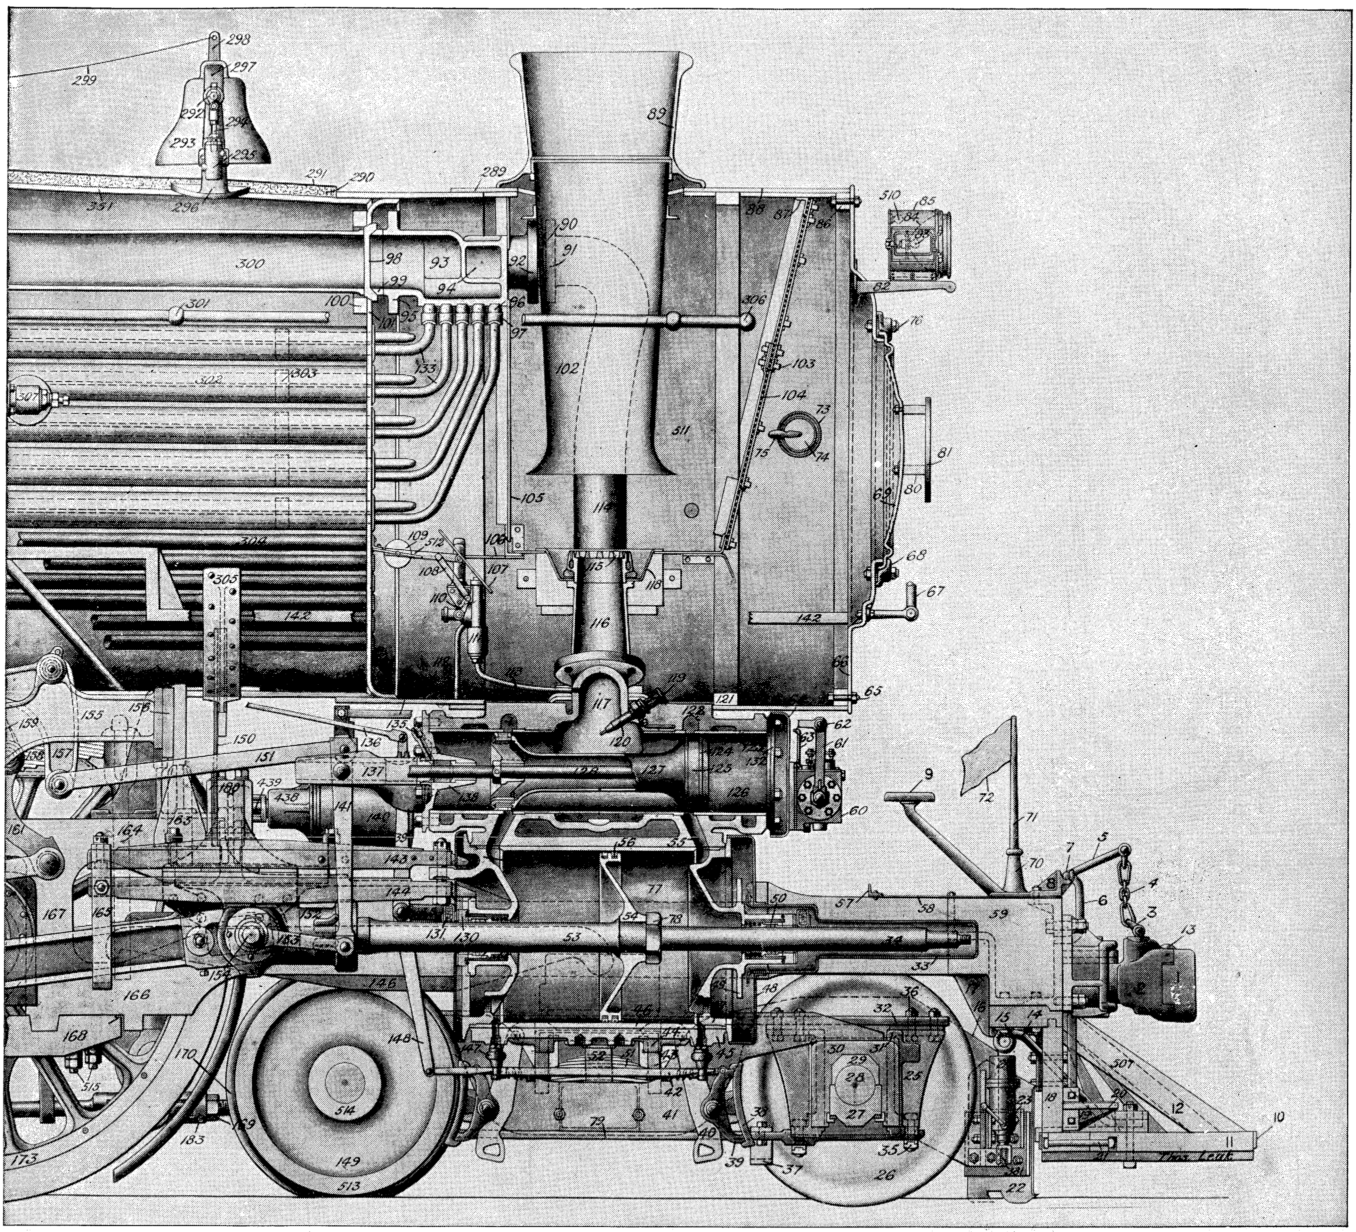
Main driving axle. 196. Main driving wheel hub. 197. Baker valve gear eccentric crank. 198. Main crank pin. 199. Reach rod. 200. Main driver spring hanger seat. 201. Frame brace. 202. Top rail of main frame. 203. Equalizer bracket. 204. Driver equalizer. 205. Lower rail of main frame. 206. Rear section of side of parallel rod. 207. Knuckle pin or side rod. 208. Connecting rod fork. 209. Connecting rod cotter for brasses. 210. Connecting rod key for brasses. 211. Connecting rod oil cup. 212. Eccentric crank clamp. 213. Eccentric rod crank pin. 214–231. Ragonnet power reverse gear details. 232. Rear driving axle spring. 233–234. Driving axle spring band and stirrup. 235. Franklin automatic driving box. 236. Franklin automatic driving box adjusting wedge. 237. Rear driving axle journal bearing. 238. Rear driving axle journal box. 239. Rear side rod flange. 240–242. Franklin automatic adjustable driving box wedge spring bracket, bolt and spring. 243. Rear driving wheel crank pin. 244. Franklin automatic adjustable driving box wedge spring cap. 245. Rear driving axle. 246–247. Driver brake beam, brakeshoe and lever. 249–250. Foundation ring bearing shoe and support. 251. (*see* Plate VII.) 300. Dry pipe—runs from steam to cylinders (*see* Plate IX.) 306. Sand box cap. 308. Sellers injector check. 309. Delivery pipe. 310. Superheater unit support. 311–312. Sand pipe and sand box. 313–314. Sand lever and sand pipe connection. 315. Sand box rod. 316. Westinghouse air pump low pressure air cylinder lubricator. 317. Westinghouse air pump high pressure air cylinder lubricator. 318–350. Westinghouse air pump details. 352. Second course of boiler shell. 353. Dome reinforcing plate. 354. Dome. 355. Front anchor for back head brace. 356. Hand rail. 357. Dome casing. 358–365. Chamber throttle valve. 366. Air pipe from duplex compressor governor to main reservoir. 367. Steam pipe from duplex compressor governor to compressor. 368. Steam valve body of duplex compressor governor. 369. Steam pipe to air compressor. 370. Chamber throttle valve throttle rod. 371–373. Whistle, whistle rod and whistle lever. 374. Check unit from maximum compressor head of duplex compressor governor. 375. Check unit for excess pressure head of duplex compressor governor. 376. Spring box for maximum pressure head of duplex compressor governor. 377. Diaphragm body for duplex compressor governor. 378. Siamese fitting for duplex compressor governor. 379. Pipe from excess pressure head of duplex compressor governor to automatic brake valve. 380. Safety valve. 382–384. Chambers throttle valve balance valve, piston and packing ring. 385. Superheater forged return bend. 386. Ragonnet reverse gear valve chest gland. 387. Beading on tubes. 388. Arch tube wash-out plug. 389. Outside throat sheet. 391. Back tube sheet. 392. Crown sheet. 393. Stiffening plate for safety valve opening. 394. Outside or roof sheet of fire box. 395. Boiler brace. 418. Combustion chamber. 419. Wash-out plug. 506. Side rod oil cup. 516. Front driving wheel crank. 517. Front driving wheel counter balance. 518–519. Baker valve gear counter balance rod and arm. 520. Main reservoir. 521. Driver spring hanger key. 523. Westinghouse compound air pump. 524. Westinghouse air pump high pressure air piston. 527. Belpaire cross stay

LOCOMOTIVE



PACIFIC OR 4–6–2 TYPE LOCOMOTIVE—CYLINDER AND SMOKEBOX DETAILS

1–9. Coupler and uncoupling lever details. 9. Front end step. 10–12. Pilot nosing, base and bar. 13. Coupler knuckle pin. 14. Pilot brace. 15. Safety chain eye. 16. Snow flanger equalizer (Ray type). 17. Pilot and buffer angle. 18. Back vertical of pilot. 19–20. Pilot step bracket trend. 21. Pilot base tie bolt. 22–24. Snow flanger details (Ray type). 25. Truck pedestal. 26. Truck wheel. 27. Truck axle box cellar. 28. Truck axle. 29. Truck axle journal bearing. 30. Truck journal box. 31. Truck pedestal rib. 32. Truck frame. 33–34. Extension piston rod casing and rod. 35. Pedestal tiebar bolt. 36. Truck pedestal bolt. 37. Truck pedestal tiebar cross tie. 38. Truck brakeshoe. 39. Truck brakehead. 40. Truck brake lever. 41. Front truck equalizer. 42. Cylinder cock slide rod. 43–44. Truck spring hanger and bracket. 45. Cylinder shell. 46. Cylinder bushing. 47. Front cylinder head. 48–49. Front cylinder head casing and flange. 50. Extension piston rod packing. 51–52. Front truck semi-elliptic spring and band. 53–54. Piston rod and piston. 55. Steam port. 56. Piston packing ring. 57–58. Front plate stiffening angle and front plate. 59. Front buffer beam. 60–63. Lubricator details (Schlacks system). 64. Front steam chest casing. 65. Boiler front bolt. 66. Boiler front. 67. Boiler front hand rail. 68–69. Smoke-box door clamp and door. 70–72. Flagstaff fixture, flagstaff and signal flag. 73–75. Spark cleaning hole cap ring, cap and handle. 76. Smoke-box door clamp bolt. 77. Cylinder. 78. Piston nut. 79. Truck pedestal tiebar. 80–81. Number plate stud and number plate. 82–85. Head-light bracket, lamp, reflector and casing (Pyle National). 86. Front smoke-box ring. 87. Netting frame. 88. Smoke-box shell. 89. Smokestack. 90–91. Steam-pipe ring and flange. 92. Superheater steam-pipe connection. 93. Saturated steam passage. 94. Superheater steam passage. 95. Superheater header (type A). 96. Superheater unit ball end. 97. Superheater unit clamp. 98. Dry pipe flange. 99. Superheater header ring. 100. Dry pipe stiffening ring. 101. Front tube sheet. 102. Smokestack lift pipe. 103–104. Netting stud and netting. 105. Diaphragm. 106–113. Superheater damper details. 114. Steam pipe. 115. Muffled exhaust nozzle. 116–117. Exhaust pipe and passage. 118. Horizontal diaphragm pocket. 119. Lubricator diaphragm terminal check valve (Schlacks system). 120. Lubricator terminal check valve steam pipe extension (Schlacks system). 121. Intermediate smoke-box ring. 122–123. Steam chest casting and bushing. 124–125. Piston valve packing and bull ring. 126. Steam chest. 127–128. Piston valve and valve stem. 129. Back cylinder head. 130. Piston rod packing (Q. ana C. type). 131. Piston rod lubricator (Q. and C. type). 132. Front steam chest head. 133. Superheater unit pipe. 134. Lubricator lever link (Schlacks system). 135. Valve stem lubricator. 136. Cylinder cock reach rod. 137. Valve stem cross head guide. 138. Back steam chest head. 139. Back steam chest head stud. 140. Driving brake cylinder. 141. Baker valve gear combination lever. 143–144. Top and bottom guides. 145. Cylinder cock shaft. 146. Driver and truck equalizer. 147. Cylinder cock. 148. Cylinder cock shaft arm. 149. Truck wheel web. 150. Buckle plate. 151. Baker gear valve rod. 152. Cross head. 153. Baker valve gear union rod. 154. Wrist or cross-head pin. 155–157. Baker valve gear frame, cross tie and bell crank. 158. Front driver spring. 159. Baker valve gear radius bar. 163. Guide yoke. 164. Front driving spring hanger. 165. Guide strap. 166. Engine frame. 167. Front pedestal leg. 168. Pedestal tie. 169. Brake pull rod adjusting nut. 170. Truck wheel flange. 173. Driver tire retaining ring. 180. Guide yoke. 183. Brake pull rod turn buckle. 289. Smokestack base reinforcing plate. 290–291. Boiler lagging and boiler jacket. 292. Hammett bell-ringer crank. 293. Bell. 294–295. Hammett bell-ringer piston rod and bell-ringer cylinder. 296–297. Bell stand and bell yoke. 298–299. Bell lever and bell cord. 300. Dry pipe. 301. Handrail bracket. 302. Superheater tube. 303. Superheater unit band. 304. Boiler tube or flue. 305. Boiler belly brace. 307. Sellers injector stop valve. 351. Front course of boiler shell. 381. Snow flanger cross tie brace (Ray type). 438–439. Driving brake cylinder head and piston rod. 507. Pilot. 510. Pyle National head-light side-light bulb. 511. Smokebox. 512. Superheater damper counter weight arm. 513. Truck wheel rim. 514. Truck wheel hub. 515. Pedestal tie bolts

ELECTRIC PASSENGER AND FREIGHT LOCOMOTIVES IN USE ON AMERICAN RAILROADS

1. Virginian Railway. Three 2-8-2 units, AAR Classification 3 (1-D-1), built by American Loco. Co., & Westinghouse Elec. and Mfg. Co.; 11,000 or 22,000 volts A.C. Total wt. 1,282,380 lb.; wt. on drivers 922,580 lb.; wt. on guiding trucks 359,800 lb.; capacity at one hr. rating 6,090 h.p. at 14.1 m.p.h.; 7,125 h.p. at 28.3 m.p.h. Starting tractive effort 277,500 lb. at 30.07% adhesion; tractive effort, hourly rating, 162,000 lb. at 14.1 m.p.h., 94,500 lb. at 28.3 m.p.h.; tractive effort continuous rating, 135,000 lb. at 14.2 m.p.h.
2. Chicago, Milwaukee, St. Paul & Pacific Railroad. One 4-6-2 and one 2-6-4 articulated units, built by Westinghouse Elec. & Mfg. Co.; 300 tons cap.; 3,000 volts D.C. Total wt. of locomotive 600,000 lb.; wt. on drivers 378,000 lb.; wt. on idle trucks 222,000 lb.; capacity at one hr. rating 4,680 h.p. Starting tractive effort 94,500 lb.; tractive effort, hourly rating, 66,000 lb.; tractive effort, continuous rating, 40,800 lb.
3. New York, New Haven & Hartford Railroad. Two 2-6-2 articulated units, built by Westinghouse Elec. & Mfg. Co.; 11,000 volts A.C. Total wt. of locomotive 356,000 lb., wt. on drivers 240,000 lb., wt. on idle trucks 116,000 lb.; capacity at one hr. rating 2,508 h.p. Starting tractive effort 52,500 lb.; tractive effort, hourly rating, 19,260 lb., continuous rating, 13,080 lb.
4. Pennsylvania Railroad. One articulated unit (4-6-0+0-6-4). Class GG1. Built by the Pennsylvania Railroad. 11,000 volt A.C. Total weight of locomotive 460,000 lb.; weight on drivers 300,000 lb.; weight on idle trucks 160,000 lb.; capacity at continuous rating 4,620 h.p. Starting tractive effort 72,800 lb.; tractive effort, continuous rating (90 miles per hour) 19,140 lb.
5. Chicago, Milwaukee, St. Paul & Pacific Railroad. Two 4-8-0 articulated units, built by General Elec. Co.; 3,000 volt D.C. Total wt. of locomotive 564,000 lb.; wt. on drivers 448,000 lb.; wt. on idle trucks 116,000 lb. Starting tractive effort 112,000 lb.; tractive effort, hourly rating, 71,000 lb.
6. Canadian National Railways. Two 4-wheel-truck type oil-electric passenger and baggage motor car, built at Point Charles Works, Montreal. Length of car body 73 ft. 9 in. over end sills; total wt. on rails 133,000 lb. Beardmore six-cylinder oil engine, 300 h.p. at 750 r.p.m. Westinghouse 198 K.W. D.C. gen.; two 600 volt 200 h.p. motors
7. New York Central Railroad. Two 4-wheel-truck type, built by Elec. Storage Battery Co. Combination battery and oil-electric; 218-cell storage battery, capacity 294 Kwh. Four motors, total rated 1,580 h.p.; motor gear ratio 4.24; driving wheels 44 in. diam. Tractive effort, max. 60,000 lb. Total wt. on drivers 257,000 lb.; 300 h.p.

OIL-ELECTRIC LOCOMOTIVES FOR PASSENGER AND FREIGHT SERVICE

1. Three-unit diesel-electric locomotive for passenger train service. This streamlined locomotive develops a total of 6,000 horse-power
2. Alco G.E. diesel-electric 660-h.p. switching locomotive
3. Diesel-electric locomotive of two units that draws a streamlined passenger train, "The 400," between Chicago and Minneapolis
4. Diesel-electric switching locomotive, 1,000 h.p.; economy, safety and cleanliness are its advantages

gas area water tube fire-box—fire flue and tube boiler; a fire-box header—fire flue superheater; main throttle valve and steam delivery and branch pipes to be placed outside of boiler and smoke-box; a turbo-fan stack-draft blower; insulation and jacketing to have an efficiency of 98%; a mechanically driven feed pump; an open de-aërating feed-water heater; a smoke-box economizer, a unit system for automatically burning solid or liquid fuel in suspension; the use of high-elastic limit, tough, ductile, high manganese-low carbon steel castings, forgings and plates; and the utilization of engine and tender leading and trailing uncoupled truck wheel weight, for necessary starting, acceleration and light power use, by means of independently operated four-wheel coupled, reversible and relatively high speed and economical steam auxiliaries. High pressure-temperature non-condensing steam locomotives can be designed and constructed at a reasonable cost, to operate safely, reliably and efficiently, at speeds as high as 110 m. per hour under roadway, track and signal conditions suitable for such train speed, and permissible improvements will greatly reduce the existing smoke and noise nuisances. In terms of the heat value of the fuel used, the thermal efficiency at the tender draw-bar can be increased from what we now ordinarily obtain in road service—4 to 6%—to from 13 to 15%. In relation to the unit of work produced, *i.e.*, gross ton miles or draw-bar horse-power hour, this shows the enormous possibilities remaining in the way of increasing steam locomotive boiler, engine and machine efficiency. Pressures will be limited for the time being in locomotive construction to around 500 pounds. The wheel loads to be encountered in 1929 by a locomotive boiler pressure higher than 500 lb. may not increase the efficiency sufficiently to compensate for the added total locomotive weight.

Higher passenger train speeds have brought up the factor of head end air resistance, and numerous designs of streamlining developed and still under advisement are for the purpose of reducing air and train resistance when trains are operated at speeds of over 75 m. per hour. However, as it is the track curvature, super-elevation and the track and transportation conditions in general that govern maximum train speeds, it is probable that streamlining will be more a factor of "styling" than of efficiency.

The use of the self-contained high-pressure-temperature steam locomotive, in combination with an improved steam distribution gear, will no doubt be continued indefinitely where heavy trains and traffic must be expeditiously and economically hauled for long distances under all sorts of profile and weather operating conditions. Where they cannot be made suitable Diesel engines or electricity may be substituted. (J. E. Mu.)

ELECTRIC LOCOMOTIVES

The electric locomotive, as commonly defined, is a motive power unit which receives its power from an overhead trolley or a third rail contact system. Certain other classifications might also rightfully be considered as electric locomotives, such as the diesel-electric, the gasoline-electric, the turbine-electric and the storage battery type.

While these units generate or furnish their own basic power, they employ electric drive quite similar to that of the straight electric locomotive. Some combination locomotives using two or three sources of power have been built.

Electric locomotives have been applied for every type of transportation service including mining, industrial plants, interurban railroads and, most conspicuously, to supersede steam service on main line railroads. For these varied services, locomotives have been constructed in a multitude of sizes and types, ranging from the so-called midget of 1½ tons for industrial service to the heavy duty, main line freight locomotives of the Virginian railway, weighing over 600 tons, rating 6,000 continuous horse-power and developing 277,500lb. tractive effort. Electric operation of different roads extends from minor installations of a few miles to that of the Pennsylvania railroad, the most extensive in the world, which connects New York, Philadelphia, Washington and Harrisburg with over 2,000mi. of electrified track.

STRAIGHT ELECTRIC LOCOMOTIVES

Types of Locomotives.—Electric locomotives are of the alternating current type or the direct current type depending upon the kind of power furnished over the trolley or third rail system. For all installations of minor extent the direct current system is invariably employed. For main line operation, both systems are used, and so far their use has been about equal in extent. From the purely technical standpoint, each system has certain advantages for any particular application, and thus the decision as to system should be dictated by local conditions. However, for uniformity and interchangeability, many countries have seen fit to standardize not only on the system, but also on the trolley voltage. The extent to which each system is employed may be seen from the tabulation which follows, showing the prevailing standards in those countries where electrification has been extensively employed:

Country or Region	*System*
United States	600, 1,500, 3,000 volts d.c. 11,000 volts, 25 cycles a.c.
South America	3,000 volts d.c.
British Empire	600, 1,500, 3,000 volts d.c.
Belgium	3,000 volts d.c.
Italy	3,000 volts d.c.
Poland	3,000 volts d.c.
Russia	3,000 volts d.c.
France	1,500 volts d.c.
Japan	1,500 volts d.c.
Holland	1,500 volts d.c.
Germany	15,000 volts, 16⅔ cycles a.c.
Switzerland	15,000 volts, 16⅔ cycles a.c.
Sweden	16,000 volts, 16⅔ cycles a.c.

All alternating current systems listed are single phase. The complications which arise in the trolley construction have placed the three phase system in the discard.

Locomotive Mechanical Design.—The mechanical parts include those portions of the locomotive which make it suitable as a vehicle, *i.e.*, the running gear, and the cab or superstructure which houses the operator and the electrical apparatus.

In contrast with the steam locomotive, the designer of an electric locomotive is offered the possibility for an infinite variety of running gear arrangements as each axle can be driven by its own motor when preferred. As a result of this potential flexibility, an almost endless number of running gear designs have been produced. Fortunately, recent progress in the art is leading to the abandonment of the more fantastic types and to greater standardization on proven designs.

Any electric locomotive mechanical design can be classified by one of the three following general types:

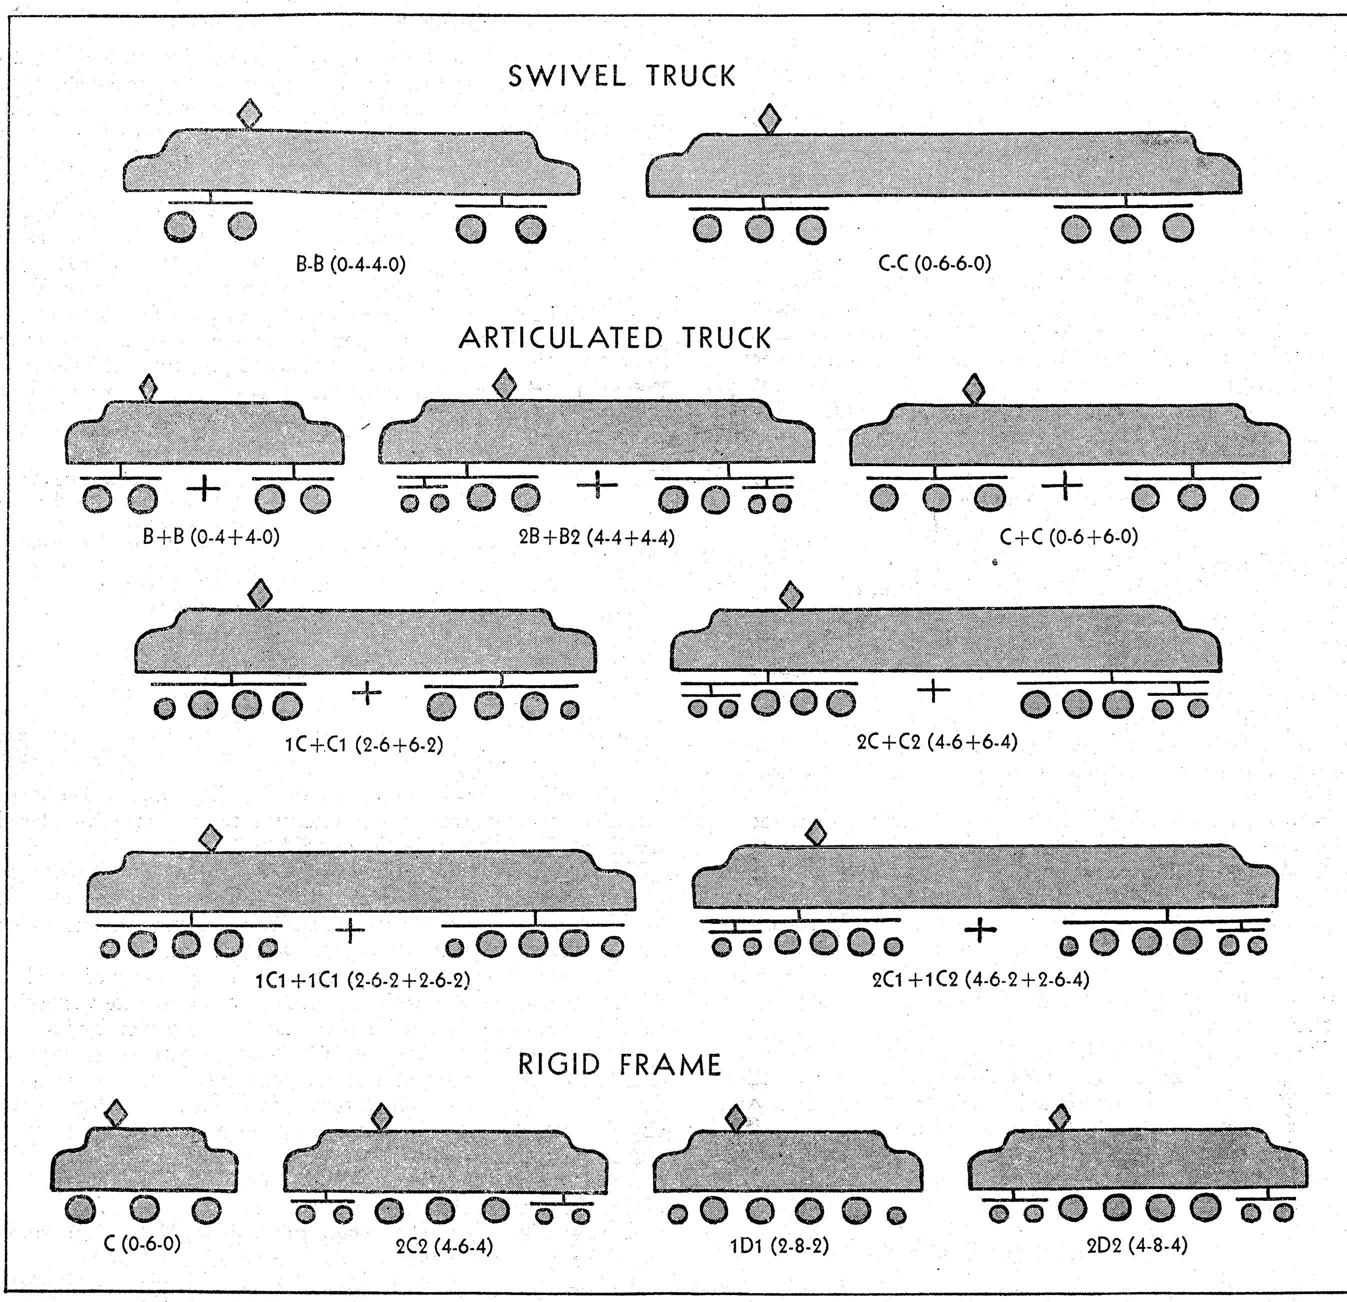
1. The swivel truck type where two independent swivel trucks carry the cab superstructure on centre pins.
2. The articulated truck type where the trucks are interconnected by joints or hinges which permit the entire draw-bar pull to be carried through the trucks themselves and none through the cab superstructure.
3. The rigid frame type where the driving axles are carried by the main locomotive frame in a rigid wheel base.

The two latter types, when applied for operation at the higher speeds, incorporate guiding trucks at the outer ends of the locomotive to improve its riding characteristics.

The types more commonly in vogue today are illustrated by the diagrams on page 284. (In this tabulation the + sign indicates that the trucks are connected at this point by a joint or hinge to form the articulation.)

Swivel truck locomotives are commonly applied to switching and transfer service where speeds are relatively low and where the flexible truck arrangement permitted by this type of locomotive ideally fits it for the sharp curves found in yard tracks. Furthermore, the swivel truck type usually offers the minimum first cost for this service.

For heavy duty service either the articulated truck or the rigid frame type is employed. While the rigid frame type generally offers a more simplified design with a lower cost, certain limitations are imposed upon its application as it is often impractical



TYPES OF ELECTRIC LOCOMOTIVE MECHANICAL DESIGN

to meet normal curve restrictions with more than four driving axles in the rigid wheel base. Thus, where large capacities are required, this type is restricted to those railroads which will permit relatively heavy axle loadings.

The articulated type has the widest possible field of application. Since it is practical to provide six to eight driving axles, this type offers the designer a wide variety of choices to meet any particular requirements.

The design of the guiding trucks is influenced largely by the prevailing speeds at which the locomotive will be called upon to operate. Single axle trucks are generally preferred for medium speeds, but above 60 m.p.h., two-axle trucks predominate. To perform effectively their function in guiding, the weight carried by each guiding axle must be from 50% to 80% of the weight carried by each driving axle. The design of the guiding trucks is a most important feature for very high speed operation. By proper design of its mechanical parts, the electric locomotive can be made safe for operation at any speeds permitted by the roadbed.

Drive.—One feature of the electric locomotive which has received much attention is the "drive," or the arrangement by which the motor torque is transmitted to the driving wheels. All locomotive drives may be classified into two general types: (*a*) the individual axle drive where each axle is driven by its own motor or motors, and (*b*) the collective drive where two or more axles are driven from one motor or group of motors. While the collective drive is somewhat the outgrowth of steam practice, both types have been widely used, although more recently, especially in America, the individual axle drive has greatly predominated as it eliminates side rods and heavy rotating parts.

The simplest form of individual axle drive is the direct geared, axle hung motor. Here the motor is mounted within the truck and geared directly to the axle to be driven. The motor is supported on one side by bearings on the axle, and on the opposite side by a nose support which rests on some portion of the truck. The field of application of this drive is somewhat restricted by space limitations, but for those cases where it is suitable it is widely used because of low cost and low maintenance expense.

When the service to which the locomotive is to be applied calls for large capacity motors operating at high speeds, experience has proven the desirability of carrying the motors on the spring-borne parts of the running gear to relieve the track from excessive unsprung weight. When this mounting is used, there must be relative movement between the spring-borne motor and the driving wheels, necessitating some form of flexible drive. There are several forms of individual axle drive which provide this flexibility, principal among which are the Buchli link drive and the centre axle drive (both extensively used in Europe), and the quill cup or quill spring drives (used extensively in America and Europe). In all of these drives, the motors are mounted above the axle with intermediate gears provided to reduce motor speed to axle speed, so that their principal differences lie in the connections between gear and axle which will permit the necessary relative movement between the two. These drives have been so perfected that satisfactory performance is obtained under the most severe present-day requirements.

Collective axle drives invariably employ side rods when used on large locomotives. One or more motors are usually geared to a jack shaft which in turn is connected to the drivers by side rods. These drives, of which there are many variations, have reached their greatest development in Europe, while in America they are being rapidly superseded by the individual axle type. The vogue which the collective drive originally enjoyed was the result, to a certain extent, of limitations in the electrical equipment which could not be overcome otherwise, but recent developments no longer make them so necessary.

Electrical Apparatus.—Locomotive designers, whether steam or electric, continually face the problem of producing units of increased capacity. In America, since about 1910, the average capacity of electric locomotives has increased from 1,000 h.p. to 5,000 h.p., or fivefold. However, the weight and clearance restrictions imposed by the roadway have shown little or no change, making it necessary to provide the larger capacity within the same limits of space and weight. These restrictions and demands are so severe that today (1940) electrical apparatus on locomotives is designed for higher speeds and higher operating temperatures than those generally found throughout the electrical industry.

The four principal types of locomotives used today, as classified according to the kind of propulsion motors, are briefly described below.

The first electric locomotive used d.c. equipment. Roughly 50% of all main line locomotives are of this type, and practically all locomotives for installations requiring units smaller than main line requirements.

The electrical apparatus for all d.c. locomotives follows the same general pattern. The series motor is universally used as its inherent characteristics are ideally suited for traction purposes. The speed of d.c. locomotives is controlled by one or more of the following methods: (*a*) by inserting in the motor circuits resistance which can be varied in value; (*b*) by series and series-parallel or parallel connection of the motors, and (*c*) by field control whereby the motor series field winding is shunted or tapped to give reduced field strength. When locomotives operate on trolley voltages under 750 volts, the traction motors are wound for full trolley voltage, but for higher voltages the motors are wound for one-half to one-quarter of trolley voltage. In the latter case, two or more armatures are permanently connected in series, and each such circuit handled in the control as if it were a single motor.

Alternating current locomotives employ several fundamental types of electrical apparatus depending upon the service to be operated. Where the prevailing speeds range from 25 to 100 m.p.h., the a.c. series commutator motor is the preferred type, and the vast majority of a.c. locomotives are equipped with this motor. The a.c. series motor is similar in its characteristic performance to the d.c. motor, but its construction involves special features to assure satisfactory commutation when operated from an a.c. trolley. As this motor has been used on many of the major electrifications it has probably reached a higher stage of development than any other type.

Speed control of the a.c. series motor driven locomotive is obtained through a multi-tap transformer located within the cab which reduces the trolley voltage to the required motor voltage. The possible wide range of voltage afforded by transformer control makes the a.c. series motor locomotive the most flexible of all types of motive power from the operating standpoint.

In the U.S.A. two other types of a.c. locomotives have been applied for heavy drag, slow speed operation in mountain grade territory. The first of these used was the phase converter or split-phase type. On this locomotive the single phase trolley supply is converted to polyphase by a phase converter located within the cab. The propulsion motors are of the three phase, wound rotor induction type. Two or more continuous running speeds are provided by reconnection of the motor windings for various pole combinations or by cascade connection of the motors. The great advantage of the phase converter locomotive is its ability to withstand abuse at starting due to the absence of all motor commutators.

The second heavy duty a.c. locomotive used in America is the motor generator type where single phase trolley power is converted by a motor generator set to direct current to drive direct current traction motors. This type combines the advantages of the d.c. motor for slow speed service with that of the a.c. high voltage trolley supply.

Except in special cases, all major apparatus on electric locomotives is highly ventilated, often by special blowers. Ventilation imposes the problems of dirt, snow and rain, but space restrictions require cooling air so that often special devices are used to assure clean air. In large locomotives, the air requirements may exceed 50,000 cu.ft. per minute.

While small locomotives may use the conventional wheel trolley, all main line units are equipped with the pantograph type of trolley. These are normally spring raised and air lowered. Current collection at extremely high speeds requires a most careful design of both the pantograph and of the contact system.

The air brake system is similar to that of the conventional steam locomotive except that the compressors are driven by electric motors. All types of electric locomotives can be arranged to give regenerative braking. In this system the motors act as generators on descending grades, convert the momentum of the train into electric energy which is returned to the trolley system, and control the train speed without the use of air brakes. The power regenerated may be from 10 to 25% of that required for traction.

When electric locomotives haul passenger trains, the trains are heated by oil fired steam boilers within the locomotive. As the cars normally operate in both electrified and non-electrified territory, the heating system must be uniform for both services.

Locomotive Performance.—More capacity per ton of locomotive can be placed in the electric locomotive than in any other type of motive power. Hence the potential capacity of electrified operation to handle heavy trains at high speeds cannot be matched by any other type of power.

The weights, dimensions and capacities of electric locomotives vary over a wide range. These variations have been caused by many factors, some of which are the operating conditions to be met, the weight and space limitations imposed by different railroads, and the speeds which the particular roads will allow. However, as a general rule, most designs will fall within the following limits which show the range to which single cab locomotives can or have been built with electrical apparatus now developed:

Mechanical Design	Total Loco. Weight Tons	Driver Axle Loading Pounds	Cont. h.p.	Max. Short Time h.p.
Swivel Truck .	40–125	20,000–63,000	500–2,000	750–3,000
Articulated Truck .	80–300	30,000–70,000	2,000–7,500	3,000–12,000

SELF-PROPELLED LOCOMOTIVES

In this classification fall the diesel-electric, the gasoline-electric, the turbo-electric and the storage battery types. Except for the prime mover and control, the equipment in any of these types is essentially the same as that of the conventional direct current locomotive.

The diesel-electric is receiving great favour as a switching locomotive, and to a lesser extent for passenger service. In road freight service its application has been nil. Most units so far constructed have not exceeded 2,000 engine h.p. per cab, but for passenger service as many as three of these cabs are placed on the train, providing a three-cab 6,000 h.p. locomotive. Designs are being made for locomotives of 4,000–6,000 h.p. in a single cab, but none have yet (1940) been placed in service.

It can reasonably be expected that the diesel locomotive will be more widely used in the future. It is yet too early in the development to foresee its final field in the railroad picture, but the trend to date is for a wide use in switching service, a field in ultra high speed passenger service and a limited use in road freight service. The gasoline-electric is used on the smaller units and where the locomotive is in service a relatively small proportion of the time. Its fuel cost is higher than that of the diesel, but its first cost is lower, hence its application is one of relative economy.

The storage battery locomotive has been most widely used in those locations were it is impractical to construct a trolley, or where the use of a diesel or gasoline engine is prohibitive. In some cases, diesel or trolley locomotives are equipped with auxiliary storage batteries to serve during those periods when they are required to operate in restricted territory.

A development has been the steam-turbine electric locomotive. Only one of these locomotives has been built (1940), this one being a two cab affair with a rating of 5,000 turbine horsepower. The locomotive has a high pressure flash boiler, burning oil, which supplies steam for the turbo-generator set. The electrical propulsion equipment is of conventional design. About one-third of the locomotive space is consumed by the condensers for the turbine. The two cabs weigh in excess of 500 tons in working order. The use of electric locomotives throughout the world is gradually being extended. While accurate statistics are not available, the total of main line locomotives is about 5,000 as of the year 1940. (C. K.)

LOCOMOTIVE COALING, the three industrial enterprises which consume most coal are railways, gas works and power stations. Of these three, gas-works engineers were the foremost to realize the need of handling their coal mechanically; those in power stations followed, and employed conveyors practically from their inception, basing their plant on the experience gained in gas works during the previous decade. The railway companies, who probably use more coal than either of the other two undertakings, continued, with one or two minor exceptions, to handle their locomotive fuel entirely by manual labour, until 1913; in the meantime American and Continental railways were leading in the adoption of machine coaling. While England has some of the finest locomotive coaling plants to be found anywhere, they are not as widely used as elsewhere. Since the coal consumed annually by locomotives amounts to many millions of tons, such devices should be provided for all important coaling yards. Large engine sheds may use as much as 600 to 700 tons of coal per day for their tenders and tank engines, while even small ones will require 200 to 300 tons.

Manual Coaling.—To load coal by transferring it manually from the truck to the tender necessitates the employment in a yard of about 30 "coal men," who do nothing else. Moreover, the time taken varies from 15 to 45 minutes for coaling a tender; this delays the engine and wastes the driver's time in the sheds. By modern mechanical means the largest locomotive can be provided with its quota of coal in three minutes by the services of a maximum number of four men; *i.e.*, one on each 8-hr. shift of the day, to operate the coal valves, and one during the first shift for filling the bunker and for assisting in the shunting of the coal wagons. It has been realized that if 100 locomotives per day have to be coaled, it is an economical proposition to do so entirely by mechanical means.

Modern methods, by which coal can be handled from the mineral truck to the locomotive tender, are very numerous. Some are quite inexpensive, while others are elaborate and costly. The determining factor is not solely the amount of coal to be handled, but the area, and more particularly the shape of the available site, which have both to be taken into consideration when deciding on the type of plant to be adopted.

The subject may be conveniently divided into three classes: locomotive coaling plant which provides for storage of coal in wagons; locomotive coaling plant in which the coal is held in suspension in overhead bunkers; locomotive coaling plant with ground storage "bings."

Installations of the first kind can only serve one tender at a time, whereas the others can serve several simultaneously. For a plant of the first class a long and narrow strip of land is required and a relatively simple mechanical device is employed, while the rest of the space is utilized for standing room for the full trucks. The disadvantage of such simple plants is that the operators must always be in attendance during the three shifts of the day.

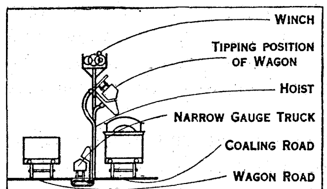

FIG. 1.—LOCOMOTIVE COALING PLANT USED BY THE LONDON, MIDLAND AND SCOTTISH RAILWAY COMPANY AT COAL YARD, KING'S CROSS, LONDON

With all locomotive coaling plants, except those where self-discharging hopper wagons are in use, the coal tippler which transfers the contents of the wagon to the rest of the handling machinery, plays a most important part and generally constitutes the most expensive item of cost. Such devices are fully dealt with under the heading WAGON TIPPLERS.

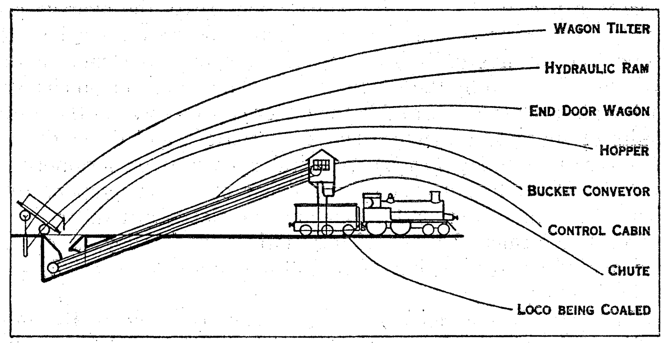

FIG. 2.—MECHANICALLY OPERATED LOCOMOTIVE COALING PLANT USED BY THE LONDON, MIDLAND AND SCOTTISH RAILWAY AT CAMDEN TOWN, LONDON, AND AT CARLISLE

The simplest type of fully mechanized locomotive coaling plant in Great Britain is that of the L.M. & S. Rly., at Kings Cross, London, which is shown in diagram, fig. 1. Here the coal is transferred from the wagons into narrow gauge trucks, which are hoisted up and emptied on the tenders. Diagram fig. 2 shows the type of mechanically operated device, as used by the L. M. & S. Rly., at Camden Town and also at Carlisle. In this an end wagon tippler unloads a truck in an under-rail hopper, thence on to a bucket conveyor which raises the coal to a point from which it can be shot on to a tender. The buckets of the conveyor are of such a size that 20 to 25 of them hold sufficient coal to charge one tender, so that the conveyor is run intermittently for each locomotive. Such an installation will coal over 100 locomotives per day, three minutes only being required to fill a large tender, with two men operating the device. In fig. 3 an installation on a different principle is shown, also used by the L.M. & S. Rly. Here the coal is taken from a rotary wagon tippler and thence, via a skip hoist and small hopper, on to a locomotive. This is in use at the Willesden coal yard, London. It is of particular interest because it is, more or less, an intermediate type. These three installations were built by the Mitchell Conveyor & Transporter Co. Ltd. For convenience of comparison figs. 1 to 6 are all drawn to the same scale.

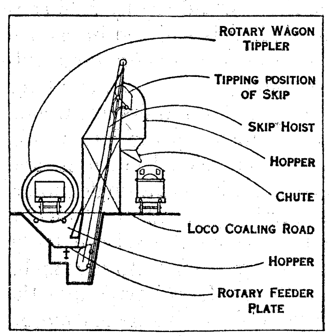

FIG. 3.—COALING PLANT USED AT THE COAL YARD, WILLESDEN, LONDON, BY THE LONDON, MIDLAND AND SCOTTISH RAILWAY

Coal in Overhead Bunkers.—With this plant a wagon tippler is used, and several methods are employed for raising the coal to the bunkers; viz., inclined hand conveyors, bucket conveyors and skip hoists. (*See* MECHANICAL HANDLING.) The latter are not, however, used in this country so much as they might be, though in America they are most usually employed.

Since such coaling installations have also to include a device for unloading the coal from the truck before it can be fed on to

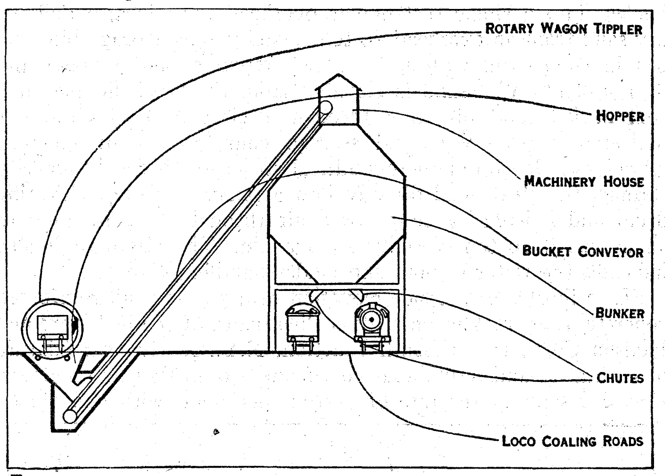

FIG. 4.—LOCOMOTIVE COALING PLANT USED AT NORTH CREWE, ALSO AT DAIRYCOTES, HULL

a conveyor or skip hoist, a system has been evolved for use where large capacities are concerned, in which a wagon tippler is so modified that a full coal truck can be lifted bodily off the rails to a level well above the bunkers, tipped and returned empty to the rails, thereby dispensing with conveyors. Such devices are, as a matter of fact, modifications of a type of wagon tippler.

In the following examples handling methods as enumerated in the foregoing are employed.

The locomotive coaling plant of the L.N.E.R. Rly. at Stratford, is the only installation of the kind in this country where a band conveyor is employed. It consists of a wagon tippler which discharges into an under-rail hopper which, in turn, feeds a band conveyor 277 ft. long, disposed at an incline of about 20°, which delivers the load at a height of 64 ft. above the rails into an overhead bunker of reinforced concrete, 120 ft. long and 45 ft. wide, which has a capacity of 800 tons. It is provided with 16 shoots, eight for each road, one on either side. These provide fuel for 400 locomotives per day, at the rate of 600 to 700 tons of coal. Less than two minutes is taken to coal one locomotive. The plant was installed by Messrs. Fraser & Chalmers, of Erith.

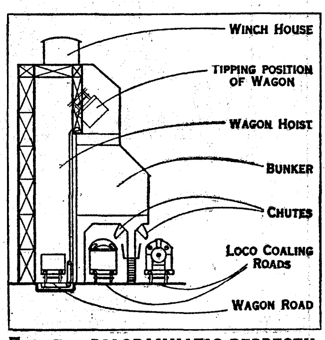

FIG. 5.—DIAGRAMMATIC REPRESENTATION OF COALING PLANT USED AT SOUTH CREWE, CHESHIRE, BY THE LONDON AND NORTH EASTERN RAILWAY

In fig. 4 is shown a diagrammatic representation of the type of locomotive coaling installation employed at North Crewe and at Dairycotes, Hull. In this a bucket conveyor is used for raising coal to the bunker. The manufacturers of this are Messrs. Spencer (Melksham) Ltd., Melksham, Wilts.

All the latest coaling plant in Great Britain is of the type in which a modification of side discharging wagon tipplers are employed (*see* fig. 5), which represents the plant at South Crewe, where the wagons are lifted vertically, while fig. 6 is a diagrammatic representation of the Nine Elms plant, in which the path of the rising wagons is steeply inclined. These installations were both built by The Mitchell Conveyor & Transporter Co. Ltd.

A coaling plant which is unique on account of its simplicity and efficiency is that used by the L.M.S. Rly Co. at their Edgehill depot. Topographical conditions being favourable, no conveyors are needed to fill the bunkers, the coal being handled by gravity with the exception of the use of a few capstans for the purpose of marshalling the wagons in position for unloading into the bunkers. Full wagons are brought along an overhead ramp and subsequently transferred to a spur track with two lines, one for the full, the other for the empty trucks; these traverse the length

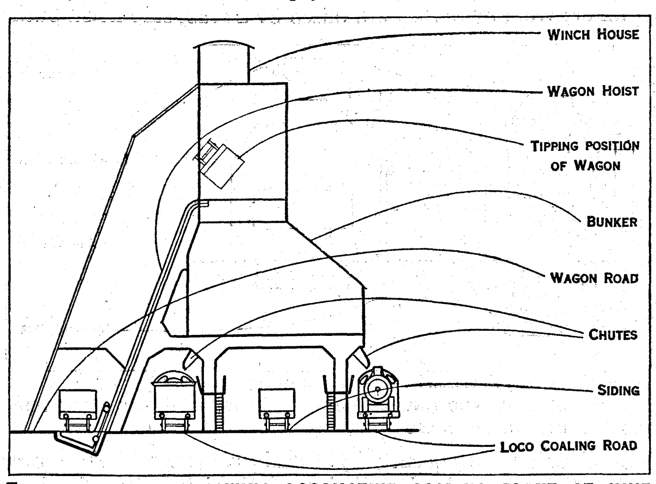

FIG. 6.—DIAGRAM SHOWING LOCOMOTIVE COALING PLANT AT NINE ELMS, LONDON

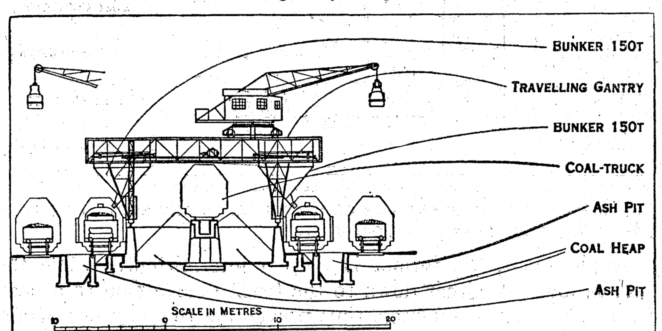
of a set of three concrete bunkers, into which the wagons are unloaded and over which the lines terminate. The empties are returned on a track with a gradient of 1:50. Each of the three bunkers holds 40 tons, with a maximum of 45. Each bunker has two outlets at a sufficient level above the engines and provided with feeding spouts, thus serving two lines, one on each side of the staging. The coal is transferred through a measuring shoot which doles it out in half-ton charges, merely by the manipulation of two levers.

Ground Storage "Bings."—The advantage of this type is that the wagons are not kept idle while they serve as storage receptacles. It is much used in Germany in conjunction with a crane and grab installation, for the purpose of coaling tenders. Such a system is shown diagrammatically in fig. 7. A travelling bridge gantry straddles a coal bing; on this the travelling crane is mounted so that it can reach both extreme positions over two rail roads, the inner ones for the locomotive and the two outer ones for the coal trucks. The bing can be accumulated by the crane from trucks on the outer roads, or from the trucks on a raised central track. The gantry is provided with two bunkers



BY COURTESY OF THE ZEITSCHRIFT DES VEREINS DEUTSCHE INGENIEURE

FIG. 7.—GERMAN TYPE OF LOCOMOTIVE COALING INSTALLATION

holding 150 tons each; these are kept full by the crane and the tender is coaled merely by lowering the bunker outlet. Pits between the outer and inner tracks (*see* fig. 7) are provided for the reception of ashes and clinkers, which are raked out during the coaling process and are likewise disposed of by the crane combination at intervals. The only drawback to this otherwise efficient installation is the grab. As a matter of fact grabs are not really suitable for discharging railway wagons. If large they are apt to damage the wagons, and in any case, much hand trimming is necessary.

In order to omit nothing appertaining to the subject, it should be mentioned that, during the time occupied in coaling locomotives, particularly in large yards, it is sometimes essential to provide appliances for the removal of ashes and soot, and the provision of dry sand. In such cases the ashes are generally raked out and dropped into a pit beneath the rails, which contains quenching water; from there they are raised by a grab, skip hoist, bucket

FIG. 8.—DIAGRAM SHOWING METHOD OF DISPOSING OF THE ASHES DURING THE COALING PROCESS

elevator, or more frequently by a chain conveyor of the scraper or drag-link type. An installation of the latter type is shown in fig. 8, which is self-explanatory. The motor is housed in a small structure between the two tracks and the speed reduction gear is in this case mounted beneath the top terminal of the conveyor.

In Germany a small pneumatic plant has been introduced (*see* fig. 9) for clearing soot from the smokebox and flues. The electro-motor is shown on the extreme right, it is direct-coupled to a rotary exhauster; a partial vacuum is produced in the receiver which is located in the central position over a rail track, for the removal of the soot. A partly flexible tube which terminates in a nozzle, is led from the receiver to the locomotive. Between the receiver and the exhauster is a dust collector, partly filled with water, which prevents the entry of gritty substances. Unlike more elaborate pneumatic plant (*q.v.*), a receiver is not here provided with an "air trap," but is, instead, fitted with a sliding gate and

telescopic shoot, the former is opened intermittently while the latter is lowered, either down to the truck floor, or on to a heap of soot already accumulated, thus preventing the entrance of air.

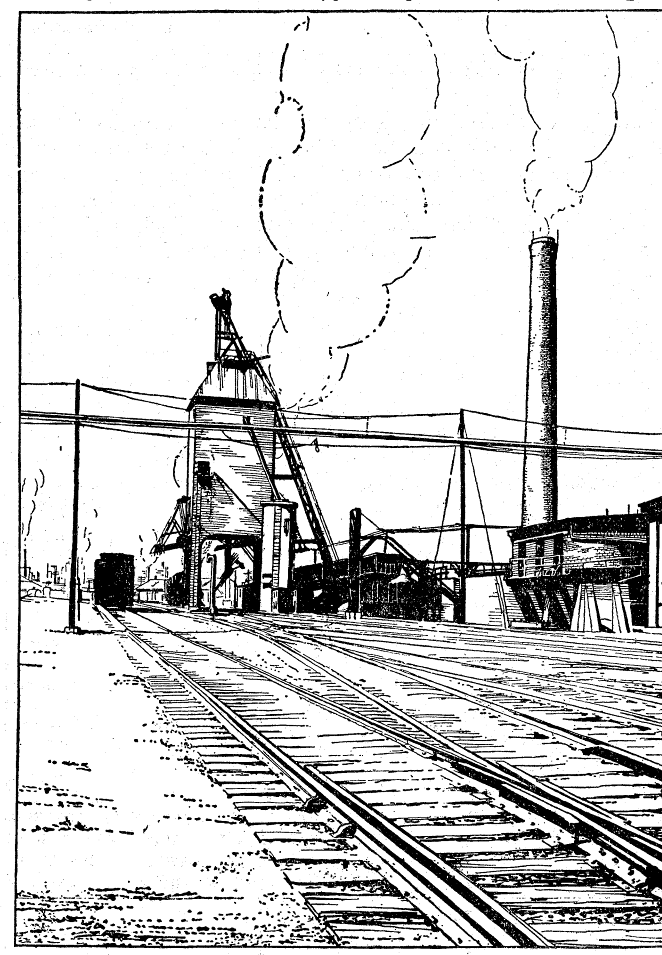
(G. F. Z.)

UNITED STATES

Owing to the tendency to eliminate fuel and water stops, the tenders of the more modern locomotives have a capacity of from 16 to 30 tons of coal, some of the coal spaces being over 26 ft. in length. To avoid making more than one stop for the purpose of supplying these tenders with fuel, provision must be made at the coal loading plants for two, instead of one, set of grates and aprons, or otherwise a swivel chute arrangement, in order to necessitate only one positioning or "spotting" of the engine under the loads. As about 10,000 American steam locomotives are now equipped with mechanical stokers, provision must also be made for the special preparation of the coal to obtain sizes other than mine-run in order not to clog the stoker operation. While such preparation is generally done at the mine, considerable equipment for this purpose must be provided at the coaling plants.

Fig. 1 shows a side elevation of a 500 ton capacity, three-track, all reinforced concrete, locomotive coaling plant, of the Lehigh Valley railroad, at Oak Island yard, Newark, N.J., receiving coal on a single track unloading hopper, 20 ft. long, elevating same at the rate of 60 tons per hour, with one 2 ton bucket, into a single rectangular overhead bin. It also delivers dry sand from an overhead 10 ton capacity sand storage bin, and has in connection with it a gravity circular sand storage and drying plant. Wet sand is elevated from the track hopper in a coal bucket, and diverting through a circular steel chute, as indicated, to the wet sand storage compartment of 50 tons capacity at the top of the cylindrical structure; is fed by gravity through the steam coil directly into a pneumatic sand elevating drum and hoisted by compressed air through a $2\frac{1}{2}$ in. pipe to an overhead 10 ton capacity storage bin. The photograph also indicates the water column and cinder handling plant.

Fig. 2 illustrates the side elevation of a 500 ton, all reinforced concrete, four-track locomotive coaling plant, of the Delaware and Hudson Company, at South Junction, N.Y., receiving a mixture of anthracite and bituminous coal from two 28 ft. track hoppers, elevating same at the rate of 75 tons per hour, with one $2\frac{1}{2}$ ton



BY COURTESY OF THE CHIEF ENGINEER, THE LEHIGH VALLEY RAILROAD

FIG. 1.—COALING PLANT OF THE LEHIGH VALLEY RAILROAD, AT OAK ISLAND YARD, NEWARK, N. J.

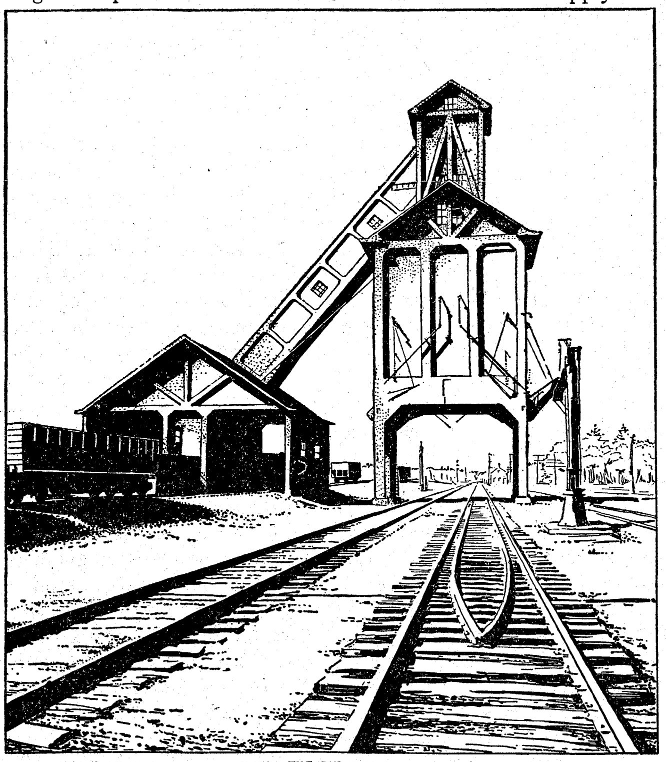
bucket, crushing to 4 in. cubes in a rotary type double-roll crusher, and depositing into either of two 250 ton pockets for delivery by gravity to locomotives on tracks below. The coal can be mixed in proportions ranging from 65% bituminous and 35% anthracite, to 25% bituminous and 75% anthracite. It also delivers dry sand through pipes and sand valves from a 10 ton overhead bin to locomotives on the coaling tracks.

Fig. 3 shows the side elevation of a 2,400 ton, all reinforced concrete, five-track locomotive coaling plant of the New York, New Haven and Hartford railroad, Cedar Hill yard, New Haven, Conn., receiving one kind of coal on a double track receiving hopper 20 ft. long, elevating same at the rate of 150 tons per hour, in two $2\frac{1}{2}$ ton buckets, and depositing without crushing into a single circular overhead storage bin, which is 55 ft. in diameter, to tracks below. It also delivers dry sand through pipes from a 15-ton bin at the top.

Fuel-oil stations consist in general of large steel storage reservoirs, elevated supply tanks, sump tanks, unloading pits, pumping plants and cranes. The unloading pits are steel or concrete boxes built between the track rails, the tank cars being "spotted" over these boxes and the fuel oil unloaded by gravity through pipes into the sump tank, where the oil is picked up by pumps and discharged into storage reservoirs or into the elevated supply tank. When cars are not being unloaded the pumps take oil from the storage reservoirs and discharge it into the elevated supply tank, from which the locomotives are supplied by gravity through track cranes. To salvage the fuel oil that is wasted, a suitable catch basin and skimming plant are provided.

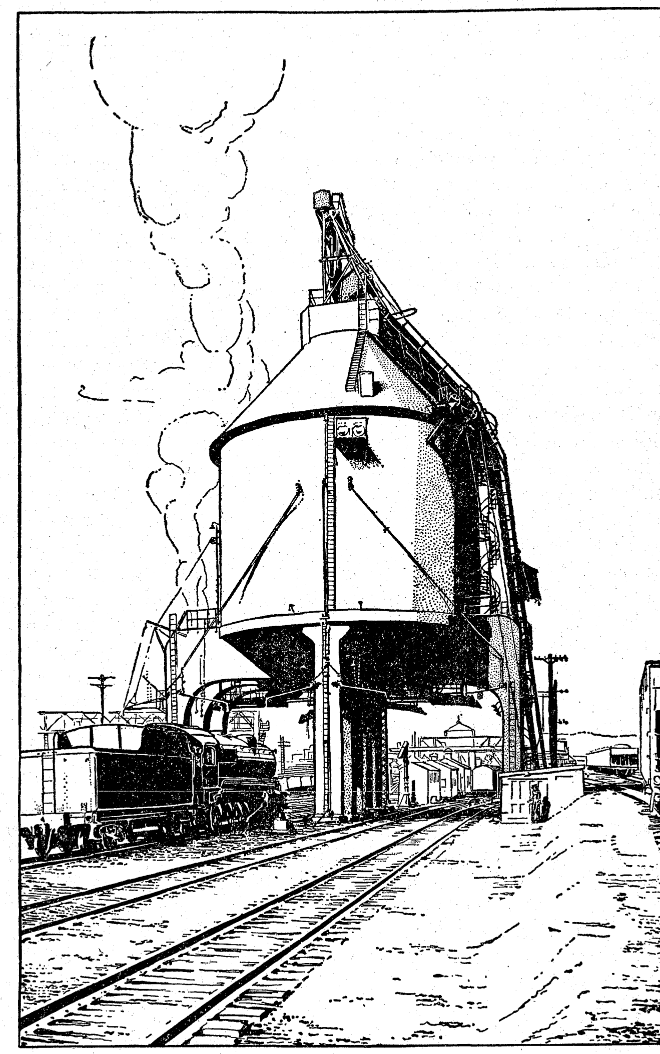
The practice of providing an accurate check on the amount of fuel supplied to the tenders is becoming more prevalent. In the case of coal, weighing devices are being installed in the form of hopper scales. Experiments are also being made in combination with certain types of stokers of a volumetric measuring device. Where fuel oil is used, the amount supplied is readily determined by gauging.

At terminals, and at the larger wayside or intermediate stations, the general practice is to combine the sand and water supply with



BY COURTESY OF THE CHIEF ENGINEER, THE DELAWARE AND HUDSON RAILROAD
FIG. 2.—COALING PLANT OF THE DELAWARE AND HUDSON RAILROAD AT SOUTH JUNCTION, NEW YORK

the fueling facilities; for example, a locomotive coal or fuel oil and water and sand plant, so that all of these supplies can be disbursed to the locomotive at one "spotting." Both coal and oil burning locomotives require dry sand supply for sanding the rail; and oil burners, in addition, require the dry sand for "sanding out" the boiler fire flues and tubes. The sand supply facilities consist of the wet sand storage, drying and handling equipment. There are three general types of sand handling facilities: (1) the small unit type, with open wet sand storage, from which the sand is wheeled to the drying stove and hoisted to the engine sand box by buckets or blown to an overhead dry storage receptacle by compressed air and then delivered to the engine sand box by gravity, (2) the independent supply plant, with drying apparatus located underneath, to which the wet sand is fed by gravity, after which it is blown by compressed air to an overhead dry sand storage bin, (3) wherein the wet sand is unloaded into a track hopper and hoisted by a conveyor to an overhead wet sand storage,



BY COURTESY OF THE CHIEF ENGINEER, THE NEW YORK, NEW HAVEN AND HARTFORD RAILROAD
FIG. 3.—COALING PLANT OF THE NEW YORK, NEW HAVEN AND HARTFORD RAILROAD, CEDAR HILL YARD, NEW HAVEN, CONN.

from where it is fed by gravity to driers, to dry sand bins and to sand boxes on the engines. The latter type has the advantage of reducing the cost for handling to the minimum. The two general methods for drying sand consist of either a stove, surrounded by a hopper containing the wet sand, or of steam heated pipe coils, conforming to a hopper, into which the wet sand is placed. (J. E. MU.)

LOCOMOTOR ATAXIA (synonyms, *Tabes dorsalis, posterior spinal sclerosis*), a progressive degeneration of the nervous system, involving the posterior columns of the spinal cord with other structures and causing muscular inco-ordination and disorder of gait and station. The essential symptoms—stamping gait, and swaying with the eyes shut, the occurrence of blindness and of small fixed pupils—were recognized by Romberg (1851), but it was the clinical genius of Duchenne and his masterly description of the symptoms which led to its acceptance as a definite disease (1858), and he named it locomotor ataxia after its most striking symptom. In 1869 Argyll Robertson discovered that the eye-pupil is inactive to light but acts upon accommodation in the great majority of cases. This most important sign is named the "Argyll Robertson pupil." With an ever-increasing knowledge of the widespread character of this disease and its manifold variations in the complex of symptoms, the tendency among neurologists is to revert to the term employed by Romberg—*tabes dorsalis*. "Locomotor ataxia," although it expresses a very characteristic feature of the disease, has this objection: it is a symptom which does not occur in the first (preataxic) stage of the disease; indeed many years may elapse before ataxy comes on, and sometimes the patient, after suffering long from the disease, may die from an intercurrent complication, without being ataxic.

It is generally recognized by neurologists that persons who are not the subjects of acquired or hereditary syphilis do not suffer from this disease; and the average time of onset after infection is ten years. (*See* NEUROPATHOLOGY.) There are three stages: (1) The preataxic, (2) the ataxic, (3) the bed-ridden paralytic. The duration of the first stage may be from one or two years, up to 20 years or even longer. In this stage various symptoms may arise. The patient usually complains of shooting, lightning-like pains in the legs, which he may attribute to rheumatism. If a physician examines him he will almost certainly find the knee-jerks absent and Argyll Robertson pupils present; probably on enquiry he will ascertain that the patient has had some difficulty in starting urination, or that he is unable to retain his water or to empty his bladder completely. In other cases, temporary or permanent paralysis of one or more muscles of the eyeball (which causes squint and double vision), a failure of sight ending in blindness, attacks of vomiting (or gastric crises), painless spontaneous fractures of bones and dislocations of joints, failing sexual power and impotence, may lead the patient to consult a physician, when this disease will be diagnosed, although the patient may not as yet have had locomotor ataxy. All cases, however, if they live long enough, pass into the second ataxic stage. The sufferer complains now of difficulty of walking in the dark; he sways with his eyes shut and feels as if he would fall (Romberg's symptom); he has the sensation of walking on wool, numbness and formication of the skin, and many sensory disturbances in the form of partial or complete loss of sensibility to pain, touch and temperature. These disturbances affect especially the feet and legs, and around the trunk at the level of the fourth to the seventh ribs, giving rise to a "girdle sensation." There may be a numbed feeling on the inner side of the arm, and muscular inco-ordination may affect the upper limb as well as the lower, although there is no wasting or any electrical change. The ataxic gait is very characteristic, owing to the loss of reflex tonus in the muscles, and the absence of guiding sensations from all the deep structures of the limbs, muscles, joints, bones, tendons and ligaments, as well as from the skin of the soles of the feet; therefore the sufferer has to be guided by vision as to where and how to place his feet. This necessitates the bending forward of the body, extension of the knees and broadening of the basis of support; he generally uses a walking stick or even two, and he jerks the leg forward as if he were on wires, bringing the sole of the foot down on the ground with a wide stamping action. If the arm be affected, he is unable to touch the tip of his nose with the eyes shut. Sooner or later he passes into the *third,* bed-ridden, stage, with muscles wasted and their tonus so much lost that he is perfectly helpless.

The complications which may arise are intercurrent affections due to septic conditions of the bladder, bed-sores, pneumonia, vascular and heart affections. About 10% of the cases, at least, develop general paralysis of the insane. This is not surprising seeing that it is due to the same cause, and the etiology of the two diseases is such as to lead many neurologists to consider them one and the same disease affecting different parts of the nervous system. *Tabes dorsalis* occurs with much greater frequency in men than in women. (*See* NEUROPATHOLOGY.)

The avoidance of all stress of the nervous system, whether physical, emotional or intellectual, is indicated, and a simple regular life, without stimulants or indulgence of the sexual passion, is the best means of delaying the progress of the disease. Great attention should be paid to micturition, so as to avoid retention and infection of the bladder. Drugs, even antisyphilitic remedies, appear to have but little influence upon the course of the disease.

LOCO-WEEDS, various North American plants of the pea family (Leguminosae), chiefly species of *Astragalus* (*q.v.*) and *Oxytropis,* which produce a disease in cattle known as "loco-disease." The name is apparently taken from the Spanish *loco,* mad. The disease affects the nervous system of the animal eating the plants, and is accompanied by exhaustion and wasting. The toxic properties of some species of *Astragalus* are due to the presence of selenium absorbed from the soil in which they grow.

LOCRI, a people of ancient Greece (Gr. *Λοκροί*), inhabiting two distinct districts, one extending from the northeast of Parnassus to the northern half of the Euboean channel, between Boeotia and Malis, the other southwest of Parnassus, on the north shore of the Corinthian gulf, between Phocis and Aetolia. The former were divided into the northern Locri Epicnemidii, situated on the spurs of Mt. Cnemis, and the southern Locri Opuntii, so named from their chief town Opus. Homer mentions only these eastern Locrians; their national hero in the Trojan War is Ajax Oileus, who often appears afterwards on Locrian coins. The Opuntians were thought by some to be of "Lelegian" origin (*see* LELEGES), but they were Hellenized early (though matriarchal customs survived among them). The westerly Locri "in Ozolae" on the Corinthian gulf, a rude and barbarous people, make no appearance in Greek history till the Peloponnesian War. The Locrian dialect resembles that of Elis. A colony of Locrians settled, about the end of the 8th century B.C., at the southwest extremity of Italy. They are often called Locri Epizephyrii from Cape Zephyrion 15 mi. S. of the city. Their founder was Euanthes. *See* LOCRI below.

LOCRI, an ancient city of Magna Graecia, Italy. The original inhabitants were, it has recently been ascertained, of Sicilian race (MacIver, *Iron Age,* 210). They occupied the Zephyrian promontory (Capo Bruzzano some 12 m. N. of Capo Spartivento), and though after three or four years they moved 12 m. north, still near the coast, 2 m. south of Gerace Marina below the modern Gerace, they still retained the name of Locri Epizephyrii, *Λοκροὶ οἱ ἐπιζεφύριοι,* to distinguish them from the Ozolian and Opuntian Locri of Greece itself. The foundation of Locri goes back to about 683 B.C. It was the first Greek community to have a written code of laws given by Zaleucus in 664 B.C. From Locri were founded the colonies of Meisma and Hipponium. It repelled the attacks of Croton and found support in Syracuse against Rhegium: it was thus an active adversary of Athenian aggrandisement. Pindar extolls it in the 10th and 11th Olympian Odes. Stesichorus (*q.v.*) was indeed of Locrian origin. Dionysius I. of Syracuse selected his wife from Locri: its territory was then increased, and the circuit of its walls was doubled, but it lost its freedom. In 356 B.C. it was ruled by Dionysius II. From the battle of Heraclea to the year 205 (when it was captured by P. Cornelius Scipio Africanus Maior, and placed under the control of his legate Q. Pleminius), Locri was continually changing allegiance between Rome and her enemies; but it remained an ally. In later Roman times it was of no great importance. It was destroyed by the Saracens in 915.

Excavations in 1889–90 discovered an Ionic temple (the Doric style being usual in Magna Graecia) at the north-west angle of the town—originally a cella with two naves, a closed pronaos on the east and an adytum at the west, later converted into a hexastyle peripteral temple with 34 painted terra-cotta columns. This was destroyed about 400 B.C. and a new temple built on the ruins, heptastyle peripteral, with no intermediate columns in the cella and opisthodomos, and with 44 columns in all. The figures from the pediment of the twin Dioscuri, who according to the legend assisted Locri against Crotona, are in the Naples museum. The environs yielded many archaic terra-cottas, and large trenches, covered with tiles, contained some 14,000 scyphoi arranged in rows. A Doric temple was also cleared under the house called Casa Marafioti: the fine equestrian group in terra cotta from the western gable is, with other objects from Locri, in the museum at Syracuse. There was also a sanctuary of Persephone from which came numerous votive tablets of the 5th century B.C. Much work has also been done in cemeteries, most of the tombs belonging to the 5th and 4th centuries, though the earliest are pre-Hellenic (9th–7th centuries.) The city walls, the length of which was nearly 5 m., consisted of three parts—the fortified castles (*φρούρα*) with large towers, on three different hills, the city proper, and the lower town—the latter enclosed by long walls running down to the sea. Under Rome, the city was restricted to the plain near the sea.

Prehistoric objects confirm the accounts of Thucydides and Polybius that the Greek settlers were preceded by Siculi.

See Orsi in *Notizie degli Scavi,* 1901–1917. (T. A.)

LÖCSE: *see* LEVOČA.

LOCUS, a term used in geometry with the meaning suggested by the Latin *locus,* place. In plane geometry it is the curve (including a straight line) which contains all points in the plane that satisfy a given condition, and which contains no points that do not satisfy the given condition; *e.g.,* in a plane the locus of a point at a given distance from a fixed point is the circle of which the fixed point is the centre and the given distance is the length of the radius. The term is also applied to figures in space of three dimensions, the locus corresponding to the circle being a sphere (considered as a surface). The locus is then a curve surface. The finding of the locus of an equation, or inversely, is a basic problem of analytic geometry (*q.v.*). Among the loci there considered are the conic sections (*q.v.*). The term is readily extended to higher dimensions.

LOCUST, any of certain insects of the family Acrididae (*see* ORTHOPTERA) which at times multiply greatly and migrate long distances in destructive swarms. In Europe, the term "locust" connotes large size; smaller acridids are called grasshoppers (*q.v.*). In North America "locust" and "grasshopper" are used for any acridid. Unfortunately cicadas (order Hemiptera) are also called locusts or harvest locusts; the 17-year locust is the periodical cicada.

The Phases of Locusts.—In 1921 B. P. Uvarov satisfactorily explained for the first time the sporadic coming of locust swarms and the apparent disappearance of the insects between times by the phase theory, later substantiated and elaborated by many workers. Each plague species exists in two phases, solitary and gregarious, connected by transitional forms. The extreme phases differ in coloration, form, physiology and behaviour. Solitary phase nymphs vary in colour and pattern, adjust their colour to

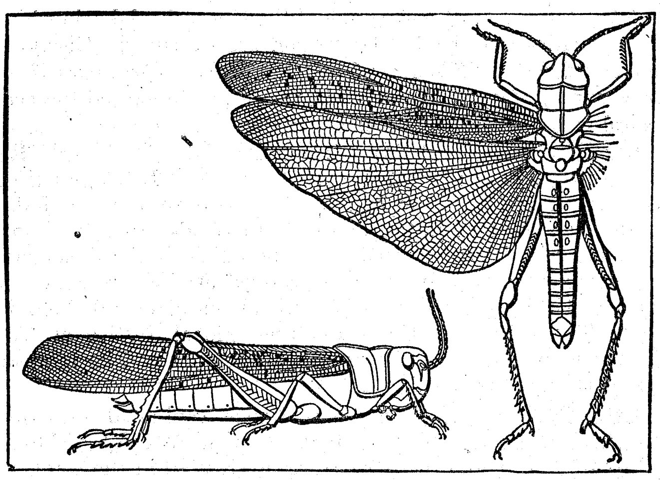


FIG. 1.—LOCUSTA MIGRATORIA IN ITS MIGRATORY PHASE

This insect is one of the chief locusts of the old world and in this phase causes great destruction to crops and other vegetation

match that of their surroundings, do not congregate, have low metabolic and oxygen-intake rates and are sluggish. Gregarious phase nymphs have a black and yellow (orange) coloration of fixed pattern, are gregarious, have high metabolic and oxygen-intake rates, and are active and nervous; their temperature is higher because their dark pigments absorb more radiation. Adults differ less in colour, but often notably in form. The solitary phase has shorter wings, longer legs, narrower pronotum with higher crest and larger head; the gregarious phase has a more saddle-shaped pronotum with broader shoulders and long, ample wings.

Progeny of the solitary phase, reared in crowds, change toward the gregarious type; and if the crowding is of sufficient degree and duration, the extreme of the gregarious migratory phase is produced. Progeny of the gregarious phase, reared in isolation, revert to the solitary phase. By rearing single nymphs in constantly agitated cages J. C. Faure (1932) showed that the effects of crowding result from the unceasing activity it induces. The solitary phase is the normal state of the species, while the gregarious phase is a physiological response to violent fluctuations in the environment. Within the territory of each species its solitary phase exists at all times and in a wide variety of oecological conditions. Swarms do not form in the regions most favourable to the species, but in marginal areas where suitable habitats are restricted and climatic balance is delicate. Here a succession of

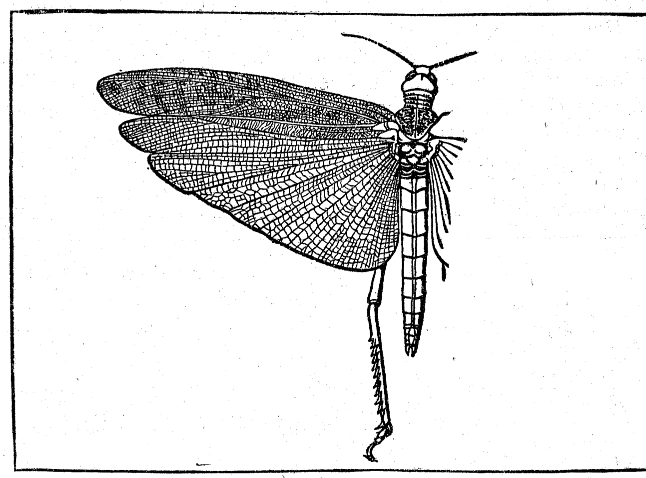

FIG. 2.—OLD WORLD LOCUST (SCHISTOCERCA GREGARIA)

favourable seasons enables the restricted populations to expand into adjoining areas, but return of unfavourable conditions forces the enlarged populations back into the small permanently habitable areas and crowding results. The exact circumstances vary with the species and region. Thus the outbreak areas of *Locusta migratoria* are of four oecological types: (1) deltas of rivers entering the Caspian and Aral seas and Lake Balkash (and similar situations in China and Africa), surrounded by arid sandy tracts; here the extent of the grassland habitat of the locust changes greatly due to irregularities of floods; (2) grassland areas adjoining deserts, subject to extreme fluctuations in precipitation with corresponding changes in extent of habitable area; (3) "islands" of dry warm soil in central Russia, a region generally too cold and wet for the species; here overcrowding occurs after several exceptionally warm dry years; (4) grasslands produced by periodic burning in the unfavourable, humid, tropical forest lands of the Philippines; their extent varies greatly, leading to frequent overcrowding and production of the gregarious phase.

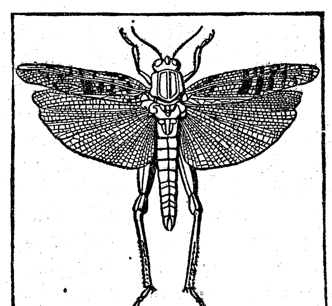

FIG. 3.—CALLIPTAMUS ITALICUS, COMMON IN SOUTHERN EUROPE

Locusts of the gregarious phase are restless and irritable; the bands of nymphs wander, and adult swarms take flight spontaneously on warm dry days when their body temperature is high. The muscular activity of flight further raises their temperature, and a swarm can therefore cease flying only when conditions change. Rain, a drop in temperature, or nightfall will usually stop a flight. The distances travelled may be great; swarms have been seen 1,200 mi. at sea, and *Schistocerca gregaria* reached England in 1869, probably from west Africa. The flights are not purposive and often end in destruction of the swarm. Some swarms are very large; a flight of the desert locust across the Red sea in 1889 was estimated as 2,000 sq.mi. in extent. The gregarious instinct is strong, and swarms remain compact even when reduced to small size by high mortality; they are dispersed, with resultant transformation into the solitary phase, only by storms and other external factors.

Important Species.—The migratory locust (*Locusta migratoria,* with its races *rossica, migratoria, migratorioides, capito* and *manilensis*) has a wider range than any other acridid. It is found in grasslands throughout Africa, most of Eurasia south of the Taiga forest, the East Indies, tropical Australia, and New Zealand. The desert locust (*Schistocerca gregaria*) inhabits dry grasslands and deserts from Africa to the Punjab. Its swarms arrive during the summer monsoons in India; in autumn they migrate to Iran and Arabia with others from Africa, and thence spread to soviet Asia, Syria, Palestine and Egypt. In late fall some return to India and East Africa, where breeding occurs during the next monsoon rains. The smaller Italian and Moroccan locusts (*Calliptamus italicus* and *Dociostaurus maroccanus*) do much injury in the Mediterranean area; the second is found discontinuously east to Turkestan. In South Africa the brown and red locusts (*Locustana pardalina* and *Nomadacris septemfasciata*) are both very destructive. In Central and South America the chief migratory species is the South American locust (*Schistocerca paranensis*), of which the nonmigratory *S. americana* of the United States may possibly be the solitary phase. The Rocky mountain locust or lesser migra-

FIG. 4.—ROCKY MOUNTAIN LOCUST (MELANOPLUS SPRETUS)

tory grasshopper (*Melanoplus mexicanus* phase *spretus*) wreaked havoc on the prairie farms of Canada and the United States in the 1870s, but later disappeared; it is probably the gregarious phase of the common and widespread *M. mexicanus* (*atlanis*), which is, with the clear-winged grasshopper (*Camnula pellucida*), a major crop pest in North America. Many other species of Acrididae in different regions occasionally increase to plague proportions, but few of them compare in economic importance with those named above.

Control Measures.—Once well started, a locust plague is almost impossible to check, and only palliative measures can be taken. These have included destruction of egg-masses laid by invading swarms (1,300 tons were destroyed in Cyprus in 1881), trenches to trap the nymphs, hopperdozers (wheeled screens, upon striking which locusts fall into troughs containing water and kerosene), poison baits and aeroplane dusting of swarms and breeding grounds with insecticides. The control problem is made difficult by the great extent of the territory affected, with many invasions beginning in sparsely populated, undeveloped regions. Permanent control requires both national and international action. It is possible because locust swarms do not arise simultaneously over wide regions, but in a few localized outbreak areas, many of which are known. From 1930–38 five International Locust conferences were held. In 1932 the Anti-Locust Research centre was set up in London; it directed international surveys and field studies and, during World War II, large-scale campaigns in Africa and Asia against the desert locust. Warnings were given of incipient outbreaks and swarm movements, and control measures were planned and supervised. Ultimately many outbreak areas may be made oecologically unsuitable for production of the gregarious phase, when the oecology and behaviour of each plague species are better known.

Faure, *Bulletin of Entomological Research* (vol. 23, 1932); A. D. Imms, *Entomological News* (vol. 55, No. 7, 1944); also works on Orthoptera (*q.v.*). (T. H. HL.)

LOCUST-TREE or **CAROB-TREE** (*Ceratonia siliqua*), a member of the tribe *Cassieae* of the family Leguminosae, the sole species of its genus, and widely diffused spontaneously and by cultivation from Spain to the eastern Mediterranean regions. The flowers have no petals and are polygamous or dioecious (male, female and hermaphrodite flowers occur). The seed-pod is compressed, often curved, indehiscent and coriaceous, but with sweet pulpy divisions between the seeds, which, as in other genera of the *Cassieae*, are albuminous. The pods are eaten by men and animals, and in Sicily a spirit and a syrup are made from them. These husks, being often used for swine, are called swine's bread, and are probably referred to in the parable of the Prodigal Son. They are also called St. John's bread, from a misunderstanding of Matt. iii, 4. Gerard (*Herball*, p. 1241) cultivated them in 1597. They were introduced in 1570.

LÓCZY, LÁJOS DE LÓCZ (1849–1920), Hungarian geologist, was born at Pressburg (Bratislava) on Nov. 2, 1849. He studied at the Zurich Polytechnic, obtaining his engineer's diploma in 1874, and from 1877–80 travelled through India and China as geologist to the expedition of Count Bela Szechenyi. In 1886 he became professor of geology at the University of Budapest, and in 1908 director of the Hungarian Geological institute. He completed geological researches in China, in Hungary and, during World War I in Serbia. His principal work, *The Scientific Results of the Expedition of Count Bela Szechenyi to Eastern Asia* (1890), comprises the first scientific description of the mountains which connect the Kuen Lun chains with the northeast Indian chains behind the red basin of Szechwan. His researches concerning the steppe-formations of the Gobi and the northern Hwang Ho territory are also of great importance. His other important work, *The Results of the Scientific Research of the Balaton*, forms a great monograph of the Hungarian lake, in which the formations of the Balaton region are explained. His posthumous works are: *The New Geological Map of (pre-War) Hungary*, and *Geology of West-Serbia*, which revolutionised the geological map of Serbia. He died at Balatonaracs May 13, 1920.

LODER, BERNARD CORNELIUS JOHANNES (1849–1935), Dutch jurist. From 1873 to 1908 Loder practised as a lawyer in Rotterdam and from 1908 to 1921 was a judge of the high court of justice of the Netherlands. In 1905, 1909, 1910 and 1922 he represented the Netherlands at the diplomatic Sea conferences at Brussels. He presided at the conference of the Scandinavian kingdoms, Switzerland and Holland, held in 1920. The Permanent Court of International Justice at The Hague appointed him its first president in 1922 and he retained this position until early in 1925.

LODÈVE, a town of southern France, capital of an arrondissement of the department of Hérault, 36 mi. W.N.W. of Montpellier by rail. Pop. (1936) 5,631. It is situated in the southern Cévennes at the point where the Soulondres joins the Lergue, a tributary of the Hérault. Two bridges over the Lergue connect the town with Carmes and two others over the Soulondres lead to the ruins of the château de Montbrun (13th century). Lodève (Luteva) existed before the invasion of the Romans, who for some time called it *Forum Neronis*. It was Christianized by St. Flour, first bishop of the city, *c.* 323. It became in the 9th century a separate countship and afterward the domain of its bishops until the revolution. During the religious wars it was sacked in 1573.

The old fortified cathedral of St. Fulcran, founded by him in 950, dates as it is now from the 13th, 14th and 16th centuries. Near the town stands the 12th century monastery of St. Michel de Grammont, now used as farm buildings. In the neighbourhood are three dolmens. The manufacture of woollens for army clothing is the chief industry.

LODGE, EDMUND (1756–1839), English writer on heraldry, was born in London on June 13, 1756, son of Edmund Lodge, rector of Carshalton, Surrey. He held a cornet's commission in the army, from which he resigned in 1773. In 1782 he became Bluemantle pursuivant-at-arms in the College of Arms. He subsequently became Lancaster herald, Norroy king-at-arms, Clarencieux king-at-arms, and, in 1832, knight of the order of the Guelphs of Hanover. He died in London on Jan. 16, 1839. He contributed the literary matter to *Portraits of Illustrious Personages of Great Britain* (1814, etc.), known familiarly as "Lodge's Portraits." His chief work on heraldry was *The Genealogy of the existing British Peerage . . .* (1832; enlarged ed., 1859).

LODGE, HENRY CABOT (1850–1924), American statesman and author, was born in Boston, Mass., on May 12, 1850. He graduated at Harvard college in 1871 and at the Harvard Law school in 1875; was admitted to the Suffolk (Mass.) bar in 1876; and in 1876–79 was instructor in American history at Harvard. He was a member of the Massachusetts house of representatives in 1880–81, and of the national House of Representatives in 1887–93. In 1893 he succeeded Henry L. Dawes as U.S. senator from Massachusetts, a place he continued to hold for nearly 32 years.

His continuous service in the Senate brought recognition during the closing years of the Roosevelt Administration and under Taft as one of the most prominent of the Republican leaders. He was a member of the Alaskan Boundary Commission of 1903, and of the U.S. Immigration Commission of 1907. He served as permanent chairman of the Republican National conventions of 1900, 1908 and 1920. During the Republican-Progressive split which led to the election of Woodrow Wilson in 1912, Lodge maintained his personal friendship with Roosevelt, while he held true to his long-established principles of party regularity by supporting Taft, the Republican nominee.

In 1914 Lodge supported Wilson's demand for the repeal of the Panama tolls exemption, but lost confidence in him as a result of the President's handling of the Mexican problem in 1914, and thereafter became one of his principal critics. He opposed Wilson's Caribbean policy and Colombia Treaty, and desired the entrance of his country into the World War after the sinking of the "Lusitania." In Jan. 1916 he offered a resolution calling for armed intervention in Mexico.

With the entrance of the United States into the World War, Lodge called for united support of the President in all policies that might increase the war effort of the United States, although he opposed the Overman Act, designed to organize war-making agencies. Wilson's peace policies Lodge neither understood nor approved. In 1915 and 1916 he himself had advocated a league of nations and the principle of compulsory arbitration, but he later confessed that he changed his mind and saw in Wilson's proposals more danger than advantage. In Aug. 1918 Lodge was elected Republican floor leader of the Senate, and becoming chairman of the Senate foreign relations committee, he was the leader of the opposition to Wilsonian peace policies. On Dec. 21, 1918, Lodge inaugurated a successful campaign against the Wilson peace plan when he insisted on the need of separating the League of Nations from the Versailles Treaty. On March 4 following Lodge with 38 Republican senators issued a declaration disapproving of the Covenant as it was and its inclusion in the treaty. He did not hope to defeat the treaty by a straight vote of disapproval; the popular demand for peace was too compelling. He did succeed, however, in attaching 15 reservations to the treaty which attracted the support of the die-hard enemies of Wilson. Wilson refused to accept the reservations, and Lodge was able to hold his group firm in refusing to pass the treaty without reservations. His tactical success was unquestionable when on March 19, 1920, the treaty, which had been reintroduced, having previously been defeated both with and without reservations, failed by seven votes, to secure the necessary two-thirds vote of the Senate, the Democratic senators voting against it at the wish of the President.

As the successful leader of the opposition to Wilson, Lodge's prestige was increased. He served as one of the four U.S. delegates at the Washington Conference on the Limitation of Armaments in 1921. His influence waned after he opposed Harding's proposal for joining the World Court, but he was re-elected to the Senate in 1922 by a narrow margin. He died at Nahant (Mass.), on Nov. 9, 1924, at the age of 74.

Senator Lodge was one of the chief congressional figures of the last decade of the 19th and the first two decades of the 20th centuries. Reputed cold and distant in manner, he enjoyed the prestige indicated by his popular appellation, the "scholar in politics," and held the respect of his colleagues on both sides of the Senate.

His literary production started early and continued until the close of his life. In 1874–76 he edited the *North American Review* with Henry Adams; and in 1879–82, with John T. Morse, Jr., he edited the *International Review*. In 1884–90 he was an overseer of Harvard college. His doctoral thesis at Harvard was published with essays by Henry Adams, J. L. Laughlin and Ernest Young, under the title *Essays on Anglo-Saxon Land Law* (1876). He wrote: *Life and Letters of George Cabot* (1877); *Alexander Hamilton* (1882), *Daniel Webster* (1883) and *George Washington* (2 vol., 1889), in the "American Statesmen" series; *A Short History of the English Colonies in America* (1881); *Studies in History* (1884); *Boston* (1891), in the "Historic Towns" series; *Historical and Political Essays* (1892); with Theodore Roosevelt, *Hero Tales from American History* (1895); *Certain Accepted Heroes* (1897); *The Story of the American Revolution* (2 vol., 1898); *The War with Spain* (1899); *A Fighting Frigate* (1902); *A Frontier Town* (1906); with J. W. Garner, *A History of the United States* (4 vol., 1906). He edited *The Works of Alexander Hamilton* (9 vol., 1885–86); *The Federalist* (1891); *André's Journal* (1903); and *Education of Henry Adams* (1918).

William Lawrence's *Henry Cabot Lodge* (1925) is the only complete biography of Lodge, though short sketches appear in a number of magazines. *Speeches and Addresses* (1909); *One Hundred Years of Peace* (1913); *Early Memories* (1913); *The Democracy of the Constitution* (1915); *War Addresses, 1915–1917* (1917); *Theodore Roosevelt* (1919); *The Senate of the United States, and Other Essays* (1921); and *The Senate and the League of Nations* (1925).

His son, GEORGE CABOT LODGE (1873–1909), also became known as an author, with *The Song of the Wave* (1898), *Poems, 1899–1902* (1902), *The Great Adventure* (1905), *Cain: a Drama* (1904), *Herakles* (1908) and other verse. (C. SEY.)

LODGE, SIR OLIVER JOSEPH (1851–1940), English physicist, was born at Penkhull, Staffordshire, on June 12, 1851. He was intended for a business career, but being attracted to science he entered University College, London, in 1872. In 1875 he was appointed reader in natural philosophy at Bedford College for Women, and in 1879 he became assistant professor of applied mathematics at University College, London. Two years later he was called to the chair of physics in University College, Liverpool, where he remained till in 1900 he was chosen first principal of the new Birmingham University. He was knighted in 1902. His original work includes investigations on lightning, the seat of the electromotive force in the voltaic cell, the phenomena of electrolysis and the speed of the ion, electromagnetic waves and wireless telegraphy, the motion of the ether near the earth, and the application of electricity to the dispersal of fog and smoke. In addition to numerous scientific memoirs he wrote, among other works, *Lightning Conductors and Lightning Guards, Signalling without Wires, Modern Views of Electricity, Electrons* and *The Ether of Space*.

After 1910 Sir Oliver Lodge became increasingly prominent as a leader of psychical research and a strong believer in the possibility of communicating with the dead, and he interested himself in a serious endeavour to reconcile science and religion. Among his publications dealing with this subject are *The Survival of Man* (1909); *Reason and Belief*, 3rd ed. (1911); *The War and After* (1915); *Raymond, or Life and Death* (1916), a memoir of his son killed in the World War, with an account of communications believed to have been received from him since; *Christopher: a Study in Human Personality* (1918). Early in 1920 he made an extensive lecturing tour of the United States, having just previously retired from his post as principal of Birmingham University. Among his later publications are *The Making of Man* (1924), *Ether and Reality* (1925), *Relativity* (1925), *Science and Human Progress* (1927), *The Reality of a Spiritual World* (1930), and *My Philosophy, containing final views on the Ether of Space,* (1933). In 1919 he received the Albert Medal of the Royal

Society of Arts for his pioneer work in wireless telegraphy. He acted as president of the British Association, of the Physical Society, of the Society for Psychical Research, of the Radio Society and of the Röntgen Society; he became an F.R.S. in 1902.

LODGE, THOMAS (*c.* 1558–1625), English dramatist and miscellaneous writer, was born about 1558 at West Ham. He was the second son of Sir Thomas Lodge, who was lord mayor of London in 1562–63. He was educated at Merchant Taylor's school and Trinity college, Oxford; taking his B.A. degree in 1577 and that of M.A. in 1581. In 1578 he entered Lincoln's Inn. When the penitent Stephen Gosson had (in 1579) published his *Schoole of Abuse,* Lodge took up the glove in his *Defence of Poetry, Music and Stage Plays* (1579 or 1580; reprinted for the Shakespeare Society, 1853), which shows a certain restraint, though neither deficient in force of invective nor backward in display of erudition. The pamphlet was prohibited, but appears to have been circulated privately. It was answered by Gosson in his *Playes Confuted in Five Actions;* and Lodge retorted with his *Alarum Against Usurers* (1584, reprinted *ib.*)—a "tract for the times" which no doubt was in some measure indebted to the author's personal experience. He was called before the Privy Council in 1581 to answer for certain matters brought against him.

In 1583 he produced *The Delectable History of Forbonius and Prisceria,* both published and reprinted with the *Alarum.* In his tales he follows the lead of Greene and Lyly.

Having, in the spirit of his age, "tried the waves" with Captain Clarke in his expedition to Terceira and the Canaries, Lodge in 1591 made a voyage with Thomas Cavendish to Brazil and the Straits of Magellan, returning home by 1593. During the Canaries expedition, to beguile the tedium of his voyage, he composed his prose tale of *Rosalynde, Euphues Golden Legacie,* which, printed in 1590, afterwards furnished the story of Shakespeare's *As You Like It.* The novel, which in its turn owes some debt to the mediaeval *Tale of Gamelyn,* is written in the euphuistic manner. It has been frequently reprinted. Before starting on his second expedition he had published an historical romance, *The History of Robert, Second Duke of Normandy, surnamed Robert the Divell;* and he left behind him for publication *Catharos, Diogenes in his Singularity,* a discourse on the immorality of Athens (London). Both appeared in 1591.

Another romance in the manner of Lyly, *Euphues Shadow, the Battaile of the Sences* (1592), appeared while Lodge was still on his travels. His second historical romance, the *Life and Death of William Longbeard* (1593), was more successful than the first. Lodge also brought back with him from the new world *A Margarite of America* (published 1596), a romance of the same description interspersed with many lyrics. Already in 1589 Lodge had given to the world a volume of poems bearing the title of the chief among them, *Scillaes Metamorphosis, Enterlaced with the Unfortunate Love of Glaucus,* more briefly known as *Glaucus and Scilla* (reprinted with preface by S. W. Singer in 1819). To this tale Shakespeare was possibly indebted for the idea of *Venus and Adonis.* Some readers would perhaps be prepared to give up this and much else of Lodge's sugared verse, fine though much of it is in quality, largely borrowed from other writers, French and Italian in particular, in exchange for the lost *Sailor's Kalendar,* in which he must in one way or another have recounted his sea adventures. If Lodge, as has been supposed, was the Alcon in *Colin Clout's come Home Again,* it may have been the influence of Spenser which led to the composition of *Phillis,* a volume of sonnets, published with the narrative poem, *The Complaynte of Elstred,* in 1593. *A Fig for Momus,* on the strength of which he has been called the earliest English satirist, and which contains eclogues addressed to Daniel and others, an epistle addressed to Drayton, and other pieces, appeared in 1595.

Lodge's ascertained dramatic work is small in quantity. In conjunction with Greene he, probably in 1590, produced in a popular vein the odd but far from feeble play of *A Looking Glasse for London and England* (printed in 1594). He had already written *The Wounds of Civile War. Lively set forth in the Tragedies of Marius and Scilla* (produced perhaps as early as 1587, and published in 1594), a good second-rate piece in the half-chronicle fashion of its age. Various critics have assigned to Lodge a share in *Mucedorus and Amadine,* played by the Queen's Men about 1588, in *George a Greene, the Pinner of Wakefield,* in Shakespeare's 2nd part of *Henry VI.,* and in *The Troublesome Raigne of John, King of England* (*c.* 1588).

In the latter part of his life—possibly about 1596, when he published his *Wits Miserie* and the *World's Madnesse,* which is dated from Low Leyton in Essex, and the religious tract *Prosopopeia* (if, as seems probable, it was his), in which he repents him of his "lewd lines" of other days—he became a Catholic and engaged in the practice of medicine, for which Wood says he qualified himself by a degree at Avignon in 1600. Two years afterwards he received the degree of M.D. from Oxford university. His works henceforth have a sober cast, comprising translations of Josephus (1602), of Seneca (1614), a *Learned Summary* of Du Bartas's *Divine Sepmaine* (1625 and 1637), besides a *Treatise of the Plague* (1603), and a popular manual, which remained unpublished, on *Domestic Medicine.* He was abroad on private affairs in 1616. From this time to his death in 1625 nothing further concerning him remains to be noted.

Lodge's works, with the exception of his translations, were edited for the Hunterian club by Edmund Gosse. The preface was reprinted in Gosse's *Seventeenth Century Studies* (1883). Of *Rosalynde* there are numerous modern editions. *See* also J. J. Jusserand, *English Novel in the Time of Shakespeare* (Eng. trans., 1890); F. G. Fleay, *Biographical Chronicle of the English Drama* (vol. ii., 1891); E. K. Chambers, *Elizabethan Stage* (1923, etc.), vol. iii. (A. W. WA.)

LODGER AND LODGINGS. The term "lodger" is used in English law in several slightly different senses. It is applied (i.) most frequently and properly to a person who takes furnished rooms in a house, the landlord also residing on the premises, and supplying him with attendance; (ii.) sometimes to a person who takes unfurnished rooms in a house finding his own attendance; (iii.) to a boarder in a boarding house (*q.v.*). It is with (i.) and (ii.) alone that this article is concerned.

Where furnished apartments are let for immediate use, the law implies an undertaking on the part of the landlord that they are fit for habitation, and, if this condition is broken, the tenant may refuse to occupy the premises or to pay any rent. But there is no implied contract that the apartments shall *continue* fit for habitation; and the rule has no application in the case of unfurnished lodgings. There is no implied warranty that the incoming tenant is a fit and proper person to occupy the lodgings and is not, *e.g.,* suffering from any infectious disease (*Humphreys v. Miller* [1917] 2 K.B. 122). In the absence of express agreement to the contrary, a lodger has a right to the use of everything necessary to the enjoyment of the premises, such as the door bell and knocker and the skylight of a staircase. Whether the rent of apartments can be distrained for by the immediate landlord where he resides on the premises and supplies attendance is a question the answer to which is involved in some uncertainty. The weight of authority seems to support the negative view (*see* Foa, *Landlord and Tenant,* 3rd ed. p. 434). As to distress on a lodger's goods for rent due by an immediate to a superior landlord *see* RENT. As to the termination of short tenancies, as of apartments, *see* LANDLORD AND TENANT. The landlord has no lien on the goods of the lodger for rent or charges. It has been held in England that keepers of lodging-houses do not come within the category of those persons (*see* also CARRIER; INNS AND INNKEEPERS) who hold themselves out to the public generally as trustworthy in certain employments; but that they are under an obligation to take reasonable care for the safety of their lodgers' goods (see *Scarborough v. Cosgrove* [1905] 2 K.B. 805). As to Scots Law *see* Bell's *Prin.* s. 236 (4).

In the United States, the English doctrine of an implied warranty of fitness for habitation on a letting of furnished apartments has only met with partial acceptance; it was repudiated, *e.g.,* in the District of Columbia, but has been accepted in Massachusetts. In the French *Code Civil* there are some special rules with regard to furnished apartments. The letting is reputed to be made for a year, a month or a day, according as the rent is so much per year, per month or per day; if that test is inapplicable, the letting is deemed to be made according to the custom of the place (art. 1,758). There are similar provisions in the Civil Codes of Belgium (art. 1,758), Holland (art. 1,622) and Spain (art. 1,581).

(A. W. R.)

LODI, town and episcopal see of Lombardy, Italy, province of Milan, 20½ mi. by rail S.E. of Milan, on a hill above the right bank of the Adda, 230 ft. above sea-level. Pop. (1936) 23,305 (town); 30,636 (commune). The city is on an eminence rising very gradually from a very rich dairy district. The cathedral (1158), with Gothic façade and 16th-century lateral tower, has a restored interior. The church of the Incoronata, erected by Battaggio (1487 onwards) in Bramantesque style, is an elegant octagonal domed structure, decorated with frescoes by the Piazza family, natives of the town, and four large altar pieces by Calisto Piazza. The 13th-century Gothic church of San Francesco has 14th-century paintings. The Palazzo Modegnani has a fine gateway in the style of Bramante, and the hospital a cloistered quadrangle. Besides an extensive trade in cheese (Lodi producing more Parmesan than Parma itself) and other dairy produce, there are manufactures of hemp ropes, linen, silk, majolica and chemicals.

The ancient Laus Pompeia lay 3½ mi. W. and the site is still occupied by a considerable village, Lodi Vecchio, with the old cathedral of S. Bassiano. In the middle ages Lodi was second to Milan in northern Italy. A dispute with the archbishop of Milan about the investiture of the bishop of Lodi (1024) began a long feud. In 1111 and again in 1158 the Milanese laid the whole place in ruins. A number of the Lodigians had settled on Colle Eghezzone; and their village soon grew up under the patronage of Frederick Barbarossa into a new city of Lodi (1162). Lodi was before long compelled to enter the Lombard League, and in 1198 it formed an offensive and defensive alliance with Milan, on which after 1416 it became dependent. The duke of Brunswick captured it in 1625 in the interests of Spain; and it was occupied by the French (1701), by the Austrians (1706), by the king of Sardinia (1733), by the Austrians (1736), by the Spaniards (1745), and again by the Austrians (1746). On May 10, 1796, was fought the battle of Lodi between the Austrians and Napoleon, which made the latter master of Lombardy.

LODI, a city of San Joaquin county, Calif., U.S.A., in the central part of the state, 34 mi. S. of Sacramento. It is on federal highway 99, and is served by the Southern Pacific, Santa Fe and Western Pacific railways. The population was 6,788 in 1930 by the federal census and was 11,079 in 1940. It is the largest grape and wine producing community in the United States, and also produces small fruits, walnuts, almonds, celery, asparagus, grain and forage crops. The city was incorporated in 1906.

LODI, a growing borough of Bergen county, New Jersey, U.S.A., off the Passaic river, adjoining Hackensack on the southwest. It is served by the Erie Railroad company. The population was 11,549 in 1930 and was 11,552 in 1940. It has important manufactures, including dyes and chemicals. Between 1900 and 1920 the population increased more than fourfold.

LODZ, a province in the west of Poland, bounded on the north-east by the province of Warsaw, on the north-west by Poznan, and on the south by the province of Kielce. Area 19,034 sq.km.; pop. (1931) 2,632,434. The province was occupied by Germany in World War II. The southern part of the province is a continuation of the plateau of Kielce, the northern part consists of lowlands washed by the Warta and its tributary, the Prosna. It was formerly covered by forests and lakes and formed the lesser principalities of Kalisz, Sieradz and Łęczyca. The forests have been mostly destroyed and agriculture and cattle-breeding are extensively carried on, the crops principally raised being rye, wheat, oats, barley and potatoes. But the importance of the area has been increased in the last century by the rapid rise of the textile industry in Lodz, Pabjanice, Tomaszów, Zgierz and other towns. Cotton spinning and weaving is the most important industry, but woollens, linens, silks and other fabrics are also manufactured, while the embroideries of Kalisz are of importance. The whole area suffered almost complete destruction during World War I, and had to face new economic problems after the restoration of the factories. Previously designed to supply the Russian and oriental markets, the textile industry of Lodz specialized in coarse materials and neglected the finer fabrics. After 1918, however, the greatly enlarged home market and the markets of western Europe demanded finer materials, and great changes were made to meet the new situation. The revival of the industry was amazing, in spite of the relative lack of new capital.

Lodz again suffered heavily from war during the German invasion of Sept. 1939. It was immediately overrun by German forces under Gen. Blaskowitz, and Berlin announced the capture of Lodz, the chief city, on Sept. 9. By a decree signed in Berlin Oct. 8, 1939 and effective after Nov. 1, the whole province was incorporated into Germany proper. The chief towns of the province, which is the most thickly-populated area of Poland after Silesia, are Lodz (pop. 1938, 665,200); Kalisz (68,300); Piotrków (51,300); Pabjanice, Tomaszów, Zgierz, Łęczyca and Sieradz.

ŁODZ (*Łódz;* also pronounced *Woodsh*), a town of Poland, in the province of Lodz, 82 mi. by rail S.W. of Warsaw. It is situated on the Lodz plateau, which at the beginning of the 19th century was covered with impenetrable forests. Now it is the centre of a group of industrial towns—Zgierz, Łęczyca and Pabjanice. Chiefly owing to a considerable immigration of German capitalists and workers, Lodz grew rapidly. The city is built about one main street, 7 mi. long, and manufactures cottons, woollens and mixed stuffs, chemicals, beer, machinery and silk. The population, which was only 50,000 in 1872, reached 672,000 by 1939. In 1921 60% were Poles and some 180,000 Jews. It is the seat of a Roman Catholic bishop. Lodz fell to the German invaders in Sept. 1939 and Hitler by decree incorporated it into the German reich.

ŁODZ, BATTLE OF, Nov. 11–25, 1914. The repulse at the end of Oct. 1914 of their first offensive in Poland (*see* VISTULA-SAN) placed the Germans in a perilous position on the Eastern Front. The Austrian armies were again in retreat, and were rapidly becoming demoralised; the Germans themselves, on the northern part of the Eastern Front, were greatly outnumbered and could expect no considerable reinforcement till the Ypres battle in the west had been decided. The evident intention of the Russian Commander-in-Chief, the Grand Duke Nicholas, was to advance on the great industrial region of Silesia. In their retreat from Warsaw and Poland the Germans had done their best by elaborate destruction of communications to impose as slow a rate as possible on this advance; but their numbers were insufficient to stem the oncoming tide of Russia's hordes by a direct defence. Invasion of German territory might be slow, but it seemed inevitable.

Ludendorff's Plan.—The German High Command solved their portion of the problem by placing Hindenburg, commander of the IX. Army, in charge of all German forces on the Eastern Front (VIII. and IX. Armies and Woyrsch's detachment) and instructing him to do his best without immediate reinforcement. Hindenburg kept Ludendorff as his chief of staff, and the latter at once proposed a characteristically bold solution. This was to withdraw the IX. Army from Central and southern Poland and, taking advantage of the excellent railway system, to transfer it north to a base between Posen and Torún (Thorn), from which to strike a blow at the Grand Duke's communications as he advanced southwest on Silesia. The plan was an audacious one. In the first place it left the direct route to the enemy's objective, the province of Silesia, barred only by the unreliable Austrians and by weak German elements. Ludendorff trusted to the destroyed communications and to the customary Russian sluggishness of manoeuvre for time sufficient to carry out the contemplated counterstroke. Secondly, East Prussia, again threatened by invasion, would be further denuded of defenders, for Ludendorff proposed to call on the VIII. Army to furnish a quota to his striking force. Lastly, the manoeuvre involved thrusting a body of between five and six corps within reach of Russian forces twice that size, and the greater the success of the blow, the deeper

the penetration into the Russian rear, the heavier would be the weight of the enemy masses concentrated on it. But the result of the battle of Tannenberg had been to persuade Hindenburg and Ludendorff that disparity in numbers could be largely discounted with the Russians as foes.

Disposition of the Russian Forces.—On the Russian side, the first fortnight of Nov. 1914 saw the high-water mark of that onward sweep towards Germany of Russia's exhaustless masses, on which the Allies had built such high hopes. There were at this time eight Russian armies deployed. The X. Army, which had replaced the defeated I. Army on the eastern frontier of East Prussia, had begun to move forward. The I. and II. Armies, to the northwest and west of Warsaw, protected the flank of the main advance by the V., IV. and IX. Armies; on the south, the III. and VIII. Armies covered the left flank by pressure on the Austrian main forces in the direction of Cracow. But progress was slow, hampered by difficulties of supply; and already the Russians were beginning to feel that shortage of munitions and of trained drafts which was to lead to their disasters of 1915. Their armies were strung out in linear formation and no central reserves were available.

The point of attack chosen by Ludendorff for the IX. Army under Mackensen, which now comprised 5½ corps and two cavalry divisions, was the junction between the I. and II. Russian Armies. The Vistula and Warta rivers, to east and west, would protect the flanks of the German advance. To prevent any transfer of Russian forces from north of the Vistula, a detachment, mainly of fortress troops, was to advance on Mława, while another pushed up the right bank of the river towards Płock.

The Russian I. Army was spread over a wide front with three corps north of the Vistula between Mława and Płock and two corps south of the river—the V. Siberian at Włocławek and the II. Corps (lately transferred from the II. Army) between Kutno and Łęczyca. The II. Army was on the Warta, west of Lodz directed on Kalisz. The V. Army was on the left of the II. and was approaching the upper Warta.

First Battle of Łodz.—Mackensen began his advance on Nov. 11. On the 12th the isolated Siberian V. Corps at Włocławek was overwhelmed and driven back on Płock. Two days later the II Corps acting as a link between the I and II Armies about Kutno, and the XXIII, the right corps of the II Army, were defeated by greatly superior numbers and driven south. Scheidemann, commander of the Russian II Army, now tried to wheel his corps from their line on the Warta to a position northeast of Lodz, the chief manufacturing town of Poland. But the German movements were too sure and rapid for the ponderous Russian counter-march. The columns of the II Army were attacked in turn as they came up and were thrown back on Lodz.

Meanwhile the two defeated corps of the I Army, now joined by the Siberian VI Corps from north of the Vistula, were forced back towards Warsaw and away from Lodz. Into the gap between the two Russian armies Mackensen thrust three divisions, the two of the XXV Res. Corps and the 3rd Guard Div. and his two cavalry divisions, with instructions to pass round the right flank of the II Army and encircle Lodz from the south. A corps formed from the Breslau garrison, which had now come up from the west, was to turn the left wing of the Russian II Army, pinned in front by the attacks of the German XI, XVII and XX Corps. Ludendorff was aiming at a second Tannenberg, in which Scheidemann's army was to fill the same role as had the unfortunate Samsonov's. The I Reserve Corps meanwhile was by attack to prevent the I Army from intervening.

By Nov. 18 the position of the Russian II Army seemed well-nigh desperate. It was being driven into a narrow semicircle round Lodz with both flanks turned, and was becoming exhausted and dispirited. But help from the V Army was now close at hand. Plehve, its commander, on receiving orders to turn back to the assistance of the II Army, acted promptly and with resolution. He attempted to rail one division north to Skierniewice but only one regiment got through before Mackensen's cavalry cut the line. The rest of the division came into action on Nov. 19, south of Lodz against the turning movement of the German XXV Res. Corps. The whole of the remainder of the V Army marched north on the 18th, the gap it left on the IV Army's right being filled with cavalry. The same night the Siberian I Corps relieved the pressure on Scheidemann's left by a successful attack on the German XI Corps. Next day the XIX Corps routed the Breslau troops. This restored the situation on the west side of Lodz, but to the east and south of the town Schaffer's XXV Res. Corps and 3rd Guard Div. were still advancing. By the evening of Nov. 20 they had completely turned the right of the Russian II Army and were attacking Lodz from the south.

During Nov. 21 Ludendorff persisted in a last effort to accomplish the destruction of the Russian II Army, but the attacks definitely failed. By the 22nd the tables had been turned, and Schaffer's force was itself completely surrounded. While part of Plehve's army, after rescuing the left of the II Army, turned to attack Schaffer's group south of Lodz, Rennenkampf, the commander of the I Army, had been ordered to dispatch forces from Lowicz and Skierniewice to gain touch with the II Army and close the German line of retreat to the north. The Lowicz force which consisted of $3\frac{1}{2}$ divisions, started on Nov. 20 and by the evening of the 22nd, in spite of three changes of command and indifferent staff work, had captured Stryków and Brzeziny, and had apparently sealed the gap between the Russian I and II Armies. The Russians actually ordered up 18 trains to remove the anticipated harvest of prisoners. The Skierniewice column of a division and a regiment accomplished nothing.

Escape of Schaffer's Force.—In the evening of the 22nd, Schaffer, heavily engaged with part of Plehve's army, south of Lodz, received a wireless order from Mackensen to cut his way out by Brzeziny. During the night of Nov. 22, in intense cold, he succeeded in slipping from the grasp of the enemy opposing him and concentrating his weary divisions to make the bid for release. Unknown to him, the Russians had already opened a breach. The centre columns of the Lowicz force had marched on to Lodz, leaving the left column, the Siberian 6th Div., isolated west of Koluszki on the Warsaw-Lodz railway. This division fought gallantly during Nov. 23 and repulsed all efforts of the XXV Res. Corps to escape. Farther west, however, the 3rd Guard Div. moving through the Galkówek forests, found the gap in the Russian net and captured Brzeziny in the early hours of Nov. 24. Encouraged by this success, the XXV Corps renewed its efforts against the hapless Siberian 6th Div., whose appeals for help were disregarded by other Russian formations within easy reach of the battlefield. Finally, the division, with both flanks turned and overborne by weight of numbers, broke and left the way open for the XXV Res. Corps to rejoin the 3rd Guard Div. at Brzeziny. Schaffer's line of retreat was now clear, and on the 25th his whole force, moving by Stryków, rejoined Mackensen. He brought with him several thousands of prisoners and a number of captured guns.

Effect of the Battle.—Ludendorff's bold stroke had stopped the grand duke's intended invasion of Silesia as effectively as Sir John Moore, by a similar move, had halted Napoleon's incursion into Spain a little more than 100 years before. Never again during the War were the Russians in a position to threaten German territory. The campaign shows well the value of mobility as a strategical weapon. On Oct. 26 the IX Army was engaged opposite Warsaw during Hindenburg's first offensive. During the next fortnight it retired 120 mi. destroying the communications as it went; reorganized and repaired its losses; was transferred by railway across the enemy front; and deployed in complete fighting trim for its new offensive on Nov. 11. This shows German organization and efficiency at its highest. The quality of German leadership was also well displayed, and was in strong contrast with the irresolution and inertia shown by some of the Russian commanders.

Schaffer's exploit was a masterly one; within a few hours of receiving his orders to retire, he had succeeded in breaking off action and setting his columns in motion to seek a way to safety, which his determination and the fine fighting spirit of his troops was to win. This compares with the inaction of many of the Russian commanders, particularly the failure of the numerous bodies within reach to come to the rescue of the Siberian 6th Div. on Nov. 23. Ludendorff had owed much to Rennenkampf's passivity for his victory at Tannenberg; here again Rennenkampf's inefficiency and lack of the will to victory saved him from the loss of Schaffer's force which his rashness and obstinancy had exposed. Yet Rennenkampf had been accounted a dashing leader of men before the War. The Grand Duke himself, Ruzski (the commander of the Northwest Front), and Plehve, who hid an iron will in a weak and wizened frame, all acted promptly and with determination to take advantage of the opportunity.

LOEB, JACQUES (1859–1924), German biologist, was born in Germany, April 7, 1859. Graduating at Ascanisches Gymnasium, Berlin, he studied medicine in Munich and Strasbourg (M.D., 1885). He was assistant in physiology at the universities of Würzburg (1886–88) and Strasbourg (1888–90), working also at the Naples biological station from 1889 to 1891. He went to the United States in 1891 and taught biology at Bryn Mawr for a year. He became assistant professor of physiology and experimental biology at the University of Chicago in 1892, being appointed associate professor in 1895 and professor in 1900. In 1902 he became professor of physiology at the University of California. From 1910 to the date of his death he was head of the division of general physiology at the Rockefeller Institute for Medical Research. He died at Hamilton, Bermuda, Feb. 11, 1924. Dr. Loeb's work was chiefly directed to a pursuit of the real distinction between living and dead matter, the thesis upon which he worked being that all living things are chemical machines and that their workings are open to the same mechanistic explanation as are those of any machines made of inert matter. His most important researches concern the effects of electrolytic, thermant and radiant energy upon living matter, regeneration, the process of fertilization in the egg and artificial parthenogenesis. In 1899 he was able to produce larvae from the unfertilized ova of the sea-urchin, and in 1915 tadpoles from the similar ova of frogs.

Among his published works are: *The Heliotropism of Animals and Its Identity with the Heliotropism of Plants* (1890); *Physiological Morphology* (1891–92); *Comparative Physiology of the Brain and Comparative Psychology* (1900); *Studies in General Physiology* (1905); *The Dynamics of Living Matter* (1906); *The Mechanistic Conception of Life* (1912); *Artificial Parthenogenesis and Fertilisation* (1913); *The Organism as a Whole* (1916); *Forced Movements: Tropisms and Animal Conduct* (1918); *Proteins and the Theory of Colloidal Behaviour* (1922); and *Regeneration from a Physico-chemical Viewpoint* (1924).

LOEB, JAMES (1867–1933), American banker and philanthropist, was born in New York city Aug. 6, 1867. Graduating from Harvard College in 1888, Loeb became a member of the firm of Kuhn, Loeb and company, bankers, New York city, retiring from business in 1901. In 1905 he founded and endowed the Institute of Musical Art in New York city. He was the founder of the Loeb Classical Library of Latin and Greek authors, works which give text and translation on facing pages. The first volume appeared in 1912. He was instrumental in founding the Deutsche Forschungsanstalt für Psychiatrie, an institution in Munich for the systematic study of the causes of mental diseases.

LOEFFLER, CHARLES MARTIN TORNOV (1861–1935), composer, was born at Mühlhausen, Alsace, Jan. 30, 1861. Part of his childhood was spent in Russia near Kiev, but he was educated in Switzerland. He studied the violin under Leonard and Massart at the Paris Conservatoire and under Joachim at the Berlin Hochschule, taking composition in Paris under Guiraud and in Berlin under Kiel. In 1881 he went to the United States, and played violin in the Boston Symphony Orchestra, but resigned in 1903 to devote himself to composition. Among his significant works after 1903 were: *A Pagan Poem* for orchestra and piano; *Memories of My Childhood,* another symphonic poem; and *Canticle of the Sun,* commissioned by Mrs. Elizabeth Sprague Coolidge, with Mme. Povla Frijsh as soloist, for the opening of the Chamber Music Hall, Library of Congress, Oct. 1925, outstanding in that first memorable chamber music festival in the capital of the United States. Other compositions were *Quartet in A Minor; Les Veillées de l'Ukraine;* and *Divertimento in A Minor,* both for orchestra and violin; *The Death of Tintagiles* for orchestra and viola d'amore; *Deux Rhapsodies* for oboe, viola and piano; *Divertissement Espagñol* for orchestra and saxophone; *By the Waters of Babylon,* a setting of Psalm 137, for female chorus; *For One Who Fell in Battle,* eight-part chorus; *Hora Mystica,* symphony; music for four strings to the memory of Victor Chapman; two symphonic poems, *La Bonne Chanson* and *La Villanelle du Diable; Three Movements; Fantastic Concerto* for orchestra and violoncello; and several songs.

LOESS, in geology, a variety of loam. Typical loess is a soft, porous rock, pale yellowish or buff in colour; one characteristic property is its capacity to retain vertical or even over-hanging walls in the banks of streams. These vertical walls have been well described by von Richthofen (*Führer für Forschungsreisende* Berlin, 1886) as they exist in China, where they stand in some places 500ft. high and contain innumerable cave dwellings; ancient roads, too, have worn their way vertically downwards deep into the deposit, forming trench-like ways. This character in the loess of the Mississippi region gave rise to the name "bluff formation." A coarse columnar structure is often exhibited on the vertical weathered faces of the rock. Another characteristic is the presence throughout the rock of small capillary tubules, which appear to have been occupied by rootlets; these are often lined with calcite. Typical loess is usually calcareous; some geologists regard this as an essential property, and when the rock has become decalcified, as it frequently is on the surface by weathering, they call it "loess-loam" (*lösslehm*). In the lower portions of a loess deposit the calcium carbonate tends to form concretions, which on account of their mimetic forms have received such names as *lösskindchen, lösspuppen, poupées du loess,* "loess dolls." Bedding is absent from typical loess. The mineral composition of loess varies somewhat in different regions, but the particles are always small; they consist of angular grains of quartz, fine particles of hydrated silicates of alumina, mica scales and undecomposed fragments of felspar, hornblende and other rock-forming silicates.

In Europe and America loess deposits are associated with the margins of the great ice sheets of the glacial period; thus in Europe they stretch irregularly through the centre eastwards from the north-west of France, and are not found north of the 57th parallel. Most geologists are agreed that the true loess is an aeolian or wind-borne rock, formed most probably during periods of tundra or steppe conditions. But it seems clear that certain deposits classed as loess in western Europe do not really belong to this category, being of alluvial origin and related to the brick-earths of south-eastern England.

LOEWE, JOHANN KARL GOTTFRIED (1796–1869), German composer, was born at Löbejün, near Halle, on Nov. 30, died at Kiel, on April 20, 1869. He wrote five operas, of which only one, *Die drei Wünsche,* was performed at Berlin in 1834, without much success; and many choral and chamber works. His best work was done in the solo ballad with pianoforte accompaniment.

See H. Bulthaupt, *Karl Loewe* (1898) in Riemann's *Berühmte Meister.*

LÖFFLER, FRIEDRICH (1852–1915), German bacteriologist, was born at Frankfort on the Oder, and after being army surgeon, became professor of hygiene at Greifswald in 1888. Together with Koch he was able to cultivate the organism of diphtheria which is known as the Klebs-Löffler bacillus. He also discovered the bacteria of erysipelas in pigs in 1882, and in 1898 inoculated successfully against the foot-and-mouth disease, the cause of which he showed to be a filterable virus. He left an unfinished history of bacteriology.

LOFFT, CAPEL (1751–1824), English miscellaneous writer, was born in London on Nov. 14, 1751. He was educated at Eton, and Peterhouse, Cambridge, which he left to become a member of Lincoln's Inn. He became the patron of Robert Bloomfield, the author of *The Farmer's Boy,* and secured for him the very successful publication of that work. Byron, in a note to his *English Bards and Scotch Reviewers,* ridiculed Lofft as "the Maecenas of shoemakers and preface-writer general to distressed versemen; a kind of gratis *accoucheur* to those who wish to be delivered of rhyme, but do not know how to bring forth." He died at Montcalieri, near Turin, on May 26, 1824.

LOFOTEN AND VESTERAALEN, a group of islands off the N.W. coast of Norway, between 67° 30′ and 69° 20′ N., and between 12° and 16° 35′ E., part of the Norwegian *amt* (county) of Nordland. The extreme length of the group from Andenaes, at the north of Andö, to Röst, is about 150 mi.; the aggregate area about 1,560 square miles. It is separated from the mainland by the Vestfjord, Tjaeldsund and Vaagsfjord, and is divided into two sections by the Raftsund between Hindö and Öst-Vaagö. To the west and south of the Raftsund lie the Lofoten islands proper, of which the most important are Öst-Vaagö, Vest-Vaagö and Moskenaesö; east and north of the Raftsund are the islands of Vesteraalen, the chief being Hindö, Langö and Andö. The islands, which are of granite or gneiss, are a partially submerged mountain range, and are lofty and rugged. The highest points are found on Öst-Vaagö, near the Raftsund and Troldfjord, and the greatest height is Higrafstind (3,811 ft.).

The long line of jagged peaks seen from the Vestfjord forms one of the most striking prospects on the Norwegian coast. The channels which separate the islands are narrow and tortuous, and generally of great depth; they have remarkably strong tidal currents, particularly the Raftsund and the famous Maelström or Moskenström near Moskenaes. Though situated within the Arctic circle, the climate of the Lofoten and Vesteraalen group is not rigorous and the coast is never frozen. The isothermal line which marks a mean January temperature of 32° F runs south from the Lofotens, passing east of Bergen onward to Gothenburg and Copenhagen. The prevailing winds are from the south-west and west, the mean temperature is 38·5° F, and the annual rainfall is 43·34 in. In summer the hills have only patches of snow. Much of the interior is bleak cranberry moor. Cattle are reared, but the growth of cereals (chiefly barley) is insignificant.

The characteristic industry is the cod fishery carried on along the east coast of the Lofotens in the Vestfjord in spring. This employs many thousands during the season from all parts of Norway. The fish, dried on the cliffs during early summer, ordinarily is exported from Bergen to Spain, Holland, Great Britain, Belgium, etc., and the fish heads are used as cattle food. Industries arising out of the fishery are the manufacture of cod-liver oil and of artificial manure in factories at Skolvaer, Henningvaer, Kabelvaag, etc. The summer cod fisheries and the lobster fishery are also valuable.

The herring is taken in large quantities off the west coasts of Vesteraalen. Skolvaer built on rocky islands off Öst-Vaagö is the "capital" and chief port and trading centre, and Kabelvaag is another fishing port. Lödingen also, at the head of the Vestfjord on Hindö, is a port of call. A church existed at Vaagen (Kabelvaag) in the 12th century, and Hans Egede, the missionary of Greenland, was pastor. Steamers trade between Hamburg or Oslo and Hammerfest, and communication locally is chiefly by small boats for there are few roads. The largest island in the group, and indeed in Norway, is Hindö, with an area of 860 square miles. On Andö there is a bed of coal at the mouth of the Ramsaa.

Lofoten became well known in World War II as the scene of British "Commando" raids against the Germans.

LOFTUS, ADAM (*c.* 1533–1605), archbishop of Armagh and Dublin, and lord chancellor of Ireland, was educated at Cambridge. He accompanied the earl of Sussex to Ireland as his chaplain in 1560, and three years later was consecrated archbishop of Armagh by Hugh Curwen, archbishop of Dublin. In 1567 he was translated to the archbishopric of Dublin, where the queen looked to him to carry out reforms in the Church. On several occasions he temporarily executed the functions of lord keeper, and in August 1581 he was appointed lord chancellor of Ireland. It was largely through his influence that the corporation of Dublin granted the lands of the priory of All Hallows as a beginning of the endowment of Trinity college, of which he was named first provost in the charter creating the foundation in 1591. Loftus died in Dublin on April 5, 1605.

See J. R. O'Flanagan, *Lives of the Lord Chancellors of Ireland* (1870).

LOG, MARITIME, an appliance for measuring the speed of a ship through the water. The oldest form of log of a practical nature was that known as the "common log." The outfit consisted of a log-ship or log-chip, log-reel, log-line and log-glass. The log-ship was a wooden quadrant about $\frac{1}{2}$ inch thick with a radius of about 5 or 6 inches, its circumference being weighted with lead to keep it upright in the sea and to retard its passage through the water. One end of a short length of thin line was passed through a hole at one of the lower corners of the log-ship and secured by a knot on the opposite side. To the other end was spliced another short length terminating in a hard wooden peg which could be inserted in a similar hole in the opposite corner. The holes were so placed that the log-ship would hang square from the span thus formed.

The log-line led from this span inboard to the ship. The first length between the log-ship when floating in the sea and the ship was known as the "stray line." It varied from 10 to 20 fathoms according to the distance necessary to veer the log-ship clear of the disturbance of the ship's wake before starting observations. The place where its inboard end joined the remainder of the log-line was marked by a piece of bunting, and the line from here towards the end in the ship was marked and measured in "knots" composed of pieces of cord worked in between the strands. The distances between the knots bore the same relation to a nautical mile (6,080 ft.) as 28 sec. to an hour (3,600 sec.); *i.e.*, they were placed 47 ft. 3 in. apart. The end of the first interval, counting from the bunting, was marked with a piece of leather, the second by a cord with two knots, the third by one with three knots, and so on. Half-way between each length was a cord with one knot. It followed, therefore, that if, say, five knots of the line ran out in 28 sec. by the sand glass, the ship had gone $5 \times 47\frac{1}{4}$ ft. in that time, *i.e.*, was moving at a rate of five knots (five nautical miles per hour). For speeds over 6 knots, a 14-second glass was employed and the speed indicated by the log-line was doubled. The form of marking adopted enabled the log to be read when taking readings at night.

The actual process of "heaving the log" was as follows: The log-line was prepared by well soaking and stretching it before marking. It was then wound evenly on the log-reel, to which its inner end was securely attached. One man held the log-reel over his head, the officer (in the navy, usually the midshipman of the watch) placed the peg in the log-ship which he then threw overboard clear and to windward of the ship, allowing the line to run out freely. When the bunting at the end of the stray line passed his hand, he called to his assistant to turn the sand-glass. When all the sand had run out, the assistant called "stop," when the log-line was quickly nipped and the knots counted, any extra portion intermediate between two markings being estimated. The strain brought on the little span next the log-ship caused the peg to be withdrawn from its hole, when the log-ship turned edge on, thus facilitating hauling it in. Normally the log was hove every hour, and under favourable conditions the common log gave very fairly accurate results. It has, however, been almost entirely superseded by automatic or "continuous" logs registering inboard on dials.

One of the earliest of these logs was invented by Edward Massey in 1802; this log was in general use in 1836 and continued so until 1861. An improved log was produced by Alexander Bain in 1846, and in 1861 Thomas Walker's "harpoon" or frictionless log was introduced. In all these the dials registering the distance travelled were close to the screw which actuated the log, *i.e.*, they towed overboard and the instrument had to be hauled in before it could be read. This inconvenience was overcome by Walker, when in 1878, he introduced his "cherub" log. Walker's "cherub" consisted of a dial secured to the taffrail of the ship, a specially plaited line of 40 to 60 fathoms in length and a screw-like rotator. To regulate the rate of spin, a brass fly-wheel, known as a "governor," was added in the later patterns. The "cherub" log gave excellent results up to a speed of about 14 knots; above that the rotator was inclined to jump out of the water, and to overcome this defect the "trident" log was introduced. This log was generally similar in appearance to the "cherub," but the line was 65 fathoms, and certain improvements were made in the mechanical parts of the counter to enable it to bear the strain of higher speeds. A further development was an electrical arrangement transmitting the readings of the counter to a dial in the chart-house.

Forbes' Log and Speed Indicator.—This apparatus records (1) the distance travelled by the ship through the water, and (2) an indication of the speed in knots at which the ship is moving through the water at any given moment. It has the advantage over the trailing form of log that it does not get fouled by seaweed or damaged by being towed astern, while it will give the speed of the ship when turning, a useful piece of information for gunnery purposes. On the other hand, it is sometimes affected by the stream line of the ship.

The transmitting apparatus consists essentially of a tube projecting through the bottom of the ship and turned so as to face forward. Water is forced through this tube by the forward movement of the ship; the flow operates a small propeller which actuates the transmitting mechanism. The water flows out through another opening facing aft. The small propeller operates a commutator which transmits electric signals to the distant recorders. It also drives a magnetic generator which generates currents of a voltage proportional to the speed. The commutator operates the dial indicating the distance travelled, while the generator excites a voltmeter graduated in knots. Arrangements are made to adjust the mechanism to suit and record accurately for an individual ship. (E. A.)

LOGAN, JOHN, also known as TAHGAHJUTE (*c.* 1725–1780), American Indian leader, by birth a Cayuga, the son of Shikellamy, a white man who had been captured when a child by the Indians, had been reared among them and had become a chief. John Logan lived for some time near Reedsville, Pa., and removed to the banks of the Ohio river about 1770. He was not technically a chief but acquired great influence among the Shawnees, into which tribe he married. He was on good terms with the whites until April 1774, when, friction having arisen between the Indians and the whites, a band of marauders, led by one Greathouse, attacked and murdered several Indians, including Logan's sister and other relatives. Believing that Capt. Michael Cresap was responsible for this murder, Logan sent him a declaration of hostilities, the result of which was the bloody conflict known as Lord Dunmore's war. Logan refused to join the Shawnee chief, Cornstalk, in meeting Gov. Dunmore in a peace council after the battle of Point Pleasant, but sent him a message now famous as an example of Indian eloquence. Logan took to drink and in 1780 was killed near Lake Erie by his nephew, whom he had attacked.

See Brantz Mayer's *Tah-gah-jute or Logan the Indian and Captain Michael Cresap* (Baltimore, 1851; 2nd ed. Albany, 1867) and F. B. Sawvel, *Logan the Mingo* (1921).

LOGAN, JOHN (1748–1788), Scottish poet, was born at Soutra, Midlothian, in 1748. In 1771 he was presented to the charge of South Leith, but was not ordained till two years later. In 1770 he published *Poems on Several Occasions by Michael Bruce*. In 1781 he published his own *Poems*. Logan was accused of having appropriated in his *Poems* (1781) verses written by Michael Bruce (*q.v.*). The statements of John Birrell and David Pearson on behalf of Bruce were included in Dr. Anderson's *Life of Logan*. The charge of plagiarism has been revived from time to time.

LOGAN, JOHN ALEXANDER (1826–1886), American soldier and political leader, was born in what is now Murphysborough, Ill., on Feb. 9, 1826. He had no schooling until he was 14; he then studied for three years in Shiloh college, served in the Mexican War as a lieutenant of volunteers, graduated from the law department of Louisville university in 1851 and practised law with success. He entered politics as a Douglas Democrat. In 1858 and 1860 he was elected to the national house of representatives. Though unattached and unenlisted, he fought at Bull Run, and then returned to Washington, resigned his seat and entered the Union army as colonel of a regiment of volunteers, which he organized. He was regarded as one of the ablest officers who entered the army from civil life. In Grant's campaigns terminating in the capture of Vicksburg he rose to the rank of major-general of volunteers; in 1863 he was placed in command of an army corps, and after the death of McPherson he was in command of the army of the Tennessee at the battle of Atlanta. When the war closed, Logan resumed his political career as a Republican and was a member of the national house of representatives from 1867 to 1871, and of the U.S. senate from 1871 until 1877 and again from 1879 until his death. He was always a violent partisan and was identified with the radical wing of the Republican party. His war record and his large personal following, especially in the Grand Army of the Republic, contributed to his nomination for vice-president in 1884 on the ticket with James G. Blaine, but he was not elected. His impetuous oratory, popular on the platform, was less adapted to the halls of legislation. When commander-in-chief of the Grand Army of the Republic in 1868–71, he successfully urged the observance of Memorial or Decoration day, an idea which probably originated with him. He died at Washington, D.C., Dec. 26, 1886. He was the author of *The Great Conspiracy: Its Origin and History* (1886), and of *The Volunteer Soldier of America* (1887). There is a fine statue of him by Saint-Gaudens in Chicago.

LOGAN, SIR WILLIAM EDMOND (1798–1875), British geologist, was born in Montreal on April 20, 1798, of Scottish parents. He was educated partly in Montreal and at the high school and University of Edinburgh, where Robert Jameson excited his interest in geology. In 1831 he took charge of a colliery and copper-smelting works in Swansea. In 1840 Logan brought before the Geological society of London his paper "On the character of the beds of clay lying immediately below the coal-seams of South Wales, and on the occurrence of coal-boulders in the Pennant Grit of that district." He pointed out that each coal-seam rests on an under-clay with rootlets of *Stigmaria,* and expressed his opinion that the under-clay was the old soil in which grew the plants from which the coal was formed. To confirm this observation he visited America in 1841 and examined the coal-fields of Pennsylvania and Nova Scotia, where he found the under-clay almost invariably present beneath the seams of coal. In 1842 he took charge of the newly established geological survey in Canada, and continued as director until 1869. Logan was elected F.R.S. in 1851. He died at Castle Malgwyn, Pembrokeshire, on June 22, 1875.

LOGAN, a city of southern Ohio, U.S.A., on the Hocking river, 48 mi. S.E. of Columbus; the county seat of Hocking county. It is served by the Chesapeake and Ohio railway. The population was 6,080 in 1930 and 6,177 in 1940. Logan is in a rich farming region, with coal, oil and natural gas near by. It has railroad shops and machine shops, and its manufactures include oil-well tools and supplies, furniture, iron and steel, brick, shoes, flour and earthenware. The village was settled about 1816, incorporated in 1839 and became a city in 1922.

LOGAN, fourth city of Utah, U.S.A., on the Logan river, 80 mi. N. of Salt Lake City; the county seat of Cache county. It is on federal highways 91 and 89, and is served by the Oregon Short Line and the Utah-Idaho Central (electric) railways. The population was 9,979 in 1930, and 11,868 in 1940. It lies at the entrance to the picturesque Logan canyon, 4,500 ft. above sea level, and commands magnificent views of the Wasatch mountains and the fertile Cache valley. Logan is the business centre of the valley, which is devoted largely to raising sugar beets, alfalfa, grain, peas and beans and to dairying and which also has several beet-sugar factories, milk condensers, grain elevators, flour mills and a pea- and bean-canning plant. There are also knitting factories and bottling works. The Utah state agricultural college (founded in 1888) is there. Logan was settled in 1859 by the Mormons from the Great Salt Lake valley and was incorporated in 1866.

LOGANBERRY or **LOGAN BLACKBERRY.** This well-known fruit is supposed to be a hybrid between the wild blackberry (*Rubus ursinus*) of the Pacific coast and the red raspberry, but this view is disputed. The fruit was raised from seed in 1881 in the garden of Judge J. H. Logan at Santa Cruz, Calif. It is grown commercially in large quantities, especially in Oregon and Washington and in England and Tasmania. The Logan is a vigorous, nearly trailing, blackberry-like plant with 3- to 5-foliate leaves, prickly canes and deep wine-red, tart, high-flavoured berries that separate from the stem as do the blackberries. The Phenomenal, originated by Luther Burbank, is very similar to the Logan, but bears slightly larger fruit. The Young (Youngberry), Boysen (Boysenberry), Pacific and Cascade are related berries that have the high aroma and flavour of the Logan and of the native blackberry. Research by Crane and Thomas in England indicates that the Logan might have originated as a hybrid of an octoploid blackberry fertilized with diploid pollen of a red raspberry. A hybrid of this kind was reported by them as similar in appearance to the Logan. Confirmation of this by others has not yet been obtained. Bailey has proposed the species name *R. loganobaccus* for this cultivated blackberry.

LOGANIACEAE, a family of dicotyledonous plants including herbs, vines, shrubs and trees, chiefly tropical but with some representatives in temperate regions. About 33 genera and 700 species are recognized. The largest and most important genus is *Strychnos* in the tropics of both hemispheres, the seeds of various species, but especially those of *S. nux vomica,* yielding the important drug strychnine (*q.v.*). Many species of *Buddleia* and one of *Gelsemium,* the yellow jessamine of the southeastern United States, are cultivated for ornamental purposes. (E. D. Ml.)

LOGANSPORT, a city of Indiana, U.S.A., on the Wabash river, at the mouth of the Eel, 67 mi. N.W. of Indianapolis; the county seat of Cass county. It is on federal highways 24 and 35 and is served by the Pennsylvania, the Wabash and five motorbus lines. The population was 18,508 in 1930 and 20,177 in 1940 (97% native white) by the federal census. The city has an area of 5.7 sq.mi. and an altitude of 600 ft. It is an important shipping point for grain, lumber, pork and other products of the rich farming region round about. There are approximately 30 important manufacturing industries with approximately 1,590 employes. Among the products are fire-fighting apparatus, heating systems, steel springs, wearing apparel, electrical equipment, machine parts, fishing tackle, bicycle tires and oxygen. A state hospital for the insane is situated there.

Title to the land in and about Logansport was acquired by the United States from the Miami and the Pottawatomie Indians by treaty in Oct. 1826. The town was laid out in 1828 and was named after a Shawnee chief, Capt. Logan (d. 1812), who was a faithful friend of the whites. It was incorporated as a town in 1831 and as a city in 1838.

LOGAR, a river and valley of Afghanistan. The Logar river drains a wide tract of country, rising in the southern slopes of the Sanglakh range and receiving affluents from the Kharwar hills, north-east of Ghazni. It joins the Kabul river a few miles below the city of Kabul. The Logar valley, which is watered by its southern affluents, is rich and beautiful, about 40 m. long by 12 wide, and highly irrigated throughout. Lying in the vicinity of the capital, the district contributes largely to its food-supply.

LOGARITHMIC DECREMENT is the measure of the rate of decay of any exponentially damped oscillatory phenomenon, usually mechanical or electrical. It is the Naperian logarithm of the ratio of the first to the second of two successive current amplitudes in the same direction. The logarithmic decrement can also be considered as a constant of a simple radio circuit, being π times the product of the resistance by the square root of the ratio of the capacity to the inductance of the circuit. Measurement of logarithmic decrement is of great importance since it makes possible the determination of the equivalent resistance of the circuits under consideration, and also gives information concerning the lengths of the wave trains. The value of the sum of the decrements of two circuits may be obtained from their resonance curve.

LOGARITHMS. By shortening processes of computation, logarithms have doubled the working speed of astronomers and engineers. The explanation of this highly practical branch of mathematics begins most conveniently with the exponential expression b^l which represents some number n, so that we may write $n=b^l$. In the elementary theory we assume b, n, l to be real numbers, b and n positive, and b greater than unity. If we know b and the exponent l, we may compute n. For example, if $b=10$, $l=3$, then $n=1{,}000$. If any two of the three numbers b, l, n are given, the third may be computed. To develop the elementary theory of logarithms we assume the number n and the base b to be given, then the exponent l may be found. For the case under consideration (when b and n are both positive and b is greater than unity), the actual existence of one and only one real value l can be established by the modern theories of irrational numbers, such as that of Dedekind. For, if we make a "cut" of all ordered real numbers by placing in one class every number α for which $b^\alpha \leqq n$, and in the other class every number β for which $b^\beta > n$, then if N is the number defined by the "cut," we must have $b^N=n$, for the reason that every other assumption leads to an evident contradiction. That is, if we assume that $b^N<n$, then another number b^{N_1} exists which lies between b^N and n, and there are numbers in the first class greater than N, which is contrary to assumption. A similar result is reached if we assume that $b^N>n$.

The number l is called the "*logarithm* of the number n to the base b"; in which case n is sometimes called the *antilogarithm* of l. From a knowledge of the properties of the expression b^l it becomes evident that certain values of the base b are more convenient than others. Thus, b is selected to be positive, because a negative b would produce undesired fluctuations in the signs of n, when l takes successively the values $1, 2, 3, 4, \cdots$, while for $l=\frac{1}{2}$, $\frac{1}{4}, \cdots$ the n would be an imaginary number. It is evident also that $b=1$ would place limitations upon the possible values of n corresponding to the real exponents l, since $1^l=1$. Accordingly, when the base is unity, 1 is the only real number having a real logarithm. If b lies between 0 and 1, then l decreases as n increases, a relation that is workable in practice, though not particularly desirable. Hence we assume, as was done above, that b is positive and greater than 1.

Of all possible values greater than 1 which might be chosen as the base, two have been selected, which yield two systems of logarithms. One value is $b=10$, used in the *common logarithms*, chosen because of certain practical advantages that accrue from a base which is the same as the scale of our number system. Common logarithms have also been called *Briggian* logarithms. The other value taken for the base is $2{\cdot}718\cdots$: it is usually represented by the letter e, and belongs to a type of irrational numbers called "transcendental numbers." The logarithms having the base e are called *natural logarithms*, or sometimes less appropriately *hyperbolic* or *Naperian logarithms*. The base 10 yields logarithms that are most convenient for the purposes of computation; the base $2{\cdot}718\cdots$ yields logarithms which lead to simpler formulas in higher analysis than other systems, and are therefore the most "natural" ones to use.

According to the definition of logarithms given above, logarithms are really exponents and therefore are endowed with the properties of exponents, viz.,

$$b^{l+l_1}=b^l\cdot b^{l_1},\quad b^{l-l_1}=b^l/b^{l_1},\quad b^{ll_1}=(b^l)^{l_1}, \tag{1}$$

where l and l_1 may be positive or negative, rational or irrational real numbers. In the theory of logarithms, if $b^l=n$, we use the notation $l=\log_b n$, and we read this, "l is the logarithm of n to the base b." As $b^0=1$ and $b^1=b$, it is evident that no matter what value different from zero the base may have, the logarithm of 1 is zero, and the logarithm of the base itself is unity. Writing $b^l=n$ and $b^{l_1}=n_1$, the three exponential formulas (1) translated into the notation of logarithms, become

$$l+l_1=\log_b nn_1,\quad l-l_1=\log_b n/n_1,\quad ll_1=\log_b (n)^{l_1}, \tag{2}$$

Substituting $\log_b n$ for l, $\log_b n_1$ for l_1, we have

$$\log_b n+\log_b n_1=\log_b nn_1,\quad \log_b n-\log_b n_1=\log_b n/n_1,$$
$$p.\ \log_b n=\log_b (n^p). \tag{3}$$

Stated in words: (1) The logarithm of a product is equal to the sum of the logarithms of the factors. (2) The logarithm of a quotient is equal to the logarithm of the dividend minus the logarithm of the divisor. (3) The logarithm of a power of a number is equal to the product of the exponent and the logarithm of the number itself.

Common Logarithms.—Since $10^0=1$ and $10^1=10$, the logarithm of 1 is zero and the logarithm of 10 is unity. Any number between 1 and 10 has a common logarithm which lies between 0 and 1. Similarly, since $10^2=100$, any number between 10 and 100 has a common logarithm which lies between 1 and 2; and since $10^3=1{,}000$, any number between 100 and 1,000 has a common logarithm which lies between 2 and 3; and so on. Thus the logarithm of 75 is nearly $1{\cdot}87506$. The integral part of the logarithm is called the *characteristic*, the decimal part is called the *mantissa*. From the relations just given we obtain the general statement that *the characteristic of the common logarithm of a number greater than* 1 *is one less than the number of integral figures*. Thus, $3768{\cdot}5$ has four integral figures, hence its logarithm has the characteristic 3. From the relations $10^0=1$, $10^{-1}={\cdot}1$, $10^{-2}={\cdot}01$, $10^{-3}={\cdot}001$, etc., we obtain a corresponding rule for decimal fractions less than unity, and also the provision that the mantissa shall be positive; namely the rule that the *characteristic of the common logarithm of a decimal fraction less than unity is negative and is numerically one more than the number of zeros immediately following the decimal point*. Thus, $0{\cdot}000107$ has three zeros immediately following the decimal point and the characteristic of its logarithm is -4. The minus sign is sometimes written above the characteristic, thus $\bar{4}$, to serve as a reminder that it applies only to the characteristic and not to the mantissa. It is simply for convenience that the mantissa, when different from zero, is always taken to be positive. This is accomplished by framing the rules for finding the characteristic, as was done above, so that, when the mantissa is not zero, the characteristic is always the integer immediately below the true value of the logarithm, and the fractional value (the mantissa) must be added to the characteristic to secure the true value of the logarithm. Thus, the logarithm of ${\cdot}07$ lies between -1 and -2; it might be taken to be -1 and a minus mantissa or -2 and a positive mantissa. The latter course is chosen, for the reason that the computation involving mantissas is simplified by taking them always positive.

The great advantage of the common system of logarithms lies in the fact that the mantissa of the same sequence of figures is the same, no matter where the decimal point is placed. Thus, 3·7568 and 375·68 have different characteristics but the same mantissa. This fact is evident from the relation

$$3{\cdot}7568 \times 100 = 375{\cdot}68,$$

which indicates that the logarithm of 3·7568 is less than of 375·68 by exactly 2, which is the logarithm of 100. This property of the mantissa and the simple rules for finding the characteristic make it possible to prepare tables of common logarithms in very much more compact form than for other systems. Characteristics are omitted altogether from the tables and are supplied by the computer.

Natural Logarithms.—To show how natural logarithms arise in analysis, we find the derivative of $y=\log_b x$, where b is any positive constant greater than 1. We obtain $y+h=\log_b(x+k)$, $h=\log_b(x+k)-\log_b x = \log_b\frac{x+k}{x} = \log_b\left(1+\frac{k}{x}\right)$, and

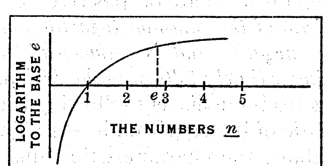
$$\frac{h}{k} = \frac{1}{x}\cdot\frac{x}{k}\cdot\log_b\left(1+\frac{k}{x}\right) = \frac{1}{x}\cdot\log_b\left(1+\frac{k}{x}\right)^{\frac{x}{k}}.$$

The derivative $\frac{dy}{dx}$ is the limit of $\frac{h}{k}$, as $k\rightarrow 0$. Thus we are led to consider the limit of $\left(1+\frac{1}{n}\right)^n$, where $n=\frac{x}{k}$. This limit can be shown to exist, but the proof, when n may assume any real values, rational or irrational, is somewhat long. It is one of the fundamental limits in mathematics. Expanding $\left(1+\frac{1}{n}\right)^n$ by the Binomial Theorem and letting $n\rightarrow\infty$, we obtain the rapidly convergent series,

$$e=1+1+\frac{1}{2!}+\frac{1}{3!}+\cdots+\frac{1}{n!}+\cdots=2{\cdot}718281828459\cdots.$$

We thus obtain $\frac{dy}{dx} = \frac{1}{x}\log_b e$. If we take the base $b=e$, so that $\log_e e=1$, this expression reduces to the simpler form $\frac{dy}{dx} = \frac{1}{x}$.

From the graph here shown it is evident to the eye that positive numbers less than 1 have negative logarithms. Numbers very close to 0 have negative logarithms whose numerical values are very large. The vertical axis is an asymptote to the curve. These statements are true also for the graphs of common logarithms and of logarithms to any base $b>1$. It is a curious special property of the graph for natural logarithms that only one of its points has co-ordinates both of which are rational numbers, namely the point (1, 0). In other words, the equation $l=\log_e n$, or $e^l=n$, can be satisfied by only one set of numbers l and n, of which both are real and rational, namely $n=1$ and $l=0$. This unexpected and curious property is rendered even more subtle by the additional fact that in all other sets of values for n and l, at least one of the two numbers is a very special type of irrational, called *transcendental*. As already stated, the base e is itself a transcendental number. A number is called transcendental when it is not algebraic; *i.e.*, when it cannot be the root of an algebraic equation, $x^m+ax^{m-1}+bx^{m-2}+\cdots+fx+g=0$, where m is any positive integer and the coefficients $a, b, \cdots, f, g$ are all integers, or zero, except that g cannot be zero since that would change the degree of the equation. Algebraic numbers include all integers and rational fractions, and also all irrational numbers which are roots of algebraic equations of the kind here described. The proof that e is transcendental was a notable achievement of the French mathematician Charles Hermite, in 1873 (*Comptes Rendus*, vol. 77, p. 285). The proof as ordinarily given is to substitute in the above equation e for x and to show that this leads to an absurdity; since the left member of the equation, after being multiplied by a suitable constant C, may be broken up into two parts, one an integral part which is not zero, and the other part having a fractional value which can be made as small as we please. Evidently the sum of an integer different from zero and a proper fraction cannot equal zero. Hence e cannot be a root of the equation.



If in the figure we imagine all algebraic numbers marked on the n-axis and also on the l-axes, the points so marked are "dense" on each axis; *i.e.*, between any two algebraic numbers, no matter how close they are to each other, there exists at least one other algebraic number, *e.g.*, the arithmetic mean of the two. If in the nl-plane we imagine all points marked which have an algebraic abscissa n and also an algebraic ordinate l, then the entire plane is "densely" covered by these algebraic points. In spite of this fact, the logarithmic curve possesses the extraordinary property of not containing any of these algebraic points, except only $n=1$ and $l=0$. With this exception, all points of the curve must have at least one co-ordinate which is an irrational of the transcendental type; the curve finds its way through this complicated maze of points without hitting more than once a point whose co-ordinates are both algebraic. "How would Pythagoras celebrate such a discovery," exclaims Felix Klein, "if the ordinary irrational seemed to him worthy of a hecatomb!"

Change of Base.—The change of logarithms from one base to another is effected by a formula obtained as follows:

If $$n=b^l=b_1^{l_1},$$

then taking the logarithm to the base b gives

$$l\cdot\log_b b=l_1\cdot\log_b b_1.$$

Since $\log_b b=1$ we have $l=l_1\cdot\log_b b_1$ or

$$\log_b n=\log_{b_1} n\cdot\log_b b_1.$$

If we take $b=10$ and $b_1=e$, we obtain

$$\log_{10} n = \log_e n\cdot\log_{10} e,\quad\text{where}\quad \log_{10} e = 0{\cdot}434294481903 25\cdots$$

is a constant factor sometimes called the *modulus* of the common system of logarithms. For the special case when $n=b$, we obtain $1=\log_c{}^b\cdot\log_b{}^c$. Suppose that we know the common logarithm of 200 and we wish to compute the natural logarithm of 200. We have from the above

$$\log_e 200=\log_{10}200\div\log_{10}e=2{\cdot}30103\cdots\div 0{\cdot}43429\cdots = 5{\cdot}2983\cdots,$$

the natural logarithm of 200.

Logarithms of Complex Numbers.—If, in the equation $b^l=n$, b is a positive real number and l is either positive or negative, but real, then n must necessarily be positive, for a positive number raised to a power that is real, though either positive or negative, always yields a positive result as its principal value. Under these restrictions a negative number has no logarithm. This limitation causes no embarrassment in computation with logarithms, for we proceed as if all factors were positive. If the number of negative factors is odd, we mark the final result as negative. From the standpoint of theory, however, the failure of the elementary exposition to include the logarithm of negative numbers indicates a lack of generality. It is found that, as soon as we drop the limitation that l shall be real, and permit l to become imaginary or complex, any number n, whether positive or negative, or even complex, has not only one logarithm, but an infinite set of them. To establish this fact we make use of two well-known theorems in trigonometry. One theorem states that the periodicity of the sine and cosine functions is $2m\pi$, where m is any integer. The other theorem, due to Cotes and Euler, is expressed by the formula

$$e^{i\theta}=\cos\theta+i\sin\theta \tag{4}$$

where $i=\sqrt{-1}$ and θ is any angle measured in radians. Accordingly we obtain,

$$e^{i\theta}=\cos\theta+i\sin\theta=\cos(\theta+2m\pi)+i\sin(\theta+2m\pi)=e^{i\theta+2im\pi}.$$

Suppose now that $n=p+iq$, and $l=c+id$, where p, q, c, d are real numbers; then, taking for simplicity e as the base of the system of logarithms, we obtain

$$p+iq=e^{c+id}=e^c \cdot e^{id}=e^c(\cos d+i\sin d). \tag{5}$$

Equating the real numbers and also the imaginary numbers we obtain the numerical relations

$$p=e^c \cdot \cos d, \qquad q=e^c \cdot \sin d.$$

Allowing for periodicity, we obtain from (5) the more general equation

$$p+iq=e^c[\cos(d+2m\pi)+i\sin(d+2m\pi)]=e^{c+i(d+2m\pi)}, \tag{6}$$

and
$$\log_e(p+iq)=c+i(d+2m\pi). \tag{7}$$

If we write $z=p+iq$ and $\rho=\sqrt{(p^2+q^2)}$, then $\log\rho=c$ and we obtain formula (7) in the form

$$\log_e z=\log_e\rho+i(d+2m\pi). \tag{8}$$

As formula (7) is a general expression which is true for every integral value of m, we see that the number of logarithms of $z=p+iq$ is infinite. Let us consider some special cases. To find the logarithm of a negative number, say -1, we take $n=-1$, $p=-1$, $q=0$, and obtain from formula (6) $c=0$, and

$$\cos(d+2m\pi)=-1,$$

therefore $d=\pi$, and finally from formula (7),

$$\log_e(-1)=i\pi(1+2m)=i\pi,\ 3i\pi,\ 5i\pi, \text{ etc.}$$

That is, the natural logarithm of -1 has, in this more general theory, an infinite number of logarithms, all imaginary. In the case of i, we find

$$\log_e i=i\left(\frac{\pi}{2}+2m\pi\right)=\frac{i\pi}{2},\ \frac{5i\pi}{2},\ \frac{9i\pi}{2}, \text{ etc.}$$

Similarly, for the logarithm of e, we obtain

$$\log_e e=1+2im\pi=1,\ 1+2i\pi,\ 1+4i\pi, \text{ etc.}$$

That is, e has one real logarithm, namely 1, all the others are imaginary. Note that the integer m may take also negative values.

The conclusion reached is that in this more general treatment of logarithmic theory, every number has an infinite set of logarithms which are all imaginary except when the number n is positive, in which case there is one real logarithm to the base e which is the same as the natural logarithm obtained by the more restricted theory.

"Gaussian" Logarithms.—When $\log_{10}a$ and $\log_{10}b$ are known, there is often great need of a process for finding $\log_{10}(a+b)$ and $\log_{10}(a-b)$, without making it necessary to pass from $\log a$ and $\log b$ to a and b. To achieve this expeditiously the Italian physicist Zecchini Leonelli in 1803 suggested a new type of tables. A five-place table of this type was published in 1812 by Karl Friedrich Gauss; hence the name "Gaussian logarithms." Six-place tables of this kind are due to Karl Bremiker, to Siegmund Gundelfinger and to George W. Jones. A seven-place table was brought out by T. Wittstein. Leonelli and Gauss used a table consisting of three columns of figures, which Gauss marked by the letters A, B, C. Gauss lets $A=\log x$, $B=\log\left(1+\frac{1}{x}\right)$, $C=\log(1+x)$, where x is a number greater than 1. It is seen that $A+B=C$. The table is arranged according to positive values of A, increasing from 0 up to a point where B vanishes within the desired degree of approximation. If now $\log(a+b)$ is to be determined from $\log a$ and $\log b$, observe that, when $a>b$ and $\frac{a}{b}=x$,

$$\log(a+b)=\log a\left(1+\frac{b}{a}\right)=\log a\left(1+\frac{1}{\frac{a}{b}}\right)=\log a+B. \tag{9}$$

The computation proceeds as follows: Find A from the equation $\log a-\log b=A$; in the table find the B which corresponds to A; add B to $\log a$.

If $a<b$, simply interchange a and b, and take

$$\log(a+b)=\log b+B.$$

To find $\log(a-b)$ from $\log a$ and $\log b$, use column B or C, according as $\log a-\log b$ is greater or less than $\log 2$. If it is greater, take $\log a-\log b=B$; here $\frac{a}{b}=1+\frac{1}{x}$, $\frac{1}{x}=\frac{a}{b}-1$; hence

$$\log(a-b)=\log b\left(\frac{a}{b}-1\right)=\log b-A. \tag{10}$$

In computing, find the A which in the table corresponds to B; subtract A from $\log b$.

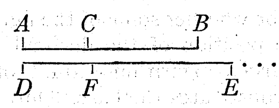
When $\log a-\log b$ is less than $\log 2$, put $\log a-\log b=C$; then $\frac{a}{b}=1+x$, $x=\frac{a}{b}-1$, and

$$\log(a-b)=\log b\left(\frac{a}{b}-1\right)=\log b+A. \tag{11}$$

In the table find the A which corresponds to C; add A to $\log b$.

Since the time of Gauss, logarithmic addition and subtraction tables have been rearranged in several different ways, by Zech and others. Some writers increase the number of columns while others reduce the number of columns to two. No agreement has yet been reached as to what arrangement is the best.

History of Logarithms.—Logarithms were invented independently by John Napier, a Scotsman, and by Joost Bürgi, a Swiss. The logarithms which they invented differed from each other and from the common and natural logarithms now in use. Napier's logarithms were published at Edinburgh in 1614 under the title, *Mirifici logarithmorum canonis descriptio.* When, in 1620, Bürgi's logarithms appeared at Prague under the title *Arithmetische und Geometrische Progresstabulen*, Napier's logarithms were already known and admired quite generally throughout Europe. To modern readers Napier's logarithms are a great curiosity, because of their singular properties and their strange mode of derivation. His theory and mode of computation are fully set forth in a second book, his *Mirifici logarithmorum canonis constructio*, which appeared in 1619, two years after his death. This book was translated into English in 1889 by W. R. Macdonald. Napier invoked kinematic notions in the development of his theory. One point moves along the line segment AB with a velocity decreasing so that when at any point C,



its velocity is proportional to the remaining distance CB. A second point starts at the same time and with the same initial velocity, moving on the unlimited line DE with uniform velocity. Then, by definition, if C and F are simultaneous positions of the two points, *DF is the logarithm of CB.* The successive distances DF, taken at equal intervals of time, yield an arithmetical series whose terms are increasing; the corresponding distances CB yield a geometric series whose terms are decreasing. In the translation of these kinematic concepts into numbers Napier begins by taking the distance $AB=10^7$, and the distance AC passed over during the first small time-interval equal to 1. Clever devices are employed for the computation of the two series. His object was to simplify trigonometric computation. Hence his book of 1614 is not what is ordinarily called a table of logarithms of numbers, but a table of logarithmic sines which can be used also as a table of the other trigonometric functions. Since $\sin 90°$ is of frequent occurrence in computation, he thought it most convenient to take its logarithm to be zero. But $\sin 90°$ is equal to the radius of the circle which he assumed to be 10^7. Hence the logarithm of 10^7 was taken to be zero.

It is of interest to develop a formula expressing the relation between Napier's logarithms of 1614 and the modern natural logarithms. If $AB=a=10^7$, $DF=x$ and $CB=y$, then $AC=a-y$. The velocity of the point C at any moment is $\frac{d(a-y)}{dt}=y.$

Integrating, we obtain $-\log_e y=t+c$, where c is a constant of integration. To determine this constant, assume the initial conditions of motion to be $t=0$ and $y=a$; substituting these values, $c=-\log_e a$. The uniform motion of the point F on the second line yields $\frac{dx}{dt}=a$ as its velocity. Consequently $x=at$, the constant of integration being zero in this case. Substituting for t and c their values, $-\log_e y=\frac{x}{a}-\log_e a$, observing that $a=10^7$ and $-\log y=\log\frac{1}{y}$, and remembering that, by Napier's definition of a logarithm, $x=\text{Nap.}\log y$, we have

$$\text{Nap.}\log y=10^7\log_e\frac{10^7}{y}\cdot \qquad (12)$$

Assuming the properties of natural logarithms, the various properties of the logarithms of Napier may be deduced from this compact formula. We see that Napier's logarithms increase as the numbers y decrease, that $y=10^7$ has the logarithm 0, and that a number y larger than 10^7 has a negative logarithm. We see also that, in Napier's system, the logarithm of a product xy of two numbers is not equal to the sum of the logarithms of the numbers x and y. How is it possible to use such numbers in computation? The answer is that according to the custom of the time, trigonometric computation was carried on by the aid of proportions, such as $\sin A:\sin C=a:c$. An unknown term $\sin A$, is found by two operations, one a multiplication and the other a division. For these two operations combined, Napier's logarithms give correct results. In other words, in his system the relation holds, $\log\sin A-\log\sin C=\log a-\log c$. Since Napier in 1614 did not take the logarithm of 1 to be 0, his logarithms, unmodified, *do not admit of a base, i.e.*, the relation of a number to its logarithm cannot be expressed by the equation $b^l=n$.

Bürgi's Logarithms.—Bürgi's publication of 1620 is in arrangement a table of antilogarithms. The logarithms are printed in red and the numbers in black. His explanation of his logarithms, under the title of the "gründliche Unterricht" was intended to be published with the tables but was finally omitted, probably to reduce the cost of publication; it was not printed until 1856 (*Archiv für Mathematik und Physik*, vol. 26, 1856, p. 316–334). Doubt has existed whether the numbers in his tables were intended to be integers or whether some of the figures form decimal fractions. Upon the position of the decimal point hinges the question whether Bürgi's logarithms admit of a base and, if they do, what value constitutes the base. Only recently has this question been cleared up. In the "gründliche Unterricht" (*loc. cit.* p. 322) Bürgi states that he takes 0 to be the logarithm of 1, but is indefinite on some other points. From his tables we copy the following pairs of corresponding numbers:

Red	0	10	20	...
Black	100000000	100010000	100020001	...

The upper line is an arithmetic series, the lower a geometric series having the ratio 1·0001. Since 0 is the logarithm of 1, it is evident that the last eight figures of the numbers in black must be looked upon as decimals. This raises the question, Is this the case also with the numbers in red integers? In the Danzig copy of the *Progresstabulen* there is on the title page a red number marked $23027\overset{\circ}{0}022$ and below it is the black number 1000000000. The little circle placed over one of the zeros in the red number is Bürgi's decimal separatrix, so that this number means in our notation 230270·022. But the Danzig title page contains certain figures clearly entered later by hand and at first it was thought that this little circle was also hand written. Against this interpretation goes the fact that the shape of this circle is very regular, such as probably would not be the case if drawn by hand. Later the Munich copy of the *Progresstabulen*, which is the only other copy known, was examined. It shows the same little circle, regular in shape, but none of the hand entries found in the Danzig copy. It is clear, therefore, that we have here a number in red with the decimal place carefully marked by a printed symbol. The conclusion is then, as pointed out by Dr. O. Mautz of Basle, that 230270·022 is the logarithm of 1000000000 divided by 100000000; *i.e.*, the logarithm of 10. A little computation reveals that this statement is equivalent to making 10 the logarithm of 1·0001. Hence the red numbers 10, 20, ··· which we quoted from Bürgi's tables are integers. The two series, one arithmetic, the other geometric, upon which Bürgi based his system are therefore as follows:

Red	0	10	20	...
Black	1·00000000	1·00010000	1·00020001	...

If 10 is the logarithm of 1·0001, it follows at once that the base of Bürgi's logarithms is $\sqrt[10]{(1\cdot0001)}=1\cdot000009999\cdots$.

But Bürgi did not have the concept of a logarithmic base any more than had Napier. Neither of them started out from the relation $b^l=n$. The possibility of defining logarithms as exponents was recognized by John Wallis in 1685 and by Johann Bernoulli in 1694, but not until 1742 do we find a systematic exposition of logarithms, based on this idea. It is given in the introduction to Gardiner's *Tables of Logarithms* and is due to William Jones. Bürgi started out with the comparison of arithmetic and geometric series, which indicates clearly that when inventing his logarithms he adopted the point of view taken before him by Michael Stifel and other algebraists for the purpose of illustrating the addition of exponents in multiplication, and the subtraction of exponents in division.

Invention of Common Logarithms.—The invention of the common system of logarithms is due to the combined effort of Napier and Henry Briggs. The share taken by each is described by Briggs in his *Arithmetica logarithmica*, 1624: "I myself, when expounding this doctrine publicly in London to my auditors in Gresham college, remarked that it would be much more convenient that zero should be kept for the logarithm of the whole sine (as in the *Canon mirificus*) but that the logarithm of the tenth part of the same whole sine, that is to say, 5 degrees 44 minutes and 21 seconds should be 10000000000. And concerning that matter I wrote immediately to the author himself; and as soon as the season of the year and the vacation of my public duties of instruction permitted I journeyed to Edinburgh, where, being most hospitably received by him, I lingered for a whole month. But as we talked over the change in the logarithms he said that he had for some time been of the same opinion and had wished to accomplish it; he had however published those he had already prepared until he could construct more convenient ones, if his affairs and his health would admit of it. But he was of the opinion that the change should be effected in this manner, that 0 should be the logarithm of unity and 10000000000 that of the whole sine; which I could not but admit was by far the most convenient. So, rejecting those which I had previously prepared, I began at his exhortation to meditate seriously about the calculation of these logarithms." This statement contains all the information that has been handed down on the part taken by the two mathematicians in the invention of common logarithms. Briggs's and Napier's suggestions, described in this passage, do not quite yield the common logarithms. If R is the radius, Briggs's suggestion was that $\log R=0$ and $\log\frac{R}{10}=10^{10}$. Napier's improved suggestion was $\log 1=0$ and $\log R=10^{10}$. It was a later change, nowhere specifically described, which replaced $\log R=10^{10}$ by $\log 10=1$. Briggs began his computing of tables by extracting the square root of 10 fifty-four times in succession and at each step dividing the logarithm by 2. Thus $\log\sqrt{10}=\log 3\cdot162\cdots=0\cdot5$; $\log\sqrt[4]{10}=\log 1\cdot778\cdots=0\cdot25$; etc. His publication of 1624 contained the logarithms to 14 places of the numbers 1 to 20,000 and from 90,000 to 100,000. The gap 20,000 to 90,000 was filled up by Adrian Vlacq, a Dutch bookseller then residing in London, who in 1628 published tables from 1 to 100,000. Tables of common logarithms of trigonometric functions were first published by Edmund Gunter in 1620; more extensive ones, computed in part by Briggs and completed by Henry Gellibrand, were published by Vlacq at his own expense. The word "characteristic" as used in the theory of logarithms first occurs in

Briggs's tables of 1624; the word "mantissa" was introduced by John Wallis in his *Algebra* of 1693 (p. 41).

Origin of Natural Logarithms.—Natural logarithms first arose as more or less accidental variations of Napier's original logarithms. Their real significance in analysis was not recognized until later. The earliest natural logarithms occur in the 1618 edition of Edward Wright's translation into English of Napier's *Descriptio*, where in an anonymous appendix, very probably written by William Oughtred, there is a small table containing logarithms of 72 sines, used in a process of interpolation. The latter are natural logarithms with the decimal point omitted. Thus, log 10 is given as 230254. where the natural logarithm of 10 is 2·30254. In the 1622 edition of John Speidell's *New Logarithms* there is included a table of logarithms of the numbers 1–1,000; except for the omission of the decimal point, these are natural logarithms. The earliest table to appear after the importance of natural logarithms in analysis was generally understood was published more than a century later, in 1770, by Johann Heinrich Lambert, an Alsatian. He included a seven-place table of natural logarithms of the numbers 1–100 in his *Zusätze zu den Logarithmischen und Trigonometrischen Tabellen.* The most elaborate natural logarithmic tables are those of the Dutch lieutenant of artillery, Wolfram, which give natural logarithms of practically all numbers from 1 to 10,000, to 48 decimal places. They were published in 1778 in J. C. Schulze's *Sammlung*.

Controversies About Logarithms of Complex Numbers.—The history of this subject affords an interesting example of how able intellects may for a long time grope hopelessly in the dark but through persistent effort may finally reach general, consistent, and elegant results. In 1712 and 1713 G. W. Leibniz and Johann Bernoulli discussed in their correspondence the question whether negative numbers have logarithms. Leibniz contended that since a positive logarithm corresponds to a number larger than unity and a negative logarithm to a positive number less than unity, the logarithm of -1 was not really true, but imaginary (non-existent); hence the ratio $-1 \div 1$, having no logarithm, is itself imaginary. Bernoulli maintained that -1 has a logarithm, since $dx : x = -dx : -x$, and, integrating, $\log x = \log(-x)$. Thus x and $-x$ have the same logarithm. A second discussion of this question took place in a correspondence between Johann Bernoulli and Leonhard Euler in the years 1727–31. Euler uncovered the inconsistencies of Bernoulli's conclusion that $\log x = \log(-x)$ and also of views which he himself had entertained. Somewhat later, Euler exchanged letters with D'Alembert on this topic and disproved the latter's contention that $\log(-1) = 0$. About 1747 Euler succeeded in creating a consistent theory of logarithms of negative and complex numbers, but D'Alembert advanced arguments against it, metaphysical, analytical, and geometrical in nature, which shrouded the subject in a dense haze and helped to prolong the controversy to the beginning of the 19th century. Euler published in 1749 an article *De la controverse entre Mrs. Leibnitz et Bernoulli sur les logarithmes, négatifs et imaginaires* which gives the modern results that $\log n$ has an infinite number of values, which are all imaginary, except when n is a positive number, in which case one logarithm out of this infinite number is real. These conclusions were so novel and the theory of imaginary numbers in algebra was so little understood that in his day Euler's theory was not understood, nor generally accepted as valid. In the early part of the 19th century the general theory of logarithms was elaborated, and Euler's results were confirmed by Martin Ohm, John Graves, John Warren, A. J. H. Vincent, Augustus De Morgan, William R. Hamilton and others.

Methods of Computing Logarithmic Tables.—For the computation of logarithms numerous processes were devised by Napier, Briggs, James Gregory, Abraham Sharp and others. Nicolas Mercator in 1668 derived the infinite series

$$\log(1+x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \cdots$$

which though convergent for $-1 < x \overline{\gtrless} 1$, is worthless for practical computation on account of its slow convergence. John Wallis in 1695 deduced from it the rapidly convergent series

$$\tfrac{1}{2}\log\frac{1+z}{1-z} = z + \tfrac{1}{3}z^3 + \tfrac{1}{5}z^5 + \cdots$$

and G. F. Vega in his *Thesaurus* of 1794 let $z = 1/(2y^2 - 1)$ and obtained expressions converging rapidly.

Bibliography.—For details on the modern technique of logarithmic computation and for lists of leading publications of logarithmic tables, *see* the *Napier Tercentenary Memorial Volume* (1915), the *Encyclopédie des sciences mathématiques*, I. (1908) 23, "Tables de logarithmes"; D'Ocagne, *Le Calcul simplifié* (1905). For a bibliography of logarithmic tables consult J. W. L. Glaisher, report of the committee on mathematical tables, published in the *Report of the British Association for the Advancement of Science for 1873*, pp. 1–175. Among recent noted publications of logarithmic tables are the following: A 10-place table of logarithms of numbers to 100,000, in 1910; also an 8-place table to 200,000, and trigonometric tables to every sexagesimal second, by J. Bauschinger and J. Peters; a 14-place table of logarithms of sines and tangents to every 10 sexagesimal seconds, in 1911, by H. Andoyer of Paris. On the history of logarithms consult recent histories of mathematics, also *The Napier Tercentenary Memorial Volume*, edited by C. G. Knott (1915). (F. Ca.)

LOGAU, FRIEDRICH, Freiherr von (1604–1655), German epigrammatist, was born at Brockut, near Nimptsch, in Silesia, in June 1604. He entered the service of the duke of Brieg, and in 1644 was made "ducal councillor." He died at Liegnitz on July 24, 1655. Logau's epigrams, which appeared in two collections under the pseudonym "Salomon von Golaw" (an anagram of his real name) in 1638 (*Erstes Hundert Teutscher Reimensprüche*) and in 1654 (*Deutscher Sinngedichte drei Tausend*), show great range and variety of expression. He satirized the court life, the useless bloodshed of the Thirty Years' War, the lack of national pride in the German people, and their slavish imitation of the French in customs, dress and speech. He belonged to the *Fruchtbringende Gesellschaft* under the name *Der Verkleinernde*, and regarded himself as a follower of Martin Opitz; but he did not allow such ties to influence his independence.

Logau's *Sinngedichte* were edited in 1759 by G. E. Lessing and K. W. Ramler, who first drew attention to their merits. A critical edition by G. Eitner (1872), who also edited a selection of Logau's epigrams for the *Deutsche Dichter des XVII. Jahrhunderts* (vol. iii., 1870). *See* H. Denker, *Beiträge zur literarischen Würdigung Logaus* (1889); W. Heuschkel, *Untersuchungen über Ramlers und Lessings Bearbeitung Logauscher Sinngedichte* (1901); P. Hempel, *Die Kunst Friedrichs von Logau*, Berlin (1917).

LOGGERHEAD (*Caretta caretta*), a carnivorous marine turtle, inhabiting tropical seas. (*See* Turtle.)

LOGGIA, a room, gallery or hall open to the air on one or more sides.

LOGIA, a title used to describe a collection of the sayings of Jesus Christ (λόγια Ἰησοῦ) and therefore generally applied to the "Sayings of Jesus" discovered in Egypt by B. P. Grenfell and A. S. Hunt. There is some question as to whether the term is rightly used for this purpose. It does not occur in the Papyri in this sense. Each "saying" is introduced by the phrase "Jesus says" (λέγει) and the collection is described in the introductory words of the 1903 series as λόγοι not as λόγια. Some justification for the employment of the term is found in early Christian literature. Several writers speak of the λόγια τοῦ κυρίου or τὰ κυριακὰ λόγια, *i.e.*, oracles of (or concerning) the Lord. Polycarp, for instance, speaks of "those who pervert the oracles of the Lord" (Philipp. 7), and Papias, as Eusebius tells us, wrote a work with the title "Expositions of the Oracles of the Lord." The expression has been variously interpreted. It need mean no more than narratives of (or concerning) the Lord; on the other hand, the phrase is capable of a much more definite meaning, and there are many scholars who hold that it refers to a document which contained a collection of the sayings of Jesus, and which is believed to be the source or the principal source of the teachings of Jesus found in Matthew and Luke but not in Mark.

"The Sayings."—These fragments, to which the term Logia is also applied, consist of (*a*) a papyrus leaf containing seven or eight sayings of Jesus discovered in 1897, (*b*) a second leaf containing five more sayings discovered in 1903, (*c*) two fragments of unknown Gospels, the former published in 1903, the latter in 1907. All these were found amongst the great mass of papyri acquired by the Egyptian Exploration Fund from the ruins of Oxyrhynchus, one of the chief early Christian centres in Egypt, situated some 120 m. S. of Cairo. The 8 sayings discovered in 1897 may be translated as follows:—

1. ". . . and then shalt thou see clearly to cast out the mote that is in thy brother's eye."

2. "Jesus saith, Except ye fast to the world, ye shall in no wise find the kingdom of God; and except ye make the sabbath a real sabbath, ye shall not see the Father."

3. "Jesus saith, I stood in the midst of the world and in the flesh was I seen of them, and I found all men drunken, and none found I athirst among them, and my soul grieveth over the sons of men, because they are blind in their heart, and see not. . . ."

4. ". . . poverty . . . ."

5. "Jesus saith, Wherever there are two, they are not without God, and wherever there is one alone, I say, I am with him. Raise the stone and there thou shalt find me, cleave the wood and there am I."

6. "Jesus saith, A prophet is not acceptable in his own country, neither doth a physician work cures upon them that know him."

7. "Jesus saith, A city built upon the top of a high hill and stablished can neither fall nor be hid."

8. "Jesus saith, Thou hearest with one ear [but the other ear hast thou closed]."

The "sayings" of 1903 are as follows:—

1. "Jesus saith, Let not him who seeks . . cease until he finds and when he finds he shall be astonished; astonished he shall reach the kingdom and having reached the kingdom he shall rest."

2. "Jesus saith (ye ask? who are those) that draw us (to the kingdom if) the kingdom is in Heaven? . . . the fowls of the air and all beasts that are under the earth or upon the earth and the fishes of the sea (these are they which draw) you and the kingdom of Heaven is within you and whosoever shall know himself shall find it. (Strive therefore?) to know yourselves and ye shall be aware that ye are the sons of the (Almighty?) Father; (and?) ye shall know that ye are in (the city of God?) and ye are (the city?)."

3. "Jesus saith, A man shall not hesitate . . . to ask concerning his place (in the kingdom. Ye shall know) that many that are first shall be last and the last first and (they shall have eternal life?)."

4. "Jesus saith, Everything that is not before thy face and that which is hidden from thee shall be revealed to thee. For there is nothing hidden which shall not be made manifest nor buried which shall not be raised."

5. "His disciples question him and say, How shall we fast and how shall we (pray?) . . . and what (commandment) shall we keep . . . Jesus saith . . . do not . . . of truth . . . blessed is he . . . ."

First Gospel Fragment.—The fragment of a lost Gospel which was discovered in 1903 contained originally about fifty lines, but many of them have perished and others are undecipherable. The translation, as far as it can be made out, is as follows:—

1–7. "(Take no thought) from morning until even nor from evening until morning either for your food what ye shall eat or for your raiment what ye shall put on. 7–13. Ye are far better than the lilies which grow but spin not. Having one garment what do ye (lack)? . . . 13–15. Who could add to your stature? 15–16. He himself will give you your garment. 17–23. His disciples say unto him, When wilt thou be manifest unto us and when shall we see thee? He saith, When ye shall be stripped and not be ashamed . . . 41–46. He said, The key of knowledge ye hid: ye entered not in yourselves, and to them that were entering in, ye opened not."

Second Gospel Fragment.—The second Gospel fragment discovered in 1907 "consists of a single vellum leaf, practically complete except at one of the lower corners and here most of the lacunae admit of a satisfactory solution." The translation is as follows:—

. . . before he does wrong makes all manner of subtle excuse. But give heed lest ye also suffer the same things as they: for the evil doers among men receive their reward not among the living only, but also await punishment and much torment. And he took them and brought them into the very place of purification and was walking in the temple. And a certain Pharisee, a chief priest, whose name was Levi, met them and said to the Saviour, Who gave thee leave to walk in this place of purification, and to see these holy vessels when thou hast not washed nor yet have thy disciples bathed their feet? But defiled thou hast walked in this temple, which is a pure place, wherein no other man walks except he has washed himself and changed his garments, neither does he venture to see these holy vessels. And the Saviour straightway stood still with his disciples and answered him, Art thou then, being here in the temple, clean? He saith unto him, I am clean; for I washed in the pool of David and having descended by one staircase, I ascended by another and I put on white and clean garments, and then I came and looked upon these holy vessels. The Saviour answered and said unto him, Woe ye blind, who see not. Thou hast washed in these running waters wherein dogs and swine have been cast night and day and hast cleansed and wiped the outside skin which also the harlots and flute-girls anoint and wash and wipe and beautify for the lust of men; but within they are full of scorpions and all wickedness. But I and my disciples who thou sayest have not bathed have been dipped in the waters of eternal life which come from . . . . But woe unto the . . . .

Probable Date of the "Sayings."—These documents have naturally excited considerable interest and raised many questions. The papyri of the "sayings" date from the 3rd century and most scholars agree that the "sayings" themselves go back to the 2nd. The year A.D. 140 is generally assigned as the *terminus ad quem.* There is a considerable diversity of judgment, however, with regard to the value of the collection. (*a*) Some scholars maintain that the collection goes back to the 1st century and represents one of the earliest attempts to construct an account of the teaching of Jesus. They are therefore disposed to admit to a greater or less extent and with widely varying degrees of confidence the presence of genuine elements in the new matter. (*b*) Sanday and many others regard the sayings as originating early in the 2nd century and think that, though not "directly dependent on the Canonical Gospels," they have "their origin under conditions of thought which these Gospels had created." The "sayings" must be regarded as expansions of the true tradition, and little value is therefore to be attached to the new material.

With the knowledge at our disposal, it is impossible to reach an assured conclusion between these two views. The real problem, to which at present no solution has been found, is to account for the new material in the "sayings." There seems to be no motive sufficient to explain the additions that have been made to the text of the Gospels. It cannot be proved that the expansions have been made in the interests of any sect or heresy. Unless new discoveries provide the clue, or some reasonable explanation can otherwise be found, there seems to be no reason why we should not regard the "sayings" as containing material which ought to be taken into account in the critical study of the teaching of Jesus.

Date of the Gospel Fragments.—The 1903 Gospel fragment is so mutilated in many of its parts that it is difficult to decide upon its character and value. It appears to be earlier than 150, and to be taken from a Gospel which followed more or less closely the version of the teaching of Jesus given by Matthew and Luke. The second Gospel fragment (1907) seems to be of later origin than the documents already mentioned. Grenfell and Hunt date the Gospel, from which it is an excerpt, about 200. There is considerable difficulty with regard to some of the details. The statement that an ordinary Jew was required to wash and change his clothes before visiting the inner court of the temple is quite unsupported by any other evidence. Nothing is known about "the place of purification" nor "the pool of David." Nor does the statement that "the sacred vessels" were visible from the place where Jesus was standing seem at all probable. But if the inaccuracy of the fragment in this important respect is admitted the historical character of the whole episode breaks down and it is probably to be regarded as an apocryphal elaboration of Matt. xv. 1–20 and Mark vii. 1–23.

See the *Oxyrhynchus Papyri,* part i. (1897), part iv. (1904), part v. (1908). (H. T. A.; X.)

LOGIC is the systematic study of the general conditions of valid inference. There are other conceptions of the scope of logic. The principal rival conceptions are opposite in character. One view would limit logic to the study of what is sometimes called formal logic and sometimes deductive logic. This view finds favour among mathematically-minded writers who wish to bring logic and mathematics into intimate connection. But while there is room for a border science between the two (*see* LOGISTIC) there is no good reason for excluding from the scope of logic any of the main types of reasoning. On the contrary, there are obvious advantages in including in one systematic study a comprehensive survey of all the main types of inference. The only other view that need be considered goes to the opposite extreme and would include under logic the psychology of thinking and the theory of knowledge. The thorough study of logic certainly requires attention to both psychological and epistemological problems. But that is a different thing from fusing them all together. This is only too likely to end in confusion, and to lead to the neglect of the properly logical problems. The tendency now under consideration is natural enough when regard is had to the historical unity of philosophy, and its resistance to differentiation into separate studies. There are still philosophers of the old school who look upon this differentiation with as much disapproval as some British statesmen of the old school feel about the increasing autonomy of various parts of the British empire. But since both psychology and theory of knowledge are now recognized as well established, autonomous disciplines, it would be sheer waste of space and time to discuss their special problems all over again under the heading of logic. The scope of logic, then, as here conceived, is that indicated in the opening sentence of this article. But in order to understand that definition or description of logic, it is necessary to understand the terms employed in the opening statement. Let us begin with the term "inference," which retains in logic much of its etymological meaning.

Inference, Judgment, Proposition, Belief, Knowledge.—*Inference* is the act or process of deriving one judgment or proposition from another or from others. The judgment or proposition so derived is also called an inference; and for the most part we shall use the term inference in this more concrete sense, that is, as meaning a derived judgment or proposition. By a "proposition" is here meant a judgment expressed in words, the judgment itself being the actual thought or belief in the mind, which may or may not be expressed in a proposition, though we cannot discuss it until it is so expressed. But this needs further elucidation. All beliefs and all knowledge consist of judgments. For our present purpose the term *belief* is wider than, and includes the term *knowledge.* All knowledge is belief; but not all belief is knowledge. In ordinary usage it would probably be denied that knowledge is belief. But that is not quite correct. In ordinary usage the term "belief" is restricted to *what we do not know but still accept as true.* This identification of *belief* with what may more correctly be called *mere belief* is awkward. For, strictly speaking, if we can believe even what we do not know for certain, we most surely believe what we do know. So that all knowledge is belief, though there is also a *mere belief* of what cannot claim to be knowledge, that is, *adequately justified belief.* In the sense explained, then, judgment may be identified with belief, with all that we know for certain, or think as more or less probable, or merely believe without any evidence worth speaking about. But what exactly is judgment?

Judgment is essentially a process of intellectual orientation. Life is only possible by continuous adjustment to surroundings, and therefore requires that living beings should take their bearings so as to adapt their actions to their environment. At the lower levels of life the orientation is rather blind and merely instructive, though never merely mechanical. The method pursued is that of "trial and error," which frequently leads to improved adaptation. In this way even the lowliest organisms learn from experience. At the human level, however, a new form of orientation emerges. It is intellectual; it consists of judgments. Intellectual orientation is, to begin with, a new instrument in the struggle for existence. It is an enormous improvement on its predecessor in the extent to which it enables man to learn from past experience, not only from his own experience but also from that of others. For it is more articulate, more clear-sighted. Situations already experienced, and successful methods of dealing with them when once discovered, are retained in the form of ideas which are helpful in new situations of the same type. The connections between things and events are not merely felt vaguely, as at the lower levels of life, but are apprehended more or less closely, and are frequently articulated in general ideas or laws of interconnection. These can then be applied to imaginary as well as to real cases. So there arise purely imaginary experiments, as distinguished from actual experiments, by the method of trial and error. The biological advantage of such imaginary experiments is obvious in all cases in which actual experiments are beset with danger. In course of time intellectual interests extend beyond the pressing needs of the moment. The order and connections of natural phenomena are studied in a spirit of disinterestedness, and thereby render possible an orientation that is characterized by greater depth of insight, and an enormously increased range of foresight. And all this intellectual work consists of judgments interconnected by "why" and "wherefore," "because" and "therefore," which constitute inference or reasoning. It is the main business of logic to trace the principal types of inference and the general conditions of their validity.

Some judgments, then, namely inferences, are derived. What about those from which they are derived or inferred? They also may be inferred from others, but sooner or later, of course, we must come to judgments which are not inferred from others. How are they obtained? Well, they are immediate judgments either of perception or of intuition. That is to say, they are the outcome either of sense-perception or of that kind of intellectual intuition by which we apprehend so-called self-evident truths. It is sometimes rather difficult to say whether a given judgment is immediate or inferred. With advance in the power of analysis and discrimination it may be seen readily that many judgments which are commonly considered to be perpetual or self-evident are really inferences, at least in part. Still, the difficulties are not, as a rule, insurmountable. But what is of special interest at present is that logic is mainly concerned with inferred judgments, and with others only in so far as they furnish a basis for inference. The nature and reliability of immediate judgments as such constitute problems which belong partly to psychology and partly to the theory of knowledge. Logic is the study of inferences, not of all kinds of beliefs.

Having explained the term inference, we must next consider what is meant by *valid* inference in the definition of logic from which we started. It means, of course, the same as *accurate, correct, sound.* But it must not be treated as synonymous with *true.* An inference is *valid* when it is justified by the evidence given in support of it. It is *true* if it expresses the facts as they are. Now careful reasoners generally aim at inferences which shall be both correct and true. But an inference may be either without the other. For example, speculators sometimes make inferences which turn out to be true although they were not really valid, that is, were not justified by the available evidence. On the other hand, propositions are sometimes refuted by a mode of reasoning commonly known as "reduction to absurdity," that is, by showing that a valid inference drawn from it is untrue. Now logic is the study of *valid* inference, not *true* inference. This is not because logic is not interested in truth, for its own function is to explain the *true* conditions of valid inference. It is simply a case of that division of labour which necessity has forced upon all the sciences. The study of the conditions of *valid* inference means the study of the general relations between inferences and premises. This is a sufficiently important task by itself. The study of the conditions of *true* inference would mean, in addition, an investigation into the truth of all possible premises—an obviously impossible task.

The Main Types of Inference or Implication.—It is obvious that one judgment can be *inferred* from another or others only when the other judgment or judgments *imply* it. Inferability and implication are, in fact, only different aspects of the same rational situation, in which judgments are so interconnected that some imply others which are thus inferable from them. Inference only makes explicit what is latent in implication. Now the judgments which imply the inference or conclusion are usually called the evidence or the premises. Sometimes the evidence consists of formulated propositions; sometimes it consists of facts of observation. This distinction is not a hard and fast one, because, on the one hand, "facts" only become evidence when they give rise to judgments, which can always be expressed in propositions; and, on the other hand, all judgments are in the last resort based on facts. But the distinction is a convenient one in some ways. There are cases in which the question of objective fact, in the usual sense of the term, does not arise.

For example, every State has its laws, which are in a sense the arbitrary (though not capricious) decisions or enactments of the legislature, and so are, in many ways, different in different states. The judges who have to administer these laws have to treat them as authoritative and final for the time being. They only have to understand them and their full implications, and to apply them to relevant cases. It is not their business to check the truth of these laws in the way in which it *is* the business of a man of science to check the truth of what are currently accepted as laws of nature. So that there are cases in which inference or reasoning is mainly concerned with the meaning and implication of certain propositions or premises, and not with the facts (if any) from which they derive. Such inference or reasoning may be called *formal,* or *deductive,* in the rather wide and loose sense of these terms that has become traditional. On the other hand, inference or reasoning which sets out from facts of observation without relying in a special degree on propositions accepted either on authority, or even provisionally for the sake of argument, may be called *inductive, material* or *empirical,* again in the loose traditional sense of these terms. As the term "deductive" is needed for another purpose, the former type of inference will be described here as *formal;* and the latter type will be called *inductive,* which is the least unsatisfactory of the traditional terms. It should be noted at once, however, that whereas *formal* reasoning can often be carried far without the intervention of inductive reasoning (or simply "induction"), induction can rarely go far without the auxiliary use of formal inference at certain stages, such as the verification of tentative hypotheses, for instance. Again, inductive reasoning constitutes what is widely known as *scientific method.* As a mere matter of convenience inductive inference will be dealt with under the heading of Scientific Method, while this article will deal mainly with formal inference, and with one or two other special types of inference.

Now the study of formal inference, as already explained, is essentially a study of the implications of propositions. For this purpose it is necessary to ascertain the main types of proposition, their several meanings and implications. This part of logic is known as the study of *immediate inference.* But under certain circumstances, which will be explained in due course, two or more propositions may, between them, imply something over and above the implications which each of them has separately, something that is not even the mere sum of their several implications. The study of these implications is known as the study of *mediate inferences.* These are the two principal divisions of formal inferences, and each of them contains a number of varieties, which we shall presently describe and explain. But before doing so it will be necessary to deal first with the ultimate assumptions or postulates of logic. These are really ultimate assumptions of reason, without which there would be no such thing as reasoning, or at least no distinction between valid and invalid reasoning. It is the business of logic to formulate them explicitly.

Ultimate Postulates of Logic.—In all reasoning (as distinguished from dogmatic assertion, *e.g.*) some proposition is asserted to be justified by some other proposition or propositions, called the evidence. Dismissing those cases in which one verbal expression is substituted for another with which it is synonymous, and which do not constitute real reasoning, one proposition can only be justified or implied by another or by others in so far as the contents of the propositions are connected in some definite way—in other words, in so far as the facts to which the propositions in question refer stand in certain connections. It is the belief in, or the knowledge of, such objective connections among natural events or objects that constitutes in the last resort the basis of all reasoning or inference. Such objective connections cannot, strictly speaking, be proved, although they are commonly assumed to exist as a matter of course. But in a study like logic it is necessary to state explicitly every assumption that is necessary for its very existence. Accordingly, we may formulate as the first postulate of logic the assumption that *there are connections among the events and objects of the real world.* If the world were not, to some extent at least, an orderly cosmos, if things just happened by chance or anyhow, there could be no genuine reasoning, and consequently no logic. This assumption may be described briefly as *the postulate of cosmic connectedness.*

Another postulate is what is known as the *principle of the uniformity of nature,* which postulates that the connections among the events and objects of the world are uniform in character. In other words, phenomena of the same kind exhibit the same kind of objective connections. From the point of view of logic this postulate is of importance as the basis of what the writer has called the *principle of the uniformity of reasons,* namely, *whatever is regarded as a sufficient reason in any one case must be regarded as a sufficient reason in all cases of the same type,* or expressed negatively, *nothing can be regarded as a sufficient reason in any one case unless it can also be regarded as a sufficient reason in all cases of that kind.* This principle is of special importance in connection with inductive inference, inasmuch as it formulates the logical basis of generalization. But it is also of importance in connection with the study of formal inference, for it is the basis of our derivation of the general rules of formal inference from an inspection of the form of inference in particular cases.

Two other postulates required for formal inference are known as the *law of contradiction* and the *law of excluded middle.* The law of contradiction is to the effect that the same predicate cannot be both affirmed and denied of the same subject—*S cannot both be P and not be P.* The law of excluded middle postulates that a given predicate must be either affirmed or denied of a given subject—*S must either be P or not be P.* Since "not to be P" is the same as "to be non-P" (that is, something other than P), the two laws may also be expressed respectively in the following formulae—*S cannot be both P and* $\overline{P}$, and *S must be either P or* $\overline{P}$ (when $\overline{\mathrm{P}}$=non-P).

IMMEDIATE INFERENCE

We have now to consider *the main types of propositions,* their meanings, and their implications. It has already been stated that a proposition is the verbal expression of judgment, and that a judgment is what one thinks, believes, or knows. For purposes of formal logic it is convenient sometimes to use the term proposition not only for the expressed content of what is actually believed, but also for any suggestion that may be believed or disbelieved, or merely understood and considered. Now there are three principal types of proposition which must be considered, namely, categorical, hypothetical and disjunctive (or alternative) propositions. A *categorical proposition* is one in which something is asserted unconditionally. It has the form *S is* (or *is not*) *P.* An *hypothetical proposition* is one which expresses an antecedent (or condition) and a consequent. Its general form is *If A, then C.* A *disjunctive proposition* is one which expresses alternatives. Its general form is *either A or B.* Categorical propositions usually contain two terms, namely, a subject (*S*) and a predicate (*P*), though there are simple forms (the so-called impersonals) which consist of one term only (the predicate). Hypothetical and disjunctive propositions contain three or four terms, or even more. But it is better to think of their component propositions rather than of their component terms. In the above forms, *A,B,C,* stand for such propositions, not for terms; e.g., "*If a triangle is equilateral* (*A*), then *it is equiangular* (*C*)"; "either *a line is straight* (*A*), or *it is curved* (*B*)." By substituting symbols for actual terms we obtain the *form,* that is the *type,* of the proposition in question. That, in fact, is the simplest way of getting at the various *kinds* of propositions; but, of course, it must be borne in mind that in actual reasoning real terms are always employed, for a propositional form is not an actual proposition, just as, in algebra, x, y, z are not actual things or even numbers, but are only devices for dealing with numbers in the most general way possible.

There are important differences between the categorical, hypothetical and disjunctive types of proposition. The categorical type is that employed when we want to assert a mere brute fact without wishing to suggest that there is any inner connection between the terms of the proposition. The hypothetical type, on the other hand, is just specially designed to express the thought that there is a connection between the antecedent and the consequent. And the disjunctive type is the most suitable one for expressing alternative possibilities, one or other of which is true, though it is not known which one is true. At the same time, these differences of function need not be exaggerated, and it is usually possible to express what is essentially the same thought in any one of the three types, as the following may serve to illustrate. *Equilateral triangles are equiangular. If a triangle is equilateral, it is equiangular. Either a triangle is equiangular or it is not equilateral.* So, generally, *SM is P=if S is M it is P=either S is P or it is not M.* In view of what has just been said and illustrated, it may be remarked that all the essentials of formal inference may be learned by a close study of categorical propositions alone in the first instance. There is no difficulty in applying to hypothetical and disjunctive arguments what has been found to hold good of categorical arguments. And these are easier to get on with at first. We shall, accordingly, confine ourselves for the present to categorical propositions and inferences.

The Quality and Quantity of Categorical Propositions.—Propositions are either affirmative or negative. These are known as differences of quality. And they are either universal or particular, that is to say, they assert something either of the whole of the subject term explicitly, or of some indefinite part of it. These are known as differences of quantity. If the two kinds of distinctions are combined in one scheme, we obtain four types of categorical proposition, the forms of which are as follows:—*Every S is P* (universal affirmative); *no S is P* (universal negative); *some S*'s *are P* (particular affirmative); *some S*'s *are not P* (particular negative). The following are examples of the several types: "Every equilateral triangle is equiangular"; "no equilateral triangle is right-angled"; "some stars are self-luminous"; "some planets are not self-luminous." In this classification of propositions the class universal propositions includes singular propositions (that is, those whose subject is a singular term) like a proper noun, for example, as well as general propositions (that is, those which have a general term, like a common noun, *e.g.*, and assert something about the whole class or kind of object or event which it is the name of). The above four types of categorical proposition are commonly called *A,E, I,O,* respectively. *A* and *I* are the vowels of "affirm," the first being used for the universal, the second for the particular, affirmative; *E* and *O,* the vowels of "nego" (Latin for *I deny*), are similarly used for the universal and the particular negative. By using the corresponding small letters to express the quality and quantity of propositions, the above formulae of the four types of categoricals can be expressed respectively as follows: *SaP; SeP; SiP; SoP.* This is a convenient symbolic method which can be used for all formal inference with great advantage.

The next thing to observe in connection with these four types of proposition is what is called the *distribution of terms* in each of them. A term is said to be distributed in a proposition when reference is made explicitly to the whole range or class of objects, etc., which the term denotes; otherwise it is said to be undistributed. Thus in *SeP* (no *S* whatever is any *P* whatever) both *S* and *P* are distributed. In *SaP* (every *S* is *P* but nothing is stated about *every P*) *S* is distributed, but *P* is not. In *SiP* (some *S*'s are *P,* nothing definite is said about all *S*'s or all *P*'s) neither *S* nor *P* is distributed. In *SoP* (some *S*'s are not any *P* whatsoever) *S* is not distributed, but *P* is. Briefly, universal propositions (*A,E*) distribute their subjects and negative propositions (*E,O*) distribute their predicates.

It is a *general rule of all formal reasoning* that no term may be distributed in the conclusion unless it is distributed in the premise or premises. For, otherwise, the conclusion would go beyond the evidence. A great many cases of invalid inference are due to a breach of this rule; and some of the most important rules of valid inference are meant to be safeguards against such a breach. Hence the importance of becoming familiar with these few points about the distribution of terms in propositions. There is no objection at all to not distributing in the conclusion a term that is distributed in the premises. Just as the maxim against extravagance does not demand that people should spend the whole of their income, but only that they should keep within it, so this rule only requires that people should not go beyond the evidence; it does not require them to exhaust the whole of it when it is unnecessary.

Opposition and Eduction.—The doctrine of immediate inference, as already remarked above, is concerned with the implications of single or isolated propositions, as distinguished from the joint implications of two or more propositions taken together. It has two main parts. One part, known as the doctrine of opposition, deals with the implications of each type of proposition in relation to others having precisely the same subject and the same predicate, but differing in quality or quantity. The other part, known as the doctrine of eductions, deals with the implications of each type of proposition in relation to others having not the same subject and the same predicate but the same terms or their contradictories. In other words, "opposition" is concerned with the relations between *SaP, SeP, SiP, SoP,* whereas "eduction" is concerned with the relations between propositions of the types $S\text{-}P$, $S\text{-}\bar{P}$, $P\text{-}S$, $P\text{-}\bar{S}$, $\bar{P}\text{-}S$, $\bar{P}\text{-}\bar{S}$, $\bar{S}\text{-}P$, $\bar{S}\text{-}\bar{P}$. These relationships look more complicated than they really are, and can be determined with comparative ease with the aid of the laws of contradiction and excluded middle, and the rule relating to the distribution of terms just explained.

Opposition.—Given *SaP, SeP* and *SoP* must both be false, otherwise, all or some *S*'s would both be *P* and not be *P,* which would violate the law of contradiction; but *SiP* must be true, as the *some S*'s must be included in *"every S"* of *SaP.* Again, given *SeP, SaP* and *SiP* must be false, otherwise all or some *S*'s would both not be and be *P,* which is against the law of contradiction; the *SoP* must be true, because its *"some S*'s" are included in all the *S*'s of which *P* is denied in *SeP.* Next, *SiP* excludes *SeP,* otherwise *"some S*'s" would both be and not be *P,* in violation of the law of contradiction; but it throws no light on *SaP, SoP,* either of which (though not both at once of course) might be true or false, when *SiP* is true, without offending against any law of thought or rule of inference. Lastly, *SoP* excludes *SaP,* otherwise *"some S*'s" would both not be and be *P,* against the law of contradiction; but it has no implication in relation to *SeP* or *SiP,* either of which (though not both) might be true or false when *SoP* is true.

To complete the study of the interrelations between these propositional types, let us consider next the implications of the *rejection* of any one of them. So far we have only considered the implications of the acceptance of any one of them. To reject *SaP* is to maintain that *not every S is P,* that is, that it is wrong to say of one or more *S*'s at least that they are *P.* But if so, then by the law of excluded middle it must be right to say of the one or more *S*'s in question that they are not *P,* or *SoP.* Thus the rejection or falsity of *SaP* implies the acceptance or truth of *SoP.* On the other hand, *SiP* and *SeP* are not affected by it; either (though not both of course) might be true or false, if *SaP* be untrue. Similarly, to reject *SeP* is to maintain that it is wrong to say of every *S* that it is not *P,* that is, that there are one or more *S*'s of which it should not be said that they are not *P.* If so, then by the law of excluded middle it must be right to say of the one or more *S*'s in question that they are *P,* or *SiP.* Thus the falsity of *SeP* implies the truth of *SiP.* But it does not affect *SoP* or *SaP,* either of which (but not both) might be true or false when *SeP* is untrue. Next, to reject *SiP* is to maintain that it is incorrect to say of even one *S* that it is *P* (for *some S*'s are *P* means "one *S* at least is *P*"). If so, then by the law of excluded middle it must be right to say of every *S* that it is not *P*, or *SeP*, which, as has already been seen, implies *SoP*. Thus the falsity of *SiP* implies the truth of both *SeP* and *SoP*, each of which, as was already shown above, excludes the truth of *SaP*, by the law of contradiction. Similarly, the falsity of *SoP* implies the truth of both *SaP* and *SiP*. For to reject *SoP* is to maintain that it cannot be said of even one *S* that it is not *P*. Hence, by the law of excluded middle, it must be said of every *S* that it is *P* or *SaP*, which implies *SiP*, and each of these implies the falsity of *SeP*.

Of the foregoing relationships the most important are those known by the special names of *contrariety* and *contradiction*. Two propositions are called *contraries* when both cannot be true at the same time, but both may be false. *SaP* and *SeP* are related in this way, as the above account shows. Again two propositions are called *contradictories* when both cannot be true at the same time, but also not false at the same time, in other words, when one of them must be true and the others false. From the above account it will be seen that *SaP* and *SoP* are related in this way, also *SeP* and *SiP*. Two propositions are also contrary when they affirm contrary predicates, like "white" and "black" of the same subject; and contradictory when they affirm contradictory predicates, like "white" and "non-white," of the same subject. It should be noted that *SiP* and *SoP*, which are commonly called *sub-contraries*, are related in a manner which is the precise reverse of that between contraries, for both can be true, and one of them must be true.

Eductions.—Given a proposition having for its terms *S-P* it always implies some proposition having for its terms $S\text{-}\bar{P}$, which is called its *obverse*. Thus *SaP*, in virtue of the law of contradiction, implies $Se\bar{P}$; since *S* cannot be both *P* and $\bar{P}$, the *S*'s which are *P* are not $\bar{P}$. Similarly, *SiP* implies *SoP*. Again, *SeP* implies $Sa\bar{P}$, in virtue of the law of extended middle; since *S* must be either *P* or $\bar{P}$, the *S*'s that are not *P* must be $\bar{P}$. Similarly *SoP* implies $Si\bar{P}$. It should be noted that in each case if the obverse is obverted the original proposition is obtained. Thus $Se\bar{P}$ implies, in virtue of the law of excluded middle, *SaP*, and so with the rest. Again, given a proposition having for its terms *S-P* it sometimes (but not always) implies a proposition having for its terms *P-S*, which is called its *converse*. Thus *SeP* implies *PeS*, for it asserts the mutual exclusion of *S* and *P*, and it makes no essential difference whether, looking at the relation from the point of view of *S*, we say *SeP* or, looking at it from the point of view of *P*, we say *PeS*.

Similarly *SiP* implies *PiS*, for it expresses the fact that some things are both *S* and *P* (*SP*), and it makes no essential difference whether these things are described as some *S*'s that are *P* or as some *P*'s that are *S*'s. *SaP* likewise expresses the fact that some things are both *S* and *P*, but whereas it tells us that these include every *S* it does not say that they include every *P*. Hence it implies *PiS*, not *PaS*. To make *SaP* imply *PaS* would violate the above-mentioned rule about the distribution of terms, for *P* is not distributed in the premise *SaP*, but is distributed in *PaS*. In other words, *SaP* may be true even when *PaS* is not true, that is, when *PoS* is true (*e.g.*, "All Englishmen are British subjects" but not "All British subjects are Englishmen," for "Some British subjects are not Englishmen"). Lastly, *SoP* has no converse, for in *PoS* the term *S* would be distributed, and it is not distributed in *SoP*; in other words *PaS* may be true at the same time as *SoP* (*e.g.*, "Some British subjects are not Englishmen," yet "All Englishmen are British subjects," so that it would not be true to say that "Some Englishmen are not British subjects"). In the case of the converse, as in the case of the obverse, we get no further forward if we take the converse of the converse. It only brings us back to the original proposition or to something less. Thus the converse of *PeS* is *SeP*, of *PiS* it is *SiP*, even where the original was *SaP*.

The obverse and the converse are the fundamental types of eduction, but by combining obversion and conversion (that is by applying them alternately, beginning with obversion and going on to conversion, and so on alternately, or beginning with conversion and going on to obversion and so on alternately), certain derivation eductions are obtainable. The following table sets out all the eductions and shows how they are obtained. The arrow $\rightarrow$ means "implies," "(o)" means "by obversion," "(c)" "by conversion."

$$
\begin{array}{ll}
SaP & \nearrow \text{(o) } Se\bar{P} \rightarrow \text{(c) } \bar{P}eS \rightarrow \text{(o) } \bar{P}a\bar{S} \rightarrow \text{(c) } \bar{S}i\bar{P} \rightarrow \text{(o) } \bar{S}oP. \\
 & \searrow \text{(c) } PiS \rightarrow \text{(o) } Po\bar{S}. \\
SeP & \nearrow \text{(o) } Sa\bar{P} \rightarrow \text{(c) } \bar{P}iS \rightarrow \text{(o) } \bar{P}o\bar{S}. \\
 & \searrow \text{(c) } PeS \rightarrow \text{(o) } Pa\bar{S} \rightarrow \text{(c) } \bar{S}iP \rightarrow \text{(o) } \bar{S}o\bar{P}. \\
SiP & \nearrow \text{(o) } So\bar{P}. \\
 & \searrow \text{(c) } PiS \rightarrow \text{(o) } Po\bar{S}. \\
\multicolumn{2}{l}{SoP \rightarrow \text{(o) } Si\bar{P} \rightarrow \text{(c) } \bar{P}iS \rightarrow \text{(o) } \bar{P}o\bar{S}.}
\end{array}
$$

All the eductions have special names which may just be mentioned here. Assuming that the terms of the original proposition are *S-P*, the *obverse* has the terms $S\text{-}\bar{P}$; the *converse* has *P-S*; the *obverted converse* has $P\text{-}\bar{S}$; the *converted obverse* or *contraposition* has $\bar{P}\text{-}S$; the *obverted contraposition* has $\bar{P}\text{-}\bar{S}$; the *inverse* has $\bar{S}\text{-}P$; the *obverted inverse* $\bar{S}\text{-}\bar{P}$.

There are some other types of immediate inference of which only one need be mentioned here as it is fairly common. A proposition containing a relative term in the predicate implies a *correlative* proposition. Thus "*S* is north of *P*" implies "*P* is south of *S*"; "*S* is the parent of *P*" implies "*P* is the child of *S*." Symbolically, *S is RP* implies *P is* Я *S*, when *R* and Я represent correlative terms.

MEDIATE INFERENCE

We have to consider now what kind of conclusions can be inferred from two or more propositions jointly that could not be inferred from any of them singly. Now two or more propositions with entirely different terms cannot between them imply more than the bare sum of their several implications. When, however, two propositions have one term in common, then the common term may mediate between the two other terms, so as to establish a relationship that could not be inferred from either proposition alone. It is such mediation of a common term between two other terms that constitutes the essence of mediate inference. Given the relationship of each of two terms to the same third term, it is possible, under certain conditions, to infer their relation to one another. Symbolically, given the relation of *S* to *M* and of *P* to *M*, it may be possible to infer the relation of *S* to *P*. The common or mediating term is called the *middle term;* the term which becomes the subject of the conclusion is called the *minor term;* the term which becomes the predicate of the conclusion is called the *major term*. The proposition which contains the minor term and middle term is called the *minor premise;* the other premise, containing the major term and the middle term, is called the *major premise*. The middle term does not occur in the conclusion, only in the premises. Thus in the following schematic mediate argument, *M is P, S is M,* therefore *S is P,* the symbols *S,M,P,* represent respectively the minor, middle and major terms, *M is P* represents the major premise, *S is M* represents the minor premise, and *S is P* represents the conclusion. Mediate inferences vary greatly in complexity. We propose to begin with the simplest type, and proceed by degrees to the more complex types. In the first instance we shall confine our account to mediate inferences consisting of categorical propositions only, leaving the others for subsequent treatment.

Mediate Inferences with Singular Terms.—Let us begin with an example of the simplest type of mediate inference. The story of the following incident will serve our purpose. At an "At Home" given by a French countess, Cardinal X. was among the early callers, and in reply to a sympathetic reference made by his hostess, to his varied and anxious experiences, remarked that he had started his clerical career rather ominously, for the very first person who confessed to him had confessed a murder. Later in the afternoon, while the cardinal was at the far end of the drawing room, Count S. called, and the hostess expressed a wish to introduce him to Cardinal X. Thereupon the count said no introduction was necessary, as he had known his holiness many years already. "In fact," said the count, "I was the very first person to confess to him." The consternation of the hostess may be imagined. Here, the conclusion that Count S. had confessed a murder is obvious. It is not implied in either of the two statements separately. It could not possibly be inferred from the cardinal's statement by itself, nor from the count's statement by itself, else neither would have said what he did. But it can be inferred from the two statements when combined, for the simple reason that in the two separate statements the two terms "a person who confessed a murder" and "Count S." are each identified with the same third (or middle) term, "the very first person who confessed to Cardinal X." They must, therefore, be identical with each other, that is, they must refer to the same person, and so the inference is that "Count S. is a person who had confessed a murder." *M is P, S is M,* therefore *S is P. S* being identical with *M,* they are really different descriptions of the same thing, and so if it was possible for *S* not to be *P,* then the same thing (called indifferently *S* or *M*) would be *P* according to the first premise, and would not be *P* if the suggested conclusion were rejected; but this would be against the law of contradiction. In the above case both premises were affirmative, and the conclusion was affirmative.

Suppose, next, that one of the premises is negative and one affirmative, say, *M is not P, S is M* (or *M is P, S is not M*). So long as we are dealing with singular terms and with relations of identity, such premises will imply the negative conclusion *S is not P.* For in such cases the two premises between them say that the two terms, *S* and *P,* are related in opposed ways to the same middle term, *M,* one of them (no matter which) affirming a relationship of identity, the other denying it (and so asserting a relationship of difference). Consequently, the two terms, *S* and *P,* must be different from each other, in other words, *S is not P.* In this case, as in the previous one, the rejection of this conclusion would violate the law of contradiction. Lastly, suppose both premises are negative, *M is not P* and *S is not M.* In this case no inference can be drawn, for we are only told that *S* and *P* are both different from *M,* and their common difference from *M* is compatible with either identity or difference between *S* and *P.*

The foregoing results hold good also when the relationship between the singular terms of a mediate argument is not one of identity, but some other *transitive relation.* A transitive relationship is such that if it holds good between one term and another, and also between this other and a third, then it holds good between the first and third terms. Identity is one such relationship, equality is another, "less than," "greater than," "parallel with," "brother of," "sister of" are other transitive relationships. All such cases can be expressed in the formula *M r P, S r M,* therefore *S r P,* when *r* stands for the affirmative of a transitive relation. In all such cases, too, when both premises are negative, no inference is justified. But the cases are rather variable when one premise is affirmative and the other is negative. Some cases, such as those dealing with relations of equality or parallelism, are like those concerned with identity, and warrant a negative conclusion. It is different with other cases, and, unfortunately, no general rule can be laid down—one must use his common sense and his knowledge of the systems of relationship concerned in the cases which arise.

Besides transitive relations there are certain other relations which commonly occur in mediate inference, and which may be called *dovetail relations.* In these cases one premise asserts one kind of relationship, the other asserts a different relationship, and the conclusion asserts yet a third kind of relationship by dovetailing or integrating the other two; *e.g.,* "*M* is the wife of *P,*" "*S* is the brother of *M,*" therefore "*S* is the brother-in-law of *P*"; or again, "*M* is due south of *P,*" "*S* is due east of *M,*" therefore "*S* is south-east of *P.*" Such inferences likewise can only be made with safety if one is conversant with the system of relations involved. But the mediate character of the inferences is essentially the same in all the cases considered so far; and the system of relations most frequently concerned are such as people of ordinary intelligence are familiar with. A suitable formula for the last type of mediate inference would be $M\ r_1\ P$, $S\ r_2\ M$, therefore $S\ r_3\ P$.

Mediate Inference with General Middle Terms.—When the middle term is general instead of singular, certain complications arise which require special care. The middle term must be the same in the two premises. But the mere fact that the same general *name* occurs in two propositions does not necessarily mean that the same *things* are referred to. The things meant in the one proposition may not be the same as those referred to in the other, and in that case, although the two propositions have a common name occurring in them, they really have no middle term or mediating link. For example, the general term "British subjects" occurs in both propositions "All Englishmen are British subjects" and "All Australians are British subjects," but the "British subjects" are different in the two cases, and so the common term does not furnish a basis for mediate inference. Only when the common term is distributed in at least one of the two propositions have they really got a middle term in the strict sense. For in that case they are sure to have something in common. When the middle term is singular, it is distributed in any case; not so when it is general. Again, when the middle term is singular the conclusion can only be singular, but when it is general the conclusion may be general or only particular, according to circumstances. Here the general rule already mentioned must be applied—no term may be distributed in the conclusion unless it is distributed in its premise. And so the conclusion must not be general (only particular) unless the minor term is distributed in the minor premise. Moreover, in a negative conclusion the major term is distributed, and this, for the same reason, is only permissible when the major term is distributed in the major premise. So long as the terms are all singular they are all distributed in any case; but when they are general it is different, and these precautions must be borne in mind.

Now, the conditions of valid inference when the terms are all singular, apply also to the cases in which the terms are general, and for the same reasons. The latter cases, we have just seen, call for special precautions. As a matter of fact, however, these special precautions relating to the distribution of terms are actually satisfied (though without any special care on our part) in the case of mediate inference with singular terms. The following more comprehensive rules of mediate inference with general terms may accordingly be formulated as the *general rules of all mediate inferences:*—

1. There are three propositions, namely two premises and a conclusion.
2. There are three distinct terms, one of which (called the middle term) occurs in both premises, and the others occur one in each premise, while one of them (the minor term) is the subject of the conclusion, and the other (the major term) is the predicate of the conclusion.
3. The middle term must be distributed at least once.
4. No term may be distributed in the conclusion unless it is distributed in its premise—that is to say, the conclusion must not be general unless the minor term is distributed in the minor premise, and the conclusion must not be negative unless the major term is distributed in the major premise.
5. One premise, at least, must be affirmative; that is to say, no inference can be drawn from two irreducibly negative premises.
6. If both premises be affirmative, the conclusion (if any) can only be affirmative.
7. If one premise is negative, the conclusion (if any) can only be negative; and conversely, if there is to be a negative conclusion, one premise must be negative.

These rules are only an application of the law of contradiction and of the general rule about the distribution of terms to mediate inference, and a statement of the essential character of such inference. They can be abridged by applying directly the principles just mentioned; they can also be expanded by added corollaries deducible from them—namely, (i.) that no conclusion can be inferred from two particular premises, (ii.) that if one premise is particular, the conclusion can only be particular, and (iii.) that no conclusion can be inferred when the major premise is particular and the minor premise is negative. But in the form given above rules 3–7 are convenient and serviceable for testing the validity of most mediate inferences.

Mediate, Deductive and Syllogistic Inference.—The traditional use of these terms is confused, and it is desirable to suggest a consistent mode of applying them. The sense here associated with the term mediate inference has already been explained. The term "deductive inference" may, more or less in accordance with tradition, be defined as inference from general propositions. Syllogism is commonly conceived as inference which is at once mediate and deductive, and confined to propositions involving only the relation of substances and attributes. Yet deductive inference is somehow identified with syllogism. The result is inconsistency and confusion. There is no good reason why the inference of a singular or a particular proposition from a general proposition should not be described as deductive inference, although it is immediate inference. On the other hand, there is no reason why mediate inferences involving singular propositions only, should not be called syllogisms, although they are not deductive; in fact, the text-books do include them among syllogisms in spite of their inconsistent definitions of syllogism. Here it is proposed to use the term syllogism as synonymous with mediate inference, for that is just what syllogism literally suggests; "putting two and two together" is no far-fetched translation of the term. So understood, a syllogism need not be deductive, though it can be and often is. On the other hand, deduction need not be mediate, though it can be, and frequently is. "Syllogism" and "mediate inference" will, therefore, be used as synonymous here. As compared with "mediate inference," the term "syllogism" has the advantage of greater brevity, even if it suffers from misleading associations. In the light of what has just been said, there is no harm in calling the above-mentioned "general rules of mediate inference" also, "*general rules of the syllogism*." In what follows the term "syllogism" will be used in place of the term "mediate inference."

Figures and Moods of Syllogisms.—A syllogism, we have seen, has two premises—a major premise containing the middle and major terms (*M* and *P*), and a minor premise containing the middle and minor terms (*M* and *S*). Each premise might have either of its terms as subject and the other for its predicate—the major premise, that is to say, might be *M-P* or *P-M*, and the minor premise might be *M-S* or *S-M*. There are thus four possible arrangements of the terms in a syllogism:—

Major premise: *M-P, P-M, M-P, P-M*.
Minor premise: *S-M, S-M, M-S, M-S*.

The conclusion in each case is assumed to be *S-P*. The names of the terms and of the premises are based on this assumption. Now, these variations in the positions of the terms of a syllogism are called differences of *figure*. It will be seen that the above four arrangements of terms are the only possible ones, and they are known respectively as the *first, second, third* and *fourth figure*. The first arrangement is the most natural and most common. In it the term which becomes the subject of the conclusion is the subject of its premise, and the term which becomes the predicate of the conclusion is the predicate of its premise. In the fourth figure the arrangement of terms is just the reverse of what it is in the first. In the second figure the middle term is the predicate in both premises. In the third figure it is the subject in both premises. Each figure is obviously a kind of scheme or *schema* which might remain the same while the premises vary in quality and quantity. In considering the figures of syllogisms, we abstracted from, or ignored, differences in the quality and quantity of the component propositions and only attended to the positions of the terms. But the propositions have, of course, quality and quantity. And the differences in the quality and quantity of the propositions in a syllogism constitute what are known as the different *moods* of syllogisms. *Prima facie* each figure may have various moods. The first figure, *e.g.*, contains the moods *MaP, SaM*, therefore *SaP*, also *MeP, SaM*, therefore *SeP*, and so on. It is consequently desirable to determine how many valid moods there are in each figure. This may be done as follows:

From the point of view of their quality and quantity, there are four types of proposition, namely, *A, E, I, O*. Any one of these might conceivably be the major premise or the minor premise of a syllogism. There are, therefore, 16 conceivable combinations of premises, namely, *AA, AI, AE, AO, IA, II, IE, IO, EA, EI, EE, EO, OA, OI, OE, OO*—in these combinations the first letter represents the major, the second the minor, premise. By applying to these the general rules of the syllogism it will be seen that eight of the 16 combinations of premises cannot justify a conclusion in any figure. These eight are *EE, EO, OE, OO* (rules) *II, IO, OI, IE* (rule 3 or 4). Only the following eight are, therefore, likely to warrant a conclusion in some figure or other, namely, *AA, AI, AE, AO, IA, EA, EI, OA*. But we cannot tell what conclusion (if any) these will justify until we have examined them with reference to the scheme of each figure separately. For each symbol represents a different proposition in different figures. In Figure I., e.g., *AA* means *MaP, SaM*, and warrants conclusion *SaP;* in Figure IV. it means *PaM, MaS*, and warrants only a particular conclusion. By examining each of the eight surviving combinations of premises in the light of the schema of each of the four figures and of the general rules of the syllogism, it will be found that the valid moods in the four figures are as follows:

Valid moods in Figure I.: *AAA, AII, EAE, EIO*.
Valid moods in Figure II.: *AEE, AOO, EAE, EIO*.
Valid moods in Figure III.: *AAI, AII, IAI, EAE, EIO, OAO*.
Valid moods in Figure IV.: *AAI, AEE, IAI, EAO, EIO*.

In the above symbols the third represents the valid conclusion, the first and second represent the major premise and minor premise respectively. By comparing the valid moods in the same figure, its peculiarities may be noted. In Figure I., *e.g.*, the minor premise is always affirmative and the major is universal. In Figure II., one premise is negative (therefore also the conclusion) and the major is universal. In Figure III. the minor premise is affirmative and the conclusion is particular. Lastly, in Figure IV., when either premise is negative the major is universal; when the major premise is affirmative, the minor is universal; and when the minor premise is affirmative the conclusion is particular. These peculiarities are known as the *special rules* of each figure. The reasons for them can be discovered easily by examining the scheme of each figure in the light of the general rules of the syllogism. But let it be said at once that the validity of any syllogism can be tested by a direct application of the general rules of the syllogism, without troubling about the special rules of the several figures, and, indeed, without troubling about the figure or the mood of the argument at all.

Abridged and Concatenated Syllogisms.—Syllogisms are among the commonest, perhaps *the* commonest, types of argument. That some people do not seem to realize this fact can only be accounted for by certain misunderstandings or oversights which may now be indicated briefly. In the first place, text-books on logic generally set out the propositions of a syllogism in some uniform order. We, too, have adopted the order of major premise first, minor premise next and conclusion last. This is merely a matter of convenience—it saves the reader's time if he can recognize each proposition at a glance. In actual argument the sequence of propositions varies in all possible ways. It requires a little practice to recognize the character of the different propositions. The number of people who cannot readily distinguish between the conclusion of an argument and its premises is simply amazing. But a syllogistic argument is syllogistic, whatever the sequence of propositions may be, and whether it is known to be such or not. There are people who use syllogisms almost as commonly as the famous Frenchman used prose, but like him, without knowing it. In the second place, in actual discourse, it is a common thing to omit a proposition that is obviously implied. This habit is at once a time-saving device and a tribute due to the intelligence of our fellows. Consequently, it is uncommon for all the three propositions of a syllogism to be stated explicitly, though what is omitted is clearly assumed to be true. Lastly, it is usually impracticable to settle a problem by means of a single syllogism, though it is done sometimes. What happens mostly is that several syllogisms (each abridged) and other types of argument as well, are employed in the course of one complex argument; and it requires some training and insight to dismember such a complex argument into its various components.

We may now consider briefly the different ways in which syllogisms are abridged and linked together. An abridged syllogism is called an *enthymeme.* As there are three propositions in a syllogism, any one of which might be omitted, there are three kinds or orders of enthymeme, called enthymemes of the first, second or third order respectively, according as the major premise is omitted, or the minor premise or the conclusion. When the general truth involved has just been referred to, the major premise is usually omitted; when the facts, to which the general truth is applied, stare one in the face, the minor premise is usually left out; when the conclusion may seem offensive and a mere insinuation may suffice, the conclusion is frequently suppressed. In arguments not remarkable for their candour, that premise will be omitted which is most likely to be challenged if stated explicitly.

A chain of connected syllogisms is traditionally called a *polysyllogism* A chain of syllogisms is not a mere accumulation of separate syllogisms. The syllogisms must be linked together, each either supporting, or supported by, another. This happens when the conclusion of one syllogism is used as a premise of another. The supporting syllogism is known as the *pro-syllogism* in relation to the supported syllogism, and this is known as the *epi-syllogism* in relation to the former. If a chain of syllogisms is so arranged that the argument passes from supporting syllogism (or pro-syllogism) to supported syllogism (or epi-syllogism), the whole argument is called *epi-syllogistic,* or *progressive,* or *synthetic.* But if the sequence is in the reverse order, that is, from supported syllogism (epi-syllogism) to supporting syllogism (pro-syllogism), then the whole argument is said to be *pro-syllogistic* or *regressive* or *analytic.* Now the individual syllogisms in a chain of syllogisms are, for the most part, abridged in the way already explained above. But such a chain of abridged syllogisms is called a *sorites,* if it is progressive, or an *epicheirema,* if it is regressive. But usage in these matters is not uniform, and there is no particular virtue in these technical names. The really important thing is to be able to recognize the actual nature of a chain of syllogisms, to analyse them into the component syllogisms, and to test the validity of each of these in the light of the general rules of mediate inference. It should never be forgotten that the strength of a chain is only equal to that of its weakest link, for that holds good also of a chain of syllogisms, or of any other complex argument.

Hypothetical Syllogisms.—So far we have only considered categorical inferences, that is inferences or arguments in which all the propositions are categorical. Once these are mastered, there is no serious difficulty in applying the various lessons to arguments composed of other kinds of propositions *mutatis mutandis.* We must now devote some attention to these other kinds of arguments. We shall begin with hypothetical arguments. But in order to understand these it is necessary to have a clear grasp of the nature of hypothetical propositions, which have been already mentioned.

The objects about which we think vary enormously in respect of concreteness, or its opposite, abstractness. We may think of some particular individual, object or place; or we may think of a general law or formula. The term *concrete* (from Latin *concrescere,* to grow together), is applied to anything that is conceived as a coalescence of many qualities and relations. The term *abstract* (from Latin *abstrahere,* to withdraw, *i.e.,* for separate consideration) is, on the other hand, applied to any quality, or relation that is considered apart from the things or situations which it qualifies or connects. Now, propositions vary in many ways according as their terms are concrete or abstract. A proposition with a singular concrete term for subject cannot express as much knowledge as a general proposition can; and the most important discoveries of science are embodied in highly abstract propositions called laws. Again, one may predicate something of a subject without actually knowing in virtue of which of its qualities the predicate belongs to it—it is just an assertion of brute fact. On the other hand, there are assertions which specify the connection between one thing and another. Now assertions of brute fact are naturally expressed in the more concrete type of proposition, whereas assertions of connections are naturally expressed in the more abstract type of proposition. And, speaking broadly, the *categorical proposition* is the more concrete type suitable for the expression of concrete facts, brute facts, whereas the *hypothetical proposition* is the more abstract type suitable for the expression of general connections. The form of the hypothetical, as already stated, is *if A, then C,* when *A* represents an antecedent, or condition, and *C* represents a consequent, or result, and the proposition asserts a general connection between the antecedent and the consequent, without special reference to concrete cases.

To feel the difference between the two types one has only to compare the categorical proposition: "This triangle is equilateral and also equiangular" with the hypothetical proposition: "If a triangle is equilateral, it is equiangular." In daily use, it is true, the distinction is not always respected and hypothetical and categorical forms are often interchanged indiscriminately. Perhaps even the most abstract hypotheticals are only valued just because of their wide reference to real things, their applicability to an extensive range of facts. Still, there are such things as suppositions which, though based on facts, are merely speculative, and have no direct reference to actual instances. And such suppositions are best expressed in the hypothetical form of proposition.

The main feature, then, of the hypothetical proposition is the assertion of a connection between an antecedent (*A*) and a consequent (*C*)—*if A, then C.* But what exactly does this imply? It implies, first of all, that the antecedent (*A*) cannot be true without the consequent (*C*) being likewise true. In other words, if the consequent is not true, the antecedent cannot be true either—*if not C then not A.* It has already been pointed out above that *if A, then C* can be expressed also in the categorical form AaC, and a reference to the eductions will show that AaC implies $\bar{C}a\bar{A}$, which is the categorical equivalent of *if not C, then not A.* On the other hand, *if A, then C* does not imply *if C, then A,* for the consequent might be true even when the antecedent is not. The categorical equivalent of *if A, then C,* as just pointed out, *is* AaC, and this does *not* imply CaA, only CiA. Consequently, one may not infer the falsity of the consequent from that of the antecedent. In other words, *if A, then C* does not imply *if not A, then not C.* This also may be confirmed by reference to the eductions, which show that AaC does not imply $\bar{A}a\bar{C}$, only $\bar{A}i\bar{C}$. Briefly, then, *if A, then C* implies (1) whenever *A* is true *C* must be true, (2) whenever *C* is not true, *A* is not true. But it does *not* imply that (3) when *C* is true *A* must be true, nor that (4) when *A* is not true then *C* is not true.

Again, the antecedent and consequent of an hypothetical proposition consist of categorical propositions, and either or both may be affirmative or negative—*if A, then C=if S is M, Q is P* or *if S is not M, Q is not P,* etc. Now the main business of an hypothetical proposition is to *affirm* a connection between the antecedent and the consequent. If is, therefore, permissible to treat all hypotheticals as affirmative, which simplifies considerably the whole business of formal inferences from hypotheticals. The traditional method is to regard an hypothetical proposition as negative when the consequent is negative. There is no serious objection to this. If we follow the traditional scheme, the four kinds of hypotheticals corresponding to the four categoricals, SaP, SeP, SiP, SoP, are *if A, then C, if A, then not C, if A then sometimes C, if A, then sometimes not C.*

After the foregoing explanations there should be no serious difficulty in dealing with immediate or mediate inferences from hypothetical propositions. In either case, if it is found easier to do so, the hypothetical propositions can be restated in categorical form, and treated in the way already explained in connection with categorical inferences. It may be noted that an hypothetical syllogism is called *pure* when it consists of hypothetical propositions only, otherwise it is called *mixed.* An example of a pure hypothetical syllogism will elucidate some of the above remarks.

> "If a triangle is equiangular, it cannot be right-angled;
> If a triangle is equilateral, it is equiangular;
> ∴If a triangle is equilateral, it cannot be right-angled."

If B, then not C, *If A, then B,* *If A, then not C.*	Corresponding to the categorical syllogism.	*MeP,* *SaM,* ∴ *SeP.*

A *mixed hypothetical syllogism* has an hypothetical major premise and a categorical minor premise, and the conclusion is categorical. Considering the implications of an hypothetical proposition, as already explained above, it should be obvious that there are only two ways in which a conclusion can be inferred in this case, namely, the categorical minor must either affirm the antecedent, or deny the consequent of the major premise. In the first case the conclusion affirms the consequent, in the second case it denies the antecedent. These are the two principal types of mixed hypothetical syllogism, and are known respectively as *constructive* and *destructive.* The respective form of each is: *If A, then C, A,* ∴ *C;* and *If A, then C, not C,* ∴ *not A.*

All that has been said above about abridged and concentrated categorical syllogisms applies also to hypothetical syllogisms, and need not be repeated.

Disjunctive Syllogisms and the Dilemma.—Having dealt with categorical and hypothetical propositions and inferences, we must turn next to the disjunctive, or alternative, types. A disjunctive proposition asserts the truth of one of two or more alternatives without specifying which. Its form is *either A or B,* where *A* and *B* represent propositions, like the *A* and *C* of a hypothetical proposition. There are various circumstances which occasion the use of the disjunctive propositions; and these must be understood if we are to have an insight into the meaning and implications of the disjunctive type of proposition and argument. Sometimes they are based on a classification of certain things into classes and sub-classes, or *genera* and *species,* as these are usually called; *e.g.,* some people constitute the class known as "graduates of the University of London," which class (or *genus*) is subdivided into the species "internal" and "external." Now I may know that *S* is a graduate without knowing whether he is an internal graduate. In that case I might say that "*S* is either an internal or an external graduate of the University of London." As the *species* of the same *genus* are usually mutually exclusive, it is likely enough that in most cases of alternative propositions on classification it is intended not only that one of the alternatives shall be true but also that *only* one of them shall be true. But that is not always so. It is possible, *e.g,* for a graduate of the University of London to have taken one degree as an external candidate and another as an internal student. In any case these are instances in which the alternatives are not mutually exclusive. It is possible, for instance, to produce approximately similar results in several different ways. The volume of a gas can be reduced either by reducing its temperature or by increasing the pressure on it. When, therefore, I observe such a result I may assert that it was produced in one or other of these two ways, yet without intending to exclude the possibility of both methods having co-operated to produce the result in question. It would, therefore, be a mistake so to interpret disjunctive propositions as to make the alternatives always mutually exclusive. The term "disjunctive" rather suggests such an interpretation, and so might be replaced with advantage by the term "alternative."

It is always possible to express oneself in such a way as to employ only mutually exclusive alternatives; but this would entail a good deal of pedantry, from which logic has already suffered much too much. On the whole it is best, and most in harmony with daily usage, to say that this alternative type of proposition asserts the truth of *one* of its alternatives, but *not* necessarily of *one only.* In other words, the alternative proposition *either A or B* implies *if not A, then B,* and *if not B, then A,* but it does *not* imply *if A, then not B* nor *if B, then not A.* As no significance attaches to the order of the alternatives in a disjunctive proposition, the second statement as to what is implied and not implied by *either A or B* was really unnecessary. Disjunctive propositions are essentially affirmative. The alternatives may be negative or affirmative; but what the proposition always asserts is, that one of the alternatives is true. The propositional form *neither A nor B* (the contradictory of *either A or B*) is not disjunctive but categorical—it asserts unconditionally *A is not true* and *B is not true.* Quantitatively, alternative propositions, when correctly used, are always universal. Particular disjunctives, when used, are the result of ignorance of the remaining alternatives, and should be expressed in a number of categoricals. For example, "some triangles are either equilateral or scalene" only means "some triangles are equilateral" and "some triangles are scalene."

Now, considering the nature of disjunctive propositions it will be seen that two such propositions, even when they contain a common alternative, do not always warrant a mediate inference; *e.g., either A or B* and *either B or C* may be summed up in the statement *A or B or C;* but such a summary is not an inference—there is nothing here that mediates and disappears. The only approximation to mediate inference with two disjunctive premises is obtained when an alternative contained in one of the two premises is the contradictory of one contained in the other. The formula is, *either A or B, either not B or C,* ∴ *either A or C.* For example: "Either an article is produced on a large scale or it is expensive; and either it is in great demand or it is not produced on a large scale; therefore, either an article is in great demand or it is expensive." Apart from the minor considerations as to whether the alternatives are affirmative or negative, this is the only type of *pure disjunctive syllogisms,* or syllogisms consisting entirely of disjunctive propositions. But there is also a type of *mixed disjunctive syllogism* consisting of a disjunctive major premise, a categorical minor premise, and usually a categorical conclusion. In the light of what has already been said about the relation of the alternatives in a disjunctive proposition it will be evident that it is only possible to infer a mediate conclusion from a disjunctive major premise, by means of a categorical minor premise, when the latter denies one of the alternatives of the former. The formula accordingly is: *Either A or B; not A;* ∴ *B* (or *not B;* ∴ *A*). This is the only type of mixed disjunctive syllogism, if we ignore (as we may) the minor variations arising from differences in the sequence of the alternatives, and their quality.

The *dilemma* might be classed among mixed hypothetical syllogisms or among mixed disjunctive syllogisms, for it contains both an hypothetical premise and a disjunctive premise; but it is customary to class it by itself and to confine the names mixed hypothetical and mixed disjunctive syllogisms to those the minor premise of which is categorical. The dilemma has two hypothetical propositions for its major premise and a disjunctive proposition for its minor premise. A single hypothetical major premise would obviously afford no scope for a disjunctive minor premise. Like the mixed hypothetical syllogism, and for the same reasons, the dilemma has two main forms, namely, the *constructive* and the *destructive.* It is constructive if the minor premise posits alternatively the two antecedents of the hypothetical major premise; it is destructive if the minor premise denies alternatively the two consequents of the major premise. It is usual also to distinguish between *complex* and *simple* dilemmas, according as the major premise has two distinct antecedents and two distinct consequents, or only one consequent for both antecedents, or only one antecedent for both consequents. We therefore have four kinds of dilemma, of which the following are the symbolic schemes. *Complex constructive dilemma: If A, then B, and if C, then D; either A or C;* ∴ *either B or D. Complex destructive dilemma: if A, then B, and if C, then D; either not B or not D;* ∴ *either not A or not C. Simple constructive dilemma: If A or C, then D; either A or C;* ∴ *D. Simple destructive dilemma: If A, then both B and D; either not B or not D;* ∴ *not A.*

There is an impression abroad that the dilemma is a captious kind of argument not to be taken seriously. But that is erroneous. The dilemma is a difficult type of argument, because it is difficult to sum up a situation adequately in two alternatives; yet unless the alternatives are exhaustive the conclusion is not valid. Still, there are cases when the thing can be done, and then the dilemma is quite sound. The school habit of illustrating the dilemma by means of amusing sophistical instances, is really unjust to the dilemma, which is used also in perfectly serious and scientific arguments. When a dilemma is felt to be unsound, one should carefully scrutinize the alternatives, which in that case are sure to be incomplete, even if expressed in such an ambiguous manner as to appear to be exhaustive. This is the only satisfactory way of dealing with unsatisfactory dilemmas; the so-called *rebuttal* of a dilemma is as futile as it is pretentious.

It need only be pointed out now that what was said above about abridged and concentrated categorical syllogisms also applies to disjunctive syllogisms and to dilemmas.

Inductive and Formal Inference.—Formal inference, as has already been suggested, is such as can be carried out and tested by means of the various rules explained above, provided one understands the meaning and implications of the propositions used as premises. Not that it is merely a matter of language. Far from it. For propositions express thoughts, and thoughts have reference to reality. Life is too short and pressing to permit of long holidays from the actual. But, for reasons already given, formal inference takes its ultimate premises for granted and does not examine their origin or credentials. If, however, their origin be investigated, it will be found that some propositions derive from direct observation, some from intuition, some are inferences from other propositions, and some are inferences from observations. With the first two types of proposition logic is not concerned; the problems of the third type have now been dealt with in the main; the problems presented by the last are the special problems of induction, and are discussed fully under SCIENTIFIC METHOD, though a few words must be said here. Inductive inference can, of course, be described in general, and more or less formal, terms. And it can be shown to involve certain types of formal inference. This has led some to suppose that the so-called methods of induction are essentially syllogistic in character. But this is erroneous. Prompted by the principle of the uniformity of reasons, explained in the early part of this article, we always try to formulate the general *principle* of every type of reasoning, such as the principle that "things which are equal to the same thing are equal to one another," the *dictum de omni et nullo* (*q.v.*), and the various methods of induction (*see* SCIENTIFIC METHOD).

Such principles, however, are not premises of actual arguments of the type in question; they are only abstract formulations of the general type, and postulates of their validity. If such principles were to be treated as premises, then every actual syllogism could be shown to be a double syllogism, one as it actually is, and another with the principle for major premise, the two normal premises being combined as minor premise—and even then the general principle would still be assumed. In reality, the attempt to treat induction as merely a case of deduction, or of syllogism, is unwarranted. Inductive inference involves much more than that. It requires a familiarity with the facts investigated, and such an insight into them as cannot be formulated at all to any purpose, but which may yet prompt inferences which may be deemed sound in spite of certain shortcomings when gauged by the standards of purely formal inference. Induction is a more difficult business than syllogism or deduction, and calls for rarer gifts. It is true, of course, that when inductive inferences have been formulated and established, they place at our service new propositions which become the starting points of formal inferences whereby present and past events can be explained, or future events can be anticipated.

But the deductive application of inductions, though far from being easy or fool-proof (to judge from many coroners' inquests) is much simpler than reliable induction from observation. For one medical man who can make a new discovery there are more than ten thousand who can make none, but who may be trusted more or less to apply correctly the discoveries of others. It is not intended, of course, to underestimate the value of formal inference in general or of deduction in particular. Such inference is, as a matter of fact, very useful in connection with inductive investigations. What inductive research aims at is the discovery of propositions from which the observed phenomena under investigation might have been inferred formally. Such inferability of the facts, from the propositions established inductively, usually constitutes their explanation. That is why *induction* is frequently described as *inverse deduction* or as the *reverse of deduction*. It remains true, however, that induction is on a rather different footing from deduction, or syllogism, and cannot be dealt with satisfactorily in quite so formal a manner as formal inference can be.

Inference from Circumstantial Evidence.—There is a common kind of inference which is like inductive inference in so far as it is inference from facts of observation, rather than like formal inference from propositions, is a reverse process, and proceeds by way of hypotheses. But, unlike most inductive or scientific methods, it is not concerned with generalizations, only with a particular case at a time. It is known as *inference from circumstantial evidence*. Probably most of the criminal cases and other mysteries one reads of in the papers and in works of fiction are detected or solved by this method of inference. It is not, however, confined to such cases. Indeed, it is a common method of historical research, and it exemplifies in an especially striking manner a mode of inference which often goes hand in hand with other forms of inference, formal and inductive, without receiving due recognition for various reasons. But, first of all, what exactly is meant by *circumstantial evidence?* It means a special form of indirect evidence, as contrasted with direct evidence. It is evidence which does not seem to bear directly on the main problem, only on certain facts which may be said to *surround* the main event which needs explanation.

Let us consider, *e.g.,* the case of a crime. If the criminal is caught in the act, there is direct evidence of the most convincing character. Mostly, however, those who plan crimes take every precaution they can possibly think of not only against being caught red-handed, but against every kind of direct observation of their crime; so that direct evidence is extremely rare in such cases. However, there are in many instances, certain "circumstances" which betray the criminal. These "circumstances" are subsidiary events which are in some way connected with the principal event. What usually happens is that certain things or occurrences, suspected of having some bearing on the main event, are treated as clues, are followed up as far as possible, and are linked up hypothetically with certain other facts and events until they suggest an hypothesis about the identity of the criminal. A satisfactory hypothesis will show that many apparently disconnected objects and events are really parts of one drama. And, in the absence of sufficient counter-evidence, the hypothesis which gives the most coherent setting of the principal event under investigation will be regarded as true. Needless to say, in the case of such an hypothesis, as in the case of every other kind of hypothesis, no evidence that is unfavourable to it may be ignored. An arbitrary selection of circumstances may send innocent people to prison, or even to the gallows—as has happened more than once.

Inference from circumstantial evidence varies enormously in degrees of complexity. Some of the most familiar types of such inference are the processes of piecing together the parts of a picture puzzle, or of solving a cross-word puzzle. The solution takes the form of putting the parts together in such a way that they constitute a coherent whole or system. More elaborate instances are furnished by the innumerable attempts at historical reconstruction, which aim at so piecing together the available evidence that the events under investigation are seen as parts of a coherent political drama, etc. Such a task is much more difficult than piecing together a picture puzzle. If the two are to be compared at all, we must think of a picture puzzle of which many parts are missing, some are damaged, and some, perhaps, are faked. There is consequently far greater scope for the play of individual fancy and ingenuity.

Systematic and Linear Inference.—The most characteristic feature of inference from circumstantial evidence is its concrete systematic character. It is all concerned, in the first instance at all events, with a particular concrete system or whole. In the vast majority of cases the investigator does not seek to get beyond the reconstruction of such a particular concrete whole of events or parts. This is true not only of the investigator of crimes, but also of the historian of every kind of subject. There are cases, indeed, in which the investigator, after satisfying himself about the nature and working of one particular concrete system or organism, proceeds to generalize his discovery and to apply it to all systems or organisms of that kind; *e.g.*, Harvey, after discovering the system of the circulation of the blood by his observations and reasonings concerning one living body, rightly applied his discovery to all similar living organisms. Here the first and most important discovery was made by inference from circumstantial evidence relating to the interconnection between the various parts of the circulatory system—arteries, veins, valves, heart and lungs. The second step was an inductive generalization. Potentially any particular criminal or historical reconstruction by means of circumstantial evidence might be generalized in the same kind of way; but it would be a futile generalization because such cases are never found to repeat themselves with sufficient closeness to make such a generalization worth while. And, just as inference from circumstantial evidence may sometimes go hand in hand with inductive inference, so it may be found in conjunction with deductive or syllogistic inference. In fact, the process of inference from circumstantial evidence is commonly guided by the deductive application of certain general truths relevant to the case.

Implicitly, if not explicitly, the detective and the historian certainly make use of their previous knowledge of human nature in general, and of the habits and mentality of certain human types in particular, though all this is only secondary or auxiliary to the primary business of integrating or constructing the systematic whole. On the other hand, a great deal of deductive and inductive reasoning is carried on under the general influence of a certain system, or universe, which implicitly guides the selection of special points of attack, which might otherwise be arbitrary, and actually do appear to be arbitrary to those who are without this feeling of contact with the controlling system. It is this that helps to determine the selection of some aspects of things rather than others for inductive investigation, and the application of some general truths rather than others in deductive reasoning. But these things are very difficult to explain fruitfully in general terms, except to the initiated.

Considerations such as the foregoing have prompted some thinkers to insist that systematic inference is the only real type of inference, and that formal inference, especially syllogistic inference, which they describe as *linear,* is rather unreal. But that is a serious mistake. The fact is that inference always has both these aspects, the systematic and the linear, or, as I should prefer to call them, the concrete and the abstract; but in some cases the concrete or systematic aspect is predominant, while the abstract, linear, or general is secondary, whereas in other cases the reverse holds good. It is not always possible to draw a hard and fast line between the two varieties of reasoning, just because the difference is only one of degree. For instance, while discussing such very general types of inference as immediate inference and syllogistic inference, we found ourselves faced by the inference of correlative propositions and inference from dovetail relationships, which, just like inference from circumstantial evidence, involve a reference to certain systems, though in their case, each system could, if necessary, be described in general terms. It really depends very largely on circumstances whether an argument is confined to certain general problems, leaving the whole system of reference in the background or is extended further into the hinterland. It depends partly on the thinker's ideas about the various topics relevant to the problem under discussion, and partly on the extent to which these views of his are shared by the people to whom the argument is addressed, when it is addressed to others.

The greater the number of relevant topics on which the reasoner already entertains definite views, the simpler and more general or abstract will be the argument by which he endeavours to solve the immediate problem. Similarly, the wider the agreement about relevant topics between the parties to the argument, the simpler and more abstract or general will the argument be. On the other hand, the fewer the convictions on relevant topics, provided the thinker knows what these are, and is not simply enjoying the bliss of ignorance, the more system-building there will have to be. And the wider the differences on relevant topics between the parties to an argument, the more comprehensive and systematic must the discussion be. That is why an argument which is convincing to the members of one party or one school of thought, may seem quite unconvincing to those of another. And if the differences extend to first principles, the argument, if it is continued long enough, is liable to become metaphysical and—interminable.

Reasoning from Analogy and Probable Inference.—In order to complete our sketch of the main types of inference, it would be necessary to explain next what is known as reasoning from analogy, and probable inference. Reasoning from analogy consists in arguing or inferring that something which is known to be true of one class of phenomena is also true of a certain other class of phenomena which resemble the former in essential respects—arguing, *e.g.*, that light is transmitted by undulations of the aether just as sounds are transmitted by undulations of the air. Probable inferences are those in which conclusions are obtained which are admittedly uncertain, but are more or less likely to be true according to certain conditions. As both these types of inference are dealt with elsewhere it is not necessary to discuss them here, but to refer the reader to the articles ANALOGY (in logic) and PROBABILITY (in logic).

Fallacies, etc.—Any violation of a rule of valid inference is called a fallacy. In calling a conclusion fallacious it is not meant that it is not true, but only that it is *not valid,* that is to say, that it is not justified by the evidence. There are, of course, many kinds of fallacy, corresponding to the various conditions to which the different kinds of inference must conform. The commonest of them are dealt with in the article FALLACY, and some others are explained in the article on SCIENTIFIC METHOD. So the subject need not be further discussed here. Some other topics commonly dealt with in the treatises on traditional logic will be found explained in the articles on CATEGORY, PREDICABLES, JUDGMENT, CONSEQUENS.

LOGIC, HISTORY OF. Logic arose, at least for the Western world, in the golden age of Greek speculation which culminated in Plato and Aristotle. There is an Indian logic, it is true, but its priority is still disputed. In any case, no influence upon Greek thought can be shown. The movement which ends in the logic of Aristotle is self-contained.

A. GREEK LOGIC

I. BEFORE ARISTOTLE

Early Nature Philosophers.—Logic needs as its presuppositions that thought should distinguish itself from things and from sense, that the problem of validity should be seen to be raised in the field of thought itself, and that analysis of the structure of thought should be recognized as the one way of solution. Thought is somewhat late in coming to self-consciousness. Implied in every contrast of principle and fact, of rule and application, involved as we see after the event, most decisively when we react correctly upon a world incorrectly perceived, thought is yet not reflected on in the common experience. Its so-called natural logic is only the potentiality of logic. The same thing is true of the first stage of Greek philosophy. In seeking for a single material principle underlying the multiplicity of phenomena, the first nature-philosophers, Thales and the rest, did indeed raise the problem of the one and the many, the endeavour to answer which must at last lead to logic. But it is only from a point of view won by later speculation that it can be said that they sought to determine the predicates of the single subject-reality, or to establish the permanent subject of varied and varying predicates. A further step, then, was necessary, and it was taken at any rate by the Eleatics, when they opposed their thought to the thought of others, as the way of truth in contrast to the way of opinion. It was Zeno, the controversialist of the Eleatic school who was regarded in after times as the "discoverer" of dialectic.

The Sophists.—In the history of the origins of logic, the sophistic age is simply the age of the free play of thought in which men were aware that in a sense anything can be debated and not yet aware of the sense in which all things cannot be so. It is the age of discussion used as a universal solvent, before it has been brought to book by a deliberate unfolding of the principles of the structure of thought determining and limiting the movement of thought itself. The sophists furthered the transition from dialectic to logic in two ways. In the first place they made it possible. Incessant questioning leads to answers. Hair-splitting, even when mischievous in intent, leads to distinctions of value. Paradoxical insistence on the accidents of speech-forms and thought-forms leads in the end to perception of the essentials. Secondly they made it necessary. The spirit of debate run riot evokes a counter-spirit to order and control it. The result is a self-limiting dialectic. This higher dialectic is a logic. It is no accident that the first of the philosophical sophists, Gorgias, on the one hand, is Eleatic in his affinities, and on the other raises in the characteristic formula of his intellectual nihilism issues which are as much logical and epistemological as ontological. The meaning of the copula and the relation of thoughts to the objects of which they are thoughts are as much involved as the nature of being. It is equally no accident that the name of Protagoras is to be connected, in Plato's view at least, with the rival school of Heracliteans. The problems raised by the relativism of Protagoras are no less fundamentally problems of the nature of knowledge and of the structure of thought. The *Theaetetus,* indeed, in which Plato essays to deal with them, is in the broad sense of the word logical, the first distinctively logical treatise that has come down to us.

Socrates.—Among the pioneers of the sophistic age Socrates stands apart. He has no other instrument than the dialectic of his compeers, and he is as far off as the rest from a criticism of the instrument, but he uses it differently and with a difference of aim. He construes the give and take of the debate-game with extreme rigour. The rhetorical element must be exorcised. The set harangue of teacher to pupil, in which steps in argument are slurred and the semblance of co-enquiry is rendered nugatory, must be eliminated. The interlocutors must in truth render an account under the stimulus of organized heckling from their equals or superiors in debating ability. And the aim is heuristic, though often enough the search ends in no overt positive conclusion. Something can be found, and something is found. Common names are fitted for use by the would-be users being first delivered from abortive conceptions, and thereupon enabled to bring to the birth living and organic notions.

Aristotle would assign to Socrates the elaboration of two logical functions:—general definition and inductive method. Rightly, if we add that he gives no theory of either, and that his practical use of the latter depends for its value on selection. It is rather in virtue of his general faith in the possibility of construction, which he still does not undertake, and because of his consequent insistence on the elucidation of general concepts, which in common with some of his contemporaries, he may have thought of as endued with a certain objectivity, that he induces the controversies of what are called the Socratic schools as to the nature of predication. These result in the formulation of a new dialectic or logic of Plato. Manifestly Socrates' use of certain forms of argumentation, like their abuse by the sophists, tended to evoke their logical analysis. The use and abuse, confronted one with the other, could not but evoke it.

Plato.—Plato's logic supplies a theory of universals in the doctrine of ideas. Upon this it bases a theory of predication. And it sets forth a dialectic with a twofold movement, towards differentiation and integration severally, which amounts to a formulation of inference. The more fully analysed movement, that which proceeds downward from less determinate to more determinate universals, is named Division. Its associations, accordingly, are to the modern ear almost inevitably those of a doctrine of classification only. Aristotle, however, treats it as a dialectical rival to syllogism, and it influenced Galilei and Bacon in their views of inference after the Renaissance. If we add to this logic of "idea," judgment and inference, a doctrine of categories in the modern sense of the word which makes the *Theaetetus,* in which it first occurs, a forerunner of Kant's *Critique of Pure Reason,* we have clearly a very significant contribution to logic.

(*a*) Of the idea we may say that whatever else it is, it is opposed to that of which it is the idea as its intelligible formula or law, the truth or validity of the phenomenon from the point of view of nexus or system. The thing of sense in its relative isolation is unstable. It is and is not. What gives stability is the insensible principle or principles which it holds, as it were, in solution. These are the ideas, and their mode of being is naturally quite other than that of the sensible phenomena which they order. The formula for an indefinite number of particular things in particular places at particular times, and all of them presentable in sensuous imagery of a given time and place, is not itself presentable in sensuous imagery side by side with the individual members of the group it orders. The law, *e.g.,* of the equality of the radii of a circle cannot be exhibited to sense, even if equal radii may be so exhibited. It is the wealth of illustration with which Plato expresses his meaning, and the range of application which he gives the idea—to the class-concepts of natural groups objectively regarded, to categories, to aesthetic and ethical ideals, to the concrete aims of the craftsman as well as to scientific laws—that have obscured his doctrine, viz., that wherever there is law, there is an idea.

(*b*) The paradox of the one in the many is none, if the idea may be regarded as supplying a principle of nexus or organization to an indefinite multiplicity of particulars. But the principle of difference must be carried into the field of ideas. Not only sense is a principle of difference. The ideas are many. The multiplicity in unity must be established within thought itself. Otherwise the objection stands: man is man, and good is good, but to say that man is good is clearly to say the thing that is not. Plato replies with the doctrine of the interpenetration of ideas, obviously not of all with all, but of some with some, the formula of identity in difference with thought itself. Nor can the opponent fairly refuse to admit it, if he affirms the participation of the identical with being, and denies the participation of difference with being, or affirms it with not-being. The *Sophistes* shows among other things that an identity-philosophy breaks down into a dualism of thought and expression, when it applies the predicate of unity to the real, just as the absolute pluralism on the other hand collapses into unity if it affirms or admits any form of relation whatsoever. Identity and difference are all-pervasive categories, and the speech-form and the corresponding thought-form involve both. For the proposition and judgment involve subject and predicate and exhibit what a modern writer calls "identity of reference with diversity of characterization." Plato proceeds to explain by his principle of difference both privative and negative predicates, and also the possibility of false predication. It is obvious that without the principle of difference, error is inexplicable. Even Plato, however, perhaps scarcely shows that with it, and nothing else but it, error is explained.

(*c*) Plato's Division, or the articulation of a relatively indeterminate and generic concept into species and sub-species with resultant determinate judgments, presumes of course the doctrine of the interpenetration of ideas laid down in the *Sophistes,* as the basis of predication, but its use precedes the positive development of that formula, though not, save very vaguely, the exhibition of it, negatively, in the antinomies of the one and the many in the *Parmenides.* It is its use, however, not the theory of it, that precedes. The latter is expounded in the *Politicus* (260 *sqq.*) and *Philebus* (16*c sqq.*). The ideal is progressively to determine a universe of discourse till true *lowest species* are reached when no further distinction in the determinate many is possible, though there is still the numerical difference of the indefinite plurality of particulars. The process is to take as far as possible the form of a continuous disjunction of contraries. We must bisect as far as may be, but the division is after all to be into limbs, not parts. The later examples of the *Politicus* show that the permission of three or more co-ordinate species is not nugatory, and that the precept of dichotomy is merely in order to secure as little of a *saltus* as possible; to avoid, *e.g.*, the division of the animal world into men and brutes. It is the middle range of the μέσα of *Philebus*, 17*a* that appeals to Bacon, not only this but their mediating quality that appeals to Aristotle. The *mediate axioms* of the one and the *middle term* of the other lie in the phrase. Plato's division is nevertheless neither syllogism nor *method of exclusions*. It is not syllogism because it is based on the disjunctive, not on the hypothetical relation, and so extends horizontally where syllogism strikes vertically downward. Again it is not syllogism because it is necessarily and finally dialectical. It brings in the choice of an interlocutor at each stage, and so depends on a concession for what it should prove. Nor is it Bacon's method of exclusions which escapes the imputation of being dialectical, if not that of being unduly combrous, in virtue of the cogency of the negative instance. The Platonic division was, however, offered as the scientific method of the school. A fragment of the comic poet Epicrates gives a picture of it at work. And the movement of disjunction as truly has a place in the scientific specification of a concept in all its differences as the linking of lower to higher in syllogism. The two are complementary, and the reinstatement of the disjunctive judgment to the more honourable rôle in inference has been made by so notable a modern logician as Lotze.

(*d*) The correlative process of Combination is less elaborately sketched, but in a luminous passage in the *Politicus* (§ 278), in explaining by means of an example the nature and use of examples, Plato represents it as the bringing of one and the same element seen in diverse settings to conscious realization, with the result that it is viewed as a single truth of which the terms compared are now accepted as the differences. The learner is to be led forward to the unknown by being made to hark back to more familiar groupings of the alphabet of nature which he is coming to recognize with some certainty. To lead on, ἐπάγειν, is to refer back, ἀνάγειν to what has been correctly divined of the same elements in clearer cases. Introduction to unfamiliar collocations follows upon this, and only so is it possible finally to gather scattered examples into a conspectus as instances of one idea or law. This is not only of importance in the history of the terminology of logic, but supplies a philosophy of induction.

(*e*) Behind Plato's illustration and explanation of predication and dialectical inference there lies not only the question of their metaphysical grounding in the interconnection of ideas, but that of their epistemological presuppositions. This is dealt with in the *Theaetetus* (184*b sqq.*). The manifold affections of senses are not simply aggregated in the individual, like the heroes in the Trojan horse. There must be convergence in a unitary principle, soul or consciousness, which is that which really functions in perception, the senses and their organs being merely its instruments. It is this unity of apperception which enables us to combine the data of more than one sense, to affirm reality, unreality, identity, difference, unity, plurality and so forth, as also the good, the beautiful and their contraries. Plato calls these pervasive factors in knowledge κοινά and describes them as developed by the soul in virtue of its own activity. They are objects of its reflection and made explicit in the few with pains and gradually. That they are not, however, psychological or acquired categories, due to "the workmanship of the mind" as conceived by Locke, is obvious from their attribution to the structure of mind and from their correlation with immanent principles of the objective order. Considered from the epistemological point of view, they are the implicit presuppositions of the construction in which knowledge consists. But as ideas, though of a type quite apart, they have also a constitutive application to reality. Accordingly, of the selected "kinds" by means of which the interpenetration of ideas is expounded in the *Sophistes*, only motion and rest, the ultimate "kinds" in the physical world, have no counterparts in the "categories" of the *Theaetetus*.

II. ARISTOTLE

Aristotle was the first to conceive of reasoning itself as the definite subject of a special science. He was therefore the founder of Logic, although he never used that name. The Aristotelian treatises in which the foundations of Logic were laid are these:—(1) The *Categories*, on names signifying things which can become predicates; (2) *De Interpretatione*, on the enumeration of conceptions and their combinations by names and propositions; (3) The *Prior Analytics*, on syllogism; (4) The *Posterior Analytics*, on demonstrative syllogism; (5) The *Topics*, on dialectical syllogism, or argument; (6) The *Sophistical Elenchi*, on sophistical or contentious syllogism, or sophistical fallacies. Aristotle does not appear to have had any one name for all these investigations. But his followers called this collection of treatises the *Organon* (The *Instrument*, that is, of Knowledge), and from it there emerged gradually a system of Logic. Their production as relatively self-contained treatises accounts for the absence of a precise definition of their field of enquiry. And this original lack of precision in the delimitation of the scope of Logic haunts the subject to this day. Aristotle gave no clear intimation as to the relation in which he supposed this field of enquiry to stand to other disciplines. In his definite classification of the sciences, into First Philosophy, Mathematics and Physics, it has no place. Its axioms, such as the law of contradiction, belong to first philosophy, but the doctrine as a whole falls neither under this head nor yet, though the thought has been entertained, under that of mathematics, since logic orders mathematical reasoning as well as all other. The speculative sciences, indeed, are classified according to their relation to form, pure, abstract or concrete, *i.e.*, according to their object. The logical enquiry seems to be conceived as dealing with the thought of which the objects are objects. It is to be regarded as a propaedeutic, which although it is in contact with reality in and through the metaphysical import of the axioms or again in the fact that the categories, though primarily taken as forms of predication, must also be regarded as kinds of being, is not directly concerned with object-reality, but with the determination for the thinking subject of what constitutes the knowledge correlative to being. Logic, therefore, is not classed as one, still less a branch of one, among the 'ologies, ontology not excepted.

The way in which logical doctrine is developed in the Aristotelian treatises fits in with this view. Doubtless what we have is in the main a reflex of the heuristic character of Aristotle's own work as pioneer. But it at least satisfies the requirement that the enquiry shall carry the plain man along with it. Actual modes of expression are shown to embody distinctions which average intelligence can easily recognize, and will readily acknowledge, though they may tend by progressive rectification fundamentally to modify the assumption natural to the level of thought from which he begins. Thus we start from the point of view of a world of separate persons and things, in which thought mirrors these concrete realities, taken as ultimate subjects of predicates. It is a world of communication of thought, where persons as thinkers need to utter in language truths objectively valid for the common world. In these truths predicates are accepted or rejected by subjects, and therefore depend on the reflection of fact in proposition. These are combinatory of parts, attaching or detaching predicates, and so involving subject, predicate and copula. At this stage we are as much concerned with speech-forms as the thought-forms of which they are conventional symbols, with Plato's analysis, for instance, into a noun and a verb, whose connotation of time is as yet a difficulty. The universal of this stage is the universal of fact, what is recognized as predicable of a plurality of subjects. The dialectical doctrine of judgment as the declaration of one member of a disjunction by contradiction, which is later so important, is struggling with one of its initial difficulties, viz., the contingency of particular events, the future solution of which remains imperfect.

The doctrine of the *Categories* is still on the same level of thought, though its grammatico-logical analysis is the more advanced one which had probably been developed by the Academy before Aristotle came to think of his friends there as "them" rather than "us." It is what in one direction gave the now familiar classification of parts of speech, in the other that of thought-categories underlying them. If we abstract from any actual combination of subject and predicate and proceed to determine the types of predicate asserted in simple propositions of fact, we have on the one hand a subject which is never object, a "first substance" or concrete thing, of which may be predicated in the first place, "second substance," expressing that it is a member of a concrete class, and in the second place quantity, quality, correlation, action and the like. The list follows the forms of the Greek language so closely that a category emerges appropriated to the use of the perfect tense of the middle voice to express the relation of the subject to a garb that it dons. In all this the individual is the sole self-subsistent reality. Truth and error are about the individual and attach or detach predicates correctly and incorrectly. There is no committal to the metaphysics in the light of which the logical enquiry is at last to find its complete justification. The point of view is to be modified profoundly by what follows—by the doctrine of the class-concept behind the class, of the form or idea as the constitutive formula of a substance, or, again, by the requirement that an essential attribute must be grounded in the nature or essence of the substance of which it is predicated, and that such attributes alone are admissible predicates from the point of view of the strict ideal of science. But we are still on the ground of common opinion, and these doctrines are not yet laid down as fundamental to the development.

Dialectic, then, though it may prove to be the ultimate method of establishing principles in philosophy, starts from the probable and conceded premises, and deals with them only in the light of common principles, such as may be reasonably appealed to or easily established against challenge. To the expert, in any study which involves contingent matter, *i.e.*, an irreducible element of indetermination, *e.g.*, to the physician, there is a specific form of this, but the reflection that this is so is something of an afterthought. We start with what is prima facie given, to return upon it from the ground of principles clarified by the sifting process of dialectic and certified by thought. The *Topics* deal with dialectic and constitute an anatomy of argumentation, or, according to what seems to be Aristotle's own metaphor, a survey of the tactical vantage-points (τόποι) for the conflict of wits in which the prize is primarily victory, though it is a barren victory unless it is also knowledge. It is in this treatise that what have been called "the conceptual categories" emerge, viz., the predicables, or heads of predication as it is analysed in relation to the provisional theory of definition that dialectic allows and requires. A predicate either is expressive of the essence or part of the essence of the subject, viz., that original group of mutually underivable attributes of which the absence of any one destroys its right to the class-name, or it is not. Either it is convertible with the subject or it is not. Here, then, judgment, though still viewed as combinatory, has the types which belong to coherent systems of implication discriminated from those that predicate coincidence or accident, *i.e.*, any happening not even derivatively essential from the point of view of the grouping in which the subject has found a place. In the theory of dialectic any predicate may be suggested for a subject, and if not affirmed of it, must be denied of it, if not denied must be affirmed. The development of a theory of the ground on which subjects claim their predicates and disown alien predicates could not long be postponed. In practical dialectic the unlimited possibility was reduced to manageable proportions in virtue of the groundwork of received opinion upon which the operation proceeded. It is in the *Topics*, further, that we clearly have a first treatment of syllogism as formal implication, with the suggestion that advance must be made to a view of its use for material implication from true and necessary principles. It is in the *Topics*, again, that we have hints at the devices of an inductive process, which, as dialectical, throw the burden of producing contradictory instances upon the other party to the discussion. In virtue of the common-stock of opinion among the interlocutors, and their potentially controlling audience, this process was more valuable than appears on the face of things. Obviously tentative, and with limits and ultimate interpretation to be determined elsewhere, it failed to bear fruit till the Renaissance, and then by the irony of fate to the discrediting of Aristotle. In any case, however, definition, syllogism, induction all invited further determination, especially if they were to take their place in a doctrine of truth or knowledge. The problem of analytic, *i.e.*, of the resolution of the various forms of inference into their equivalents in that grouping of terms or premises which was most obviously cogent, was a legacy of the *Topics*. The debate-game had sought for diversion and found truth, and truth raised the logical problem on a different plane.

At first the problem of formal analysis only. We proceed with the talk of instances and concern ourselves first with relations of inclusion and exclusion. The question is as to membership of a class, and the dominant formula is the *dictum de omni et nullo*. Until the view of the individual units with which we are so far familiar has undergone radical revision, the primary inquiry must be into the forms of a class-calculus. Individuals fall into groups in virtue of the possession of certain predicates. Does one group include, or exclude, or intersect another with which it is compared? We are clearly in the field of the diagrams of the older text-books, and much of the phraseology is based upon an original graphic representation in extension. The middle term, though conceived as an intermediary or linking term, gets its name as intermediate in a homogeneous scheme of quantity, where it cannot be of narrower extension than the subject nor wider than the predicate of the conclusion. It is also, as Aristotle adds, middle in position in the syllogism that concludes to a universal affirmative. Again so long as we keep to the syllogism as complete in itself and without reference to its place in the great structure of knowledge, the nerve of proof cannot be conceived in other than a formal manner. In analytic we work with an ethos different from that of dialectic. We presume truth and not probability or concession, but a true conclusion can follow from false premises, and it is only in the attempt to derive the premises in turn from their grounds that we unmask the deception. The passage to the conception of system is still required. The *Prior Analytics*, then, are concerned with a formal logic to be knit into a system of knowledge of the real only in virtue of a formula which is at this stage still to seek. The forms of syllogism, however, are tracked successfully through their figures, *i.e.*, through the positions of the middle term that Aristotle recognizes as of actual employment, and all their moods, *i.e.*, all differences of affirmative and negative, universal and particular within the figures, the cogent or legitimate forms are alone left standing, and the formal doctrine of syllogism is complete. Syllogism already defined becomes through exhibition in its valid forms clear in its principle. It is a speech-and-thought-form in which certain matters being posited something other than the matter posited necessarily results because of them, and though it still needs to receive a deeper meaning when presumed truth gives way to necessary truth of premises, the notion of the class to that of the class-concept, collective fact to universal law, its formal claim is manifest. "Certain matters being posited." Subject and predicate not already seen to be conjoined must be severally known to be in relation with that which joins them, so that more than one direct conjunction must be given. "Of necessity." If what are to be conjoined are severally in relation to a common third, it does perforce relate or conjoin them. "Something other." The conjunction was by hypothesis not given, and is a new result by no means to be reached, apart from direct perception save by use of at least two given conjunctions. "Because of them," therefore. Yet so long as the class-view is prominent there is a suggestion of begging of the question. The class is either constituted by enumeration of its members, and passing by the difficulty involved in the thought of "its" members, is an empirical universal of fact merely, or it is grounded in the class-concept. In the first case it is a formal scheme which helps knowledge and the theory of knowledge not at all. We need then to develop the alternative, and to pass from the external aspect of all-ness to the intrinsic ground of it in the universal, which, whatsoever the assistance it receives from induction in some sense of the word, in the course of its development for the individual mind, is secured against dependence on instances by insight into the systematic nexus of things. The conception of linkage needs to be deepened by the realization of the middle term as the ground of nexus in a real order which is also rational.

Aristotle's solution of the paradox of inference, viz., of the fact that in one sense to go beyond what is in the premises is fallacy, while in another sense not to go beyond them is futility, lies in his formula of implicit and explicit, potential and actual. The real nexus underlying the thought-process is to be articulated in the light of the voucher by intelligence as to the truth of the principles of the various departments of knowledge which we call sciences, and at the ideal limit it is possible to transform syllogism into systematic presentation, so that, differently written down, it is definition. But for human thought sense, with its accidental setting in the matter itself incognizable, is always with us. The activity of thought is never so perfectly realized as to merge implication in intuition. Syllogism must indeed be objective, *i.e.,* valid for any thinker, but it is also a process in the medium of individual thinking, whereby new truth is reached. A man may know that mules are sterile and that the beast before him is a mule, yet believe her to be in foal "not viewing the several truths in connection." The doctrine, then, that the universal premise contains the conclusion not otherwise than potentially is with Aristotle cardinal. The datum of sense is only retained through the universal. It is possible to take a universal view with some at least of the particular instances left uninvestigated. Recognition that the class-concept is applicable may be independent of knowledge of much that it involves. Knowledge of the implications of it does not depend on observation of all members of the class. Syllogism as formula for the exhibition of truth attained, and construction or what not as the instrumental process by which we reach the truth, have in writers since Hegel and Herbart tended to fall apart. Aristotle's view is other. Both are syllogisms, though in different points of view. For this reason, if for no other, the conception of movement from the potential possession of knowledge to its actualization remains indispensable. Whether this is explanation or description, a problem or its solution, is of course another matter.

In the *Posterior Analytics* the syllogism is brought into decisive connection with the real by being set within a system in which its function is that of material implication from principles which are primary, immediate and necessary truths. Hitherto the assumption of the probable as the true rather than as what will be conceded in debate has been the main distinction of the standpoint of analytic from that of dialectic. But the true is true only in reference to a coherent system in which it is an immediate ascertainment of thought or to be deduced from a ground which is such. The ideal of science or demonstrative knowledge is to exhibit as flowing from the definitions and postulates of a science, from its special principles, by the help only of axioms or principles common to all knowledge, and these not as premises but as guiding rules, all the properties of the subject matter, *i.e.,* all the predicates that belong to it in its own nature. In the case of any subject-kind, its definition and its existence being avouched by thought, "heavenly body" for example, the problem is, given the fact of a non-self-subsistent characteristic of it, such as the eclipse of the said body, to find a ground which expressed the cause in virtue of which the adjectival concept can be exhibited as belonging to the subject-concept in the strict sense. We are under the necessity, then, of revising the point of view of the syllogism of all-ness. We discard the conception of the universal as a predicate applicable to a plurality, or even to all, of the members of a group. The exhaustive judgment, if attainable, could not be known to be exhaustive. The universal is the ground of the empirical "all" and not conversely. A formula such as the equality of the interior angles of a triangle to two right angles is only scientifically known when it is not of isosceles or scalene triangle that it is known, nor even of all the several types of triangle collectively, but as a predicate of triangle recognized as the widest class-concept of which it is true, the first stage in the progressive differentiation of figure at which it can be asserted.

Three points obviously need development, the nature of definition, its connection with the syllogism in which the middle term is cause or ground, and the way in which we have assurance of our principles.

Definition is either of the subject-kind or of the property that is grounded in it. Of the self-subsistent, definition is by exposition of genus and differentia. It is indemonstrable. It presumes the reality of its subject in a postulate of existence. It belongs to the principles of demonstration. *Highest genera* and groups below *lowest species* are indefinable. The former are susceptible of elucidation by indication of what falls under them. The latter are only describable by their accidents. There can here be no true differentia. The artificiality of the limit to the articulation of species was one of the points to which the downfall of Aristotle's influence was largely due. Of a non-self-subsistent or attributive conception definition in its highest attainable form is a recasting of the syllogism, in which it was shown that the attribute was grounded in the substance of the self-subsistent subject of which it is predicated. Eclipse of the moon, *e.g.,* is a privation of light from the moon by the interposition of the earth between it and the sun. In the scientific syllogism the interposition of the earth is the middle term, the cause or "because"; the residue of the definition is conclusion. The difference, then, is in verbal expression, way of putting, inflexion. If we pluck the fruit of the conclusion, severing its nexus with the stock from which it springs, we have an imperfect form of definition, while, if further we abandon all idea of making it adequate by exhibition of its ground, we have, with still the same form of words, a definition merely nominal or lexicographical.

The rest is a consideration of scientific inquiry as converging in the investigation of the link or "because" as ground in the nature of things. Real ground and thought-link fall together. The advance from syllogism as formal implication is a notable one. It is not enough to have for middle term a *causa cognoscendi* merely. We must have a *causa essendi.* The planets are near, and we know it by their not twinkling, but science must conceive their nearness as the cause of their not twinkling and make the *prius* in the real order of the middle term of its syllogism. In this irreversible catena proceeding from ground to consequent, we have left far behind such things as the formal parity of genus and differentia considered as falling under the same predicable, and hence justified in part Porphyry's divergence from the scheme of predicables. We need devices, indeed, to determine priority or superior claim to be "better known absolutely or in the order of nature," but on the whole the problem is fairly faced.

Of science Aristotle takes for his examples sometimes celestial physics, more often geometry or arithmetic, sometimes a concrete science, *e.g.,* botany. In the field of pure form, free from the disconcerting surprises of sensible matter and so a field of absolute necessity, no difficulty arises as to the deducibility of the whole body of a science from its first principles. In the sphere of abstract form, mathematics, the like may be allowed, abstraction being treated as an elimination of matter from the σύνολον by one act. When we take into account relative matter, however, and traces of a conception of abstraction as admitting of degree, the question is not free from difficulty. In the sphere of the concrete sciences where law obtains only ὡς ἐπὶ τὸ πολύ this ideal of science can clearly find only a relative satisfaction with large reserves. In any case, however, the problem as to first principles remains fundamental.

If we reject the infinite regress and the circle in proof (circulus in probando) which resolves itself ultimately into proving A by B and B by A, we are confronted by the need for principles of two kinds, those which condition all search for truth and those which are the peculiar or proper principles of special sciences, their "positions," viz., the definitions of their subjects and the postulates of the existence of these. All are indemonstrable and cannot be less sure than the body of doctrine that flows from them. They must indeed be recognized as true, primary, causative and the like. But they are not congenitally present in the individual in a determinate shape. The doctrine of latency is mystical and savours of Plato's reminiscence. Yet they must have something to develop from, and thereupon Aristotle gives an account of a process in the psychological mechanism which he illustrates by comparative psychology, wherein a λόγος or meaning emerges, a "first" universal recognized by induction. Yet νοῦς, intelligence, is the principle of first principles. It is infallible, while, whatever the case with perception of the special sensibles, the process which combines particulars is not. On the side of induction we find that experience is said to give the specific principles, "the phenomena being apprehended in sufficiency." On the side of intuition, self-evidence of scientific principles is spoken of. Yet dialectic is auxiliary and of methodological importance in their establishment. Mutually limiting statements occur almost or quite side by side. We cannot take first principles "as the bare precipitate of a progressively refined analysis" nor on the other as constitutive a priori forms. The solution seems to lie in the conception of a process that has a double aspect. On the one hand we have confrontation with fact, in which, in virtue of the rational principle which is the final cause of the phenomenal order, intelligence will find satisfaction. On the other, we have a stage at which the rational but as yet not reasoned concepts developed in the medium of the psychological mechanism are subject to processes of reflective comparison and analysis, and, with some modification, maintained against challenge, till at length the ultimate universals emerge, which rational insight can posit as certain, and the whole hierarchy of concepts from the "first" universals to τὰ ἀμερῆ are intuited in a coherent system. Aristotle's terminology is highly technical, but, as has often been observed, not therefore clear. Here two words at least are ambiguous, "principle" and "induction." By the first he means any starting-point, "that from which the matter in question is primarily to be known," particular facts, therefore, premises and what not. What, then, is meant by principles when we ask in the closing chapter of his logic how they become known? The data of sense are clearly not the principles in question here. The premises of scientific syllogisms may equally be dismissed. Where they are not derivative they clearly are definitions or immediate transcripts from definitions. There remain, then, primary definitions and the postulates of their realization, and the axioms or common principles "which he must needs have who is to reach any knowledge." In the case of the former, special each to its own science, Aristotle may be thought to hold that they are the product of the psychological mechanism, but are ascertained only when they have faced the fire of a critical dialectic and have been accepted from the point of view of the integral rationality of the system of concepts. Axioms, on the other hand, in which the sciences inter-connect through the employment of them in a parity of relation, seem to be implicit indeed in the psychological mechanism, but to come to a kind of explicitness in the first reflective reaction upon it, and without reference to any particular content of it. They are not to be used as premises but as immanent laws of thought, save only when an inference from true or admitted premises and correct in form is challenged. The challenge must be countered in a *reductio ad impossibile* in which the dilemma is put. Either this conclusion or the denial of rationality. Even these principles, however, may get a greater explicitness by dialectical treatment. The relation, then, of the two orders of principle to the psychological mechanism is different. The kind of warrant that intelligence can give to specific principles falls short of infallibility. Celestial physics, with its pure forms and void of all matter save extension, is not such an exemplary science after all. Rationality is continuous throughout. A λόγος emerges with some beings in direct sequence upon the persistence of impressions. Sense is of the "first" universal, the form, though not of the ultimate universal. The rally from the rout in Aristotle's famous metaphor is of units that already belong together, that are of the same regiment or order. On the other hand, rationality has two stages. In the one it is relatively immersed in sense, in the other relatively free. The same break is to be found in the conception of the relation of receptive to active mind in the treatise *Of the Soul*. The one is impressed by things and receives their form without their matter. The other is free from impression. It thinks its system of concepts freely on the occasion of the affections of the receptivity. Aristotle is fond of declaring that knowledge is of the universal, while existence or reality is individual. It seems to follow that the cleavage between knowledge and reality is not bridged by the function of thought in relation to "induction." What is known is not real, and what is real is not known. It is in induction, which claims to start from particulars and end in universals, that we must, if anywhere within the confines of logical inquiry, expect to find the required bridge. The Aristotelian conception of induction, however, is somewhat ambiguous. He had abandoned for the most part the Platonic sense of the corresponding verb, viz., to lead forward to the as yet unknown, and his substitute is not quite clear. Perhaps confrontation with facts is the general meaning. But how does he conceive of its operation? There is in the first place the action of the psychological mechanism in the process from discriminative sense upwards wherein we realize "first" universals. This is clearly an unreflective, prelogical process, not altogether lighted up by our retrojection upon it of our view of dialectical induction based thereon. The immanent rationality of this first form, in virtue of which at the stage when intelligence acts freely on the occasion of the datum supplied, it recognizes continuity with its own self-conscious process, is what gives the dialectical type its meaning. Secondly, we have this dialectical "induction as to particulars by grouping of similars" whose liability to rebuttal by an exception has been already noted in connection with the limits of dialectic. This is the incomplete induction by simple enumeration which has so often been laughed to scorn. It is a heuristic process liable to failure, and its application by a nation of talkers even to physics where non-expert opinion is worthless somewhat discredited it. Yet it was the fundamental form of induction as it was conceived throughout the scholastic period. Thirdly we have the limiting cases of this in the inductive syllogism, a syllogism in the third figure concluding universally, and yet valid because the copula expresses equivalence, and in analogy in which instances are weighed and not counted. In the former Aristotle's illustration does not combine particular facts into a lowest concept, but specific concepts into a generic concept, and in the construction of definite inductions the ruling thought with Aristotle is already, though vaguely, that of causal relation. It appears safer, notwithstanding, to take the less subtle interpretation that dialectical induction struggling with instances is formally justified only at the limit, and this, where we have exhausted and know that we have exhausted the cases, is in regard to individual subjects rarely and accidentally reached, so that we perforce illustrate rather from the definite class-concepts falling under a higher notion. After all, Aristotle must have had means by which he reached the conclusions that horses are long-lived and lack gall. It is only, then, in the rather mystical relation of νοῦς to the first type of induction as the process of the psychological mechanism, that an indication of the direction in which the bridge from individual being to universal knowledge is to be found can be held to lie.

Enough has been said to justify the great place assigned to Aristotle in the history of logic. He laid down the programme which the after history of logic was to carry out.

The Aristotelian theory of the universal of science as secure from dependence on its instances and the theory of linking in syllogism remain a heritage for all later logic, whether accepted in precisely Aristotle's formula or no. It is because the intervening centuries had the Aristotelian basis to work on, that the rest of our logical tradition is what it is. We stand upon his shoulders.

III. LATER GREEK LOGIC

After Aristotle we have, as regards logic, what the verdict of after times has rightly characterized as an age of *Epigoni*. So far as the Aristotelian framework is accepted we meet only minor corrections and extensions of a formal kind. If there is conscious and purposed divergence from Aristotle, enquiry moves, on the whole, within the circle of ideas where Aristotelianism had fought its fight and won its victory. Where new conceptions emerge, the imperfection of the instruments, mechanical and methodological, of the sciences renders them unfruitful until their rediscovery in a later age. We have activity without advance, diversity without development. Attempts at comprehensiveness end in the compromises of eclecticism.

The Stoics are of some importance. Despite the fact that their philosophic interests lay rather in ethics and physics, their activity in what they classified as the third department of speculation was enormous and has at least left ineffaceable traces on the terminology of philosophy. Logic is their word, and consciousness, impression and other technical words come to us, at least as technical words, from Roman stoicism. Even inference, though apparently not a classical word, throws back to the Stoic name for a conclusion.

Another doctrine of the Stoics which has interest in the light of certain modern developments is their insistence on the place of the λεκτόν in knowledge. Distinct alike from thing and mental happening, it seems to correspond to "meaning." Along the same lines is their use of the hypothetical form for the universal judgment, and their treatment of the hypothetical form as the typical form of inference.

The Stoical categories, too, have an historical significance. They are apparently offered in place of those of Aristotle, an acquaintance with whose distinctions they clearly presume. Recognizing a linguistic side to "logical" theory with a natural development in rhetoric, the Stoics endeavour to exorcise considerations of language from the contrasted side. They offer pure categories arising in series, each successive one pre-supposing those that have gone before. Yet the substance, quality, condition absolute πῶς ἔχον and condition relative of Stoicism have no enduring influence outside the school, though they recur with eclectics like Galen.

Epicureans.—In falling back upon the atomism of Democritus, Epicurus had to face some questions of logic. In the inference from phenomena to further phenomena positive verification must be insisted on. In the inference from phenomena to their non-phenomenal causes, the atoms, with their inaccessibility to sense, a different canon of validity obtains, that of non-contradiction. He distinguishes, too, between the inference to combinations of atoms as universal cause, and inference to special causes beyond the range of sense. In the latter case alternatives may be acquiesced in. The practical aim of science is as well achieved if we set forth possible causes as in showing the actual cause. More probably it reflects the fact that Epicurus was, on the whole, dominated by the influences that produced Pyrrhonism.

Sceptics.—The school of Pyrrho has exercised a more legitimate influence. The major premise of syllogism, says the Pyrrhonist, is established inductively from the particular instances. If there be but one of these uncovered by the generalization, this cannot be sound. If the crocodile moves its upper, not its lower jaw, we may not say that all animals move the lower jaw. The conclusion then is really used to establish the major premise, and if we still will infer it therefrom we fall into the circular proof. Could Mill say more? But again. The inductive enumeration is either of all cases or of some only. The former is in an indeterminate or infinite subject-matter impossible. The latter is invalid.

Neo-Platonists.—In the history of logic Neo-platonism is of importance because of its production of a whole series of commentators on the Aristotelian logic. Not only the *Introduction* of Porphyry, which had lasting effects on the Scholastic tradition, but the commentaries of Themistius and Simplicius. It was the acceptance of the Aristotelian logic by Neo-platonism that determined the Aristotelian complexion as the logic of the next age. If Alexander is responsible for such doctrines as that of the *intellectus acquisitus,* it is to Porphyry, with his characteristically Platonist preference for the doctrine of universals, and for classification, that we owe the scholastic preoccupation with the realist controversy, and with the *quinque voces, i.e.,* the Aristotelian predicables as restated by Porphyry.

B. SCHOLASTICISM

The living force in the spiritual life of the Roman empire was, after all, not philosophy, but religion, and specifically Christianity. With the extension of Christianity to the Gentile world, it at length became necessary for it to orientate itself towards what was best in Greek culture. There is a Stoic element in the ethic of the Pauline epistles, but the theological affinity that the Johannine gospel with its background of philosophic ideas, exhibits to Platonic and Neoplatonist teaching caused the effort at absorption to be directed rather in that direction. Neoplatonism had accepted the Aristotelian logic with its sharper definition than anything handed down from Plato, and except the logic of the Sceptics, there was no longer any rival discipline of the like prestige. The logic of the Stoics had been discredited by the sceptical onset, but in any case there was no organon of a fitness even comparable to Aristotle's for the task of drawing out the implications of dogmatic premises. Aristotelian logic secured the imprimatur of the revived Platonism, and it was primarily because of this that it passed into the service of Christian theology. The contact of the Church with Platonism was on the mystical side. Orthodoxy needed to counter heretical logic not with mysticism, itself the fruitful mother of heresies, but with argument. Aristotelianism approved itself as the controversial instrument, and in due course held the field alone. The upshot is what is called Scholasticism. Scholasticism is the Aristotelianism of mediaeval orthodoxy as taught in the "schools" or universities of Western Europe. It takes form as a body of doctrine drawing its premises from authority, sometimes in secular matters from that of Aristotle, but normally from that of the documents and traditions of systematic theology, while its method it draws from Aristotle, as known in the Latin versions, mainly by Boethius, of some few treatises of the *Organon* together with the *Isagoge* of Porphyry. It dominates the centres of intellectual life in the West, because, despite its claim to finality in its principles or premises, and to universality for its method, it represents the only culture of a philosophic kind available to the adolescent peoples of the Western nations just becoming conscious of their ignorance. Christianity was the one organizing principle that pulsed with spiritual life. The vocation of the student could find fulfilment only in the religious orders. Scholasticism embodied what the Christian community had saved from the wreckage of Greek dialectic. Yet with all its effective manipulation of the formal technique of its translated and mutilated Aristotle, Scholasticism would have gone under long before it did through the weakness intrinsic to its divorce of the form and the matter of knowledge, but for two reasons. The first is the filtering through of some science and some new Aristotelian learning from the Arabs. The second is the spread of Greek scholarship and Greek manuscripts westwards, which was consequent on the Latin occupation of Constantinople in 1204. It was respited by the opportunity which was afforded it of fresh draughts from the Aristotle of a less partial and purer tradition, and we have, accordingly, a golden age of revived Scholasticism beginning in the 13th century, admitting now within itself more differences than before. It is to the schoolmen of the two centuries preceding the Turkish capture of Constantinople that controversial refinements usually associated with the name of Scholasticism are attributable. The *Analytics* of Aristotle now entered quite definitely into the logical thought of Scholasticism and we have the contrast of a *logica vetus* and *logica nova.* The respite, however, was short. The flight of Byzantine scholarship westward in the 15th century revealed, and finally, that the philosophic content of the Scholastic teaching was as alien from Aristotle as from the spirit of the contemporary revolt of science, with its cry for a new medicine, a new nautical astronomy and the like. The doom of the Scholastic Aristotle was nevertheless not the rehabilitation of the Greek Aristotle. Between him and the tide of feeling at the Renaissance lay the whole achievement of Arab science. That impatience of authority to which we owe the Renaissance, the Reformation and the birth of Nationalism, is not stilled by the downfall of Aristotle as the *nomen appellativum* of the schools. The appeal is to experience, somewhat vaguely defined, as against all authority, to the book of nature and no other. At last the world undertakes to enlarge the circle of its ideas.

C. THE RENAISSANCE

Accordingly what is in one sense the revival of classical learning is in another a recourse to what inspired that learning, and so is a new beginning. There is no place for a reformed Aristotelian logic, though the genius of Zabarella was there to attempt it. Nor for revivals of the competing systems, though all have their advocates. Scientific discovery was in the air. The tradition of the old world was too heavily weighted with the Ptolemaic astronomy and the like to be regarded as other than a bar to progress. But from the new point of view its method was inadequate, too, its contentment with an induction that merely leaves an opponent silent when experiment and the application of a calculus were within the possibilities. The transformation of logic lay with the man of science, hindered though he might be by the enthusiasm of some of the philosophers of nature. Henceforth the Aristotelian logic, the genuine no less than the traditional, was to lie on the other side of the Copernican change.

The demand is for a new organon, a scientific method which shall face the facts of experience and justify itself by its achievement in the reduction of them to control. It is a notable feature of the new movement, that except verbally, in a certain licence of nominalist expression, due to the swing of the pendulum away from the realist doctrine of universals, there is little that we can characterize as Empiricism. Facts are opposed to abstract universals. Yes. Particulars to controlling formulae. No. Experience is appealed to as fruitful where the formal employment of syllogism is barren. But it is not mere induction, with its "unanalysed concretes taken as ultimate" that is set up as the substitute for deduction. Rather a scientific process, which as experiential may be called inductive, but which is in other regards deductive as syllogism, is set up in contrast to syllogism and enumeration alike. This is to be seen in Zabarella, in Galilei, and in Bacon. The reformed Aristotelian logic of the first-named with its *inductio demonstrativa,* the mathematico-physical analysis followed by synthesis of the second, the *exclusiva,* or method of exclusions of the last, agree at least in this, that the method of science is one and indivisible, while containing both an inductive and a deductive moment. That what, *e.g.,* Bacon says of his method may run counter to this is an accident of the tradition of the quarrel with realism. So, too, with the scholastic universals. Aristotle's form had been correlated, though inadequately, with the idea of function. Divorced from this they are fairly stigmatized as mental figments or branded as ghostly entities that can but block the path. But consider Bacon's own doctrine of forms. Or watch the mathematical physicist with his formulae. The faith of science looks outward as in the dawn of Greek philosophy, and subjectivism such as Hume's has as yet no hold. Bacon summing up the movement so far as he understood it, in a rather belated way, has no theory of knowledge beyond the metaphor of the mirror held up to nature. Yet he offers an ambitious logic of science, and the case is typical.

Galilei.—The science of the Renaissance differs from that of the false dawn in Greek times in the fact of fruitfulness. It had the achievement of the Old World in the field of mathematics upon which to build. It was in reaction against a dialectic and not immediately to be again entrapped. In scientific method, then, it could but advance, provided physics and mathematics did not again fail of accord. Kepler and Galilei secured it against that disaster. The *ubi materia, ibi geometria* of the one is the battle-cry of the mathematico-physical advance. The scientific instrument of the other, with its moments of analysis and construction, *metodo risolutivo* and *metodo compositivo,* engineers the road for the advance. The new method of physics is verifiable by its fruitfulness, and so free of any immediate danger from dialectic. Its germinal thought may not have been new, but if not new, it had at least needed rediscovery from the beginning. For it was to be at once certain and experiential. A mathematico-physical calculus that would work was in question. The epistemological problem as such was out of the purview. The relation of physical laws to the mind that thought them was for the time a negligible constant. When Descartes, having faithfully and successfully followed the mathematico-physical inquiry of his more strictly scientific predecessors, found himself compelled to raise the question how it was possible for him to know what in truth he seemed to know so certainly, the problem entered on a new phase. The scientific movement had happily been content for the time with a half which, then and there at least, was more than the whole.

Bacon was no mathematician, and so was out of touch with the main army of progress. By temperament he was rather with the Humanists. He was content to voice the cry for the overthrow of the dominant system as such, and to call for a new beginning, with no realist presuppositions. He is with the nominalists of the later Scholasticism and the naturalists of the early Renaissance. He echoes the cry for recourse to nature, for induction, for experiment. He calls for a logic of discovery. But at first sight there is little sign of any greater contribution to the reconstruction than is to be found in Ramus or many another dead thinker. The syllogism is ineffective, belonging to argumentation, and constraining assent where what we want is control of things. It is a mechanical combination of propositions, as these of terms, which are counters to express concepts often ill-defined. The flight from a cursory survey of facts to wide so-called principles must give way to a gradual progress upward from propositions of minimum to those of medium generality, and in these consists the fruitfulness of science. Yet the induction of the Aristotelians, the dialectical induction of the *Topics,* content with imperfect enumeration and throwing the burden of disproof upon the critic, is puerile, and at the mercy of a single instance to the contrary. In all this there is but little promise for a new organon. It is neither novel nor instrumental. On a sudden Bacon's conception of a new method begins to unfold itself. It is inductive only in the sense that it is identical in purpose with the ascent from particulars. It were better called *exclusiva* or elimination of the alternative, which Bacon proposes to achieve, and thereby guarantee his conclusion against the possibility of an instance to the contrary.

Bacon's method begins with a digest into three tables of the facts relevant to any inquiry. The first contains cases of the occurrence of the quality under investigation, colour, *e.g.,* or heat in varying combinations. The second notes its absence in combinations so allied to certain of these that its presence might fairly have been looked for. The third registers its quantitative variation according to quantitative changes in its concomitants. The method now proceeds on the basis of the first table to set forth the possible suggestions as to a general explanatory formula for the quality in question. In virtue of the remaining tables it rejects any suggestion qualitatively or quantitatively inadequate. If one suggestion, and one alone, survives the process of attempted rejection it is the explanatory formula required. If none, we must begin afresh. If more than one, recourse is to be had to certain devices of method, in the enumeration of which the methods of agreement, difference and concomitant variations find a place beside the crucial experiment, the glaring instance and the like. An appeal, however, to such devices, though a permissible "first vintage" is relatively an imperfection of method, and a proof that the tables need revision. The positive procedure by hypothesis and verification is rejected by Bacon, who thinks of hypothesis as the will o' the wisp of science, and prefers the cumbrous machinery of negative reasoning.

Historically he appears to have been under the dominance of the Platonic metaphor of an alphabet of nature, with a consequent belief in the relatively small number of ultimate principles to be determined, and of Plato's conception of Division, cleared of its dialectical associations and used experimentally in application to his own molecular physics. True it is that the rejection of all the co-species is a long process, but what if therein their simultaneous or subsequent determination is helped forward? They, too, must fall to be determined sometime, and the ideal of science is fully to determine all the species of the genus. This will need co-operative effort as is described in the account of Solomon's House in the *New Atlantis.* But once introduce the conception of division of labour as between the collector of data on the one hand and the expert of method, the interpreter of nature at headquarters on the other, and Bacon's attitude to hypothesis and to negative reasoning is at least in part explained. The hypothesis of the collector, the man who keeps a rain-gauge, or the missionary among savages, is to be discounted from as a source of error. The expert on the other hand may be supposed, in the case of facts over which he had not himself brooded in the course of their acquisition, to approach them without any presumption this way or that. He will, too, have no interest in the isolation of any one of several co-ordinate inquiries. That Bacon underestimates the importance of selective and of provisional explanatory hypotheses even in such fields as that of chemistry, and that technically he is open to some criticism from the point of view that negative judgment is derivate as necessarily resting on positive presuppositions, may be true enough. It seems, however, no less true that the greatness of his conception of organized common effort in science has but rarely met with due appreciation.

In his doctrine of *forms,* too, the "universals" of his logic, Bacon must at least be held to have been on a path which led forward and not back. His forms are principles whose function falls entirely within knowledge. They are the formulae for the control of the activities and the production of the qualities of bodies. Forms are qualities and activities expressed in terms of the ultimates of nature, *i.e.,* normally in terms of collocations of matter or modes of motion. (The human soul is still an exception.) Form is bound up with the molecular structure and change of structure of a body, one of whose qualities or activities it expresses in wider relations. A mode of motion, for instance, of a certain definite kind, is the form of heat. It is the recipe for, and at the same time is, heat, much as H_2O is the formula for and is water. Had Bacon analysed bodies into their elements instead of their qualities and ways of behaviour, he would have been the logician of the chemical formula. Here, too, he has scarcely received his meed of appreciation.

His influence on successors has rather lain in the general stimulus of his enthusiasm for experience, or in the success with which he represents the cause of nominalism, and in certain special devices of method handed down, till through Hume or Herschel they affected the thought of Mill. For the rest he was too Aristotelian, if we take the word broadly enough, or, as the result of his Cambridge studies, too Ramist, when the interest in scholastic issues was fading, to bring his original ideas to a successful market.

Bacon's Logic, then, like Galilei's, intended as a contribution to scientific method, a systematization of discovery by which, given the fact of knowledge, new items of knowledge may be acquired, failed to convince contemporaries and successors alike of its efficiency as an instrument. It was an ideal that failed to embody itself and justify itself by its fruits. It was otherwise with the mathematical instrument of Galilei.

Descartes stands in the following of Galilei. It is concurrently with signal success in the work of a pioneer in the mathematical advance that he comes to reflect on method, generalizes the method of mathematics to embrace knowledge as a whole, and raises the ultimate issues of its presuppositions. In the mathematics we determine complex problems by a construction link by link from axioms and simple data clearly and distinctly conceived. Three moments are involved. The first is an *induction, i.e.,* an exhaustive enumeration of the simple elements in the complex phenomenon under investigation. This resolution or analysis into simple, because clear and distinct, elements may be brought to a standstill again and again by obscurity and indistinctness, but patient and repeated revision of all that is included in the problem should bring the analytic process to fruition. It is impatience, a perversity of will, that is the cause of error. Upon the analysis there results *intuition* of the simple data. With Descartes intuition does not connote givenness, but its objects are evident at a glance when induction had brought them to light. Lastly we have *deduction,* the determination of the most complex phenomena by a continuous synthesis or combination of the simple elements. Synthesis is demonstrative and complete. It is in virtue of this view of derived or mediate knowledge that Descartes speaks of the (subsumptive) syllogism as "of avail rather in the communication of what we already know." Syllogism is not the synthesis which together with analysis goes to constitute the new instrument of science. The celebrated *Regulae* of Descartes are precepts directed to the achievement of the new methodological ideal in any and every subject matter, however reluctant.

D. MODERN LOGIC

I. THE LOGIC OF EMPIRICISM

Hobbes.—With Hobbes logic is a calculus of marks and signs in the form of names. Naming is what distinguishes man from the brutes. It enables him to fix fleeting memories and to communicate with his fellows. He alone is capable of truth in the due conjunction or disjunction of names in propositions. Syllogism is simply summation of propositions, its function being communication merely. Analysis is the sole way of invention or discovery. There is more, however, in Hobbes, than the paradox of nominalism. Spinoza could draw upon him for the notion of genetic definition. Leibniz probably owes to him the thought of a calculus of symbols, and the conception of demonstration as essentially a chain of definitions. His psychological account of syllogism is taken over by Locke. Hume derived from him the explanatory formula of the association of ideas, which is, however, still with Hobbes a fact to be accounted for, not a theory to account for facts, being grounded physically in "coherence of the matter moved." Finally Mill took from him his definition of cause as sum of conditions, which played no small part in the applied logic of the 19th century.

Locke.—Locke's logic comprises, amid much else, a theory of general terms and of definition, a view of syllogism, and a declaration as to the possibility of inference from particular to particular, a distinction between propositions which are certain but trifling, and those which add to our knowledge though uncertain, and a doctrine of mathematical certainty. As to the first, "words become general by being made the signs of general ideas, and ideas become general by separating from them" all "that may determine them to this or that particular existence. By this way of abstraction they are made capable of representing more individuals than one." This doctrine has found no acceptance. Not from the point of view for which idea means image. Berkeley, though at length the *notions* of spirits, acts and relations give him pause, prefers the formula which Hume expresses in the phrase that "some ideas are particular in their nature but general in their representation," and the after-history of "abstraction" is a discussion of the conditions under which one idea "stands for" a group. Not from those for whom general ideas mean schematic concepts, not imageable. The critic from this side has little difficulty in showing that abstraction of the kind alleged still leaves the residuum particular, *this* redness, *e.g.,* not *redness.* It is, however, of the sorts constituted by the representation which his abstraction makes possible that definition is given, either by enumeration of the simple ideas combined in the significance of the sortal name, or "to save the labour of enumerating," and "for quickness and despatch sake," by giving the next wider general name and the proximate difference. We define essences of course in a sense, but the essences of which men talk are abstractions, "creatures of the understanding." Man determines the sorts or nominal essences, nature the similitudes. The fundamentally enumerative character of the process is clearly not cancelled by the recognition that it is possible to abbreviate it by means of technique. So long as the relation of the nominal to the real essence has no other background than Locke's doctrine of perception the conclusion that what Kant afterwards calls analytical judgments a priori and synthetic judgments a posteriori exhaust the field follows inevitably, with its corollary, which Locke himself has the courage to draw, that the natural sciences are in strictness impossible. Mathematical knowledge is not involved in the same condemnation, solely because of the "archetypal" character, which, not without indebtedness to Cumberland, Locke attributes to its ideas. The reality of mathematics, equally with that of the ideals of morals drawn from within, does not extend to the "ectypes" of the outer world. The view of reasoning which Locke enunciates coheres with these views. Reasoning from particular to particular, *i.e.,* without the necessity of a general premise, must be possible, and the possibility finds warranty in a consideration of the psychological order of the terms in syllogism. As to syllogism specifically, Locke in a passage which has an obviously Cartesian ring, lays down four stages or degrees of reasoning, and points out that syllogism serves us in but one of these, and that not the all-important one of finding the intermediate ideas. He is prepared readily to "own that all right reasoning may be reduced to Aristotle's form of syllogism," yet holds that "a man knows first, and then he is able to prove syllogistically." The distance from Locke to Stuart Mill along this line of thought is obviously but small.

Hume.—Apart from the adoption by Hume of the association of ideas as the explanatory formula of the school—it had been allowed by Malebranche within the framework of his mysticism and employed by Berkeley in his theory of vision—there are few fresh notes struck in the logic of sensationalism. The most notable of these are Berkeley's treatment of "abstract" ideas and Hume's change of front as to mathematical certainty. What, however, Hume describes as "all the *logic* I think proper to employ in my reasoning," viz., his "rules by which to judge cause and effects," had, perhaps, farther-reaching historical effects than either. In these the single method of Bacon is already split up into separate modes. We have Mill's inductive methods in the germ, though with an emphasis which is older than Mill's Bacon's *form* has already in transmission through Hobbes been transmuted into *cause* as antecedent in the time series. It may, perhaps, be accounted to Hume for righteousness that he declares —whether consistently or not is another matter—that "the same effect never arises but from the same cause," and that he still follows Bacon in the conception of *absentia in proximo*. It is "when in any instance we find our expectation disappointed" that the effect of one of "two resembling objects" will be like that of the other that Hume proposes to apply his method of difference.

J. S. Mill.—Mill's *System of Logic* marked a fresh stage in the history of empiricism. Mill aspired after a doctrine of method such as should satisfy the needs of the natural sciences, notably experimental physics and chemistry as understood in the first half of the 19th century, and *mutatis mutandis,* of the moral sciences naturalistically construed. In uniting with this the Associationism which he inherited, through his father, from Hume, he revealed at once the strength and weakness of the dual conception of naturalism. His rare thoroughness and rarer candour made it at once unnecessary and impossible that the work should be done again.

If judged by what he denies, viz., the formal logic of Hamilton and Mansel, whose Aristotelian and scholastic learning did but accentuate their traditionalism, and whose acquiescence in consistency constituted in Mill's view a discouragement of research, such as men now incline to attribute at the least equally to Hume's idealism, Mill is only negatively justified. If judged by his positive contribution to the theory of method he may claim to find a more than negative justification for his teaching in its success. In the field covered by scholastic logic Mill is frankly associationist. He aims at describing what he finds given, without reference to insensible implications of doubtful validity and value. The upshot is a psychological account of what from one aspect is evidence, from the other, belief. So he explains "concept or general notions" by an abstraction which he represents as a sort of alt-relief operated by attention and fixed by naming, association with the name giving to a set of attributes a unity they otherwise lack. This is manifestly, when all is said, a particular psychological event, a collective fact of the associative consciousness. It can exercise no organizing or controlling function in knowledge. So, again, in determining the "import" of propositions, it is no accident that in all save existential propositions it is to the familiar rubrics of associationism—co-existence, sequence, causation and resemblance—that he refers for classification, while his general formula as to the conjunctions of connotations is associationist through and through. It follows consistently enough that inference is from particular to particular. Mill holds even the ideas of mathematics to be hypothetical, and in theory knows nothing of a non-enumerative or non-associative universal. A premise that had the utmost universality consistent with this view can clearly be of no service for the establishment of a proposition that has gone to the making of it. Nor again of one that has not. Its use, then, can only be as a memorandum. It is a shorthand formula of registration. Mill's view of ratiocinative process clearly stands and falls with the presumed impossibility of establishing the necessity for universals of another type than his, for what may be called principles of construction. His critics incline to press the point that association itself is only intelligible so far as it is seen to depend on universals of the kind that he denies.

In Mill's inductive logic, the nominalistic convention has, through his tendency to think in relatively watertight compartments, faded somewhat into the background. Normally he thinks of what he calls phenomena no longer as psychological groupings of sensations, "states of mind," but as things and events in a physical world howsoever constituted and apprehended. His free use of relating concepts, that of sameness, for instance, bears no impress of his theory of the general notion, and it is possible to put out of sight the fact that, taken in conjunction with his nominalism, it raises the whole issue of the possibility of the equivocal generation of formative principles from the given contents of the individual consciousness, in any manipulation of which they are already implied. Equally, too, the deductive character, apparently in intention as well as in actual fact, of Mill's experimental methods fails to recall the point of theory that the process is essentially one from particular to particular. The nerve of proof in the processes by which he establishes causal conjunctions of unlimited application is naturally thought to lie in the special canons of the several processes and the axioms of universal and uniform causation which form their background. The conclusions seem not merely to fall within, but to depend on these organic and controlling formulae. They follow not merely according to them but from them. The reference to the rule is not one which may be made and normally is made as a safeguard, but one which must be made, if thought is engaged in a forward and constructive movement at all. Yet Mill's view of the function of "universal" propositions had been historically suggested by a theory—Dugald Stewart's—of the use of axioms. Once more, it would be possible to forget that Mill's ultimate laws or axioms are not in his view intuitions, nor forms constitutive of the rational order, nor postulates of all rational construction, were it not that he has made the endeavour to establish them on associationist lines. It is because of the failure of this endeavour to bring the technique of induction within the setting of his Humian psychology of belief that the separation of his contribution to the applied logic of science from his sensationism became necessary, as it happily was easy. Mill's device rested special inductions of causation upon the laws that every event has a cause, and every cause has always the same effect. It rested these in turn upon a general induction enumerative in character of enormous and practically infinite range and always uncontradicted. Though obviously not exhaustive, the unique extent of this induction was held to render it competent to give practical certainty or psychological necessity. A vicious circle is obviously involved. It is true, of course, that ultimate laws need discovery, that they are discovered in some sense in the medium of the psychological mechanism, and that they are nevertheless the grounds of all specific inferences. But that truth is not what Mill expounds, nor is it capable of development within the limits imposed by the associationist formula.

It is deservedly, nevertheless, that Mill's applied logic has retained its pride of place amid what has been handed on, if in modified shape, by writers, *e.g.,* Sigwart and Bernard Bosanquet whose theory of knowledge is quite alien from his. He prescribed regulative or limiting formulae for research as it was actually conducted in his world. His grasp of the procedure by which the man of science manipulated his particular concrete problem was admirable. In especial he showed clear understanding of the functions of hypothesis and verification in the investigations of the solitary worker, with his facts still in course of accumulation, and needing to be lighted up by the scientific imagination. He was therefore enabled to formulate the method of what Bacon had tended to despise as merely the "first vintage." Bacon spent his strength upon a dream of organization for all future discovery. Mill was content to codify. The difference between Bacon and Mill lies chiefly in this, and it is because of this difference that Mill's contribution, spite of its debt to the Baconian tradition, remains both characteristic and valuable. It is of course possible to criticize even the experimental canons with some severity. The caveats, however, which are relevant within the circle of ideas within which Mill's lesson can be learned and improved on, seem to admit of being satisfied by relatively slight modifications in detail, or by explanations often supplied or easily to be supplied from points brought out amid the wealth of illustration with which Mill accompanied his formal or systematic exposition of method. The critic has the right of it when he points out, for example, that the practical difficulty in the Method of Agreement is not due to plurality of causes, as Mill states, but rather to intermixture of effects, while, if the canon could be satisfied exactly, the result would not be rendered uncertain in the manner or to the extent he supposes. Again the formula of the Joint-Method, which contemplates the enumeration of cases "which have nothing in common but the absence of one circumstance," is ridiculously unsound as it stands. Or, on rather a different line of criticism, the use of corresponding letters in the two series of antecedents and consequents, raises, it is said, a false presumption of correlation. Nay, even the use of letters at all suggests that the sort of analysis that actually breaks up its subject-matter is universally or all but universally applicable in nature, and this is not the case. Finally, the conditions of the methods are either realized or not. If they are realized the work of the scientist falls entirely within the field of the processes preliminary to the satisfaction of the canon. The latter becomes a mere memorandum or formula of registration. So is it possible "to have the engineer hoist with his own petard." But the conditions are not realized and in an experiential subject-matter are not realizable. Not one circumstance only in common, but "apparently one relevant circumstance only in common" is what we are able to assert. If we add the qualification of relevance we destroy the cogency of the method. If we fail to add it, we destroy the applicability.

The objections turn on two main issues. One is the exaggeration of the possibilities of resolution into separate elements that is due to the acceptance of the postulate of an alphabet of nature. This so soon as noted can be allowed for. It is to the combination of this doctrine with a tendency to think chiefly of experiment, of the controlled addition or subtraction of these elements one at a time, that we owe the theoretically premature linking of a as effect to A as cause. This too can be met by a modification of form. The other issue is perhaps of more significance. It is the oscillation which Mill manifests between the conception of his formula as it is actually applicable to concrete problems in practice, and the conception of it as an expression of a theoretical limit to practical procedure. Mill seems most often to think of the former, while tending to formulate in terms of the latter. At any rate, if relevance *in proximo* is interpolated in the peccant clause of the canon of the Joint-Method, the practical utility of the method is rehabilitated. So, too, if the canon of the Method of Agreement is never more than approximately satisfied, intermixture of effects will in practice mean that we at least often do not know the cause or antecedent equivalent of a given effect, without the possibility of an alternative. Finally, it is on the whole in keeping with Mill's presuppositions to admit even in the case of the method of difference that in practice it is approximative and instructive, while the theoretical formula, to which it aims at approaching asymptotically as limit, if exact, is in some sense sterile. Mill may well have himself conceived his methods as practically fruitful and normally convincing with the limiting formula in each case more cogent in form but therewith merely the skeleton of the process that but now pulsed with life.

Enough has been said to show why the advance beyond the letter of Mill was inevitable while much in the spirit of Mill must necessarily affect deeply all later experientialism. After Mill experientialism takes essentially new forms. In part because of what Mill had done. In part also because of what he had left undone. After Mill means after Kant and Hegel and Herbart, and it means after the emergence of evolutionary naturalism. Mill, then, marks the final stage in the achievement of a great school of thought.

II. THE LOGIC OF RATIONALISM

Spinoza.—A fundamental contrast to the school of Bacon and Locke is afforded by the great systems of reason, owning Cartesian inspiration, which are identified with the names of Spinoza and Leibniz. Spinoza's philosophy is expounded *ordine geometrico* and with Euclidean cogency from a relatively small number of definitions, axioms and postulates. But how we reach our assurance of the necessity of these principles is not made specifically clear. The invaluable tractate *De Intellectus emendatione,* in which the agreement with and divergence from Descartes on the question of method could have been fully elucidated, is unhappily not finished. We know that we need to pass from what Spinoza terms *vague experience,* where imagination with its fragmentary apprehension is liable to error and neither necessity nor impossibility can be predicated, right up to *intellection.* And what Spinoza has to say of the requisites of definition and the marks of intellection makes it clear that insight comes with coherence, and that the work of method on the "inductive" side is by means of the unravelling of all that makes for artificial limitation to lay bare what can then be seen to exhibit nexus in the one great system. When all is said, however, the geometric method as universalized in philosophy is rather used by Spinoza than expounded.

Leibniz.—With Leibniz, on the other hand, the logical problem holds the foremost place in philosophical enquiry. From the purely logical thesis, developed at quite an early stage of his thinking, that in any true proposition the predicate is contained in the subject, the main principles of his doctrine of Monads are derivable with the minimum of help from his philosophy of dynamics. *Praedicatum inest subjecto.* All valid propositions express in the last resort the relation of predicate or predicates to a subject, and this Leibniz holds after considering the case of relational propositions where either term may hold the position of grammatical subject, $A=B$ and the like. There is a subject, then, or there are subjects which must be recognized as not possible to be predicated, but as absolute. For reasons not purely logical Leibniz declares for the plurality of such subjects. Each contains all its predicates: and this is true not only in the case of truths of reason, which are necessary, and ultimately to be exhibited as coming under the law of contradiction, "or, what comes to the same thing, that of identity," but also in the case of truths of fact which are contingent, though a sufficient reason can be given for them which "inclines" without importing necessity. The extreme case of course is the human subject. "The individual notion of each person includes once for all what is to befall it, world without end," and "it would not have been our Adam but another, if he had had other events." Existent subjects containing eternally all their successive predicates in the time-series are substances, which when the problems connected with their activity or, dynamically speaking, their force, have been resolved, demand—and supply—the metaphysic of the Monadology.

Complex truths of reason or essence raise the problem of definition, which consists in their analysis into simpler truths and ultimately into simple—*i.e.,* indefinable ideas, with primary principles of another kind—axioms, and postulates that neither need nor admit of proof. These are identical in the sense that the opposite contains an express contradiction. In the case of non-identical truths, too, there is a priori proof drawn from the notion of the terms, "though it is not always in our power to arrive at this analysis" so that the question arises, specially in connection with the possibility of a calculus, whether the contingent is reducible to the necessary or identical at the ideal limit.

Leibniz's remaining legacy to later logicians is the conception of *Characteristica Universalis* and *Ars Combinatoria,* a universal denoting by symbols and a calculus working by substitutions and the like. The two positions that a subject contains all its predicates, and that all non-contingent propositions, *i.e.*, all propositions not concerned with the existence of individual facts ultimately analyse out into identities—obviously lend themselves to the design of this algebra of thought, though the mathematician in Leibniz should have been aware that a significant equation is never an identity. Leibniz, fresh from the battle of the calculus in the mathematical field, and with his conception of logic, at least in some of its aspects, as a generalized mathematic, found a fruitful inspiration, harmonizing well with his own metaphysic, in Bacon's alphabet of nature. He, too, was prepared to offer a new instrument. That the most important section, the list of forms of combination, was never achieved—this, too, was after the Baconian example while the mode of symbolization was crude with $a=ab$ and the like—matters little. A new technique of manipulation—it is, of course, no more—had been evolved.

III. KANT'S AND POST-KANTIAN LOGIC

Kant.—Kant's treatment of technical logic was wholly traditional, and in itself is almost negligible. It is comprised in an early essay on the mistaken subtlety of the syllogistic figures, and a late compilation by a pupil from the introductory matter and running annotations with which the master had enriched his interleaved lecture-room copy of Meyer's *Compendium* of 1752. Wolff's general logic, "the best," said Kant, "that we possess," had been abridged by Baumgarten and the abridgement then subjected to commentation by Meyer. With this traditional body of doctrine Kant was, save for matters of minor detail, quite content. Logic was of necessity formal, dealing as it must with those rules without which no exercise of the understanding would be possible at all. Upon abstraction from all particular methods of thought these rules were to be discerned a priori or without dependence on experience by reflection solely upon the use of the understanding in general. The science of the form of thought abstracted in this way from its matter or content was regarded as of value both as a propaedeutic and as canon. It was manifestly one of the disciplines in which a position of finality was attainable. Aristotle might be allowed, indeed, to have omitted no essential point of the understanding. What the moderns had achieved consisted in an advance in accuracy and methodical completeness. "Indeed, we do not require any new discoverers in logic," said the discoverer of a priori synthesis, "since it contains merely the form of thought." Applied logic is merely psychology, and not properly to be called logic at all. The technical logic of Kant, then, justifies literally a movement among his successors in favour of a formal conception of logic with the law of contradiction and the doctrine of formal implication for its equipment. Unless the doctrine of Kant's "transcendental logic" must be held to supply a point of view from which a logical development of quite another kind is inevitable, Kant's mantle, so far as logic is concerned, must be regarded as having fallen upon the formal logicians.

The Formal Logicians, of whom Twesten and H. L. Mansel may be regarded as typical, take thought and "the given" as self-contained units which, if not in fact separable, are at any rate susceptible of an abstraction the one from the other so decisive as to constitute an ideal separation. The laws of the pure activity of thought must be independently determined, and since the contribution of thought to knowledge is form, they must be formal only. They cannot go beyond the limits of formal consistency or analytical correctness. They are confined to the determination of what the truth of any matter of thought, taken for granted upon grounds psychological or other, which are extraneous to logic, includes or excludes. The unit for logic is the concept taken for granted. The function of logic is to exhibit its formal implications and repulsions. It is questionable whether even this modest task could be really achieved without other reference to the content abstracted from than Mansel, for example, allows. The analogy of the resolution of a chemical compound with its elements which is often on the lips of those who would justify the independence of thought and the real world, with an agnostic conclusion as to non-phenomenal or trans-subjective reality, is not really applicable. The oxygen and hydrogen, for example, into which water may be resolved are not in strictness indifferent one to the other, since both are members of an order regulated according to laws of combination in definite ratios. Or, if applicable, it is double-edged. Suppose oxygen to be found only in water. Were it to become conscious, would it therefore follow that it could infer the laws of a separate or independent activity of its own? Similarly forms of thinking, the law of contradiction not excepted, have their meaning only in reference to determinate content, even though distributively all determinate contents are dispensable. The extreme formalist is guilty of a fallacy of composition in regard to abstraction.

It does not follow, however, that the laws asserted by the formal logicians are invalid or unimportant. There is a permissible abstraction, and in general they practise this, and although they narrow its range unduly, it is legitimately to be applied to certain characters of thinking. As the living organism includes something of mechanism—the skeleton, for example—so an organic logic doubtless includes determinations of formal consistency. The skeleton is meaningless apart from reference to its function in the life of an organism, yet there are laws of skeleton structure which can be studied with most advantage if other characters of the organism are relegated to the background. To allow, however, that abstraction admits of degrees, and that it never obliterates all reference to that from which it is abstracted, is to take a step forward in the direction of the correlation of logical forms with the concrete processes of actual thinking. What was true in formal logic tended to be absorbed in the correlationist theories.

Herbart.—The brief logic of Herbart is altogether formal, too. Logical forms have for him neither psychological nor metaphysical reference. We are concerned in logic solely with the systematic clarification of concepts which are wholly abstract, so that they are not merely not ultimate realities, but also in no sense actual moments of our concrete thinking. The first task of logic is to distinguish and group such concepts according to their marks, and from their classification there naturally follows their connection in judgment. It is in the logic of judgment that Herbart inaugurates a new era. He is not, of course, the first to note that even categorical judgments do not assert the realization of their subject. That is a thought which lies very near the surface for formal logic. He had been preceded, too, by Maimon in the attempt at a reduction of the traditional types of judgment. He was, however, the first whose analysis was sufficiently convincing to exorcise the tyranny of grammatical forms. The categorical and disjunctive judgment reduce to the hypothetical. By means of the doctrine of the quantification of the predicate, in which with his Leibnizian conception of identity he anticipated Beneke and Hamilton alike, universal and particular judgments are made to pull together. Modal, impersonal, existential judgments are all accounted for. Only the distinction of affirmative and negative judgments remains unresolved, and the exception is a natural one from the point of view of a philosophy of pluralism. There was little left to be done here save in the way of an inevitable *mutatis mutandis,* even by Lotze and F. H. Bradley. From the judgment viewed as hypothetical we pass by affirmation of the antecedent or denial of the consequent to inference. This point of departure is noteworthy, as also is the treatment of the inductive syllogism as one in which the middle term is resoluble into a group or series (*Reihe*). In indicating specifically, too, the case of conclusion from a copulative major premise with a disjunctive minor, Herbart seems to have suggested the cue for Sigwart's exposition of Bacon's method of exclusions.

Herbart exercised a far-reaching influence in the development of later logic. Directly he affected a school of thought which contained one logician of first-rate importance in Drobisch. In less direct relation stands Lotze, who, although under other influences he developed a different view even in logic, certainly let no point in the doctrine of his great predecessor at Göttingen escape him. A Herbartian strain is to be met with also in the thought of writers much farther afield, for example F. H. Bradley, far though his metaphysic is removed from Herbart's. Herbart's influence is to be found, too, in the evolution of what is called *Gegenstandstheorie.*

Lotze.—As a logician Lotze stands among the masters. His *flair* for the essentials in his problem, his subtlety of anaylsis, his patient willingness to return upon a difficulty from a fresh and still a fresh point of view, and finally his fineness of judgment, make his logic so essentially logic of the present and of its kind not soon to be superseded, that nothing more than an indication of the historical significance of some of its characteristic features need be attempted here.

In Lotze's pure logic it is the Herbartian element that tends to be disconcerting. Logic is formal. Its unit, the logical concept, is a manipulated product and the process of manipulation may be called abstraction. Processes of the psychological mechanism lie below it. The paradox of the theory of judgment is due to the ideal of identity, and the way in which this is evaded by supplementation to produce a non-judgmental identity, followed by translation of the introduced accessories with conditions in the hypothetical judgment is thoroughly in Herbart's manner. The reduction of judgments is on lines already familiar. Syllogism is no instrumental method by which we compose our knowledge, but an ideal to the form of which it should be brought. It is, as it were, a schedule to be filled in, and is connected with the disjunctive judgment as a schematic setting forth of alternatives, not with the hypothetical, and ultimately the apodictic judgment with their suggestion that it is the real movement of thought that is subjected to analysis. Yet the resultant impression left by the whole treatment is not Herbartian. The concept is accounted for in Kantian terms. There is no discontinuity between the prelogical or sub-logical conversion of impressions into "first universals" and the formation of the logical concept. Abstraction proves to be synthesis with compensatory universal marks in the place of the particular marks abstracted from. Synthesis as the work of thought always supplies, besides the mere conjunction or disjunction of ideas, a ground of their coherence or noncoherence. It is evident that thought, even as dealt with in pure logic, has an objectifying function. Its universals have objective validity, though this does not involve direct real reference. The formal conception of pure logic, then, is modified by Lotze in such a way as not only to be compatible with a view of the structural and functional adequacy of thought to that which at every point at which we take thinking is still distinguishable from thought, but even inevitably to suggest it. That the unit for logic is the concept and not the judgment has proved a stumbling-block to those of Lotze's critics who are accustomed to think in terms of the act of thought as unit. Lotze's procedure is, indeed, analogous to the way in which, in his philosophy of nature, he starts from a plurality of real beings, but by means of a reductive movement, an application of Kant's transcendental method, arrives at the postulate or fact of a law of their reciprocal action, which calls for monistic and idealist interpretation. He starts, that is, in logic, with conceptual units apparently self-contained and admitting of nothing but external relation, but proceeds to justify the intrinsic relation between the matter of his units by appeal to the fact of the coherence of all contents of thought. Indeed, if thought admits irreducible units, what can unite? Yet he is left committed to his puzzle as to a reduction of judgment to identity, which partially vitiates his treatment of the theory of judgment. The outstanding feature of this is, nevertheless, not affected, viz., the attempt that he makes, inspired clearly by Hegel "to develop the various forms of judgment systematically as members of a series of operations, each of which leaves a part of its problem unmastered and thereby gives rise to the next." As to inference, finally, the ideal of the articulation of the universe of discourse, as it is for complete knowledge, when its disjunctions have been thoroughly followed out and it is exhaustively determined, carried the day with him against the view that the organon for gaining knowledge is syllogism. The Aristotelian formula is "merely the expression, formally expanded and complete, of the truth already embodied in disjunctive judgment, namely, that every S which is a specific form of M possesses as its predicate a particular modification of each of the universal predicates of M to the exclusion of the rest." Schleiermacher's separation of inference from judgment and his attribution of the power to knowledge in process cannot find acceptance with Lotze. The psychologist and the formal logician do indeed join hands in the denial of a real movement of thought in syllogism. Lotze's logic, then, is formal in a sense in which a logic which does not find the conception of synthetic truth embarrassing is not so. It is canon and not organon. In the one case, however, where it recognizes what is truly synthesis, *i.e.*, in its account of the concept, it brings the statics of knowledge, so to speak, into integral relation with the dynamics. And throughout, wherever the survival from 1843, the identity bug-bear, is for the moment got rid of in what is really a more liberal conception, the statical doctrine is developed in a brilliant and informing manner. Yet it is in the detail of his logical investigations, something too volatile to fix in summary, that Lotze's greatness as a logician more especially lies.

With Lotze the ideal that at last the forms of thought shall be realized to be adequate to that which at any stage of actual knowledge always proves relatively intractable is an illuminating projection of faith. He takes courage from the reflection that to accept scepticism is to presume the competence of the thought that accepts. He will, however, take no easy way of parallelism. Our human thought pursues devious and circuitous methods. Its forms are not unseldom scaffolding for the house of knowledge rather than the framework of the house itself. Our task is not to realize correspondence with something other than thought, but to make explicit those justificatory notions which condition the form of our apprehension. "However much we may presuppose an original reference of the forms of thought to that nature of things which is the goal of knowledge, we must be prepared to find in them many elements which do not directly reproduce the actual reality to the knowledge of which they are to lead us." The impulse of thought to reduce coincidence to coherence reaches immediately only to objectivity or validity. The sense in which presupposition of a further reference is to be interpreted and in which justificatory notions for it can be adduced is only determinable in a philosophic system as a whole, where feeling has a place as well as thought, value equally with validity.

Lotze's logic then represents the statical aspect of the function of thought in knowledge, while, so far as we go in knowledge thought is always engaged in the unification of a manifold which remains contradistinguished from it, though not, of course, completely alien to and unadapted to it. The further step to the determination of the ground of harmony is not to be taken in logic, where limits are present and untranscended.

Hegel.—The so-called "Logic" of Hegel and of other German idealists belongs to the history of Metaphysics rather than to the history of Logic properly so called.

IV. LOGIC FROM 1880–1928

The logic of this period exhibits, though in characteristically modified shapes, all the main types that have been found in its past history. There is an intellectualist logic coalescent with an absolutist metaphysic as aforesaid. There is an epistemological logic with sometimes formalist, sometimes methodological leanings. There is a formal-symbolic logic engaged with the elaboration of a relational calculus. Finally, there is what may be termed psychological-voluntaryist logic. It is in the rapidity of development of logical investigations of the third and fourth types and the growing number of their exponents that the present shows most clearly the history of logic in the making. All these movements are logic of the present, and a very brief indication may be added of points of historical significance.

Bradley.—Of intellectualist logic Bradley (*Principles of Logic* 1883) and Bernard Bosanquet (*Logic,* 1888) may be taken as typical exponents. The philosophy of the former concludes to an Absolute by the annulment of contradictions. His metaphysical method is, like Herbart's, not identifiable with his logic, and the latter has for its central characteristic its thorough restatement of the logical forms traditional in language and the text-book in such a way as to harmonize with the doctrines of a reality whose organic unity is all-inclusive. The thorough recasting that this involves, even of the thought of the masters when it occasionally echoes them, has resulted in a phrasing uncouth to the ear of the plain man with his world of persons and things in which the former simply think about the latter, but it is fundamentally necessary for Bradley's purpose. The negative judgment, for example, cannot be held in one and the same undivided act to presuppose the unity of the real, project an adjective as conceivably applicable to it and assert its rejection. We need, therefore, a restatement of it. With Bradley reality is the one subject of all judgment immediate or mediate. The act of judgment "which refers an ideal content (recognized as such) to a reality beyond the act" is the unit for logic. Grammatical subject and predicate necessarily both fall under the rubric of the adjectival, that is, within the logical idea or ideal content asserted. This is a meaning or universal which can have no detached or abstract self-subsistence. As found in judgment it may exhibit differences within itself, but it is not two, but one, an articulation of unity, not a fusion which could only be a confusion, of differences. With a brilliant subtlety Bradley analyses the various types of judgment in his own way, with results that must be taken into account by all subsequent logicians of this type. The view of inference with which he complements it is only less satisfactory because of a failure to distinguish the principle of nexus in syllogism from its traditional formulation and rules, and because he is hampered by the intractability which he finds in certain forms of relational construction.

In the new edition of his *Principles* (1922) Bradley repudiates his previous assumption of ideas divorced from judgments, and of judgments divorced from inferences. The concrete conceptual fact is inference, of which mere ideas and simple judgment are abstractions. Inference is the ideal self-development of a given object taken as real. The given object is an ideal content before us, and it is taken to be real as being in one with reality, or the real universe. The possibility of inference rests upon the fact that the object is not only itself, but is also contained as an element in a whole; in fact, it *is* itself only as being so contained. From the nature of the case inference must always be incomplete, and subject to unknown conditions. But this ultimate problem does not concern Logic.

Bosanquet is, perhaps, more able than Bradley has shown himself, to use material from alien sources and to penetrate to what is of value in the thought of writers from whom he disagrees. He treats the book-tradition, however, with a judicious exercise of freedom in adaptation, *i.e.,* constructively as datum, never eclectically. In his fundamental theory of judgment his obligation is to Bradley. It is to Lotze, however, that he owes most in the characteristic feature of his logic, viz., the systematic development of the types of judgment and inference from less adequate to more adequate forms. His fundamental continuity with Bradley may be illustrated by his definition of inference. "Inference is the indirect reference to reality of differences within a universal, by means of the exhibition of this universal in differences directly referred to reality."

In the new edition of his *Logic* (1911) Bosanquet defends at length his metaphysical absolutism and the coherence theory of Truth. No finite individual is self-dependent or self-contained, that is, a real substance. Even the self finds its reality in something beyond itself. Hence absolutism. But an individual not self-complete can be predicated of the whole of which it is a part. With regard to Truth he maintains that Truth is its own criterion, and can only be tested by more of itself. Any system can be tested further only by being made more complete. The coherence theory of Truth is further elaborated by Bosanquet in his *Implication and Linear Inference* (1920). All inference, it is maintained therein, is of the same type, namely, implication. The essence of implication is interrelation between the parts of a system (or concrete universal), which makes modification in some parts clues to the modification of others. Syllogistic inference, he says, is linear, not systematic, and therefore not true inference. In true inference we survey a system of facts, see it in its relation to the whole of reality, and read off the implications. The inference is immediate if we can read off the implications directly; it is mediate if we must construct this system first. The starting point of all inference is the realization that to deny the truth of *all* propositions would involve self-contradiction, as it would deny this very denial. We must consequently believe *some* propositions, even if we question the truth of this or that proposition. In true inference we transfer our certainty that *some* propositions are true to the truth of the proposition inferred. In the last resort, all inferences may be reduced to the alternatives. "Either this proposition is true, or no proposition is." Within the system from which we start we read off conclusions the denial of which would shatter the whole world of our experience.

Sigwart.—Of epistemological logic in one sense of the phrase, Lotze is still to be regarded as a typical exponent. Of another type Chr. Sigwart may be named as representative. Sigwart's aim was to "reconstruct logic from the point of view of methodology." His problem was the claim to arrive at propositions universally valid, and so true of the object, whosoever the individual thinker. His solution within the Kantian circle of ideas, was that such principles as the Kantian principle of causality were justified as "postulates of the endeavour after complete knowledge." What Kant has shown is not that irregular fleeting changes can never be the object of consciousness, but only that the ideal consciousness of complete science would be impossible without the knowledge of the necessity of all events. "The universal presuppositions which form the outline of our ideal of knowledge are not so much laws, which the understanding prescribes to nature . . . as laws which the understanding lays down for its own regulation in its investigation and consideration of nature. They are a priori because no experience is sufficient to reveal or confirm them in unconditional universality; but they are a priori . . . only in the sense of presuppositions without which we should work with no hope of success and merely at random and which therefore we must believe." Finally they are akin to our ethical principles. With this coheres his dictum, with its far-reaching consequences for the philosophy of induction, that "the logical justification of the inductive process rests upon the fact that it is an inevitable postulate of our effort after knowledge, that the given is necessary and can be known as proceeding from its grounds according to universal laws." It is characteristic of Sigwart's point of view that he acknowledges obligation to Mill as well as to Ueberweg. The transmutation of Mill's inductions into a postulate is an advance of which the psychological school of logicians have not been slow to make use. The comparison of Sigwart with Lotze is instructive, in regard both to their agreement and their divergence as showing the range of the epistemological formula.

Johnson.—The most ambitious of recent works on Logic is that of W. E. Johnson (3 vols. 1921–4, vol. 4 to follow). Johnson attempts to combine the epistemological with the empirical view of Logic. Logic, he holds, is concerned with the analysis and criticism of thought, and it is impossible to draw a rigid distinction between Logic and Philosophy, or between Logic and Science. Thought has two aspects, an epistemic and a constitutive aspect. The constitutive consists of the content of knowledge; the epistemic is that which depends on the variable conditions and capacities for the acquisition of knowledge. The unit of logic is the proposition, of which truth or falsity can be significantly predicated, and of which the intensive aspect is the most important. "Implication" is potential inference, and assumes different relations in different cases. There are two principles of deduction:—The applicative principle states that *All S is P* warrants the inference of *The given S is P;* (2) the implicative principle states that a compound proposition of the form *"x" and "x implies y"* warrants the inference of *"y."* The syllogism involves both principles. These principles require universal premises and these are obtained by *induction,* a term which he applies to every process of reaching a generalization from instantial premises. He enumerates four types of induction, namely (1) *intuitive,* (2) *summary,* (3) *demonstrative* and (4) *probable.* Of these the last corresponds to ordinary empirical induction; and the second is the old "perfect" induction. *Intuitive* induction is the process by which we obtain the principles of Logic, of Mathematics, etc. These are obtained by reflection on particular instances in one of two ways:—(1) the *counter-applicative* way, when we see that what is true of a given instance is true of any other instance; (2) the *counter-implicative* way, when, having made an inference which is valid we see that its validity is due to a certain form of relation between the premises and the conclusion. *Demonstrative* induction includes certain types of hypothetical syllogism in which an instantial premise leads to a universal conclusion, and the familiar canons of induction, reformulated by him as four "figures" of agreement, difference, composition and resolution. Under *probable* inductions he distinguishes *pure generalization* from *class-fractional inductions,* which are usually known as statistical generalizations. From all these forms of induction he distinguishes *eduction,* the argument from "certain instances of S which are M are P" to "the next S that is M will also be P." The discussion of many psychological and philosophical problems is a feature of Johnson's *Logic.*

New Principles, etc.—The above accounts of Bradley, Bosanquet and Johnson contain references to new formulations or reformulations of various logical principles and types of inference. In this connection reference may also be made to E. E. C. Jones's *New Law of Thought* (1918) which reformulates the old Law of Identity in the form of a "Law of Significant Association" (according to which every Subject of Predication is an identity of denotation in diversity of intension) and to A. Wolf's *Essentials of Logic,* and *Essentials of Scientific Method* (1925, 1926) in which there are formulated the "Principle of Uniformity of Reasons" (namely, whatever is regarded as a sufficient reason in any one case must be regarded as a sufficient reason in all cases of the same type), and a number of types of inference which had not been formulated before.

Symbolic Logic.—Of symbolic logic all that needs to be said here is, that from the point of view of logic as a whole, it is to be regarded as a legitimate praxis as long as it shows itself aware of the sense in which form alone is susceptible of abstraction, and is aware that in itself it offers no solution of the logical problem. "It is not an algebra," said Kant of his technical logic, and the kind of support lent recently to symbolic logic by the *Gegenstandstheorie* identified with the name of Alexius Meinong (b. 1853) is qualified by the warning that the real activity of thought tends to fall outside the calculus of relations and to attach rather to the subsidiary function of denoting. The future symbolic logic as coherent with the rest of logic, in the sense which the word has borne throughout its history, seems to be bound up with the question of the nature of the analysis that lies behind the symbolism and of the way in which this is justified in the setting of a doctrine of validity. The "theory of the object" itself, while affecting logic alike in the formal and in the psychological conception of it very deeply, does not claim to be regarded as logic or a logic, apart from a setting supplied from elsewhere.

Pragmatist Logic.—Finally we have a logic of a type fundamentally psychological, if it be not more properly characterized as a psychology which claims to cover the whole field of philosophy, including the logical field. The central and organizing principle of this is that knowledge is in genesis, that the genesis takes place in the medium of individual minds, and that this fact implies that there is a necessary reference throughout to interests or purposes of the subject which thinks because it wills and acts. Historically this doctrine was formulated as the declaration of independence of the insurgents in revolt against the pretensions of absolutist logic. It drew for support upon the psychological movement that begins with Fries and Herbart. It has been chiefly indebted to writers who were not, or were not primarily, logicians, to Avenarius, for example, for the law of the economy of thought, to Wundt, whose system, and therewith his logic, is a pendant to his psychology, for the volitional character of judgment, to Herbert Spencer and others. A judgment is practical and not to be divorced without improper abstraction from the purpose and will that informs it. A concept is instrumental to an end beyond itself, without any validity other than its value for action. A situation involving a need of adaptation to environment arises and the problem it sets must be solved that the will may control environment and be justified by success. Truth is the improvised machinery that is interjected, so far as this works. It is clear that we are in the presence of what is at least an important half-truth, which intellectualism with its statics of the rational order viewed as a completely articulate system has tended to ignore. It throws light on many phases of the search for truth, upon the plain man's claim to start with a subject which he knows, whose predicate which he does not know is still to be developed, or again upon his use of the negative form of judgment, when the further determination of his purposive system is served by a positive judgment from without, the positive content of which is yet to be dropped as irrelevant to the matter in hand. The movement has, however, scarcely developed its logic except as a polemic. What seems clear is that it cannot be the whole solution. While man must confront nature from the human and largely the practical standpoint, yet his control is achieved only by the increasing recognition of objective controls. He conquers by obedience. So truth works and is economical because it is truth. Working is proportioned to inner coherence. It is well that the view should be developed into all its consequences. The result will be to limit it, though perhaps also to justify it, save in its claim to reign alone.

BIBLIOGRAPHY.—Prantl's *Geschichte der Logik* (4 vols. 1885–70, re-issued 1926) gives a full account of the history of logic to the close of the Middle Ages; Harms's *Geschichte der Logik* (1881) brings the history up to Leibniz; Ueberweg's *System der Logik* (4th ed. 1874, Eng. Transl. 1871) and T. Ziehen's *Lehrbuch der Logik* (1920) contain historical sketches. *See* also the bibliographies under LOGIC, LOGISTIC, SCIENTIFIC METHOD and KNOWLEDGE, THEORY OF.

(H. W. BL.; A. WO.)

LOGISTIC is not a special branch of logic for it is the realization of the ideal of logic, the exhibition of form. The word "logistic" is an old name revived with a new meaning to denote what has been variously referred to as "symbolic logic," "algebra of logic," "mathematical logic" and "algorithmic logic." These different terms are, however, not exact synonyms. Symbolic logic is the study of the various types of deductions; it is distinguished from the special branches of pure mathematics by its generality. It uses symbols, but this is not its distinctive characteristic, for other sciences use symbols. The generality of symbolic logic is due to the fact that it is based upon a few fundamental, undefined concepts, called "primitives," and upon one or more fundamental postulates, called "primitive propositions" from which everything asserted is deduced. An "algebra of logic" denotes a special set of postulates and primitive concepts, so that there are various algebras differing with respect to the fundamental notions employed. "Mathematical logic" is concerned with the logistic development of mathematics from the fewest possible number of primitive concepts and primitive propositions. In the widest sense of the term, Logistic may be said to be the science of the most general principles of deduction, expressed in ideographic symbols, and developed so as to exhibit the interconnection of these principles.

Ideographic Symbols.—Ordinary language is not only ambiguous, it is also vague and insusceptible of precise analysis. It confounds those distinctions upon which exact reasoning must be based, and is thus often simple when the ideas involved are complex. Consequently civilized languages are well-suited to express complicated facts briefly but are ill-adapted to express simple notions simply. For example, the Commutative Laws, "$a+b=b+a$," "$ab=ba$," would, if expressed in ordinary language, be absurdly prolix. It is, therefore, impossible to carry out complicated processes of deduction without the aid of symbols specially devised to simplify the operations required. Symbols may be used merely to abbreviate the writing of ordinary words, but the utility of such symbols is slight. The S,M,P, used in expositions of the traditional syllogism were probably at the outset mere shorthand devices. Nevertheless, even these symbols suggest the importance for logic of form as such, since there is abstraction from the particular meanings for which S,M, or P, might stand. Abstraction is necessary in order to secure generality; hence, the importance of this device.

A satisfactory logical symbolism must satisfy two different kinds of conditions. First, the symbols must be as concise as possible, so that they can be easily comprehended at a glance; secondly, the symbols must be such as to facilitate the deduction of conclusions according to a mechanical process in which thinking is reduced to a minimum. The symbols must, in other words, provide a calculus of reasoning, *i.e.*, an instrument for economizing thought, so that difficult operations can be performed without the trouble of thinking about them. The importance of good symbolism is revealed in the development of mathematics which has, throughout, been conditioned by the adequacy of the symbols it employs. An adequate set of symbols both presupposes analysis of the fundamental ideas and aids further analysis. Ideograms, which directly represent concepts, are better fitted than phonograms to fulfil these requirements. Although conciseness is in practice indispensable, all that is logically necessary is that the symbols should be exact and unique. The purpose of these ideographic symbols is not to translate words already in use, but to denote unambiguously explicit concepts, involving no reference to any special subject-matter. Their use, therefore, marks the achievement of the ideal of form, which it is the purpose of logic to exhibit.

The Generalization of Logic.—To be completely formal is to be completely general. Consequently there are various degrees of approximation to this ideal of form. Aristotle's theory of the syllogism is the earliest attempt to exhibit the formal principles of deduction. It suffers from three main defects: (1) its restriction to a single mode of deduction, the syllogism; (2) its failure to symbolize the relations involved; (3) its defective analysis of these relations. The recognition of non-syllogistic modes of deduction, combined with the attempt to use symbols as the basis of operations, led to rapid elaboration of symbolic systems; whilst the distinction and analysis of the different relations employed in deduction made possible that logistic development of mathematics that marks the culmination of the ideal of form.

It is not difficult to see that the familiar syllogism: "All men are mortal, Socrates is a man, therefore Socrates is mortal" is not a logically simple form. Nor did even the traditional logic assert the conclusion but only the fact that the premises jointly imply the conclusion. It must then, first, be restated in the form: "If all men are mortal and Socrates is a man, then Socrates is mortal." Now it is clear that the validity of the reasoning does not depend upon the fact that *Socrates* is mentioned. It would do just as well if we substituted Plato, or Newton, or any other individual. Thus what we are asserting is a relation between "being a man" and "being a mortal." We can, therefore, replace "Socrates" by a symbol, x, denoting an undetermined individual. Such a symbol is called a variable. Let us write for the second premise "$\hat{x}$ is a man." Here x denotes an empty place to be filled with an appropriate individual. Such an expression as "x is a man" is called a propositional function. It becomes a proposition when the name of an individual is substituted for $\hat{x}$; it will be a true proposition if the individual is human. A similar analysis applies to "Socrates is mortal" which is of the same form. But "all men are mortal" is not of the same form, since it asserts a relation between all the individuals that are human and all those that are mortal. It is thus a compound proposition and requires analysis into "'$\hat{x}$ is a man' implies '$\hat{x}$ is mortal' no matter what x may be." Thus we see that the copula "are" in the major premise denotes a different relation from the copula "is" in the minor premise. The difference may be provisionally stated by saying that "all men are mortal" asserts a relation between the class *men* and the class *mortals*, whereas "Socrates is a man" asserts that a given individual belongs to a class. Confusion between these relations is hardly to be avoided so long as we rely for our analysis upon the verbal expression of these propositions. The separation between these two forms cannot be clearly effected until an adequate symbolism is devised. Such a symbolism will, at the same time, afford a basis of operations.

The Logical Calculus.—The canonical forms of the Aristotelian syllogism reveal an attempt to employ symbols to test the validity of the reasoning involved. We have seen that these symbols were inadequate so that the forms were not completely analysed. The purpose of a calculus is to state the premises in ideographic symbols in such a manner that all the conclusions implied can be drawn in accordance with rules of transformation analogous to those of mathematical operations. Thus thought is economized and accuracy ensured. In the first attempts to develop an adequate symbolism certain formal analogies with mathematical operations were stressed, sometimes with unfortunate results. The foundations of such an algebra of logic were laid down by George Boole (1815–64); it has been subsequently developed by Ernst Schroeder (1841–1902), Charles Saunders Peirce (1839–1914), Louis Couturat (1868–1914) and Mrs. Ladd-Franklin. Its transformation into an instrument for the logical analysis of mathematical concepts was not achieved until Peano invented a non-algebraic notation. This development cannot be followed in detail. All that can be attempted here is to give some account of certain fundamental notions employed in the subsequent logical analysis. We begin with the unanalysed concept of a class as a set of individual objects. Let us select from the universe of conceivable objects all those that are lawyers. This is the class "lawyers." In the same way, select the class "knights." It is assumed that the combination of two classes will itself be a class. There are two essential modes of combining classes, represented by the conjunctions "and" and "or." Thus we may form the class of those objects that are "lawyers and knights." This is the class "knighted lawyers." Obviously this mode of combination is analogous to mathematical multiplication. Hence, "knighted lawyers" is called the *logical product* of "knights" and "lawyers." Again, we may form the class of those objects that are either "knights" or "lawyers"; or of those who are either "solicitors" or are "barristers" and so on. Thus for example we obtain the class "solicitors or barristers." This mode of operation is obviously analogous to mathematical addition. Hence the class "solicitors or barristers" is called the *logical sum* of "solicitors" and "barristers." These two operations may be defined as follows:

The *logical product* of two classes is the class included in each of them and including every class included in each.

The *logical sum* of two classes is the class including each of them and included in every class including them.

In these definitions we have assumed the unanalysed concept of the relation of one class to another which contains it. This is analogous to the relation of part to whole. We may then say, somewhat metaphorically, that the logical product of two classes (x and y) is the *largest* class including them both; whereas their logical sum is the *smallest* class including them both. It is not necessary to assume that the elements of the logical sum should be exclusive. Following the mathematical analogies, we may represent the logical product of x and y by "$x \times y$" or by "xy"; and their logical sum by "$x+y$." Bearing in mind that these operations are to be completely formal, therefore completely general, we see that the symbols x and y must represent *any* classes. Also "xy" and "$x+y$" must also represent classes. But these may be classes the elements of which have no objects in common. Hence, since no objects are found in both classes, their logical product will be a class with no members. For example, the product of "squares" and "circles" is the class "squared circles." But there are no squared circles; hence, this is a class with no members. Or again, the product of "living beings" and "temples" is a class with no members. It follows, therefore, that in order to secure complete generality, we must admit the notion of an empty class, *i.e.*, a class with no members. This is called the "null-class." Let us represent the null-class by 0, standing for nothing. Clearly "$x+0=x$." Hence, from the above definition of the logical sum it follows that the null-class is contained in every class. Again, "$x \times 0=0$." That is, whatever x may be, the class "$x \times 0$" is the class containing both x and nothing. But what is both x and nothing is nothing. It is easy to see that the only class that remains unaltered no matter what class is selected from it is the class with no members, *i.e.*, the null-class.

Again following the mathematical analogies, we see that "$x \times 1=x$." From the above definition of the logical product of two classes, we see that, if x represents *any* class, "$x \times 1$" must represent that class which contains the individuals common to x and to 1. Hence, 1 represents the universe of conceivable objects, since this is the only class in which all the individuals in *any* class are contained. That is to say, any class x is contained in 1.

Inclusion and Implication.—So far we have been concerned only with the calculus of classes, and we have assumed the relation of "inclusion in." Boole constructed his calculus by means of the relation "equals." But we shall see that *equality* is not fundamental, for it can be defined in terms of *inclusion in.* The calculus of classes can be interpreted as a calculus of propositions if the literal symbols, x, y, etc., are regarded as the class of moments at which a proposition is true, or is false. Thus "$x=0$" would mean "x is false"; "$x=1$" would mean "x is true." There are, however, certain formal differences between the calculus of classes and the calculus of propositions, which makes their complete identification impossible. These differences cannot be discussed here. All that we can do is to show the bearing of this twofold interpretation upon the relations between propositions. We take as the fundamental relation "inclusion in." This is a primitive idea; hence, it is indefinable. Its meaning, therefore, can only be indicated. The relation "is included in" is frequently represented by $<$, owing to its formal analogy with "is less than." It is important to remember that $<$ as used in the logical calculus is an ideographic symbol and must not be translated as "less than." If now, we take x, y, etc., as representing classes, then "$x<y$" signifies that the class x is contained in, or makes part of, the class y. Hence, "$x<y$" can be read: "All the x's are y's."

Like "less than," $<$ has the important property of being asymmetrical. We can now see that "$=$" can be defined in terms of $<$, as follows:

$$\text{“}a=b \cdot = : a<b \cdot b<a\text{”}\ Df.$$

This definition affords a good example of logistic method. It must be observed that the symbol "$=$" which connects the two sides of the identity is not the same symbol as the "$=$" which connects a and b; for to the second $=$ belongs the symbol "*Df*" written at the end. That is, the symbol "$\ldots\ldots = \ldots\ldots Df$" must be taken as a whole. It signifies "is equivalent by definition." We shall see that this convention is of great importance in the development of logistic. The dot between "a<b" and "b<a" signifies the conjoint assertion of these two relations. This is analogous to the logical product of two classes. We see then, that the single relation "$=$" is equivalent to the simultaneous relation "a<b" and "b<a." The formal properties of equality can be deduced from this definition. Thus, for example, that it is symmetrical follows from the fact that it involves the conjunction of a relation and its converse. (*See* CONVERSION.) Again since, $<$ is transitive, and $=$ is defined in terms of $<$, it follows that $=$ is transitive. Thus we see that the properties of the defined relation "$=$" can be deduced from the properties of the fundamental relation. This fundamental relation, called *inclusion* for classes, is called *subsumption* for concepts, and *implication* for propositions. If now we substitute for x and y not the classes a and b, but the propositions p and q, then we read "p<q" as "p implies q." We can now define the equivalence of propositions in the same form as the equality of classes. Representing "is equivalent to" by "$\equiv$," we have:

$$\text{“}p\equiv q \cdot = \cdot p<q \cdot q<p\text{”}\ Df.$$

This can be read: "'p is equivalent to q' is the defined equivalent of 'p implies q' and 'q implies p'."

On the propositional interpretation of the calculus, p and q can have only the values 0 and 1, *i.e.*, "false" and "true." It must be borne in mind that we are throughout dealing with an extensional calculus. It follows that p is equivalent to q when, and only when, both are true, or both are false. These are called the truth-values of p and q. Thus the truth-value of p is *truth* when p is true, and falsehood when p is false. We here introduce an assumption that is not required in the calculus of classes but is required for the calculus of propositions, viz., that "The proposition, p, is equivalent to 'p is true'." Given that "not-p" is equivalent to "p is false," we have "$p=0 \cdot \equiv \cdot \text{not-}p=1$." It is convenient to write "$-p$" for "not-p," *i.e.*, for "p is false."

Now, we have seen that the null-class is contained in any class, x; and that any class, x, is contained in the universe 1. Symbolising this relation of inclusion by $<$, we have the following results:

$$0<x,\ x<1.\ 0<0,\ 1<1.$$

We can now state these results on the propositional interpretation. Let p and q represent any two propositions. Then if both are false, $p=q$ (*i.e.*, $p=0$; and $q=0$); if both are true, $p=q$ (*i.e.*, $p=1$, and $q=1$). In either of these cases p can be substituted for q, since we are concerned only with their truth-values, *i.e.*, their extensions. We can now rewrite the four combinations given above, in a form convenient for the propositional interpretation:

$$\text{(i) } -p<q;\ \text{(ii) } p<q;\ \text{(iii) } -p<-q;\ \text{(iv) } p<q.$$

Here $<$ denotes "implies." Thus we see from (i) that a false proposition implies any true proposition; and from (iii) that a false proposition implies any false proposition. Hence, *a false proposition implies any other proposition, true or false.* This is an inevitable consequence of the fact that the null-class is contained in every class. From (ii) and (iv) we see that a true proposition, q, is implied by any true proposition p, and from (i) that q is implied by any false proposition. Hence, *a true proposition is implied by any proposition.* The consequences given in italics are known as the "paradoxes of implication." They are not, however, paradoxes, but are the inevitable consequences of the extensional point of view of the calculus. The appearance of paradox is due to the confusion between implication and inference.

Propositional Functions and Descriptions.—So far, following the method of Boole, Peirce and Schroeder, we have taken the calculus of classes as fundamental and have interpreted it as applying either to classes or to propositions. This twofold interpretation has awkward results which cannot be discussed here. A more satisfactory method is to make the calculus of propositions fundamental and to derive the calculus of classes from it. This is the method developed by Bertrand Russell. Following his line of approach, we can now deal more precisely with the notion of a propositional function referred to above. A propositional function is an expression containing one or more variables, and is such that when appropriate values are substituted for the variables, it expresses a proposition. Thus "$\phi\hat{x}$" is a propositional function if the substitution of any symbol denoting an individual for x results in a proposition. For example, the substitution of the symbol A, representing a definite individual, in the function "$\hat{x}$ is a man," yields the determinate proposition "A is a man." It will be true if A is in fact the name of a man, false if A is not the name of a man. Individuals such as A,B,C, etc., which can be substituted for x in "$\hat{x}$ is a man" so as to make the resulting propositions true are the set of individuals satisfying the function. These are clearly the set of individuals who are human, *i.e.*, the class of *men.* Thus a class is the extension of a propositional function involving one variable. That is, it is the set of values which satisfy the function, and the function is a method of collecting together all the propositions in which the names of these individuals occur.

It must be noted that a proposition is true, or it is false. But a propositional function is always true, or sometimes true. This notion of being "always true" is quite different from being "true," for it means "true in all cases," whereas there are no cases of a proposition. It is this fact that gives rise to difficulty in the propositional interpretation of the class calculus. Let us write "$\phi\hat{x}$ always" for "$\phi\hat{x}$ is always true." Then, just as "$-p$" means "p is false," so "$-\phi\hat{x}$ always" means "$\phi\hat{x}$ is always false." Similarly, "$-\phi\hat{x}$ sometimes" means "$\phi\hat{x}$ is sometimes false."

We can now define the logical product and the logical sum of sets of propositions:

The *logical product* of a set of propositions is a propositional function that is always true, *i.e.*, true for all values of the variable.

The *logical sum* of a set of propositions is a propositional function that is sometimes true, *i.e.*, true for one or more values of the variable.

Russell employs the following convenient notation:

"$(x) \cdot \phi\hat{x}$" expresses "For all values of x, ϕx," *i.e.*, the logical product. "$(\exists x) \cdot \phi\hat{x}$" expresses "For some value of x, ϕx," *i.e.*, the logical sum. Thus, if ϕ represents "is mortal," then "$(x) . \phi\hat{x}$" would mean "Everything is mortal"; whilst "$(\exists x) \cdot \phi\hat{x}$" would mean "There is something which is mortal." Again, "ϕSocrates" would mean "Socrates is mortal."

Similarly, "(x)-$\phi\hat{x}$" asserts that "$\phi\hat{x}$ is always false." Hence, there is no set of values satisfying the function "$\phi\hat{x}$." Thus a propositional function that is always false determines the null-class.

We have so far assumed that the symbols that can be substituted for x in "ϕx" are *names, i.e.,* symbols for individuals. It is easy to see that there is an important difference between *names* and symbols which do not name an individual, but *describe* it, *e.g.,* "the oldest inhabitant," "the author of Waverley" and so on. Russell calls such symbols "definite descriptions" and he compares them with such symbols as "a man," "an author," which are called "indefinite descriptions." Thus a *definite description* is of the form "*the so-and-so*"; an *indefinite description* is of the form "*a so-and-so.*" The distinction between a name and a definite description is important. A name must be the name of *something*; that is, a name must have application. But a description need not apply, and in that case the propositional function in which the description occurs will be false. Thus "the author of the *Iliad*" will be a description that describes nothing, unless one, and only one, person wrote the *Iliad.* In this way we see that such phrases as "the author of Waverley," "the most perfect Being," "the man in the Moon" do not simply *name* individuals, but are descriptions which may, or may not, apply. It is clear that this analysis of descriptive phrases has an important bearing upon such traditional philosophical arguments as the ontological proof.

Just as every description of the form "The author of *Waverley*" has been falsely supposed to apply to something, so every grammatically correct sentence has been supposed to be significant. Hence arose certain difficulties known as "vicious-circle difficulties." To avoid these difficulties Bertrand Russell developed the theory of types. Very briefly we may state the theory as follows. It had been generally supposed that, given a function "$(x) \cdot \phi\hat{x}$," any values could be substituted for x, and that the result would be a significant proposition whether true or false. But Russell suggested that the difficulties could be avoided, if the values were restricted to those of a certain type, appropriate to the function. If an inappropriate value were substituted the result would be, not a false, but a meaningless proposition. As developed by Russell the theory of types avoided the contradiction of the vicious-circle difficulties, but itself depended upon the Axiom of Reducibility, which in turn gave rise to serious difficulties. The whole matter is too controversial to be dealt with here. A method which dispenses with the Axiom of Reducibility has been suggested by Frank P. Ramsey.

The Two Forms of Syllogism.—We can now see the exact nature of the distinction between the two premises of the syllogism that we considered before. "All men are mortal" asserts that for all values of the variables one propositional function implies another; whereas "Socrates is mortal" asserts that "Socrates" is a value that satisfies a given propositional function, *i.e.,* is a member of the class defined by the propositional function. This distinction was first recognized by *Gottlob Frege* and *Guiseppe Peano,* the second of whom denoted the relation of an individual to the class of which it is a member by ϵ. Let α denote a class. Then "$x\epsilon\alpha$" means "x is a member of the class α." We can now define the inclusion of one class in another in terms of implication. At this point we must distinguish "is included in" from "implies." Keeping $<$ for "implies," we will denote "is included in" by $\supset$. Then we obtain the following definition of "the class α is included in the class β."

$$\alpha \supset \beta : = \cdot x\epsilon\alpha <_x \cdot x\epsilon\beta \quad Df.$$

Here the subscript x has the same meaning as (x), viz. it means "for all values of x." Now write α for "men," β for "mortals" and x for "Socrates." Then we have:

$$\alpha \supset \beta \cdot x\epsilon\alpha <_x \cdot x\epsilon\beta \qquad (1)$$

Here we have made explicit the distinction between the two premises. Now consider the syllogism, "all men are mortal, all mortals are fallible, therefore all men are fallible." Using the same symbols as before and adding γ to denote the class of "fallible beings" the syllogism can be stated:

$$\alpha \supset \beta \cdot \beta \supset \gamma \cdot < \cdot \alpha \supset \gamma \qquad (2)$$

Again we see that the two syllogisms are of different forms. Syllogism (1) and (2) could be written in the notation of propositional functions as follows:

$$(x) \cdot \phi x < \psi x : \phi\gamma : < \psi\gamma \qquad (1)$$

$$(x) \cdot \phi x < \psi x : (x)\psi x < \psi\chi : < (x)\phi x < \chi x \qquad (2)$$

Here again the notation makes the distinction explicit.

The Calculus of Relations.—The earlier symbolic logicians made little, or no, attempt to deal with relations. Yet their importance is obvious. Most propositions of everyday life express relations between two or more terms, *e.g.,* "Brutus killed Caesar," "Peter gave Paul a sum of money for a reward," etc. Still keeping to the extensional point of view, we can see that relations can be regarded as a class of ordered couples, a class of ordered trios, etc. That is, just as a class is the set of values satisfying a propositional function involving one variable, so a relation is the set of values satisfying a propositional function involving two or more variables. Relations have, however, some properties which have no analogues for classes. These properties are of the utmost importance in the logistic development of mathematics, but they cannot be discussed here (*see* MATHEMATICS, FOUNDATIONS OF).

THE LOGISTIC DEVELOPMENT OF MATHEMATICS

Symbolic Logic and Mathematics.—Once symbolic logic was freed from its dependence upon the forms of ordinary algebra, it became an instrument of precision for the analysis of fundamental concepts. Moreover, in achieving its ideal of generality, logic and mathematics have become indistinguishable. That is to say, all the fundamental concepts of mathematics are defined in terms which are involved in any complicated process of thought, and are thus seen not to depend upon any specific notion such as that of discrete and continuous magnitude, as had been traditionally supposed. This position has been established in the only way in which it could have been established, viz., by the detailed working out of mathematics from purely logical concepts. This achievement is mainly due to the work of Frege, Peano, Russell and Whitehead, but it has recently been carried to a more satisfactory completion by Ludwig Wittgenstein and Frank P. Ramsey.

The method consists in the development of a system in which all the assumptions involved are made explicit, and all other propositions are deduced from these assumptions by the process of substituting for variables values of those variables, and by the use of defined equivalents. Frege laid the foundations of this logical analysis in the *Grundlagen der Arithmetik* (1884), *Grundgesetze der Arithmetik* (1893–1903) and various important articles in periodicals. In the latter book Frege developed arithmetic from purely logical premises. But his notation was so difficult that his work remained almost without influence upon subsequent investigators. Peano began in 1894 the publication of the *Formulaire de Mathématique,* in which he elaborated a symbolism fitted to perform the required analysis of fundamentals. Russell, using the notation of Peano, and basing his work upon the logical analysis of Frege, produced in 1910, in collaboration with Whitehead, the *Principia Mathematica,* which may be said to mark an epoch in the development of logistic. In this work we find an extreme logical rigour which results in a detailed analysis of *all* the concepts of mathematics. The advance on Peano consists in the fact that no postulates are required except those of logic; hence, the independence of various mathematical branches is no longer required. It is impossible here to do more than indicate the method employed.

In this system the negation of p, symbolised by "$\sim$p," which is read, "p is false," is taken as a primitive idea. Hence, we have p and $\sim$p. In order that deduction may be possible, there must be such a relation between one proposition and another that, if we know that the first is true, we can infer that the second is true. That is, we assume the fundamental principle "whatever is implied by a true proposition is true." Let p and q be two propositions between which this relation holds. Then we can state this relation as follows: "Either p is false or q is true." This is the logical sum of $\sim p$ and q. It is called *disjunction.* Assuming this relation as a second primitive idea, we can now define "implication" in terms of these two primitive ideas: *disjunction* and *negation*. Disjunction is symbolised by $\vee$. Hence, "$p \vee q$" means "either p or q." Thus we get:

$$“p < q \cdot = \cdot \sim p \vee q \ Df.”$$

This is the relation that holds between two propositions when it is not the case that the first is true and the second false. It is usually called "material implication." It is important to observe that this relation is not equivalent to formal deducibility. That is to say, from "$p < q$" we are not justified in asserting that it follows that "p can be inferred from q." In order that this latter relation should hold we need also the assertion that p is true. Thus, from "$p.p < q$" we can infer "q"; but from "$p < q$" alone we can only infer that it is not the case that p is true and q false. If this fact be remembered, the confusion between implication and inference, which gives rise to the appearance of paradox, will be avoided. Important though this relation of inferribility is, it is not required in the logistic development of mathematics.

It has been seen that in the system of *Principia Mathematica*, the relation of material implication is not assumed, but defined.

It must be noted that "definition" is not itself a primitive idea. A symbol, or set of symbols, is defined when some other set of symbols is given which can be substituted for it. Definition is, therefore, a symbolic device; it is technically convenient but not logically necessary. Nevertheless, the substitution for a given set of symbols of defined equivalents constitutes an important element in logistic method. Whereas in the development of a mathematical system the logical principles of proof have hitherto been taken for granted, this system employs formal principles which are used both as premises in the argument and as rules of deduction. There is required in addition a non-formal principle of deduction asserting that the primitive propositions apply to all the possible values of the variable propositions that occur in their statement. This assumption makes possible the substitution of sets of special cases of the original propositions, which make explicit the consequences of these propositions. In this way the whole system is developed from one, or more, primitive ideas and a few primitive propositions which are purely logical. Thus all the propositions of arithmetic are shown to follow from the analysis, in purely logical terms, of the fundamental ideas of arithmetic. In this way mathematics is reduced to pure logic, and the achievement of the ideal of form is complete.

LOGOCYCLIC CURVE: *see* Curves, Special.

LOGOGRAPHI, in Greek λογογράφοι, writers of λόγοι or compositions of any sort, especially in prose. (1) In Attic, professional speech-writers. (2) In modern usage (since C. F. Creuzer, d. 1858), pre-Herodotean writers of chronicles, from the doubtfully historical Cadmus of Miletus (*q.v.*) to Pherecydes (*q.v.*), all make extensive use of mythology, hence the importance of their fragments; their attempts at systematization and criticism are primitive. Their dialect is Ionic. Mention may be made of the following: Hecataeus of Miletus (550–476); Acusilaus of Argos,[1] who paraphrased in prose (correcting the tradition where it seemed necessary) the genealogical works of Hesiod; Charon of Lampsacus (*c.* 450), author of histories of Persia, Libya, and Ethiopia, of annals (ὧροι) of his native town, and of the chronicles of Lacedaemonian kings; Xanthus of Sardis in Lydia (*c.* 450), author of a history of Lydia; Hellanicus of Mytilene; Stesimbrotus of Thasos, opponent of Pericles and reputed author of a political pamphlet on Themistocles, Thucydides, and Pericles; Hippys and Glaucus, both of Rhegium, the first the author of histories of Italy and Sicily, the second of a treatise on ancient poets and musicians; Damastes of Sigeum, pupil of Hellanicus, author of genealogies of the combatants before Troy (an ethnographic and statistical list), of short treatises on poets, sophists, and geographical subjects.

Bibliography.—*Fragments*, in C. W. Müller, *Fragmenta Historicorum Graecorum*, and F. Jacoby, *Fragmente der griechischen Historiker: comment*. *See* also Christ-Schmid, Geschichte d. gr. Literatur, 6, p. 449.

LOGOS, a common term in ancient philosophy and theology. It expresses the idea of an immanent reason in the world, and, under various modifications, is met with in Indian, Egyptian and Persian systems of thought. But the idea was developed mainly in Hellenic and Hebrew philosophy, and we may distinguish the following stages:

1. **The Hellenic Logos.**—To the Greek mind, which saw in the world a κόσμος (ordered whole), it was natural to regard the world as the product of reason, and reason as the ruling principle in the world. So we find a Logos doctrine more or less prominent from the dawn of Hellenic thought to its eclipse. It rises in the realm of physical speculation, passes over into the territory of ethics and theology, and makes its way through at least three well-defined stages. These are marked off by the names of Heraclitus of Ephesus, the Stoics and Philo.

It acquires its first importance in the theories of Heraclitus (6th century B.C.), who, trying to account for the aesthetic order of the visible universe, broke away to some extent from the purely physical conceptions of his predecessors and discerned at work in the cosmic process a λόγος analogous to the reasoning power in man. On the one hand the Logos is identified with γνώμη and connected with δίκη, which latter seems to have the function of correcting deviations from the eternal law that rules in things. On the other hand it is not positively distinguished either from the ethereal fire, or from the εἱμαρμένη and the ἀναγκη according to which all things occur. Heraclitus holds that nothing material can be thought of without this Logos, but he does not conceive the Logos itself to be immaterial. Whether it is regarded as in any sense possessed of intelligence and consciousness is a question variously answered. But there is most to say for the negative. This Logos is not one above the world or prior to it, but in the world and inseparable from it. Man's soul is a part of it. It is *relation*, therefore, as Schleiermacher expresses it, or reason, not speech or word. And it is objective, not subjective, reason. Like a law of nature, objective in the world, it gives order and regularity to the movement of things, and makes the system rational.

The failure of Heraclitus to free himself entirely from the physical hypotheses of earlier times prevented his speculation from influencing his successors. With Anaxagoras a conception entered which gradually triumphed over that of Heraclitus, namely, the conception of a supreme, intellectual principle, not identified with the world but independent of it. This, however, was νοῦς, not Logos. In the Platonic and Aristotelian systems, too, the theory of ideas involved an absolute separation between the material world and the world of higher reality, and though the term Logos is found the conception is vague. With Plato the term selected for the expression of the principle to which the order visible in the universe is due is νοῦς or σοφία, not λόγος. It is in the pseudo-Platonic *Epinomis* that λόγος appears as a synonym for νοῦς. In Aristotle, again, the principle which sets all nature under the rule of thought, and directs it towards a rational end, is νοῦς, or the divine spirit itself; while λόγος is a term with many senses, used as more or less identical with a number of phrases, οὗ ἕνεκα, ἐνέργεια, ἐντελέχεια, οὐσία, εἶδος, μορφή, etc.

In the reaction from Platonic dualism, however, the Logos doctrine reappears in great breadth. It is a capital element in the system of the Stoics. With their teleological views of the world they naturally predicated an active principle pervading it and determining it. This operative principle is called both Logos and God. It is conceived of as material, and is described in terms used equally of nature and of God. There is at the same time the special doctrine of the λόγος σπερματικός, the seminal

[1]There is some doubt as to whether this Acusilaus was of Peloponnesian or Boeotian Argos. Possibly there were two of the name. For an example of the method of Acusilaus *see* Bury, *op. cit.* p. 19.

Logos, or the law of generation in the world, the principle of the active reason working in dead matter. This parts into λόγοι σπερματικοί, which are akin, not to the Platonic ideas, but rather to the λόγοι ἔνυλοι of Aristotle. In man, too, there is a Logos which is his characteristic possession, and which is ἐνδιάθετος, as long as it is a thought resident within his breast, but προφορικός when it is expressed as a word. This distinction between Logos as *ratio* and Logos as *oratio*, so much used subsequently by Philo and the Christian fathers, had been so far anticipated by Aristotle's distinction between the ἔξω λόγος and the λόγος ἐν τῇ ψυχῇ. It forms the point of attachment by which the Logos doctrine connected itself with Christianity. The Logos of the Stoics (*q.v.*) is a reason in the world gifted with intelligence, and analogous to the reason in man.

JEWISH CONCEPTS

2. **The Hebrew Logos.**—In the later Judaism the earlier anthropomorphic conception of God and with it the sense of the divine nearness had been succeeded by a belief which placed God at a remote distance, severed from man and the world by a deep chasm. The old familiar name Yahweh became a secret; its place was taken by such general expressions as the Holy, the Almighty, the Majesty on High, the King of Kings, and also by the simple word "Heaven." Instead of the once powerful confidence in the immediate presence of God there grew up a mass of speculation regarding on the one hand the distant future, on the other the distant past. Various attempts were made to bridge the gulf between God and man, including the angels, and a number of other hybrid forms of which it is hard to say whether they are personal beings or abstractions. The Wisdom, the Shekinah or Glory and the Spirit of God are intermediate beings of this kind and even the Law came to be regarded as an independent spiritual entity. Among these conceptions that of the Word of God had an important place, especially the creative Word of Genesis i. Here, as in the other cases, we cannot always say whether the Word is regarded as a mere attribute or activity of God, or an independent being, though there is a clear tendency towards the latter. The ambiguity lies in the twofold purpose of these activities: (1) to establish communication with God; (2) to prevent direct connection between God and the world. The word of the God of revelation is represented as the creative principle (*e.g.* Gen. i. 3; Psalm xxxiii. 6), as the executor of the divine judgments (Hosea vi. 5), as healing (Psalm cvii. 20), as possessed of almost personal qualities (Isaiah lv. 11; Psalm cxlvii. 15). Along with this comes the doctrine of the angel of Yahweh, the angel of the covenant, the angel of the presence, in whom God manifests Himself and who is sometimes identified with Yahweh or Elohim (Gen. xvi. 11, 13; xxxii. 29–31; Exod. iii. 2; xiii. 21), sometimes distinguished from Him (Gen. xxii. 15, etc.; xxiv. 7; xxviii. 12, etc.), and sometimes presented in both aspects (Judges ii., vi.; Zech. i.). To this must be added the doctrine of Wisdom, given in the books of Job and Proverbs. At one time it is exhibited as an attribute of God (Prov. iii. 19). At another it is strongly personified, so as to become rather the creative thought of God than a quality (Prov. viii. 22). Again it is described as proceeding from God as the principle of creation and objective to Him. In these and kindred passages (Job xv. 7, etc.) it is on the way to become hypostatized.

The Hebrew conception is partially associated with the Greek in the case of Aristobulus, the predecessor of Philo, and, according to the fathers, the founder of the Alexandrian school. He speaks of Wisdom in a way reminding us of the book of Proverbs. The pseudo-Solomonic *Book of Wisdom* (generally supposed to be the work of an Alexandrian flourishing somewhere between Aristobulus and Philo) deals both with the Wisdom and with the Logos. It fails to hypostatize either. But it represents the former as the framer of the world, as the power or spirit of God, active alike in the physical, the intellectual and the ethical domain and apparently objective to God. In the Targums, on the other hand, the three doctrines of the word, the angel and the wisdom of God converge in a very definite conception. In the Jewish theology God is represented as purely transcendent, having no likeness of nature with man and making no personal entrance into history. Instead of the immediate relation of God to the world the Targums introduce the ideas of the *Mēmrā* (word) and the *Shechīnā* (real presence). This Memra (=Ma'amar) or, as it is also designated, *Dibbūrā*, is a hypostasis that takes the place of God when direct intercourse with man is in view. In all those passages of the Old Testament where anthropomorphic terms are used of God, the Memra is substituted for God. The Memra proceeds from God and retains the creaturely relation to God. It does not seem to have been identified with the Messiah.

3. **Philo.**—In the Alexandrian philosophy, as represented by the Hellenized Jew Philo, the Logos doctrine assumes a leading place and shapes a new career for itself. Philo's doctrine is moulded by three forces—Platonism, Stoicism and Hebraism. He detaches the Logos idea from its connection with Stoic materialism and attaches it to a thorough-going Platonism. It is Plato's idea of the Good regarded as creatively active. Hence, instead of being merely immanent in the Cosmos, it has an independent existence. Platonic too is the doctrine of the divine architect who seeks to realize in the visible universe the archetypes already formed in his mind. Philo was thus able to make the Logos theory a bridge between Judaism and Greek philosophy. It preserved the monotheistic idea yet afforded a description of the Divine activity in terms of Hellenic thought; the Word of the Old Testament is one with the λόγος of the Stoics. And thus in Philo's conception the Logos is much more than "the principle of reason, informing the infinite variety of things, and so creating the World-Order"; it is also the divine dynamic, the energy and self-revelation of God. The Stoics indeed sought, more or less consciously, by their doctrine of the Logos as the Infinite Reason to escape from the belief in a divine Creator, but Philo, Jew to the core, starts from the Jewish belief in a supreme, self-existing God, to whom the reason of the world must be subordinated though related. The conflict of the two conceptions (the Greek and the Hebrew) led him into some difficulty; sometimes he represents the Logos as an independent and even personal being, a "second God," sometimes as merely an aspect of the divine activity. And though passages of the first class must no doubt be explained figuratively —for Philo would not assert the existence of two Divine agents— it remains true that the two conceptions cannot be fused. The Alexandrian philosopher wavers between the two theories and has to accord to the Logos of Hellas a semi-independent position beside the supreme God of Judaea. He speaks of the Logos (1) as the agency by which God reveals Himself, in some measure to all men, in greater degree to chosen souls. The appearances recorded in the Old Testament are manifestations of the Logos, and the knowledge of God possessed by the great leaders and teachers of Israel is due to the same source; (2) as the agency whereby man, enmeshed by illusion, lays hold of the higher spiritual life and rising above his partial point of view participates in the universal reason. The Logos is thus the means of redemption; those who realize its activity being emancipated from the tyranny of circumstance into the freedom of the eternal.

CHRISTIAN ADAPTATIONS

4. **The Fourth Gospel.**—Among the influences that shaped the Fourth Gospel that of the Alexandrian philosophy must be assigned a distinct, though not an exaggerated, importance. There are other books in the New Testament that bear the same impress, the epistles to the Ephesians and the Colossians, and to a much greater degree the epistle to the Hebrews. The development that had thus begun in the time of Paul reaches maturity in the Fourth Gospel, whose dependence on Philo appears (1) in the use of the allegorical method, (2) in many coincident passages, (3) in the dominant conception of the Logos. The writer narrates the life of Christ from the point of view furnished him by Philo's theory. True, the Logos doctrine is only mentioned in the prologue to the Gospel, but it is presupposed throughout the whole book. The author's task indeed was somewhat akin to that of Philo, "to transplant into the world of Hellenic culture a revelation originally given through Judaism." This is not to say that he holds the Logos doctrine in exactly the same form as Philo. On the contrary, the fact that he starts from an actual knowledge of

the earthly life of Jesus, while Philo, even when ascribing a real personality to the Logos, keeps within the bounds of abstract speculation, leads him seriously to modify the Philonic doctrine. Though the Alexandrian idea largely determines the evangelist's treatment of the history, the history similarly reacts on the idea. The prologue is an organic portion of the Gospel and not a preface written to conciliate a philosophic public. It assumes that the Logos idea is familiar in Christian theology, and vividly summarizes the main features of the Philonic conception—the eternal existence of the Logos, its relation to God (πρὸς τὸν θεόν, yet distinct), its creative, illuminative and redemptive activity. But the adaptation of the idea to John's account of a historical person involved at least three profound modifications:—(1) The Logos, instead of the abstraction or semi-personification of Philo, becomes fully personified. The Word that became flesh subsisted from all eternity as a distinct personality within the divine nature. (2) Much greater stress is laid upon the redemptive than upon the creative function. The latter indeed is glanced at ("All things were made by him"), merely to provide a link with earlier speculation, but what the writer is concerned about is not the mode in which the world came into being but the spiritual life which resides in the Logos and is communicated by him to men. (3) The idea of λόγος as Reason becomes subordinated to the idea of λόγος as Word, the expression of God's will and power, the outgoing of the divine energy, life, love and light. Thus in its fundamental thought the prologue of the Fourth Gospel comes nearer to the Old Testament (and especially to Gen. i.) than to Philo. As speech goes out from a man and reveals his character and thought, so Christ is "sent out from the Father," and as the divine Word is also, in accordance with the Hebrew idea, the medium of God's quickening power.

What John thus does is to take the Logos idea of Philo and use it for a practical purpose—to make more intelligible to himself and his readers the divine nature of Jesus Christ.

5. **The Early Church.**—In many of the early Christian writers, as well as in the heterodox schools, the Logos doctrine is influenced by the Greek idea. The Syrian Gnostic Basilides held (according to Irenaeus i. 24) that the Logos or Word emanated from the νοῦς or personified reason, as this latter emanated from the unbegotten Father. The completest type of Gnosticism, the Valentinian, regarded Wisdom as the last of the series of aeons that emanated from the original Being or Father, and the Logos as an emanation from the first two principles that issued from God, Reason and Truth. Justin Martyr, the first of the sub-apostolic fathers, taught that God produced of His own nature a rational power, His agent in creation, who now became man in Jesus. With Tatian the Logos is the beginning of the world, the reason that comes into being as the sharer of God's rational power. With Athenagoras He is the prototype of the world and the energizing principle of things. Theophilus taught that the Logos was in eternity with God as the counsellor of God, and that when the world was to be created God sent forth this counsellor from Himself as the λόγος προφορικός, yet so that the begotten Logos did not cease to be a part of Himself. With Hippolytus the Logos, produced of God's own substance, is both the divine intelligence that appears in the world as the Son of God, and the idea of the universe immanent in God. The early Sabellians held that the Logos was a faculty of God, the divine reason, immanent in God eternally, but not in distinct personality prior to the historical manifestation in Christ. Origen, referring the act of creation to eternity instead of to time, affirmed the eternal personal existence of the Logos. In relation to God this Logos or Son was a copy of the original and as such inferior to that. In relation to the world he was its prototype and its redeeming power.

In the later developments of Hellenic speculation nothing essential was added to the doctrine of the Logos. Philo's distinction between God and His rational power or Logos in contact with the world was generally maintained by the eclectic Platonists and Neo-Platonists. By some of these this distinction was carried out to the extent of predicating (as was done by Numenius of Apamea) three Gods:—the supreme God; the second God, or Demiurge or Logos; and the third God, or the world. Plotinus explained the λόγοι as constructive forces, proceeding from the ideas and giving form to the dead matter of sensible things.

See the histories of philosophy and theology, and works quoted under HERACLITUS; STOICS; PHILO; JOHN, THE GOSPEL OF ST., etc., and for a general summary of the growth of the Logos doctrine, E. Caird, *Evolution of Theology in the Greek Philosophers* (1904), vol. ii.; A. Harnack, *History of Dogma;* E. F. Scott, *The Fourth Gospel,* ch. v. (1906); J. M. Heinze, *Die Lehre vom Logos in der griech. Philosophie* (1872); J. Réville, *La Doctrine du Logos* (1881); Aal, *Gesch. d. Logos-Idee* (1899); and the *Histories of Dogma,* by F. Loofs, R. Seeberg. (S. D. F. S.; A. J. G.)

LOGOTHETE, originally the title of a variety of administrative officials in the Byzantine empire, *e.g.,* the λογοθέτης τοῦ δρόμου, who was practically the equivalent of the modern postmaster-general; and the λογοθέτης τοῦ στρατιωτικοῦ, the logothete of the military chest. Gibbon defines the great Logothete as "the supreme guardian of the laws and revenues," who "is compared with the chancellor of the Latin monarchies." From the Eastern empire the title was borrowed by the West, though it only became firmly established in Sicily, where the *logotheta* occupied the position of chancellor elsewhere, his office being equal if not superior to that of the *magnus cancellarius.*

See Du Cange, *Glossarium, s.v. Logotheta.*

LOGROÑO, an inland province of northern Spain, the smallest of the eight provinces formed in 1833 out of Old Castile; bounded N. by Burgos, Álava and Navarre, W. by Burgos, S. by Soria and E. by Navarre and Saragossa. Pop. (1940) 221,160; area, 1,946 sq.mi. The portion skirting the Ebro forms a spacious and for the most part fertile undulating plain, called La Rioja. In the west the Cerro de San Lorenzo, the culminating point of the Sierra de la Demanda, rises 7,562 ft., and in the south the Pico de Urbion reaches 7,388 ft. The products of the province are chiefly cereals, good oil and wine (especially in the Rioja), fruit, silk, flax and honey. Large tracts of country are covered with vines and olive groves. Iron and argentiferous lead are mined in small quantities. A railway along the right bank of the Ebro connects the province with Saragossa, and from Miranda there is railway communication with Madrid, Bilbao and France. Besides Logroño and Calahorra (*qq.v.*) the only towns with over 5,000 inhabitants are Haro (8,353), Alfaro (8,067) and Arnedo (6,008). The province fell into the hands of Francisco Franco's insurgents in the first stages of the civil war of 1936–39.

LOGROÑO, the capital of the Spanish province of Logroño, on the right bank of the river Ebro and on the Saragossa-Miranda de Ebro railway. Pop. (1940) 43,709 (mun., 46,182). The district was in ancient times inhabited by the *Berones* or *Verones* of Strabo and Pliny, and their *Varia* is identified with the modern suburb of the city of Logroño now known as Varea. Logroño was named by the Romans *Juliobriga* and afterwards *Lucronius.* It was unsuccessfully besieged by the French in 1521, and occupied by them from 1808 to 1813. Nationalists captured it during the civil war of 1936–39. Logroño is an ancient walled town, finely situated on a hill 1,204 ft. high. Its bridge of twelve arches across the Ebro was built in 1138, but has frequently been restored. The crooked but picturesque alleys of the older quarters are in striking contrast with the broad avenues and squares laid out in modern times. Commercial centre of the fertile plain of the Rioja, Logroño has an important trade in wine.

LOGROSCINO (or LO GROSCINO), **NICOLA** (1700?–1763?), Italian musical composer, was born at Naples and was a pupil of Durante. In 1738 he collaborated with Leo and others in the hasty production of *Demetrio;* in the autumn of the same year he produced a comic opera *L'inganno per inganno,* the first of a long series of comic operas, the success of which won him the name of "il Dio dell' opera buffa." He went to Palermo, probably in 1747, as a teacher of counterpoint; as an opera composer he is last heard of in 1760, and is supposed to have died about 1763. As a musical humorist, however, he deserves remembrance, and may justly be classed alongside of Rossini.

LOGUE, MICHAEL (1840–1924), Irish ecclesiastic, was born at Kilmacrenan, Co. Donegal, on Oct. 1, 1840. He was appointed professor of theology and belles-lettres at the Irish College in Paris, where he was ordained a priest in 1866. He became Bishop of Raphoe in 1879, archbishop of Armagh in 1887, and in 1893 was raised to the cardinalate. During World War I he deprecated participation by the clergy in Sinn Fein agitations, but in 1918 opposed conscription on moral grounds. In 1919 and 1921 he rigorously denounced the campaign of murder against the police and the military, at the same time criticising severely the policy and methods of the British Government. He died at Armagh on Nov. 19, 1924.

LOGWOOD, an important dyestuff for fabrics made from fibres of vegetable origin. Logwood comes into commerce in blocks weighing about 400lb., which are hard and dense and possess a brown-red colour. It was imported into Europe soon after the discovery of South America, and has been cultivated in Jamaica since the year 1715. Logwood is the heartwood of the *Haematoxylon campechianum* (family *Leguminosae*), a tree distinguished by its peculiar ribbed appearance. It is largely employed for the production of black and compound shades on woollen material, mainly in conjunction with a chromium mordant, and for the black dyeing of silk. "Logwood extract," obtained by lixiviating the freshly cut wood with water and evaporating the solution in vacuo, is manufactured in the neighbourhood of the plantations, and imported into Great Britain for dyeing purposes. Logwood contains the colouring principle *haematoxylin*, $C_{16}H_{14}O_6.3H_2O$, which was first isolated by Chevreul in 1810. This, which is not a dyestuff, when oxidized, readily passes into *haematein*, $C_{16}H_{12}O_6$, the true colouring matter, and such an oxidizing process is now applied to logwood extract, and the so-called "haematein paste" which is largely in use is a product of this character. Unaged extracts can, however, also be employed for dyeing when an oxidizing mordant is employed. The constitution of haematoxylin and haematein have been elucidated by the researches of W. H. Perkin, R. Robinson and their pupils (*Chem. Soc. Trans.*, 1902, etc.). (A. G. P.)

LOHARU, an Indian state, in the southeast corner of the Punjab. Area, 226 sq.mi.; pop. (1941) 27,892; estimated gross revenue, £9,500. The town of Loharu had a population in 1931 of 2,956.

LOHENGRIN, the hero of the German version of the legend of the knight of the swan. The story is based on two common motives: the metamorphosis of human beings into swans, and the curious wife whose question brings disaster. Lohengrin's guide (the swan) was originally the little brother who, in one version of "the Seven Swans," was compelled through the destruction of his golden chain to remain a swan. The swan played a part in classical mythology as the bird of Apollo, and in Scandinavian lore the swan maidens, who have the gift of prophecy, constantly appear. The wife's inquisitiveness is "Cupid and Psyche" again, and bore in mediaeval times a similar mystical interpretation. The incidents of "Lohengrin" are localized on the Lower Rhine. By the Germans the tale was attached loosely to the Grail legend (*see* GRAIL, THE HOLY and PERCEVAL); in France it was adapted to glorify the family of Godfrey de Bouillon.

The German story appears at the end of Wolfram von Eschenbach's *Parzival*, where Parzival's son, Loherangrîn (*i.e.*, Garin le Loherain [*q.v.*], or Garin of Lorraine) is sent from the castle of the Grail to the help of the young duchess of Brabant. Guided by the swan he reaches Antwerp, and marries the lady on condition that she shall not ask his origin. On the breach of this condition years afterwards Loherangrîn departs, leaving sword, horn and ring behind him. About 1290, a Bavarian disciple of Wolfram's developed the story into an epic of nearly 8,000 lines, incorporating episodes of Lohengrin's prowess in tournament, his wars with Henry I. against the heathen, and incidentally providing a picture of noble life. The epic of Lohengrin is put by the anonymous writer into the mouth of Wolfram, who is made to relate it during the Contest of the Singers at the Wartburg, and the poem is thus linked to German tradition. Its connection with Parzival implies a mystic application. The consecrated wafer shared by Lohengrin and the swan is the means taken by the poet to give the tale the character of a Christian allegory. The story was followed in its main outlines by Wagner in his opera.

The French legend is attached to the house of Bouillon, and though William of Tyre refers to it about 1170 as fable, it was incorporated without question by later annalists. It forms part of the cycle of the *chansons de geste* dealing with the crusade, and relates how Helyas, knight of the swan, is guided by the swan to help the duchess of Bouillon and marries her daughter Ida or Beatrix in circumstances exactly parallel to the adventures of Lohengrin and Elsa of Brabant. Their daughter marries Eustache, count of Boulogne, and has three sons, the eldest of whom, Godfrey, is the future king of Jerusalem. But in French story Helyas is not the son of Parzival, but of the king of Lillefort, and the story of his birth, of himself, his five brothers and one sister is but the fairy-tale of "the Seven Swans" persecuted by the wicked grandmother. The house of Bouillon was not alone in claiming the knight as an ancestor, and the tradition probably originally belonged to the house of Cleves.

See *Lohengrin*, ed. Rückert (Quedlinburg and Leipzig, 1858); another version of the tale, *Lorengel*, is edited in the *Zeitschr. für deutsches Altertum* (vol. 15); modern German translation of *Lohengrin*, by H. A. Junghaus (Leipzig, 1878); Conrad von Würzburg's fragmentary *Schwanritter*, ed. F. Roth (Frankfurt, 1861). *See* Elster, *Beiträge zur Kritik des Lohengrin* (Halle, 1884), and R. Heinrichs, *Die Lohengrindichtung und ihre Deutung* (Hamm i. West., 1905).

French Versions.—Reiffenberg, *Le Chevalier au cygne et Godfrey de Bouillon* (1846–48), in *Mon. pour servir à l'hist. de la province de Namur;* C. Hippeau, *La Chanson du chevalier au cygne* (1874); H. A. Todd, *La Naissance du chevalier au cygne, an inedited French poem of the 12th cent.* (Mod. Lang. Assoc., Baltimore, 1889); *cf.* the Latin tale by Jean de Haute Seille (Johannes de Alta Silva) in his *Dolopathos* (ed. Oesterley, Strasbourg, 1873).

English Versions.—In England the story first appears in a short poem preserved among the Cotton mss. of the British Museum and entitled *Chevelere assigne.* This was edited by Utterson in 1820 for the Roxburghe club, and again by Gibbs in 1868 for the E.E.T.S., with a set of photographs of a 14th-century ivory casket, on which the story is depicted in 36 compartments. An English prose romance, *Helyas Knight of the Swan*, translated by Robert Copland, and printed by W. Copland about 1550, is founded on a French romance *La Génealogie . . . de Godeffroy de Boulin* (pr. 1504) and is reprinted by Thoms in *Early Prose Romances*, vol. iii. It was also printed by Wynkyn de Worde in 1512. A modern edition was issued in 1901 from the Grolier club, New York.

LOHMANN, GEORGE ALFRED (1865–1901), English cricketer, son of Stewart Lohmann, stockbroker, was born in London on June 2, 1865, and educated at Louvain School, Wandsworth. He worked on the Stock Exchange, but in 1884 became a professional cricketer, and played for Surrey. Lohmann was at the height of his form in the years 1888–90. From 1886, for ten years, he played in the Gentlemen *v.* Players matches, and during this period three times visited Australia. It was at Sydney in 1887, 1888 and 1892, that his best bowling was seen. Surrey's position in cricket was largely due to his skill as a bowler and to his all-round excellence. In 1893 he visited South Africa for his health, but returned to play for Surrey again in 1895. The England *v.* Australia match at Lords in 1896 witnessed his last appearance in first-class cricket. He returned to South Africa, where he died at Matjesfontein on Dec. 1, 1901.

LOIN, that part of an animal lying between the upper part of the hip-bone and the last of the false ribs on either side of the backbone, hence the butcher's term for a joint of meat cut from that part of the body. The upper part of a loin of beef is known as the "surloin," commonly corrupted into "sirloin." In the plural the word is a term for the lower part of the human body at the junction with the legs, covered by the loin-cloth, the almost universal garment among primitive peoples.

LOIRE, a department of central France, made up in 1793 of the old district of Forez and portions of Beaujolais and Lyonnais, all formerly included in the province of Lyonnais. Pop. (1936) 650,226. Area 1,853 square miles. It is bounded north by the department of Saône-et-Loire, east by those of Rhône and Isère, south by Ardèche and Haute-Loire, and west by Puy-de-Dôme and Allier. From 1790 to 1793 it constituted, along with that of Rhône, a single department (Rhône-et-Loire). The river Loire rises in the department of Haute Loire to the south but traverses the department of Loire from south to north, and that department reaches west to the Mts. du Forez and east to the hills edging the Rhône valley, going beyond these to reach that river just south of Vienne. The valley floor in the south is the basin of Forez, an ancient lake floored by Tertiary strata, and the Loire, after subsequently passing through narrow defiles, enters the smaller basin of Roanne, also an old lake basin similarly floored. The hill frame is mainly formed of Archaean and Carboniferous rocks set in north-east to south-west lines to form the Mt. Pilat (4,705 ft.), Mts. du Lyonnais, Mts. du Beaujolais and Mts. du Charolais on the east, and the Mts. du Forez (Pierre sur Haute, 5,381 ft.) on the west. The climate on the heights is cold and healthy, it is unwholesome in the marshy plain of Forez, mild in the valley of the Rhône. The annual rainfall varies from 39 to 48 in. on the Forez mountains, but only reaches 20 to 24 in. in the vicinity of Montbrison. The plains of Forez and Roanne produce wheat and rye, and some oats, barley and colza. The vine is cultivated in the valley of the Rhône, on the lower slopes of the Forez mountains and on the hills west of the plain of Roanne. The forests of Mt. Pilat and the Forez chain yield good-sized pines and wood for mining purposes. The so-called Lyon chestnuts are to a large extent obtained from Forez; the woods and pasture lands of Mt. Pilat yield medicinal plants, such as mint. The pasture lands of the plain and mountains of Forez support live stock, notably the famous Charolais oxen. Poultry-rearing and bee-keeping are considerable industries. The department is rich in mineral springs, the waters of St. Galmier, Sail-sous-Couzan, St. Romain-le-Puy and St. Alban being largely exported. The chief wealth of the department lies in the coal deposits of the basin of St. Étienne (*q.v.*), the second in importance in France; quarrying is also active. Metal-working industries are centred in the south-east of the department, where are the great manufacturing towns of St. Étienne, Rive-de-Gier, St. Chamond and Firminy. At St. Étienne there is a national factory of arms, in which as many as 10,000 were employed; it makes cycles, motorcars, dynamos and accessories for electric lighting, apparatus for making acetylene gas, locks, edge-tools, common cutlery, chain cables for the mines, files, rails, etc. The glass industry is carried on at Rive-de-Gier and St. Galmier. St. Étienne and St. Chamond are centres for the fabrication of silk ribbons, elastic ribbons and laces, and the dressing of raw silks. The arrondissement of Roanne manufactures cotton stuffs, muslins and the like. That of Montbrison produces table linen. The department has numerous dye-works, flour-mills, paper works, tanyards, brickworks, silk-spinning works and hat factories. It is served by the P.L.M. railway, Roanne being the junction of important lines from Paris to Lyon and St. Étienne. Within the department the Loire is hardly used for commercial navigation; there are canals from Roanne to Digoin (13 mi. in the department), and from Givors to Rive-de-Gier (7 mi.) and the Rhone (7 mi.).

Loire comprises three arrondissements—St. Étienne, Montbrison and Roanne—with 32 cantons and 338 communes. It is in the region of the XIII. army corps (Clermont-Ferrand) and the *diocèse* and *académie* (educational division) of Lyon, where also is its court of appeal. St. Étienne is the capital, other leading towns being Roanne, Montbrison, Rive-de-Gier, St. Chamond, Firminy and Le Chambon. St. Bonnet-le-Château, besides old houses, has a church of the 15th and 16th centuries, containing paintings of the 15th century; St. Rambert and St. Romain-le-Puy have priory churches of the 11th century; and at Charlieu there are remains of a Benedictine abbey founded in the 9th century, including a porch decorated with fine Romanesque carving, old houses, etc.

LOIRE, the longest river of France, rising at 4,500 ft. in the recent volcanic peak of Gerbier de Jonc on the central plateau, and flowing north and west to the Atlantic. After a course of 18 m. it follows a picturesque channel along the foot of the basaltic rocks of Le Puy district, through narrow gorges and small plains. At Vorey, it is joined by the Arzon (left) and becomes navigable for rafts. The north-westerly direction of the Loire and its affluent the Allier is due to a tilting of the central plateau of France in Tertiary times so that the river valleys are filled with Tertiary deposits, on to which the Loire flows after passing the gorges of St. Victor. It again penetrates the hills of Carboniferous rocks before reaching the plain of Roanne. In this course it is joined by a large number of streams, the most important being the Coise (right), the Lignon du Nord and the Aix (left). Below Roanne the Loire is accompanied by a canal to Digoin (35 m.), thence by the so-called "lateral canal of the Loire" to Briare (122 m.).

At Digoin the Loire receives the Arroux, and gives off the canal du Centre (which utilizes the valley of the Bourbince) to Chalon-sur-Saône. Before reaching Nevers the Loire passes off the central plateau and on to the Jurassic rocks which form the rim of the Paris basin, over which rocks it flows in a northerly direction. Just beyond Nevers it is joined by the Allier (left); this river rises 30 m. S.W. of the Loire and follows an almost parallel course. Above Nevers the Loire is joined by the Aron (right), along which a canal proceeds northward, and below the confluence of the Allier gives off the canal du Berry to Bourges. Near Sancerre the river leaves the Jurassic rocks and has worn a valley through the Cretaceous uplands. At Briare it gives off a canal northward to the Seine. Between Gien and Blois the river flows in a wide arc across the Tertiary rocks of the Paris basin, passing Orléans, whence the canal d'Orléans, following the river Cens, communicates with the Briare canal. Passing Blois the Loire receives (right) the Cisse, and, after passing Tours, the three important left-hand tributaries of the Cher, Indre and the Vienne. Below Saumur it is frequently divided by long sandy islands fringed with osiers and willows; while upon arriving at Les Ponts-de-Cé (south of Angers) it is split into several distinct branches and studded with islands. At Angers it passes off the Cretaceous and on to the Palaeozoic and Archaean rocks of the Armorican massif.

The principal tributaries are: left, the Thouet at Saumur, the Layon and the Evre; right: the Authion, and, most important tributary of all, the Maine, formed by the junction of the rivers Mayenne, Sarthe and Loir. It receives the Erdre (right) at Nantes and the Sèvre-Nantaise (left), and farther on the canalized Achenau (left) and the navigable Etier de Méan (right) near St. Nazaire. Below Nantes, between which point and La Martinière (below Pellerin) the channel is embanked, the river is known as the Loire Maritime and widens out between marshy shores, passing Paimboeuf on the left and finally St. Nazaire, where it is $1\frac{1}{2}$ m. broad. The length of the channel of the Loire is about 625 m. A lateral canal, known as the Maritime canal of the Loire, between Le Carnet and La Martinière enables large ships to ascend to Nantes. It is $9\frac{1}{2}$ m. long, and $19\frac{1}{2}$ (capable of being increased to 24) ft. deep. At each end is a lock 405 ft. long by 59 ft. wide. The canal de Nantes à Brest connects this city with Brest.

The Loire is navigable only in a very limited sense. During the drought of summer thin and feeble streams thread their way between the sandbanks of the channel; while at other times a stupendous flood submerges wide reaches of land. When the flood waters of two or more tributaries arrive serious inundations result. Attempts to control the river began at a very early date, and in the middle ages the bed between Orléans and Angers was enclosed by dykes 10 to 13 ft. high. In 1783 a double line of dykes 23 ft. high was completed from Bec d'Allier downwards. In modern times embankments, aided by dredging operations extending over a large number of years, have ensured a depth of 18 ft. in the channel between La Martinière and Nantes. Several towns have constructed special works to defend themselves against the floods; Tours, the most exposed of all, being surrounded by a circular dyke; and in the upper Loire reservoirs have been constructed to store flood waters.

LOIRE-INFÉRIEURE, a maritime department of France, made up in 1790 of a portion of Brittany on the right and of the district of Retz on the left of the Loire, and bounded west by the ocean, north by Morbihan and Ille-et-Vilaine, east by Maine-et-Loire and south by Vendée. Pop. (1936) 659,428. Area 2,695 sq.mi. The department consists of flat land on each side of the estuary of the Loire, and its surface is varied only by the presence of weak ribs running west-north-west and east-south-east and continuing those of Brittany; the northernmost one, on the borders of Ille-et-Vilaine, reaches 377 ft., the *Sillon* *de Bretagne* stretching on the right bank of the estuary from Nantes towards the Vilaine hardly exceeds 250 ft. Seaward from the *Sillon,* and behind St. Nazaire, are peat-bogs including Grande Brière which recently supplied old trees for joiners' work; near the coast are large salt-marshes, with Guérande as a salt-refining centre. The district south of the Loire lies equally low; its most salient feature is the lake of Grandlieu, covering 27 sq.m., and surrounded by low and marshy ground, but so shallow ($6\frac{1}{2}$ ft. at most) that drainage would be comparatively easy. Canals are an important feature of the department, and the Nantes to Brest canal uses the Erdre up to within four m. of Nort, where it crosses to a tributary of the Vilaine. The south side of the Loire estuary has been canalized from Le Pellerin to Paimboeuf, and vessels drawing over 21 ft. can reach Nantes. The climate is equable and drier than that of Brittany. At Nantes the mean annual temperature is 54·7°, the annual rainfall being 25·6 inches.

Horse, mule and cattle raising prospers. Good butter and cheese are produced. Poultry also is reared, and there is a good deal of bee-keeping. Much wheat, oats, buckwheat, potatoes and root-crops are grown, also leguminous plants, especially near Nantes. Vines and cider apples are grown. The woods are of oak in the interior and pine on the coast. Some iron is extracted in the department. North-west of Ancenis coal is obtained. The granite of the sea-coast and of the Loire up to Nantes is quarried. Steam-engines are built for the navy at Indret, below Nantes; the forges of Basse-Indre are famous for their iron; and large quantities of lead are smelted at Couëron. There are considerable foundries at Nantes, Chantenay and St. Nazaire, and shipbuilding yards at Nantes and St. Nazaire. Pickles and preserved meats are prepared at Nantes, sardines cured at Le Croisic, which is the centre of the fishing industry, and in the neighbouring communes, and sugar, brushes, macaroni and similar foods, soap and chemicals are made at Nantes, and paper, sugar and soap at Chantenay. The department is served by State railways, the Orleans company and the Western company. The department is divided into the three arrondissements of Nantes, Châteaubriant and St. Nazaire. There are 46 cantons and 220 communes. The appeal court is at Rennes, where is also the centre of the *académie* (educational division), to which it belongs. It is in the region of the XI. army corps (Loire. Inf.) (Nantes), and forms the bishopric of Nantes under the archbishop of Tours.

The principal places are Nantes, the capital, St. Nazaire and Châteaubriant. On the west coast the town of Batz, and neighbouring villages, are inhabited by a small community with a distinct costume and dialect, claiming descent from a Saxon or Scandinavian stock. Guérande has well-preserved ramparts and 15th century gates, a church dating from the 12th to the 16th centuries and other old buildings. At St. Philbert-de-Grandlieu there is a church with portions belonging to the beginning of the 11th century. Cisson has a 13th century castle and a market-hall built of wood. There are many megalithic monuments in the department.

LOIRET, a department of central France, made up of the three districts of the ancient province of Orléanais—Orléanais proper, Gâtinais, and Dunois. It is bounded north by Seine-et-Oise, north-east by Seine-et-Marne, east by Yonne, south by Nièvre and Cher, south-west and west by Loir-et-Cher and north-west by Eure-et-Loir. Area, 2,630 sq.mi. Pop. (1936) 343,865. The department is a plain drained by the Loire from east to west, receiving the Loiret in the west on its left bank; this stream is only a few miles long, but so large that it is supposed to be an underground branch of the Loire. Towards the north the drainage is to the Seine by the Essonne and the Loing. The Sologne (*see* LOIR-ET-CHER) and the Beauce (*see* EURE-ET-LOIR) extend into the department on the south-west and north-west respectively. In the east is La Gâtine (capital Montargis), a region of wildernesses producing saffron and honey. The historic forest north of Orléans is slowly giving place to arable land. The lateral canal of the Loire from Roanne stops at Briare, from which town the *canal de Briare* connects with the Seine by the Loing valley, which is joined by the Orléans canal below Montargis. The mean temperature is a little above that of Paris; the rainfall varies from 18·5 in. in the exposed Beauce to 27·5 in. in the well-wooded Sologne. Hailstorms cause destruction in the Loire valley and the neighbouring regions.

Sheep, cattle, horses, pigs, poultry, especially geese, and bees are reared. The chief cereals are wheat and oats, rye, barley, meslin, buckwheat; potatoes, beetroot, colza and forage plants and vines are grown, largely for vinegar. The woods consist of oak, elm, birch and pine; fruit trees thrive in the department, and Orléans is a great centre of nursery gardens. Gien is an important centre for the manufacture of faience. Porcelain buttons and beads are made at Briare. There are iron and copper foundries, which make agricultural and other implements. There are wool-spinning and wool manufacture carried on. The two arrondissements are those of Orléans and Montargis, with 31 cantons and 349 communes. The department forms part of the *académie* (educational division) of Paris. It forms also the bishopric of Orléans under the archbishops of Paris. It is in the military region of the Xth Army Corps (Orléans); and has its court of appeal at Orléans. The churches of Cléry (15th century), of Ferrières (13th and 14th centuries) of Puiseaux (12th and 13th centuries) and Meung (12th century) are interesting. At Germigny-des-Prés there is a church built originally at the beginning of the 9th century and rebuilt in the 19th century, on the old plan and to some extent with the old materials. Yèvre-le-Châtel has an interesting 13th century château, and Sully-sur-Loire the fine mediaeval château rebuilt at the beginning of the 17th century by Maximilien de Béthune, duke of Sully, the famous minister of Henry IV. There are remains of a Gallo-Roman town (perhaps the ancient *Vellaunodunum*) at Triguères and of a Roman amphitheatre near Montbouy.

LOIR-ET-CHER, a department of central France, formed in 1790 from a small portion of Touraine, the Perche, but chiefly from the Dunois, Vendômois and Blésois, portions of Orléanais. It is bounded N. by Eure-et-Loir, N.E. by Loiret, S.E. by Cher, S. by Indre, S.W. by Indre-et-Loire and N.W. by Sarthe. Pop. (1936) 240,908. Area, 2,479 sq.mi. The department stretches from the river Cher in the south through the one-time marshy Sologne, now largely drained, and across the Loire to the south-east corner of the hills of Perche, rising in the department to 840 ft., and draining to the Loir which flows westwards to join the Maine above Angers. Between Loir and Loire is the southern part of the Beauce (*see* EURE-ET-LOIR). In the tufa walls here and there in the valleys of Cher and Loir dwellings have been excavated, as at Les Roches in the Loir valley. The Sologne is famous for hunting and fishing. The Loire and, with the help of the Berry canal, the Cher are navigable. The climate is temperate and mild, though that of the Beauce tends to dryness and that of the Sologne to dampness. The mean annual temperature is between 52° and 53°. The department is primarily agricultural. The northern region of the department yields abundant wheat and oats, besides rye and potatoes. Vines thrive on the valley slopes, the vineyards falling into four groups—those of the Cher, which yield fine red wines, the Sologne, the Blésois and the Vendômois. In the valleys fruit-trees and nursery gardens are numerous; the asparagus of Romorantin and Vendôme is well-known. The Sologne supplies pine and birch for fuel, and there are extensive forests around Blois and on both sides of the Loir. There is good pasture in the valleys. Sheep are the chief stock; the Perche breed of horses is famous for lightness and strength. Formerly the speciality of Loir-et-Cher was the production of gun-flints. Stone-quarries are numerous. The chief industries are cloth-manufacture, leather-dressing, glove-making, lime-burning, the manufacture of "sabots" and boots and shoes, hosiery and linen goods. The department is served chiefly by the Orléans railway.

The arrondissements are those of Blois, Romorantin and Vendôme, with 24 cantons and 297 communes. Loir-et-Cher forms part of the educational division (académie) of Paris. Its court of appeal and the headquarters of the Xth army corps, to the regions of which it belongs, are at Orléans. Blois, the capital, the seat of a bishop under the archbishop of Paris, Vendôme, Romorantin and Chambord are the chief towns. In addition to those of Blois and Chambord there are numerous fine châteaux in the department, of which that of Montrichard with its 11th century donjon, that of Chaumont (15th and 16th centuries), and that of Cheverny (17th century) in the late Renaissance style are the most important. Those at St. Aignan, Lassay, Lavardin and Cellettes may also be mentioned. Churches wholly or in part Romanesque architecture are found at Faverolles, Selles-sur-Cher, St. Aignan and Suèvres. The village of Trôo is built close to ancient tumuli and has a 12th century church, and among other remains those of a lazar-house of the Romanesque period. There are several megaliths in the department.

LOISY, ALFRED FIRMIN (1857–1940), French Catholic theologian, was born at Ambrières in French Lorraine of peasant parents. The boy was sent into the ecclesiastical schools of St. Dizier, without any intention of a clerical career; but he decided for the priesthood, and in 1874 entered the Grand Seminaire of Chalons-sur-Marne. He was ordained priest in 1879. After being curé successively of two villages in that diocese, Loisy went in May 1881, to study and take a theological degree, to the Institut Catholique in Paris, where he ultimately became professor. He was dismissed from his professorship in 1893 in consequence of an article on "La Question biblique et l'inspiration des Ecritures" contributed by him to his bi-monthly review, *L'Enseignement biblique.* The promulgation of the papal bull *Providentissimus Deus* by Leo XIII. led him to discontinue the review. Meanwhile he had brought his *Evangiles synoptiques* down to the confession of Peter. Loisy then became chaplain to a Dominican convent and a girls' school at Neuilly, but he soon resigned these appointments to continue his critical work in seclusion at Bellevue. A paper on "La Religion d'Israel" (*Revue du clergé français,* Oct. 1900) was condemned by Archbishop Richard and by the pope. Loisy then began to lecture on biblical criticism at the Ecole des Hautes Etudes Pratiques. Meanwhile he made a European reputation by his *L'Evangile et l'église* (1902, Eng. trans., 1903), which was a Catholic answer to Harnack's *Wesen des Christentums.* The book was condemned by the archbishop, but Leo XIII. declined to condemn the *Etudes évangéliques,* which appeared about the same time. But after the accession of Pius X., both these books, with *Autour d'un petit livre* (1903) and *Le Quatrième Evangile* (1903) were placed on the Index. Loisy made a partial submission, which was regarded as unsatisfactory at Rome; he retired first to Dreux, then to his home in Lorraine.

But in 1908 he published the now completed *Evangiles synoptiques,* embodying the results of the "higher criticism," followed by *Simples Réflexions sur le décret Lamentabili et sur l'encyclique Pascendi.* The Holy Office pronounced the major excommunication on Loisy on March 7, 1908. From 1909 to 1932 Loisy was professor of Church history at the Collège de France. His works include *L'Evangile selon Marc* (1912); *Les mystères païens et le mystère chrétien* (1914); *Les Actes des Apôtres* (1920); *L'Apocalypse de Jean* (1923). Loisy died June 1, 1940.

The Loisy controversy attracted great attention throughout Europe, and the literature is extensive. *See* Loisy's own *Autour d'un petit livre* (1903); A. Houtin, *La Question biblique au XIXe Siècle* (1902); C. A. Briggs and F. von Hügel, *The Papal Commission and the Pentateuch* (1907).

LOJA (formerly written *Loxa*), a town of southern Spain, in the province of Granada, on the Granada-Algeciras railway. Pop. (1940) 11,023 (mun., 23,998). Loja, which has sometimes been identified with the ancient *Ilipula,* or with the *Lacibi* (*Lacibis*) of Pliny and Ptolemy, first emerges in the Arab chronicles of the year 890. It was taken by Ferdinand III. in 1226, but was soon afterwards abandoned, and was not finally recaptured until 1486. The narrow and irregular streets of Loja wind up the sides of a steep hill surmounted by a Moorish citadel; many of the older buildings, including a fine Moorish bridge, were destroyed by an earthquake in 1884, although two churches of the early 16th century remained intact. An iron bridge spans the river Genil, which flows past the town on the north. The place was of great military importance, ranking with the neighbouring town of Alhama as one of the keys of Granada. Its products consist chiefly of coarse woollens, silk, paper, leather and salt. Insurgents captured Loja early in the civil war of 1936–39.

LOKEREN, an important industrial town of Belgium between Ghent and Antwerp (in East Flanders on the Durme). Pop. (1939) 25,562. It lies at the southern point of the district called Waesland. It is sometimes called the "Garden of Belgium." The clayey-gravel nature of the soil and the dampness of the atmosphere are very favourable to the cultivation of flax. Root crops have been grown here with great success since the 18th century. Industries include the spinning of wool, flax and hemp, and the manufacture of linen, canvas, etc.

LOKO, a small tribe similar to the Losso and the Mende, between the Rokele and Great Skarcies rivers north-east of Freetown in Sierra Leone.

See N. W. Thomas, *Anthropological Report on Sierra Leone* (1916).

LOKOIYA: *see* LOATUKO.

LOKOJA, a town of Nigeria, British West Africa, at the junction of the Niger and Benue rivers, founded in 1860 by the British consul, W. B. Baikie. It became the military centre of the Royal Niger Company and, later, capital of Northern Nigeria. It is in the province of Kabba, 250 mi. from the mouth of the Niger. With the opening of railways the Benue and Niger rivers ceased to form the chief commercial highways, and Lokoja from about 1910 declined as a trading centre; it also ceased to be the capital of Northern Nigeria (*see* NIGERIA and KABBA).

LOLLARDS, the name given to the English followers of John Wycliffe (*q.v.*); it is of uncertain origin; but the generally received explanation derives it from the verb *lollen* or *lullen,* to sing softly. The word is much older than its English use; there were Lollards in the Netherlands at the beginning of the 14th century, who were akin to the Fratricelli, Beghards and other sectaries of the recusant Franciscan type. The earliest official use of the name in England occurs in 1387 in a mandate of the bishop of Worcester against five "poor preachers," *nomine seu ritu Lollardorum confoederatos.* It is probable that the name was given to the followers of Wycliffe because they resembled those offshoots from the great Franciscan movement which had disowned the pope's authority and set before themselves the ideal of *Evangelical poverty.*

The Dominium of the Poor.—In the 14th century it became manifest that the two different ideas of the place of the church in the world had become irreconcilable. The church chose to abide by the idea of Hildebrand and to reject that of Francis of Assisi; and the revolt of Ockham and the Franciscans, of the Beghards and other spiritual fraternities, of Wycliffe and the Lollards, were all protests against that decision. Gradually there came face to face a great political Christendom, whose rulers were statesmen, with aims and policy of a worldly type, and a religious Christendom, full of the ideas of separation from the world by self-sacrifice and of participation in the benefits of Christ's work by an ascetic imitation. The war between the two ideals was fought out in almost every country in Europe in the 14th century. In England Wycliffe's whole life was spent in the struggle, and he bequeathed his work to the Lollards. The main practical thought with Wycliffe was that the church, if true to her divine mission, must aid men to live that life of evangelical poverty by which they could be separate from the world and imitate Christ, and if the church ceased to be true to her mission she ceased to be a church. Wycliffe was a metaphysician and a theologian, and had to invent a metaphysical theory—the theory of *Dominium*—to enable him to transfer, in a way satisfactory to himself, the powers and privileges of the church to his company of poor Christians; but his followers were content to allege that a church which held large landed possessions, collected tithes greedily and took money from starving peasants for baptizing, burying and praying, could not be the church of Christ and his apostles.

Lollardy was most flourishing and most dangerous to the ecclesiastical organization of England during the ten years after Wycliffe's death. It had spread so rapidly and grown so popular that a hostile chronicler could say that almost every second man was a Lollard. Wycliffe had organized in Lutterworth an association for sending the gospel through all England, a company of poor preachers somewhat after the Wesleyan method of modern times, and, although proscribed, these "poor preachers" with portions of their master's translation of the Bible in their hand to guide them, preached all over England. In 1382, two years before the death of Wycliffe, the archbishop of Canterbury got the Lollard opinions condemned by convocation, and began the long conflict of the church with the followers of Wycliffe. His success was very limited. He could neither suppress Lollardy at Oxford, whence it spread rapidly among the clergy and ultimately reached Scotland, nor prevent the patronage of individual preachers by noblemen and gentlemen of Wycliffite sympathies. Merchants and burgesses supported the new movement with money, and when Richard II. issued an ordinance (July 1382) ordering every bishop to arrest all Lollards, the Commons compelled him to withdraw it. Thus protected, the "poor preachers" won masses of the people to their opinions, and Leicester, London and the west of England became their headquarters.

Innovations.—The most explicit statement of the opinions of the early Lollards is contained in the document commonly known as the Conclusions of 1395. This manifesto asserts that temporal possessions ruin the church and drive out the Christian graces of faith, hope and charity; that the priesthood of the church in communion with Rome was not the priesthood Christ gave to his apostles; that the monk's vow of celibacy had for its consequence unnatural lust, and should not be imposed; that transubstantiation was a feigned miracle, and led people to idolatry; that prayers made over wine, bread, water, oil, salt, wax, incense, altars of stone, church walls, vestments, mitres, crosses, staves, were magical and should not be allowed; that kings should possess the *jus episcopale,* and bring good government into the church; that no special prayers should be made for the dead; that auricular confession made to the clergy, and declared to be necessary for salvation, was the root of clerical arrogance and the cause of indulgences and other abuses in pardoning sin; that all wars were against the principles of the New Testament, and were but murdering and plundering the poor to win glory for kings; that the vows of chastity laid upon nuns led to child murder; that many of the trades practised in the commonwealth, such as those of goldsmiths and armourers, were unnecessary and led to luxury and waste. These Conclusions really contain the sum of Wycliffite teaching; and, if we add that the principal duty of priests is to preach, and that the worship of images, the going on pilgrimages and the use of gold and silver chalices in divine service are sinful, they include almost all the heresies charged in the indictments against individual Lollards down to the middle of the 15th century.

If the formal statements of Lollard creed are to be got from these Conclusions, the popular view of their controversy with the church may be gathered from the ballads current at the time, and from the Piers Ploughman poems. *Piers Ploughman's Creed* (*see* LANGLAND, WILLIAM) was probably written about 1394, when Lollardy was at its greatest strength; the ploughman of the *Creed* is a man gifted with sense enough to see through the tricks of the friars, and with such religious knowledge as can be got from the creed, and from Wycliffe's version of the Gospels. The *Ploughman's Complaint* tells the same tale. It portrays popes, cardinals, prelates, rectors, monks and friars, who call themselves followers of Peter and keepers of the gates of heaven and hell, and pale poverty-stricken people, cotless and landless, who have to pay the fat clergy for spiritual assistance, and asks if these are Peter's priests.

Persecutions.—With the accession of the Lancastrian dynasty the church began a more direct attack upon the Lollards. It was hampered by a strong anti-clerical party in the House of Commons, which twice petitioned the crown to seize the temporalities of the church and apply them to such national purposes as relief of taxation, maintenance of the poor and the support of new lords and knights. Nevertheless the church succeeded in obtaining statutory authority for the capital punishment of heretics, in particular by the act *De Heretico Comburendo* of 1401, and the period of persecution began. In the earlier stages of Lollardy, when the court and the clergy managed to bring Lollards before ecclesiastical tribunals backed by the civil power, the accused generally recanted and showed no disposition to endure martyrdom for their opinions. They became bolder in the beginning of the 15th century. William Sawtrey refused to recant and was burnt at St. Paul's Cross (March 1401), and other martyrdoms followed. The Lollards, far from daunted, united a struggle for social and political liberty to the hatred felt by the peasants towards the Romish clergy. Jak Upland (John Countryman) took the place of Piers Ploughman, and upbraided the clergy, and especially the friars, for their wealth and luxury. Wycliffe had published the rule of St. Francis, and had pointed out in a commentary upon the rule how far friars had departed from the maxims of their founder, and had persecuted the *Spirituales* (the Fratricelli, Beghards, Lollards of the Netherlands) for keeping them to the letter. Jak Upland put all this into rude nervous English verse:

> Freer, what charitie is this
> To fain that whoso liveth after your order
> Liveth most perfectlie,
> And next followeth the state of the Apostles
> In povertie and pennance:
> And yet the wisest and greatest clerkes of you
> Wend or send or procure to the court of Rome,
> . . . and to be assoiled of the vow of povertie.

Meanwhile, Archbishop Arundel was attacking Lollardy in its academic stronghold, the University of Oxford, and procured the issue of severe regulations in order to purge the university of heresy. In 1408 he proposed and carried in convocation the famous *Constitutiones Thomae Arundel* intended to put down Wycliffite preachers and teaching. They provided amongst other things that no one was to be allowed to preach without a bishop's licence, that preachers preaching to the laity were not to rebuke the sins of the clergy, and that Lollard books and the translation of the Bible were to be searched for and destroyed. Under Henry V. a more determined effort was made to crush Lollardy. Hitherto its strength had lain among the country gentlemen who were the representatives of the shires. The new king by directing the trial for heresy of Sir John Oldcastle, Lord Cobham thereby did something to check the spread of Lollardy among the aristocracy, and the persecution of the humbler Lollards continued. This policy aroused little resentment; during the successful war with France little sympathy was felt for men who had declared that all war was but the murder and plundering of poor people for the sake of kings. Mocking ballads were composed upon the martyr Oldcastle, and this dislike of warfare was one of the chief accusations made against him.

But Arundel could not prevent the writing and distribution of Lollard books and pamphlets. The *Ploughman's Prayer,* which appeared about this time, declared that true worship consists in three things—in loving God, and dreading God and trusting in God above all other things; and it showed how Lollards, pressed by persecution, became further separated from the religious life of the church. Notwithstanding the repression, Lollardy fastened in new parts of England, and Lollards abounded in Somerset, Norfolk, Suffolk, Essex, Lincolnshire and Buckinghamshire.

The termination of the Great Schism and the condemnation of Huss by the Council of Constance led to still more vigorous proceedings against Lollard preachers and books. From this time Lollardy appears to be banished from the fields and streets, and takes refuge in houses and places of concealment. There was no more wayside preaching, but instead there were *conventicula occulta* in houses, in peasants' huts, in sawpits and in field ditches, where the Bible was read and exhortations were given, and so Lollardy continued. In 1428 Archbishop Chichele confessed that the Lollards seemed as numerous as ever, and that their literary and preaching work went on as vigorously as before. It was found also that many of the poorer parish priests, and a great many chaplains and curates, were in secret association with the Lollards, so that in many places processions were never made and worship on saints' days was abandoned. For the Lollards were hardened by persecution, and became fanatical in the statement of their doctrines.

Survivals.—The opinions of the later Lollards can best be gathered from the learned and unfortunate Pecock, who wrote his elaborate *Repressor* against the "Bible-men," as he calls them. He summed up their doctrines under 11 heads: they condemn the having and using images in the churches, the going on pilgrimages to the memorial or "mynde places" of the saints, the holding of landed possessions by the clergy, the various ranks of the hierarchy, the framing of ecclesiastical laws and ordinances by papal and episcopal authority, the institution of religious orders, the costliness of ecclesiastical decorations, the ceremonies of the mass and the sacraments, the taking of oaths and the maintaining that war and capital punishment are lawful. When these points are compared with the Lollard Conclusions of 1395, it is plain that Lollardy had not greatly altered its opinions after 55 years of persecution. All the articles of Pecock's list, save that on capital punishment, are to be found in the Conclusions, and may be traced to Wycliffe himself. Pecock's idea was that all the statements which he was prepared to impugn came from three false opinions or "trowings," viz., that no governance or ordinance is to be esteemed a law of God which is not founded on Scripture, that every humble-minded Christian man or woman is able without "fail and defaut" to find out the true sense of Scripture, and that having done so he ought to listen to no arguments to the contrary; he elsewhere adds a fourth (i. 102), that if a man be not only meek but also keep God's law he shall have a true understanding of Scripture, even though "no man ellis teche him saue God." These statements, especially the last, show the connection between the Lollards and mystics of the 14th century, such as Tauler and Ruysbroeck, who accepted the teachings of Nicholas of Basel, and formed themselves into the association known as the Friends of God.

The persecutions were continued down to the reign of Henry VIII., and when the writings of Luther began to appear in England the clergy were not so much afraid of Lutheranism as of the increased life they gave to surviving Wycliffite opinions. "It is," wrote Bishop Tunstall to Erasmus in 1523, "no question of pernicious novelty, it is only that new arms are being added to the great band of Wycliffite heretics." Lollardy, which continued down to the Reformation, did much to shape the movement in England. The subordination of clerical to lay jurisdiction, the reduction in ecclesiastical possessions, the insisting on a translation of the Bible which could be read by the "common" man were all inheritances bequeathed by the Lollards.

LOLLIUS, MARCUS, Roman general, the first governor of Galatia (25 B.C.), consul in 21. In 16, when governor of Gaul, he was defeated by the Sigambri (Sygambri), Usipetes and Tencteri, German tribes who had crossed the Rhine. This defeat is coupled by Tacitus with the disaster of Varus. Lollius was subsequently (2 B.C.) attached in the capacity of tutor and adviser to Gaius Caesar (Augustus's grandson) on his mission to the East. According to Velleïus Paterculus and Pliny, he was a hypocrite and cared for nothing but amassing wealth.

See Suetonius, *Augustus,* 23, *Tiberius,* 12; Vell. Pat. ii. 97. 102; Tacitus, *Annals,* i. 10, iii. 48; Pliny, *Nat. Hist.* ix. 35 (58); Dio Cassius, liv. 6; *see* also J. C. Tarver, *Tiberius the Tyrant* (1902), pp. 200 foll.

LOLO (*Nesu*), a hill people dwelling in the Chinese and Indo-Chinese borderlands, related to the Lisu (*q.v.*) and Moso and probably to the Mantse. They are particularly noted for a written character running in lines from top to bottom as in Chinese. Their mss. are numerous, and often finely illuminated. The Lolo writing was regarded by Lacouperie (*Journ. R. Asiat. Soc.* XIV., i.) as the link connecting the systems of India, Malaysia, Indo-China, Korea and Japan. Traces of polyandry have been reported of them. They worship the sky.

LOMBARD LEAGUE. The attempt of the emperor Frederick I. to re-establish imperial power in Italy led to a coalition, formed in March 1167, between the cities of Cremona, Mantua, Bergamo and Brescia. This league was soon joined by other cities, among which were Milan, Parma, Padua, Verona, Piacenza and Bologna, and the allies began to build a fortress near the confluence of the Tanaro and the Bormida, which, in honour of Pope Alexander III. was called Alessandria. During the absence of Frederick from Italy from 1168 to 1174, the relations between the pope and the league became closer, and Alexander became the leader of the alliance. The decisive struggle began when Frederick attacked Alessandria in 1174, but the historical importance of the war is due to the defeat inflicted on the emperor by the league at Legnano, May 29, 1176. The peace of Constance (June 25, 1183) which ended the struggle left only a shadowy authority to the emperor in Italy.

In 1226 the league was renewed against the emperor Frederick II. and was one of the principal forces opposed to the Hohenstaufen thenceforward until their final overthrow.

For a full account of the Lombard League *see* C. Vignati, *Storia diplomata della Lega Lombarda* (Milan, 1866); J. Ficker, *Zur Geschichte des Lombardenbundes* (Vienna, 1868); H. Prutz, *Kaiser Friedrich I.,* Bd. ii. (Danzig, 1871–74); W. von Giesebrecht, *Geschichte der deutschen Kaiserzeit,* Bd. v. (Leipzig, 1888).

LOMBARDO, the name of a family of Venetian sculptors and architects; their surname was apparently Solaro, and the name of Lombardo was given to the earliest known, Martino, who emigrated from Lombardy to Venice in the middle of the 15th century and became celebrated as an architect. He had two sons, Moro and Pietro, of whom the latter (*c.* 1435–1515) was one of the greatest sculptors and architects of his time, while his sons Antonio (d. 1516) and Tullio (d. 1559) were hardly less celebrated. Pietro's work as an architect is seen in numerous churches, the Vendramini-Calargi palace (1481), the doge's palace (1498), the façade (1485) of the *scuola* of St. Mark and the cathedral of Cividale del Friuli (1502); but he is now more famous as a sculptor, often in collaboration with his sons; he executed the tomb of the doge Mocenigo (1478) in the church of San Giovanni e Paolo at Venice, and a bas-relief for the tomb of Dante at Ravenna, and in 1483 began the beautiful decorations in the church of Sta Maria de' Miracoli at Venice, which is associated with his workshop. (*See* also VENICE for numerous references to the work of the Lombardi.) Antonio's masterpiece is the marble relief of St. Anthony making a new-born child speak in defence of its mother's honour, in the Santo at Padua (1505). Tullio's best-known works are the four kneeling angels (1484) in the church of San Martino, Venice, a coronation of the Virgin in San Giovanni Crisostomo and two bas-reliefs in the Santo, Padua, besides two others formerly in the Spitzer collection, representing Vulcan's Forge and Minerva disputing with Neptune.

A LOLO FROM INLAND CHINA, WITH ARM SHIELD

LOMBARDS or **LANGOBARDI,** a Suevic people who appear to have inhabited the lower basin of the Elbe and whose name is believed to survive in the modern Bardengau to the south of Hamburg. They are first mentioned in connection with the year A.D. 5, when they were defeated by the Romans under Tiberius, afterwards emperor. In A.D. 9, however, after the destruction of Varus's army, the Romans gave up their attempt to extend their frontier to the Elbe. At first, with most of the Suevic tribes, they were subject to the hegemony of Maroboduus, king of the Marcomanni, but they revolted from him in his war with Arminius, chief of the Cherusci, in the year 17. We again hear of their interference in the dynastic strife of the Cherusci some time after the year 47.

From this time they are not mentioned until the year 165, when a force of Langobardi, in alliance with the Marcomanni, was defeated by the Romans, apparently on the Danubian frontier. It has been inferred from this incident that the Langobardi had already moved southwards, but the force mentioned may very well have been sent from the old home of the tribe, as the various Suevic peoples seem generally to have preserved some form of political union. From this time onwards we hear no more of them until the end of the 5th century.

Shortly before this time the Langobardi appear to have taken possession of the territories formerly occupied by the Rugii whom Odoacer had overthrown in 487, a region which probably included the present province of Lower Austria. At this time they were subject to Rodulf, king of the Heruli, who, however, took up arms against them. The result was the total defeat of the Heruli by the Langobardi under their king Tato and the death of Rodulf at some date between 493 and 508. By this time the Langobardi are said to have adopted Christianity in its Arian form. Tato was subsequently killed by his nephew Waccho. The latter reigned for 30 years, though frequent attempts were made by Ildichis, a son or grandson of Tato, to recover the throne. Waccho is said to have conquered the Suabi, possibly the Bavarians, and he was also involved in strife with the Gepidae, with whom Ildichis had taken refuge. He was succeeded by his youthful son Walthari, who reigned only seven years under the guardianship of a certain Audoin. On Walthari's death (about 546?) Audoin succeeded. He also was involved in hostilities with the Gepidae, whose support of Ildichis he repaid by protecting Ustrogotthus, a rival of their king Thorisind. In these quarrels both nations aimed at obtaining the support of the emperor Justinian, who, in pursuance of his policy of playing off one against the other, invited the Langobardi into Noricum and Pannonia, where they now settled.

A large force of Lombards under Audoin fought on the imperial side at the battle of the Apennines against the Ostrogothic king Totila in 553, but the assistance of Justinian, though often promised, had no effect on the relations of the two nations, which were settled for the moment after a series of truces by the victory of the Langobardi, probably in 554. The resulting peace was sealed by the murder of Ildichis and Ustrogotthus, and the Langobardi seem to have continued inactive until the death of Audoin, perhaps in 565, and the accession of his son Alboin, who had won a great reputation in the wars with the Gepidae. It was about this time that the Avars, under their first Chagun Baian, entered Europe, and with them Alboin is said to have made an alliance against the Gepidae under their new king Cunimund. The Avars, however, did not take part in the final battle, in which the Langobardi were completely victorious. Alboin, who had slain Cunimund in the battle, now took Rosamund, daughter of the dead king, to be his wife.

In 568 Alboin and the Langobardi, in accordance with a compact made with Baian, which is recorded by Meander, abandoned their old homes to the Avars and passed southwards into Italy, where they were destined to found a new and mighty kingdom.

(F. G. M. B.)

The Lombard Kingdom in Italy.—Alboin's reign in Italy was brief. In 572, according to Lombard tradition, he fell a victim to the revenge of his wife Rosamund, the daughter of the king of the Gepidae, whose skull Alboin had turned into a drinking cup. But in these few years the Lombards had established themselves in the north of Italy, whence in the next decade they frequently raided Frankish territory beyond the Alps. Chiefs were placed, or placed themselves, first in the border cities, like Friuli and Trent, which commanded the north-eastern passes, and then in other principal places; and this arrangement became characteristic of the Lombard settlement. Its principal seat was the rich plain watered by the Po and its affluents, which was in future to receive its name from them; but their power extended across the Apennines into Liguria and Tuscany, and then southwards to the outlying dukedoms of Spoleto and Benevento. Ticinum (Pavia), the one place which had obstinately resisted Alboin, became the seat of their kings.

Alboin was succeeded by a Lombard noble named Cleph who reigned for only 18 months. For the next ten years (574–584) no single noble was able to obtain recognition as king. In the latter year, threatened by a Frankish invasion, the Lombards chose as king Authari, the son of Cleph, to whom is principally due the consolidation of the Lombard power in Italy. Under him the independence of the dukes was reduced and something was done towards their transformation into royal officers. In this, Authari's success was limited. The dukedoms of the northern marches, Trent and Friuli, with the important dukedom of Turin, long retained the independence natural to a border government in early times. The great dukedom of Benevento in the south, with its neighbour Spoleto, threatened at one time to be a separate principality, and even to the last resisted, with varying success, the full claims of the royal authority at Pavia.

The kingdom of the Lombards lasted more than 200 years, from Alboin (568) to the fall of Desiderius (774), but it was never complete in point of territory. Throughout the greater part of this period there were three capitals in Italy—the Lombard one, Pavia; the Latin one, Rome; the Greek one, Ravenna. It was, moreover, long before the Lombards became amalgamated with the native Italian population, and the process was very far from complete when the kingdom came to an end. The Lombards were profoundly influenced by Italian civilization. They ultimately accepted Catholic christianity, and their kings and dukes behaved like other Germanic rulers in the West as benefactors to churches. They allowed the subject Italian population to live under Roman law, and their own royal charters are full of formulas derived from the phraseology of the Roman private deed. Nevertheless throughout the period of their kingdom the Lombards were essentially aliens in Italy. They threatened the independence of the papacy, and its influence within Italy and beyond the Alps was normally hostile to them. The new element which they introduced into the Italian complex of races was never strong enough to dominate Italy as the Franks dominated northern Gaul.

Authari married Theodelinda, a daughter of Garibald, duke of the Bavarians. She played an important part in Lombard history as the mediator between the Lombards and the Catholic Church. Authari, who had brought her to Italy, died shortly after his marriage (591). But Theodelinda had so won on the Lombard chiefs that they bid her as queen choose the one among them whom she would have for her husband and for king. She chose Agilulf, duke of Turin (592–615), a Thuringian noble by birth. Agilulf remained an Arian, and he was a very uneasy neighbour, not only to the Greek exarch, but to Rome itself. But he was favourably disposed both to peace and to the Catholic Church. The Arian and Catholic bishops went on for a time side by side; but the Lombard kings and clergy gradually yielded to the religious influences around them. Gregory the Great, opposed as he was to the new barbarian kingdom, recognized that the empire could never expel the Lombards from Italy, and endeavoured to promote peace between the Italians and Agilulf. Under these conditions the pope and the king of the Lombards naturally became the two real powers in the north and centre of Italy.

Agilulf was followed, after two unimportant reigns, by his son-in-law, the husband of Theodelinda's daughter, King Rothari (636–652), the first Lombard king to issue a body of law in his own name. From Rothari (d. 652) to Liutprand (712–744) the Lombard kings strove to enlarge their boundaries, and contended with the aristocracy of dukes inherent in the original organization of the nation. Their old enemies the Franks and the Slavs or Huns, ever ready to break in on the north-east, and sometimes called in by mutinous and traitorous dukes of Friuli and Trent, were constant and serious dangers. By the popes they were always looked upon with dislike and jealousy; with the Greek empire there was chronic war. In the last phase of the kingdom it produced two rulers of unusual ability. Liutprand, who destroyed the independence of the great southern duchies, Benevento and Spoleto, and Aistulf who threatened Rome itself. Their success led directly to the events which brought the Lombard kingdom to an end. The popes, thoroughly alarmed, and hopeless of aid from the East, turned to the family which was rising into power among the Franks of the West, the mayors of the palace of Austrasia. Pope Gregory

III. applied in vain to Charles Martel. But with his successors Pippin and Charles the popes were more successful. In return for the transfer by the pope of the Frankish crown from the decayed line of Clovis to his own, Pippin crossed the Alps, defeated Aistulf and gave to the pope the lands won by the Lombards from the empire, Ravenna and the Pentapolis (754–756). Finally, invited by Pope Adrian I., Pippin's son Charlemagne once more descended into Italy. As the Lombard kingdom began, so it ended, with a siege of Pavia. Desiderius, the last king, became a prisoner (774), and the Lombard power perished. Charlemagne, with the title of king of the Franks and Lombards, became master of Italy.

For the subsequent history *see* the article ITALY. For the Lombard League *see* the articles under that title and COMMUNE: *Mediaeval. See* also T. Hodgkin, *Italy and her Invaders,* vols. v. and vi. (2nd ed. 1916) and bibliography in V. Chevalier, *Répertoire des Sources Historiques du Moyen Âge* (1905). (R. W. C.; X.)

LOMBARD'S KOP, BATTLE OF: *see* SOUTH AFRICAN WAR, 1899–1902.

LOMBARDY, a territorial division of Italy, bounded on the north by the Alps, south by Emilia, east by Venetia and west by Piedmont. It has an area of 9,183 sq.mi. Lombardy is divided into nine provinces with the following population figures according to the census of April 21, 1936.

Province	Area in sq. mi.	Population 1936	Density per sq. mi.
Bergamo	1,065	605,810	568.8
Brescia	1,833	744,571	406.2
Como	798	501,752	628.8
Cremona	678	369,483	544.9
Mantua	903	407,977	451.8
Milan	1,066	2,175,838	2,041.1
Pavia	1,144	492,096	430.2
Sondrio	1,234	142,919	115.8
Varese	462	395,896	856.9
Lombardy	9,183	5,836,342	635.6

Milan, the chief city, is the greatest railway centre of Italy, being the nearest great town to the tunnels of the St. Gotthard and the Simplon. The other railway centres of the territory are Mortara, Pavia and Mantua. The most important rivers are the Po, which follows, for the most part, the southern boundary of Lombardy, and the Ticino, one of the largest tributaries of the Po, which forms for a considerable distance the western boundary.

The majority of the Italian lakes, those of Garda, Idro, Iseo, Como, Lugano, Varese and Maggiore, lie wholly or in part within it.

The climate of Lombardy is thoroughly continental; in summer the heat is greater than in the south of Italy, while the winter is very cold, and bitter winds, snow and mist are frequent. In the summer rain is rare beyond the lower Alps, but a system of irrigation, unsurpassed in Europe, and dating from the middle ages, prevails, so that a failure of the crops is hardly possible.

There are three zones of cultivation: in the mountains, pasturage; the lower slopes are devoted to the culture of the vine, fruit trees (including chestnuts) and the silkworm; while in the regions of the plain, large crops of maize, rice, wheat, oats, rye, flax and wine are produced, and thousands of mulberry trees are grown for the benefit of the silkworms, the culture of which in the province of Milan has entirely superseded the sheep breeding for which it was famous during the middle ages.

Milan is the principal silk market in the world. Of the usual 50,000 workers in the silk weaving and allied industries, about half are employed in mills in or near Como, while the other mills are mostly in Milan and Turin. The chief centre of silk weaving is Como, but the silk is commercially dealt with at Milan, and there is much exportation. A very considerable amount of cotton is manufactured, but most of the raw cotton has to be imported, the cultivation being insignificant in Italy. Lombardy has 58.45% of the spindles and 71.7% of the looms existing in Italy. Milan also manufactures motor-cars, though Turin is the principal centre in Italy for this industry. There are copper, zinc and iron mines, and numerous quarries of marble, alabaster and granite. In addition to the above industries the chief manufactures are felt, woollens, hats, rope, paper-making, iron-casting, gun-making and printing.

Lombardy is indeed the most industrial district of Italy and as such was heavily bombed by the Allies in World War II.

In most of the provinces of Lombardy there are far more villages than in other parts of Italy except Piedmont; this is attributable partly to their mountainous character. There are numerous and important hydro-electric plants directly connected with those of the Apennines. For Lombardy in the Iron Age *see* GOLASECCA and COMACINES. Previous to the fall of the Roman republic Lombardy formed part of Gallia Transpadana, and it was Lombardy, Venetia and Piedmont, the portion of the Italian peninsula north of the Po, that did not receive citizenship in 89 B.C. but only Latin rights. The gift of full citizenship in 49 B.C. made it a part of Italy proper, and Lombardy and Piedmont formed the 11th region of Augustus (Transpadana) while Venetia and Istria formed the 10th. It was the second of the regions of Italy in size, but the last in number of towns; it appears, however, to have been prosperous, and cultivation flourished in its fertile portions.

Lombardy has been for the last 150 years politically the most active part of Italy; it played also a leading role in the rise and fall of fascism.

For details of subsequent history *see* LOMBARDS and ITALY; and for architecture *see* ARCHITECTURE. G. T. Rivoira in *Lombardic Architecture* (2 vols. London, 1910), successfully demonstrates the classical origin of much that had hitherto been treated by some authorities as "Byzantine." In the development of Renaissance architecture and art Lombardy played a great part, inasmuch as both Bramante and Leonardo da Vinci resided in Milan at the end of the 15th century.

LOMBOK, one of the Lesser Sunda islands, Dutch East Indies. It lies due east of Java, with the island of Bali between it and the Javanese coast, the Lombok strait separating it from Bali, with which it forms a residency. Lombok has an area of 1,825 sq.mi. It is very mountainous, being divided for nearly its whole length by two mountain chains, separated by a valley, which slopes upwards, gradually, in terrace formation, and is broken in the centre by a ridge of low hills. The southern chain, which runs from south-east to south-south-west, does not exceed 1,000 ft., but the northern chain, beginning with Gunong Wangsit, 11½ mi. N. of Ampenam, rises eventually to 12,290 ft. in Gunong Rinjeng or Rinjani (the Peak of Lombok) one of the highest volcanoes of the Malay archipelago. Lower peaks flank the mountain, united by a plateau 7,200 ft. in height, and containing a fine lake, Danu (Segara Anak). Of the many small rivers none is navigable. The coast is very bold in places, with cliffs rising precipitously from the sea, but there are good anchorages in bays on the west and east coasts.

The flora includes, amongst the palms usual to the tropics, a great palm, a species of *Corypha,* which is a striking feature of the plains, and several Australian forms; the fauna comprises monkeys (*Macacus cynomolgus*), deer, and wild pigs, and many beautiful birds, large green pigeons, eight kinds of kingfishers, a ground thrush (*Pitta concinna*), grass-green doves, little crimson and black flower-peckers, large black cuckoos, king-crows, golden orioles, and fine jungle-cocks, and dragon flies abound. For the scientist, Lombok possesses a very great interest, in that it is the most westerly point of a former Australian or Pacific continent which must have broken up before Java, Sumatra, Bali, etc., were separated from Asia, and probably before the extreme south-eastern portion of Asia was raised above the waters of the ocean. Lombok strait, which has depths exceeding 600 fathoms, marks the edge of the Asian continental shelf. Wallace drew a line from the strait northwards, between Celebes and Borneo, and then passing eastwards, between the Sangir islands and Mindanao, into the Pacific ocean, to denote the frontier between the Asian and the Australian regions, which has been known since as the *Wallace line.* It is supported by the fact that there are marked differences between the flora and fauna of Bali and Lombok, the barbets, fruit-thrushes, and woodpeckers of the former being practically unknown in the latter, whilst the cockatoos, honeysuckers, and mound-builders (Megapodidae), of Lombok are equally foreign to Bali. Recent observations however have established that some intermingling of species is taking place, and it has been ascertained since Wallace's time that the line cannot be applied strictly to all forms of life, and that to spiders, for instance, it cannot be applied at all, so that, to be exact, Lombok, in a biological sense, denotes the commencement of a transitional area in which the Asiatic forms of life are gradually supplanted completely by Australian forms.

The population of Lombok (1930) was 701,290 (146 Europeans and Eurasians), composed very largely of Sasaks, the indigenous inhabitants of the island, of Malayan origin, and akin to the indigenous population of the neighbouring island of Sumbawa, with some Balinese who confine themselves mostly to the north-west. The Sasaks are Mohammedan and a clean and industrious folk, with villages and houses built after the Balinese pattern, and with customs resembling those of the Balinese under whose domination they live. Sasaks use the Balinese script for writing and their literature consists of Javanese and Malayan translations. Industry has reached a fairly high level, clothes and mats are woven, there are workers in gold, silver, and iron, and the people are clever as agriculturists, their rice and coffee cultivation having reached a fairly advanced stage. There are some Chinese traders. Mataram is the capital and headquarters of administration, a short distance inland from Ampenam, the chief port of Lombok, which is on the western coast; landing there is difficult during the west monsoon. From Ampenam and the port of Labuan Hadji, on the east coast, a frequent steamer service is maintained by the Dutch Royal Packet Navigation Company with Bali and Java ports, Celebes (Macassar), and with Sumbawam Sumba, Flores and Timor. There is good road communication but no railway, and there is cable connection with Java, *via* Bali.

As early as 1640 Lombok was regarded by the sultan of Macassar as being under his rule, and when his power was shattered by the Dutch in 1667–8, a Sumbawa chief, signatory to the Bongay contract, endeavoured to impose his sovereignty on the island, in which the Dutch assisted, peacefully. Civil war in Sumbawa left Lombok the prey of, first pirate adventurers from Macassar, then of the Balinese who planted colonies in north Lombok and set about establishing their rule. Balinese intervention commenced about 1692, Dutch endeavours to get the signatories to the Bongay treaty to take action to counteract it were unsuccessful, and eventually the Balinese succeeded in establishing four kingdoms in Lombok; Mataram, Karang Asem, Pagasangen, and Pagutan. In 1843, Mataram entered into a contract with the Dutch, agreeing to acknowledge Karang Asem in Bali as the suzerain power. In 1849 the Dutch were at war with Karang Asem and Klungklung in Bali, and were assisted by Mataram, which, as a reward, was given Karang Asem (Bali), as a fief; but, although friendly relations with the Dutch and Mataram continued until 1872, in that year Mataram, looking upon itself as independent, and not suzerain to the Dutch, refused to send its regular embassy to Batavia, and, in 1891, interfered in the domestic politics of Bali. At the same time it cruelly oppressed the Sasak population of Lombok, so that the latter made ineffectual attempts to throw off the Balinese yoke, finally invoking Dutch aid. This was given, and in 1894, after one expedition had met with disaster, a second was successful in overthrowing the government of Mataram. Lombok was made a division of the residency of Bali and Lombok, under an assistant-resident at Ampenam, and was divided into two districts, East and West Lombok; a third district, Central Lombok, was created in 1898, the capitals of the three districts being at Mataram, Praja, and Sisi. Lombok was occupied by the Japanese in 1942.

See A. R. Wallace, *The Malay Archipelago* (1890); W. Cool, *With the Dutch in the East* (1897). (E. E. L.)

LOMBROSO, CESARE (1836–1909), Italian criminologist, was born on Nov. 18, 1836, at Verona, of a Jewish family. He studied at Padua, Vienna and Paris, and in 1862 became professor of psychiatry at Pavia, then director of the lunatic asylum at Pesaro, and later professor of forensic medicine and of psychiatry at Turin, where he eventually filled the chair of criminal anthropology. In 1872 he made announcement that the disorder known as *pellagra* (*q.v.*) was due to a poison contained in diseased maize, eaten by the peasants, and he returned to this subject in *La Pellagra in Italia* (1885). To Auguste Comte Lombroso owed an exaggerated tendency to refer all mental facts to biological causes, but he surpassed all his predecessors by the wide scope and systematic character of his researches. He held that the criminal population exhibits a higher percentage of physical, nervous and mental anomalies than non-criminals; and that these anomalies are due partly to degeneration, partly to atavism. The criminal is a special type, standing midway between the lunatic and the savage. (*See* CRIMINOLOGY.) Lombroso died suddenly at Turin on Oct. 19, 1909.

His works include; *L'Uomo delinquente* (1889); *L'Uomo di genio* (1888, Eng. trans. 1891); *Genio e follia* (1877); *La donna delinquente* (1893, 3rd ed. 1915, Eng. trans. 1895); *Le Crime, causes et remèdes* (1899, Eng. trans. 1911); *Delitti vecchi e delitti nuovi* (Turin, 1902); *Nuovi studi sul genio* (2 vols., Palermo, 1902).

See Kurella, *C. Lombroso* (Hamburg, 1892); a biography by his daughters, P. Carrara and G. Ferrero (1906 and 1915), and K. Kurella, *C. Lombroso: a Modern Man of Science* (1911).

LOMÉNIE DE BRIENNE, ÉTIENNE CHARLES DE (1727–1794), French politician and ecclesiastic, was born at Paris on Oct. 9, 1727, of a Limousin family, dating from the 15th century. After a brilliant career as a student he entered the Church. In 1752 he was appointed grand vicar to the archbishop of Rouen, in 1762 bishop of Condom, and in 1763 archbishop of Toulouse. In 1770 he became an academician. He was on three occasions the head of the *bureau de jurisdiction* at the general assembly of the clergy; he addressed to Turgot a number of *mémoires* on political and social questions, one of them, treating of pauperism, being especially remarkable. As president of the Assembly of Notables (1787) he attacked the fiscal policy of Calonne, whom he succeeded as head of the *conseil des finances* on May 1, 1787. He made the parlement register edicts dealing with internal free trade, the establishment of provincial assemblies and the redemption of the *corvée*. To crush opposition to the stamp duty and the proposed new general land-tax the parlement was exiled to Troyes (Aug. 15, 1787), and only returned to Paris on its agreement to an alternative plan prolonging for two years the tax of the two *vingtièmes* (a direct tax on income). But a further attempt to force the parlement to register an edict for raising a loan of 120 million *livres* met with determined opposition. The struggle of the parlement against the incapacity of Brienne ended on May 8 in its consenting to an edict for its own abolition; but with the proviso that the states-general should be summoned to remedy the disorders of the state. Brienne, who had been made archbishop of Sens, now had to face almost universal opposition; he was forced to suspend the *Cour plénière* which had been set up to take the place of the parlement, and himself to promise that the states-general should be summoned. On Aug. 29, he had to retire, leaving the treasury empty. On Dec. 15 following, he was made a cardinal, and spent two years in Italy. After the outbreak of the Revolution he returned to France, and took the oath of the civil constitution of the clergy in 1790 (*see* FRENCH REVOLUTION). He was repudiated by the pope, and in 1791 had to give up the biretta at the command of Pius VI. Both his past and present conduct made him an object of suspicion to the revolutionaries; he was arrested at Sens on Nov. 9, 1793, and died in prison, on Feb. 16, 1794.

The chief works published by Brienne are: *Oraison funèbre du Dauphin* (1766); *Compte-rendu au roi* (1788); *Le Conciliateur*, in collaboration with Turgot (Rome, Paris, 1754). *See* also J. Perrin, *Le Cardinal Loménie de Brienne . . . épisodes de la Révolution* (Sens, 1896).

LOMOND, LOCH, the largest and most beautiful of Scottish lakes, situated in the counties of Stirling and Dumbarton. It is about 23 m. long; its width varies from 5 m. towards the south end to $\frac{1}{3}$ m. at the narrows to the north of the Isle of the Vow; the greatest depth is 630 ft. It is only 23 ft. above sea-level. It contains 30 islands, the largest of which is Inchmurrin. Twenty-four of them form an archipelago at the widest part of the loch. From the west the loch receives the Inveruglas, the Douglas, the Luss, the Finlas and the Fruin. From Balloch in the south it sends off the Leven to the Clyde; from the east it receives the Endrick, the Blair, the Cashell and the Arklet; and from the north the Falloch. Ben Lomond (3,192 ft.) dominates the landscape; but there are other majestic hills, particularly on the west and north-west banks. The fish are sea-trout, lake-trout, pike and perch, with some salmon. Inversnaid, where a fort was built in 1713 to subdue the clan, was in the heart of the Macgregor country, and the name of Rob Roy is still given to his cave on the loch side a mile to the north and to his prison 3 m. to the south.

LOMONÓSOV, MIKHAIL VASILIEVICH (*c.* 1711–1765), Russian poet and man of science, was born in the village of Denisovka (the name of which was afterwards changed in honour of the poet), situated on an island not far from Kholmogorî, in the government of Archangel. His father, a fisherman, took the boy into his trade at the age of ten, but he had a passion for learning, and made his way to Moscow when he was 17. There he obtained admission into the Zaikonospasski school, and in 1734 he was sent from Moscow to St. Petersburg (now Leningrad). There he was chosen as one of the young Russians sent to complete their education in foreign countries. He studied metallurgy at Marburg; he also began to write poetry; imitating German authors, among whom he is said to have especially admired Günther. His *Ode on the Taking of Khotin from the Turks* was composed in 1739. On his return to Russia he was made professor of chemistry in the university of St. Petersburg; he ultimately became rector, and in 1764 secretary of State. He died in 1765.

In the history of Russian letters he is above all important as the man who reformed the Russian language and helped to make it an effective literary medium by his *Rhetoric,* his *Russian Grammar,* and his essay *On the Use of Sacred Books in the Russian Tongue*. His task was to find a middle course between the complicated Slavonic language used in the church services, with its elaborate syntax derived from Greek, and spoken Russian. Not only did he fix the literary language, but he wrote magnificent verse which had an enduring effect on later Russian poetry.

LOMZA, a town of Poland in the province of Bialystok on the Narew, 103 mi. by rail N.E. from Warsaw. Lomza is an old town, one of its churches having been erected before 1000. In the 16th century it carried on a brisk trade with Lithuania and Prussia. It was well fortified and had two citadels, but nevertheless often suffered from the invasions of the Germans and Tatars, and in the 17th century it was twice plundered by the Cossacks of the Ukraine. In 1795 it was under Prussian rule and after 1807 it was under Russian rule till 1918. Pop. (1931) 25,045. It was taken by the U.S.S.R., 1939, and Germany, 1941.

LONAVALA, a town of India, in the Poona district of Bombay, at the top of the Bhor Ghat pass in the Western Ghats, by which the Great Indian Peninsula railway climbs from Bombay to Poona. Pop. including Khandala (1941) 10,876. It contains locomotive works, and head works of the Tata Hydro Electric scheme are situated here.

LONDON ("JACK"), JOHN GRIFFITH, novelist, born at San Francisco (Calif.), Jan. 12, 1876. After a hard-working boyhood he became an oyster pirate, and then a member of the fish patrol, and at 17 signed as seaman on a sealing vessel. He went with the first rush to the Klondike in 1897, and tramped across the United States and Canada. In 1904 he went (as war correspondent) to Japan, and in 1914 to Mexico. In 1906 he and his wife started in a small yacht on a voyage round the world, described in *The Cruise of the Snark* (1911). He died at Glen Ellen (Calif.), Nov. 22, 1916. His novels, and other writings, fall sharply into two classes—those which he wrote for money, as he frankly admitted in his letters, and those whose sincerity and militancy made him at one time the American Socialist best known outside the U.S.A. *The Iron Heel* (1907), *The War of the Classes* (1904), *Revolution and other Essays* (1910), are the chief of these latter; *The Iron Heel* has had an enormous circulation in the Old World. With these should be classed *The People of the Abyss* (1903), a valuable sociological study of London's East End. Of his other works the best are his semi-autobiographical works: *Martin Eden* (1909) and *John Barleycorn* (1913); but wide popularity has been gained by his novels of adventurous life and wild or half-tamed animals, such as *White Fang* (1906), *The Call of the Wild* (1903) and *South Sea Tales* (1911).

See *The Book of Jack London,* by his wife, Charmian London (1921); and E. B. Payne, *The Soul of Jack London* (1926).

LONDON, a city and port of entry of Middlesex county, Ontario, Canada, situated 121 mi. S.W. of Toronto, on the river Thames and the Canadian National, Canadian Pacific, the London and Port Stanley railways and the Trans-Canada airways. Pop. (1941) 78,264. The local nomenclature is largely a reproduction of that of the great city whose name it has borrowed. Situated in a fertile agricultural district, it is a large distributing centre. Among the industries are petroleum refineries, and factories for the manufacture of agricultural implements, railway carriages and various minor commodities. The educational institutions include the Western university, with courses in arts, medicine and theology (founded in 1878 under the patronage of the Church of England). London was founded in 1825–26.

LONDON, the capital of England and the mother city of the British empire, is the largest city in the world, containing, in the administrative county and the ring of suburbs an area, known as Greater London, of about 693 sq.mi. and a population of 8,700,000 in 1938. The heart of London is "the City," the ancient core round which the gigantic urban and suburban area has developed. It covers but 677 ac. and constitutes one of the smallest of the 29 municipal divisions that go to make up the Administrative County of London, which has an area of about 117 sq.mi. The City is a county corporate, the other 28 divisions are metropolitan boroughs. The "outer ring," which is included within Greater London and the Metropolitan Police area, comes under the jurisdiction of one or other of the counties of Middlesex, Essex, Kent, Surrey and Hertfordshire, although each district has its own local administrative authority. The 28 metropolitan boroughs, each of which is noticed in a separate article, are:—

1. *North of the Thames.*—The following, commencing on the west, lie on the river: Hammersmith, Fulham, Chelsea, Westminster (here comes the City), Stepney and Poplar; north of these, and adjoining the northern boundary, are: Kensington, Paddington, Hampstead, St. Pancras, Islington, Stoke Newington and Hackney; and between these two groups are (St.) Marylebone, Holborn, Finsbury, Shoreditch and Bethnal Green.

2. *South of the Thames.*—Wandsworth, Battersea, Lambeth, Southwark, Bermondsey, Deptford, Greenwich and Woolwich (these touching the river and two small parts of Woolwich being on its north bank), Camberwell and Lewisham.

Geographical Situation.—London is situated in the London basin, which is drained by the lower Thames. The basin is formed by a downfold in the chalk, which underlies all the area between the North Downs and the Chilterns. This downfold is floored with very thick deposits of London clay, an impervious, sticky, water-holding deposit, upon which are scattered remnants of later coverings of sands and gravels.

The general relief of the land is low, the ground rarely rising above 400 feet. There are, nevertheless, two outstanding features. These are, first, the flood plain of the Thames, some 3 mi. wide, rising gently from the river to about 25 ft. (O.D.), covered with gravel and alluvial deposits, among which river silt, fine sand and peat predominate. Owing largely to the shrinkage of the previously water-logged peat and silt, which took place as a result of embanking and the consequent drying out of these softer elements, the gravels lie generally several feet above the level of the alluvium. Here and there the drop from one to the other can be distinguished in the low relief. Both gravel and silt, however, lie mainly below the level of high tide today, and but for the embankments would be more or less submerged at every high tide and would revert to marshland; the gravels in the neighbourhood of the Thames are saturated with water every time the tide rises. The flood plain throughout historical times has been avoided rather than sought out for settlement, but there is plenty

of evidence that it formed the home of prehistoric peoples from the Stone age until the coming of the Romans.

The second feature consists of two low, undulating plateaus rising above the flood plain to north and south in a couple of usually well-marked terraces covered with gravel. The rise of the southern plateau is continuous with that of the North Downs beyond London, except in the southwest, where a broad, gravel-floored vale, once, possibly, occupied by a precursor of the river Mole, links the Thames at Kingston with the Wandle valley at Merton and isolates the hills of Richmond and Wimbledon. On the north the land rises steadily to the hills of Hampstead and Highgate, and beyond to Finchley and Hendon, but drops steeply to the broad trench of the Lea valley in the east, and more gently to the broad clay vale of the Brent in the northwest. The lower terrace of the plateau, known as the Taplow terrace, lies between 50 and 100 ft. above sea level and drops somewhat steeply to the flood plain 25 ft. or so below. It may be easily distinguished in the steep descent from the Strand to the Embankment, or from Upper and Lower Thames street to the river, or in the drop from St. Giles's to Charing Cross. Above this terrace a higher one may be distinguished, generally referred to as the Boyn hill terrace. It lies approximately at between 100 and 150 ft. above sea level; gravels which represent its floor form the greater heights of Richmond hill and Putney common and cap the long spur of Islington hill.

The Thames winds in broad, tidal meanders between the edges of the flood plain, cutting now into the northern, now into the southern rim. Before its regulation and confinement between embankments, backwaters and ancient channels surrounded many sandy islands along its course. The names of some of them are perpetuated in the districts of Battersea, Bermondsey and Chelsea. A group of such islots filled the angle that the river makes at Lambeth, the most northerly being the famous Thorney, on which the Abbey of St. Peter (the predecessor of our Westminster Abbey) was founded. The broad, shallow course of the Thames as it crossed the flood plain from Lambeth towards Charing Cross was probably a fordable reach in Roman times, and there has been much conjecture as to the probability of the crossing of the Roman road in the neighbourhood of Westminster (or even of Lambeth) bridge, before its diversion to pass through the City. The northern section of the Watling street seems to trend towards a crossing here, and the alignment of the road along the edge of the Tyburn valley could be laid out from the high ground west of the Darent, south of the Thames, near the known end of the southern section of the street. But the remains of Roman occupation are so few at Westminster that it is unlikely that the Watling street ever crossed the Thames by ford or ferry here.

Just below Westminster and Whitehall the river takes a sharp bend to the east and flows for a couple of miles at the foot of the Taplow terrace, leaving a great stretch of reclaimed marsh to the south, occupied now by Lambeth, Southwark, Bermondsey and Rotherhithe. Owing to the set of the current against the northern shore, in this reach the river is deeper and narrower than at Westminster or—further downstream—at the Isle of Dogs, where it is relatively broad and shallow. Across the brink of the gravel terrace which here directly overlooks the Thames, several small tributary valleys have been trenched, cutting the terrace into low hills which drop abruptly some 40 or 50 ft. to the river, and slope also steeply to the side valleys that separate them.

Two of these small hills appear to have formed the site of the earliest London, which, according to one widely held theory, began its existence with the construction of a bridge across the Thames by the Romans. The selection of the site by the Romans would be based on the practicability of an approach and crossing as far down stream as possible. As regards approach there is no place on the north bank except this stretch between the Tower of

London and Waterloo bridge where the 50 ft. contour line approaches the river, until Staines is reached. This steep bank washed by relatively deep water, would facilitate approach from the north and by river, but the crossing of the flood plain from the south must always have presented difficulties. It is this great expanse of marshland south of the City that lends support to a theory that London arose, not as a river crossing, but as the river port of Verulamium (St. Albans) with which it communicated by the ridgeways between Colne and Lea and by the two tributaries themselves. The Thames and the flood plain have afforded ample evidence that the river was a highway from earliest times, and that it formed a line of communication with the Continent and the numerous small riverside settlements long before the Roman invasion. The steep edge which the two hills present to the deep river at London and to the stream valleys that isolate them, must have made defense of the site relatively easy. The gravel that covers the hills provided London's earliest water-supply, for the banks of the small tributaries oozed with springs. Many of these were important throughout mediaeval times and their names are still household words—St. Bride's well, Clerkenwell, St. Clement's well, Holywell for instance; the Roman bath in Strand lane is still fed by water percolating through the gravels. Apart from ease of access and capability of defense, other physical conditions conducive to settlement would be the abundance of food and building materials. Fish, including salmon, was plentiful in the Thames; game, as well as timber—invaluable both for constructional purposes and as fuel—flourished in the great forest of Middlesex, behind, while the Taplow terrace was covered with brick-earth which provided a light, rich soil as well as material for brick-making.

The later growth and development of London was strongly influenced by the distribution of the terrace gravels. Settlement only advanced into the flood plain where embankments provided protection from flooding, or where small hummocks of gravelly material caused a slightly greater elevation. Outside London it was the Taplow gravels and the Upper Tertiary and Drift gravels remaining in scattered fragments on the London clay that determined the settlement in villages. Apart from the bridgehead at Southwark, it was not until water could be brought from a distance and distributed widely in pipes, and until scientific drainage and sewerage were introduced, that settlement of any density was

possible on the flood plain or on the London clay; even today large areas of the latter and of the alluvial marshland remain untenanted.

Apart from the Thames gravel terraces, which have played so important a part in the site and expansion of London, and the small patches of gravel that provided sites for villages in the lowlying clay vale of the Brent, the sands and gravels of the London basin, where they cover large areas, have not been conducive to settlement, for they provided but poor soil. Much of the land became common grazing land, and has been preserved as open common, for it is to these sandy and gravelly patches that we owe many of the high open spaces which are such an asset to the modern metropolis.

London's Lost Rivers.—The streams of London that traversed the terraces and flood plain to join the Thames deserve mention, for in spite of 2,000 years of occupation and the fact that many of them have long been reduced to the status of covered-in sewers, their valleys can still be traced in the mild relief. Along the slopes of their valleys broke out the springs on which early London depended largely for water supply, and their tidal estuaries gave shelter to shipping and access to the heart of the City. Westbourne, Tyburn and Turnmill brook were streams that rose 3 or 4 mi. from the City, in the hills of Hampstead and Highgate, capped with Bagshot sands that form the northern background of central London. The Westbourne, Kilburn or Bayswater brook, as it was variously called, collected its waters from a number of tributaries on the south and west flanks of Hampstead hill. It flowed through what is now West Hampstead, took the line taken today by Kilburn High road and where Kilburn L.M.S. station now is, received a number of tributaries; it then traversed the districts of Paddington, Westbourne Park and Bayswater, followed the line of the Serpentine in Hyde park, flowed under the Knight's bridge (at Knightsbridge), followed roughly the line of Sloane street, under Bloody bridge at Sloane square (the great pipes that carry the water across Sloane square station today may be seen from the platform), and entered a marshy area that was probably once a backwater of the Thames in the neighbourhood of Ebury bridge. Its lower course is now the Ranelagh sewer.

The Tyburn, a smaller stream, but noteworthy as forming at one period an important water-supply for London, had its sources in central Hampstead, not far from Swiss Cottage, passed west of Primrose hill where it received a tributary from the Belsize district, flowed through our Regents park, crossed the future Marylebone road by Madame Tussaud's, took the same path as the present Marylebone lane, whose windings follow those of the stream, crossed Oxford street—the old Tyburn road—and wound its way to the west of where Bond street now is to the line of Piccadilly, just west of Half Moon street, where the dip in the main road can still be clearly distinguished. It crossed the Green park and, trenching the edge of the Taplow terrace, descended to the flood plain on the site of Buckingham palace. Then it probably lost itself in the tidal marshes. Today its representative storm sewer finds an artificial outlet a little to the south of Vauxhall bridge as the King's Scholars' Pond sewer.

The Turnmill brook, which has been identified with the Holborn and the River of Wells, and was known in its lower tidal section as the Fleet, had its upper tributaries in what are now the Highgate ponds. It flowed down through Kentish Town, Camden Town and the flats of Somers Town to a marshy area at King's Cross, where it was crossed by Battle bridge. Thence it cut a deep channel through the gravels of the Taplow terrace to enter the Thames close to where Blackfriars bridge now stands. Its deep valley was for long an obstacle to east and west traffic between the City and Westminster, owing to the steep gradients of Holborn hill and Snow hill. Today Farringdon street runs above the bed of the river and Holborn viaduct carries the traffic across the valley. A little to the north of the City, the Walbrook rose in a number of springs from the Taplow gravel. Its two head streams passed by culverts through the northern wall of the Roman city and the united stream passed beneath the site of the Bank of England and out to the Thames by a broad tidal creek about where Cannon street station stands. In the 15th century the northern section of Walbrook within the walls was vaulted over. At that time the stream was flowing some 18 ft. above its original bed. Down to the time of the Great Fire it formed one of the principal sewers of the City. The tidal estuary of the stream, known as Dowgate, was, perhaps, the earliest representative of the Port of London. Near its outlet and on the site of Cannon street station stood the guildhall of the merchants from the Rhine, known as the Steleyard.

On the south side of the Thames a succession of streams flowed from the low plateau on to the flood plain and followed more or less indeterminate courses to the Thames. Of these the Wandle and Ravensbourne, which rise as bournes on the dip slope of the North Downs, still bring down large volumes of water to the Thames, the former draining Croydon, Wallington and Carshalton, Mitcham, Merton, Earlsfield and Wandsworth, and the latter Addington, Hayes, Bromley, Catford, Lewisham and Deptford. The minor streams that drained the gravel terraces on the south—Effra, Falcon brook and a stream sometimes called the Neckinger, now flow underground. The waters of the Effra still occasionally cause trouble by flooding basements and undermining roads.

Thames Embankments.—The Thames follows a winding course through London and the fine embankments on its northern side form, in parts, an important means of communication between the City and the southwesterly parts of the town and exits, the finest of them, the Victoria embankment (popularly known as "the Embankment") runs between Blackfriars and Westminster bridges; formed in 1864–70, open gardens fringe it on the landward side, and it is lined with fine public and private buildings; beneath runs the District railway and on its surface the L.C.C. trams. The bold sweep of the Thames, here some 300 yd. wide, the towers of Westminster on the one hand and the dome of St. Paul's on the other, make up a fine prospect. Beyond the Houses of Parliament and the Victoria Tower gardens the embankment is continued by Grosvenor road and the Chelsea embankment (laid out in 1871–74) fronting Battersea park across the river, shaded by a pleasant avenue and lined with handsome houses. Below London bridge the river is embanked for a short distance in front of the Tower of London, and above Westminster bridge the Albert embankment extends for nearly 1 mi. along the south bank, in front of St. Thomas's hospital. The London County hall, completed 1932, has its own embankment; and the realization of a scheme, referred to below, for the development of the south bank of the Thames in the neighbourhood of Hungerford bridge may involve the continuation of the south side embankment at least as far as Waterloo bridge.

Bridges and Tunnels.—Fourteen road-bridges cross the Thames within the county of London. Of these London bridge, connecting the City with Southwark and Bermondsey, stands first in historical interest and in importance as a modern highway. The old bridge, famous for many generations, bearing its rows of houses and its chapel in the centre, was completed early in the 13th century. It was 308 yd. long and had 20 narrow arches through which the tides formed dangerous rapids. It stood some 60 yd. below the existing bridge, which was built of granite by John Rennie and his son, Sir John Rennie, and completed in 1831; it was widened in 1904, by means of corbels projecting on either side. There was no bridge below London bridge until 1894, when the Tower bridge was opened. This is a suspension bridge with a central portion, between two lofty and massive stone towers, consisting of bascules which can be raised by hydraulic machinery to admit the passage of vessels.

The bridges in order above London bridge are as follows: railway bridges being bracketed—Southwark (Cannon Street), (Blackfriars), Blackfriars, Waterloo (Charing Cross or Hungerford—with a footway), Westminster, Lambeth, Vauxhall (Grosvenor), Chelsea, Albert, Battersea (Battersea), Wandsworth (Putney—with footway), Putney and Hammersmith. In 1937 was completed the demolition of Waterloo bridge, a massive stone structure of nine arches carrying a level roadway, engineered by John Rennie and opened in 1817, and considered one of the finest stone bridges in the world. Serious subsidences of certain arches decided the London County Council, in spite of strong opposition from those who deplored the demolition of Rennie's work, to replace it by a bridge of five equal arches of 230 ft. span, designed by Sir Giles Gilbert Scott. The new bridge, which was opened without ceremony on Aug. 11, 1942, carries six lanes of traffic. The building of a great new road bridge to connect the south side at Waterloo station with the Strand and Charing Cross road has been for some time under consideration. The estimated cost of the scheme approaches £12,000,000. The present Westminster bridge, of iron on granite piers, was opened in 1862 and succeeded that built in 1739–50, the view from which was appreciated by Wordsworth in his sonnet beginning "Earth has not anything to show more fair." The complete reconstruction of Vauxhall bridge was undertaken in 1902, and the new bridge was opened in 1906. The new Lambeth bridge was opened in July 1932. Its length is 776 ft. There are five steel arches, the centre span being 22 ft. 9 in. above T.H.W. level. The overall width is 60 ft., and the roadway 36 ft. The Chelsea bridge was rebuilt as a self-anchored suspension bridge, with four traffic lanes and footways, and was opened in 1937. The old lattice-girder Wandsworth bridge was replaced by a new steel bridge, opened in Aug. 1940, built on two granite-faced piers and having four traffic lanes. Putney bridge was widened 1931–34 to take six traffic lanes.

Some of the "tube" and other metropolitan railway lines cross the river in tunnels beneath its bed. There are also several tunnels under the river below London bridge, namely: Tower subway, constructed in 1870 for foot-passengers, but no longer used; Greenwich tunnel (1902) for foot-passengers; Blackwall tunnel (1897), constructed by the County Council for both pedestrians and vehicles between Greenwich and Poplar; Woolwich tunnel, for foot-passengers only, opened in 1912, and the Rotherhithe tunnel (opened in 1908), $1\frac{1}{4}$ mi. long, for foot-passengers and vehicles. The Thames tunnel (1825–43), 2 mi. below London bridge, became a railway tunnel in 1865. The County Council maintains a free ferry at Woolwich. It has been decided to duplicate Blackwall tunnel.

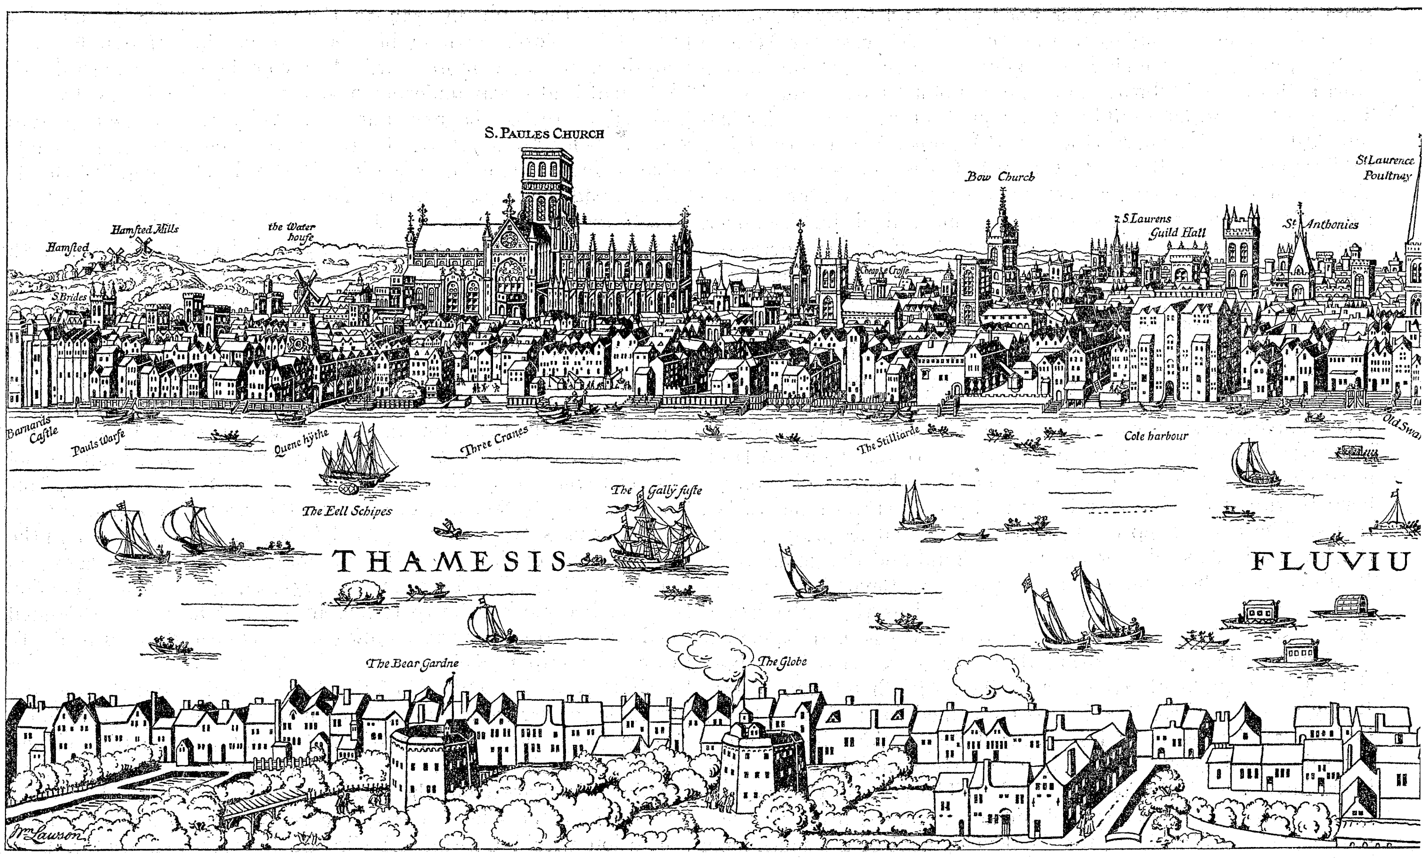
Climate.—The climate of London is equable and the weather variable, owing to the steady indraught of warm moisture-laden winds from the Atlantic and the frequent passage of cyclones, whose southern quadrants usually cross the London basin. Prevailing winds are from the southwest. As a result of the shelter afforded by the Chilterns and the North downs, and occasional inclusion within Continental climatic influences in winter, London has a smaller rainfall than the Wealden or Chiltern areas. It has also a greater range of temperature, and would experience more sunshine but for the pall of smoke that sometimes shuts out the sky in the winter half of the year. This nuisance is abating, however. The mean annual temperature is 50° F.; the mean annual rainfall is about $23\frac{1}{2}$ in.

Central London.—Central London can conveniently be considered in four sections:—the City, the Port, the East End, and the West End.

The City is essentially the small area situated upon the two low hills separated by the Walbrook valley, on which the Romans founded it. The lie of its streets is still to some extent determined by the lines of the Roman walls, upon the ruins of which the mediaeval walls were raised, and the gates that gave access to all parts of the country. Its wards still correspond more or less closely to estates formerly held by the great city families, and the boundaries in certain cases still represent the courses of ancient streams. The City is the market of London today, as in the past, though Cheapside, Eastcheap, Poultry and Vintry are now but street names. There are the great exchanges: the Baltic, Wool, Iron and Steel, and Coal; and the unique insurance corporation of Lloyd's. Finally we have the great money markets, including the Bank of England, the joint stock and merchant banks, the discount houses and the stock exchange. Apart from these it must be remembered that every important business house in the world has representatives in London. So it is also with the great transport organizations and the great news agencies. In other words London is a world exchange for almost every commodity.

Nor must it be forgotten that London is an important centre of industry. Light engineering and the preparation of foodstuffs are among the more important.

The Port of London is, of course, closely allied to the market, though less closely than in earlier days—for enormous quantities of goods are dealt in on the London markets that never touch the quays. The early silting up of the Walbrook meant that Dowgate was the first of the small London hithes to become obsolete; the Fleet was used at least till 1502, when we find that boats carrying fish and fuel could be rowed as far as Holborn bridge. Apart from these two stream estuaries, the port consisted,



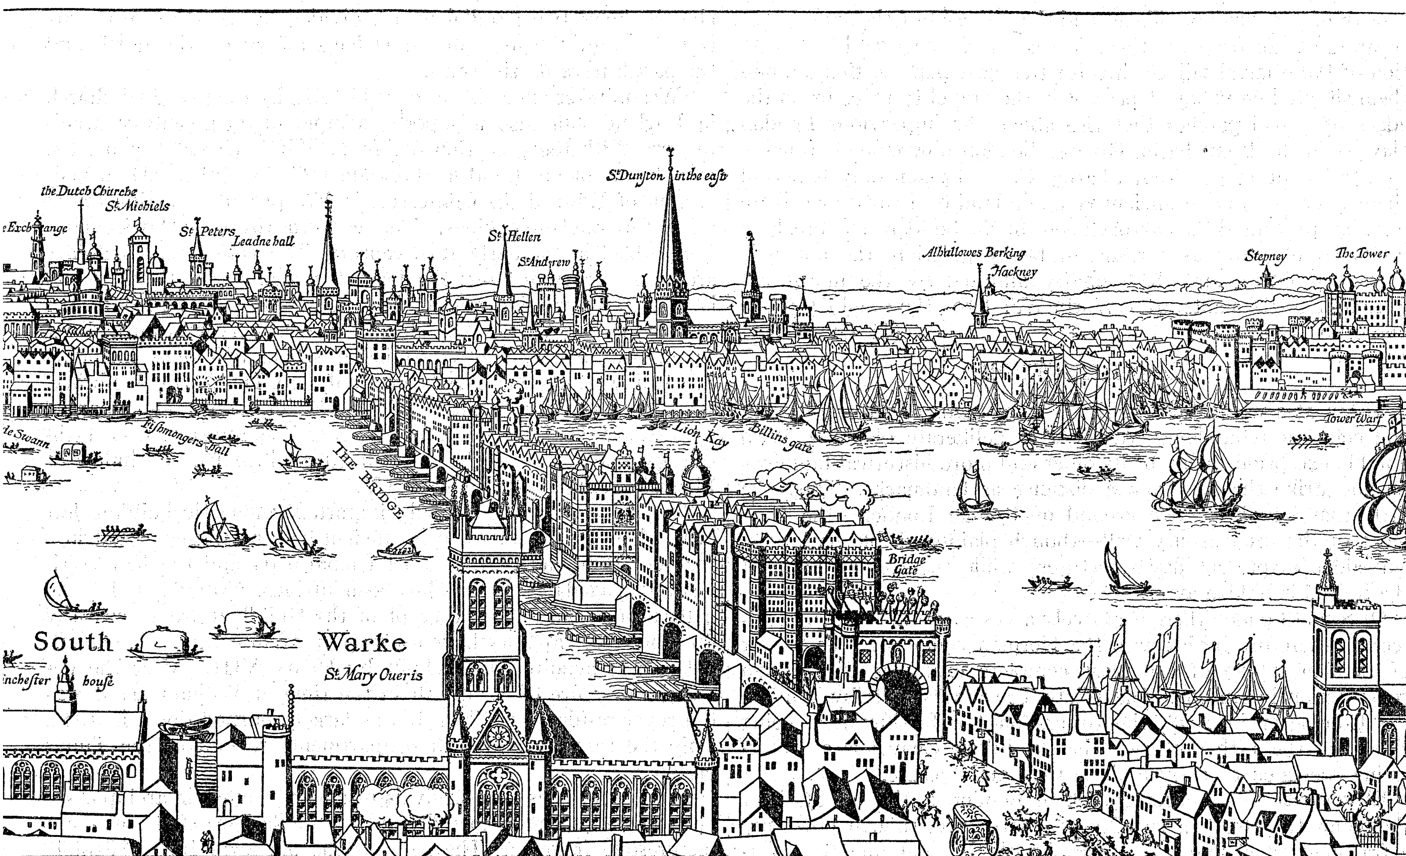
VIEW OF LONDON IN THE 17TH CENTURY, FROM THE SURREY SIDE OF THE THAMES, AFTER A DRAWING BY A CONTEMPORARY ARTIST, VISCHER. ON THE LEFT IS SHOWN "OLD ST. PAUL'S," BUILT DURING THE 12TH AND 13TH CENTURIES, AND DESTROYED BY FIRE IN 1666. IT WAS THE HIGHEST CHURCH IN EUROPE, BEING 520 FEET TO THE TOP OF THE STEEPLE. ON THE RIGHT IS THE ORIGINAL LONDON BRIDGE, BUILT BY

from very early Saxon times of the two hithes: Queenhithe and Billingsgate. Owing to the increasing tonnage of vessels and to the serious impediment caused by old London bridge, in spite of the drawbridge allowing ships to pass through it to Queenhithe, Billingsgate, below bridge, gradually overhauled and superseded its rival. Originally a general port, Billingsgate in 1699 became a free port for fish. By 1588, the congestion in the small hithes, where alone it was legal to land goods, became so great that other legal quays had to be established between Billingsgate and the Tower. By the middle of the 16th century London had drawn to herself the bulk of the trade of southeast England. In the reign of Charles I the Legal quays had to be supplemented by "Suffrance Wharves," whose numbers were gradually increased until by 1896 there were 113. Many of the old Legal wharves and quays retain their name to this day; Galley quay, Botolph's wharf, Three Cranes in the Vintry, for instance. The traffic of coal, which dates back to the 14th century, employed an increasing number of craft on the Thames; sea coal, so-called to distinguish it from charcoal, gave its name to Sea Coal lane, which leads east from Farringdon street, at a point just north of the old Fleet bridge (now Ludgate circus) where the colliers, before returning to the Tyne laden with ballast, discharge their coal; and today coal is one of the main items of traffic above the bridge.

The prosperity of the port as well as the growing tonnage of the ships necessitated constantly increasing accommodation. In 1661 the first of London's docks was built at Blackwall. This was a private undertaking and was not a dock in the modern sense, for it had no gates and could not retain the water at the ebb. In 1700 the Howland Great Wet dock at Rotherhithe was made, but it was not till a century later that, with the construction of the West India dock, the development of the modern port began. At the beginning of the 19th century it took a month or six weeks to discharge an East Indiaman; the construction of the St. Katharine dock in 1828 made it possible to accomplish the work in a week or less. The tonnage of a large ship at that time would be about 500; today a ship of 18,000 or 20,000 tons can be discharged in a couple of days. The trade of the modern port is not, however, confined to the docks. Riverside wharves with modern equipment and vast warehouse accommodation have sprung up, and making up in nearness to market and despatch in unloading what they lacked in facilities for dealing with large vessels at low water, have played a very important part in the development of the port. The Thames always has been, and probably always will be, a "lighter" port. The Thames lighter-men were for centuries an important company with important privileges; the wharfingers and the lighter-men between them now undertake something approaching half the traffic of the port.

The difficulty of obtaining sufficient water on the dock sills for the ever-increasing draught of modern shipping led to the construction of the Victoria and Albert docks (1880–85, extended 1921) in the flood plain north of the Woolwich reach, and—especially since 1909, when the Port of London Authority (see *Port and Commerce,* below) bought out the dock companies for £23,000,000 and put an end to the competition and inefficiency inseparable from multiple ownership and divided control—the port has continued to develop in a downstream direction. After World War I the Authority commenced a huge program: the Victoria and Albert docks were extended by the large and magnificently equipped George V dock in 1921; dredging of the channel as far as the entrance to the Millwall and West India docks was undertaken and maintained; and Tilbury dock (with a low-water depth of 38 ft. on the sills), which had been built in 1886 to accommodate the liners of the day, was extended in 1926–29 by a new entrance dock, 1,000 ft. long by 110 ft. wide, a dry dock (752 ft. by 110 ft.), and a passenger landing-stage large enough for the largest ocean-going steamers. (*See* TILBURY DOCKS.)

The East End.—The Port proper with London river and the Pool below bridge is closely associated with the East End, a somewhat squalid section of London, which has, nevertheless, a number of fine, wide streets. Here dwell the dock and riverside



A PRIEST, PETER OF COLE CHURCH; BEGUN IN 1176 AND FINISHED IN 1209, AFTER THE ARCHITECT'S DEATH, BY THREE LONDON MERCHANTS. THE ARCHITECT WAS BURIED IN A CHAPEL ON THE BRIDGE. UNTIL 1750 IT WAS THE ONLY BRIDGE ACROSS THE THAMES. ABOVE THE GATE ARE SEEN HEADS OF CRIMINALS. IN THE 18TH CENTURY THE HOUSES WERE REMOVED, AND IN 1825 THE PRESENT BRIDGE WAS BEGUN

workers, and here also are large settlements of foreigners, of whom a large proportion are Jews of varying nationality, engaged in small businesses such as clothing factories and retail shops. A dense population hems in the City on the north side in Bethnal Green, Shoreditch, Islington and Holborn, though the City itself has a resident population of only 8,780 (est. 1938). In this connection it is interesting to note that 4,949 suburban trains (of which 2,877 were London Passenger Transport Board trains) entered the City termini daily in the month of July 1937, and that the day population of the City is over 1,000,000 persons.

The West End, which originated as a separate entity with the establishment of the court and parliament in the neighbourhood of the Abbey of St. Peter on Thorney island, developed along the Oxford road and the Strand road that linked the City to Westminster. The marshy islands and tidal creeks round Thorney long remained uninhabited and were only densely settled in modern times. The old creeks at Whitehall, Scotland Yard and Millbank have always been liable to flood at spring tides, especially during a strong wind, as witness the disaster in Jan. 1928, when the tide at the flood spilled over the embankments and flooded the basements of houses in the lowlying districts.

The first important extension of London was along the Taplow terrace that extends west of the City and north of the Westminster flats. The Strand was lined with houses as far as Charing Cross by the middle of the 16th century, and buildings were continuous from the City to Hyde park by the beginning of the 18th century.

The fashionable West End residential area lies about the parks in Mayfair, Belgravia, Kensington, Brompton, with an extension southwards and northwards into parts of Chelsea and St. Johns Wood. Kensington and Brompton have always been high-class shopping centres, as well as high-class residential quarters; and it is noteworthy that in Park lane, the squares of Mayfair, the western half of Piccadilly and Belgravia, great hotels and huge blocks of flats and offices—in many cases with ground-floor shops—are now taking the places of splendid mansions and gardens.

The Shopping Area.—The great West End shopping area stretches from Holborn viaduct westwards along Oxford street to the Marble arch and St. James's, and starts again at Knightsbridge to continue through South Kensington to Chelsea. Southwark, the ancient bridge-head and southern outlet of the City, grew but slowly, like Westminster, on account of the marshes. The embankment, partly natural and partly artificial, and the causeway extending into the marsh were the earliest developed parts of the district.

A significant change of recent years has been the spread westward of activities formerly confined to the City. Much of Bloomsbury behind the British museum has been demolished and the site has been acquired for the University of London, whose 43 schools and colleges are scattered over a wide area. The new buildings designed by Charles Holden, were begun in 1933, the Tower building being opened in Oct. 1937. The Foundling site, sold for about £2,000,000, was preserved as a playground for neighbourhood children. Work on its layout began in 1936.

The character of many of London's streets has been altered. A change regretted by many is the passing of Nash's Regent street and the Quadrant. Devonshire house, one of the last of Piccadilly's great mansions, disappeared in 1924 and was replaced by hotels and flats; a like fate overtook the ducal mansions of Grosvenor house and Norfolk house. Dorchester house, in Park lane, was demolished and replaced by a hotel. There are many new theatres, "cinemas," and restaurants; Grosvenor street, which flanks Buckingham Palace gardens, is now a street of offices; the widening of the Strand proceeds slowly.

The City is changing its aspect even more rapidly. The Bank of England was refashioned and enlarged upwards within its sphinx-like outer walls; Lloyd's built a magnificent new home in the shipping quarter and tall modern buildings are springing up everywhere in the narrow City streets.

The Suburbs.—The London suburbs have been formed by the growth of surrounding villages and the filling-in of the spaces that separated them from the City. Water-supply governed the selection of the original village sites for the most part, so that we find them situated on valley slopes cut in the gravel terraces or on the edges of gravel patches that rise above the impervious London clay, as in the Brent basin. Greater London now extends roughly to a radius of 15 mi. from Charing Cross, broken only here and there where a patch of ancient common land or a royal or private park has prevented the encroachment of the builder. The breaking up of large estates as a result of heavy taxation, the domestic servant problem, and the mobility afforded by the motor car were active stimulants after World War I to "the swelling of the immortal Wen." (H. Or.; X.)

ARCHITECTURE

Taken as a whole London shows many signs of natural growth and constant rebuilding, and fewer of deliberate planning. With notable exceptions many of its older and more historical buildings do not strike the eye from a distance as landmarks. Thus, the little that remains above ground of Roman London—the fragment of the original city wall—though plainly visible, is largely embedded in present day structures; while the Roman bath off the Strand is hidden away.

Of Saxon London there is scarcely a vestige; and London architecture therefore begins with the Norman conquest. The Tower of London is one of the most complete examples of Norman construction in Europe. The White Tower was built by William the Conqueror in 1078, the towers on the fortifications being chiefly of the 13th century. The St. John's Chapel is an interesting specimen of early ecclesiastical architecture.

Churches.—The oldest church in London is that of St. Bartholomew the Great, a fine Norman structure, though now only a fragment; it should be compared with the contemporary Waltham Abbey, where will be found the counterpart to what is missing from it, and vice versa; it contains the tomb of Rahere, founder of the priory and of the adjacent hospital, which is the oldest in Great Britain.

The *Temple church (1185), which originally belonged to the Knights Templars, was one of the four ancient round churches in England; the entrance porch is Norman; the chancel one of the best pieces of Early English work in London. It was badly and drastically restored in the 19th century and the "round" was gutted in 1941.

Southwark cathedral, which has been restored with great care, was formerly the church of St. Mary Overie's Priory; it is a large cruciform building, mainly in a typical Early English style, and is rich in monuments contemporary with Shakespeare whose theatre, the Globe, was hard by.

The church of *Austin Friars comprised the 14th century nave of the old Augustinian Priory church and was the church of the London Dutch colony. It was completely destroyed by air raids.

Other interesting City churches which survived the Great Fire of 1666 are *All Hallows, Barking, the burial place of many who were executed on Tower Hill (largely 15th-century Perpendicular and noted for its fine brasses and late 17th-century carved wood font cover; very badly damaged, though the tower, 1658, survives; the wrecking revealed a Saxon arch); St. Andrew's Undershaft (so named because a maypole used to be set up before an older church), rebuilt 1520–32 and containing font and Jacobean tombs, including a monument to John Stow, the chronicler of the survey of London (d. 1605); St. Ethelburga, externally the quaintest old church in London, and containing a 15th-century arcade; *St. Giles, Cripplegate (14th century, rebuilt 1545 and recently restored), of which most of the mediaeval work, including the tower (upper part 1683–84), survives. The chapel at the east end of the north aisle contains Elizabethan and Jacobean monuments. It is the burial place of Fox, Milton and Frobisher; Cromwell was married and Defoe baptized there. St. Helen's, Bishopsgate (13th and 14th centuries), the Westminster abbey of the City, is rich in monuments, including those of Sir Thomas Gresham and other old City merchant princes. The present church shows two parallel naves, divided by a 15th-century arcade: that of the nuns of St. Helen's priory on the north and the parish nave on the south.

*Westminster abbey is not only historically the principal church in England, but also a superb example of 13th-century architecture. With the exception of Henry VIII's chapel (1519), the church was planned and in the main built by Henry III in veneration of Edward the Confessor, and to provide a fitting burial place for England's kings. The western towers (Hawksmoor) were added in the early 18th century. The conventual buildings are 13th century or later; the Jerusalem chamber at the west end is a most interesting annex. It was seriously damaged at the crossing during World War II, and the Deanery was burned out as was the cloister and Westminster school buildings, including the hall with its hammer-beam roof and Dr. Busby's library. Westminster hall was built by William Rufus (1097), and enlarged by Richard II (1398). St. Margaret's, Westminster, is a 15th-century Perpendicular church with a magnificent east window of Flemish glass (temp. Henry VII).

The *Charterhouse, the only important monastic building left in London, has lost many of its ancient buildings, used as lodgings for poor gentlemen. The chapel (unharmed) and the hall (seriously damaged) have fine Jacobean fittings. *Merchant Taylors hall (burned out) and the crypt of the Guildhall are noteworthy specimens of 14th–15th century civil architecture. St. James' palace was acquired and rebuilt by Henry VIII. After the destruction by fire of Whitehall in the time of William III it was the royal residence until itself was largely burned down in 1809. Only the gateway and certain apartments remain of the Tudor building.

London contains few survivals of ancient domestic architecture but the gables and timbered front of Staple Inn, Holborn, are a picturesque fragment. The halls of the old legal Inns (*Middle Temple, Lincoln's Inn, Barnard's Inn and Staple Inn) retain much of the woodwork of this period. The hall of *Gray's Inn, with hammer-beam roof and fine woodwork, along with the library, were gutted, while the east end of Middle Temple hall was badly damaged. Other contemporaneous buildings of which remains survive are the little group by Lincoln's Inn gateway, comprising the chapel and some of the rooms in Old square. Good specimens of domestic buildings are *Holland house, of which the library (Thorpe) and other parts were wrecked; Charlton house; Eastbury Manor house, Barking; and Trinity almshouses, Mile End road. Lambeth palace contains work of various periods. The chapel and crypt are Early English, dating from 1245 down to quite modern times.

Inigo Jones.—The dominating genius of Inigo Jones (1572–1652) has left its mark on nearly all Jacobean and Caroline work erected in England. The most remarkable of all his buildings is the Banqueting hall, Whitehall, the only part built of his grand conception for Whitehall palace. Other examples of his work are Lincoln's Inn chapel, the churches of St. Catherine Cree; St. Paul's, Covent Garden (much of which is only a reproduction of the original design, destroyed by fire); and alterations to *St. Alban's, Wood street, which was burned out, though the tower remains. He was also responsible for the arcade on the north side of Covent Garden, which was demolished in 1928, and for the west side of Lincoln's Inn fields; also the small but admirable Water gate at the bottom of Buckingham street, Adelphi; Queen's house and the River block, Greenwich hospital; and Lindsey house and Ashburnham house among domestic buildings. Jones's more important contemporaries include his assistant and relative, John Webb, and John Pratt, author of much of the work in the City, including the Vintners' hall. *Brewers' hall, the finest of those rebuilt after the fire of 1666 and dating from 1670–73 (Caine), was completely wrecked. The City halls, usually ascribed to Sir Christopher Wren, are undoubtedly the work of Pratt, Talman, May and Brettingham, who collaborated with Wren in the reconstruction of the City buildings after the great fire of 1666.

Wren.—Sir Christopher Wren's (1632–1723) majestic conception of *St. Paul's cathedral put him in the front rank of architects of all time. St. Paul's, the "trade mark of London,"

*Buildings marked with an asterisk were damaged in World War II as described.

is the finest example of Renaissance architecture in England, and owes very little to foreign influence. The altar was destroyed and the north transept damaged. The graceful lanterns, spires and steeples of Wren's churches, grouped round the dome of St. Paul's, lend to the City an architectural feature that stands comparison with any other city in the world. Notable among them are the wonderful steeples of *St. Mary-le-Bow (a superb piece of architectural design; interior gutted); *St. Bride's, Fleet street (completely gutted); *St. Vedast, Foster lane (wrecked and scorched, but can be restored); St. Magnus, London bridge; and the lead spires characteristic of Wren's genius, St. Martin's, Ludgate and St. Margaret Pattens. There are also some less successful essays in the Gothic manner, for which he had no sympathy: St. Mary Aldermary and St. Dunstan's-in-the-East—but his most successful effort in this style is the tower of St. Michael's, Cornhill, which is strongly reminiscent of Magdalen tower, Oxford. Internally, the main features are the skilful use of plaster such as was to be seen in *St. Stephen's, Walbrook, *St. Mildred's, Bread street and *St. Clement Danes, and which still exists in St. Margaret's Lothbury. St. Mildred's and St. Clement's were ruined, though St. Stephen's can be restored. Wren's richly ornamental woodwork survives in the pulpit of St. Margaret's; the altar piece of *St. James's, Piccadilly (badly damaged, but capable of reconstruction); though the organ case, fittings and vestry of *St. Lawrence Jewry (completely gutted) and the pulpit of *St. Clement Danes, a magnificent specimen of Grinling Gibbons's work, have been lost. Most of these pieces were of oak, a rather hard material, but Gibbons successfully introduced lime and pearwood for delicate carvings. In addition to Grinling Gibbons, Jonathan Mayne (carver), Jean Tijou (metal worker), Cibber and Bird (sculptors) were among the able craftsmen employed by Wren.

Among the public buildings erected by Wren for royalty and the government were Greenwich observatory, Westminster abbey (repairs), *Kensington palace (upper stories damaged); Hampton Court (additions), Winchester palace (not completed), Marlborough house, St. James's and Windsor (extensive alterations), the Monument (commemorating the Great Fire), and his wonderful additions to Inigo Jones's work at Greenwich hospital. His *Chelsea hospital (seriously hurt in one part) for old soldiers is of a magnificent homeliness. *Buckingham palace (slightly damaged) is the work, not of Wren, but of Capt. Wynn (largely altered by Nash). An excellent design of the period is the Middle Temple gateway. Morden college, Blackheath, a Wren design, shows clever blending of stone and brickwork.

Of Wren's successors perhaps only Sir William Chambers stands out prominently. His design for *Somerset house (river front damaged), though decidedly too utilitarian, is far finer than Barry's *Houses of Parliament (commons chamber burned out). The work of the brothers Adam was largely an adaptation, usually skilful but dull and lifeless, of Roman ornament to English mansions. A former feature of London was the number of residences built, usually fringing the parks, for peers, etc., by eminent architects; as Ely, Spencer, Dover, Gwydyr, Carrington, Stafford, Clarence and *Bridgewater houses, the last damaged but still standing. Their disappearance, owing to the heavy cost of upkeep, indicates the gradual displacement of the titled landlord by the new rich.

After the brothers Adam the caustic pen-drawings of Pugin brought about a return to true principles. To him is due the revival of Gothic detail, in many ways sound, but unsuited to modern times. Heavily transomed windows with leaded lights gave way at last to a demand for more light in this fog-laden atmosphere. Large windows, divided by heavy metal bars, giving a maximum of light, mark modern examples of London architecture: the County hall, Adelaide house, Bush house and Lloyds.

The developments of the 20th century on the whole indicated a slow awakening to the aesthetic advantages obtainable from strict adherence to the decorative minimum. The 19th century, however, in forging the means and tools by which a more satisfactory contemporary expression could be obtained, left largely a legacy of redundant extravagance which was not soon outlived. The legacy dies hard and the great concerns of state, local government, commerce and industry in the years before World War II still vied with each other in the magnificence of their buildings. This produced a city rich in individual examples of architecture. Among these, noteworthy buildings such as the County hall (1912), the offices of Adelaide house (1925), London Transport headquarters (1929), and London university (1937) showed progressive development in the increasing simplification of external appearance, together with a tendency to preserve classic calm and solidity. On the other hand, the more spatial expression made possible by steel, or reinforced concrete, frame construction (still with a classic restfulness) was visible in the Kodak buildings (1911), the premises of Messrs. Heal (1917), the Horticultural hall (1929) and a block of flats, 65 Ladbroke grove (1938). The absence of central guidance and control by planning legislation, however, not only denied the possibilities of relating such individual examples to their immediate localities, but prevented the realization of a wider necessity: that of welding London into a unified and interrelated whole. To this end, the County of London Plan (1943) for the redevelopment of the county area, prepared for the London county council (which accepted it in principle), suggested a comprehensive and elastic program which included the co-ordination of industry and the recreation of community life in the vast aggregate of Greater London. Greater architectural importance than ever before was thus planned for the buildings of the community, with the emphasis on schools, local and civic centres and churches, as an integral and pivotal part of the domestic development.

To understand the present state of London architecture a sense of history is essential. The ancient City, which for many centuries contained the majority of the population, has been rebuilt again and again, and the same holds true of the parts near the City; but there remain here and there in several districts of inner London interesting survivals of original building. Mayfair, despite encroachments, still stands as the quarter of 18th-century aristocracy as Bloomsbury remains that of the earlier 19th-century professional classes. Westminster again and Chelsea show streets and groups of houses belonging to an age before either of them was identified with London proper. North and south of Hyde park and Kensington gardens, are substantial residential districts typifying, though poorly, the last stand of style.

COMMUNICATIONS

Railways.—From the grouping of the trunk railways effected at the beginning of 1923 it results that each company, excepting the Great Western (Paddington station) possesses more than one principal terminus in London. The Southern system has eight stations, terminal wholly or in part, of which Waterloo serves for the southwest of England and the rest for various services to the south and southeast; the Continental services are worked from Victoria, excepting those via Southampton (from Waterloo). The London, Midland and Scottish system has Euston (northwestern and Scottish services), St. Pancras (midland and Scottish), Broad street (suburban), and Fenchurch street, used jointly with the London and North-Eastern company and the Port of London Authority for services mainly to Thames estuarine stations (north bank). The London and North-Eastern system has King's Cross (northern and Scottish), Marylebone (midland), and Liverpool street (eastern services). Systems of joint lines and running powers, such as those over the West London extension line and the Metropolitan extension through the city, afford com-

*Buildings marked with an asterisk were damaged in World War II as described.

munication between the main lines, but for goods traffic mainly, with little passenger traffic. On the other hand the main lines, which themselves carry very heavy suburban traffic, especially southward, eastward, and northward, are adequately connected by the urban electric railway services next to be noticed, and in some instances have joint workings with them. The most extensive electrified suburban system in the world is that of the Southern railway, which extends to Maidstone, Gillingham, Brighton, Worthing, Hastings, Eastbourne, Portsmouth, Bognor Regis, Havant and Reading, as well as over most of London south of the Thames.

Underground Railways.—The purely urban railways include those running: (*a*) in tunnels (of brick) close below the surface, or in cuttings, (*b*) in deep-level "tubes," or metal-lined tunnels—though the outlying suburban extensions of both types of railway commonly come to the surface. The shallow underground lines of the first type are those of the Metropolitan and Metropolitan District systems, the earliest part of which was opened in 1863 and was worked by steam engines. The impossibility of proper ventilation, and various other disadvantages of steam traction, led to experiments with electric working in 1900, and complete electric traction was gradually introduced in 1906. The first "tube" railway in the world was the Tower subway, 1,340 ft. long. From Tower Hill it passed under the Thames to Vine street, about 200 ft. beyond Pickle Herring street. It was formally opened on Aug. 2, 1870, but ran for only a few months. On Christmas eve the same year the tunnel was opened to foot passengers, but it was finally closed to the public shortly after the opening of Tower bridge on June 30, 1894, although it had been popular until then. It is now used for other purposes. Although a failure as a cable-operated railway, its method of construction established the principles upon which the present electric system has been built (see *Railway Mag.* Nov.–Dec. 1943). The first "tube" with electric traction was the City and South London (1890), followed by the Waterloo and City (1898) and the Central London line (1900). Concurrently with the electrification of the old steam lines, extensions of lines proceeded rapidly, until now such outlying centres as Acton, Ealing, Hounslow, Putney and Uxbridge on the west, Aylesbury, Harrow, Chesham, Watford, Edgware, Cockfosters and High Barnet on the north, Barking on the east, and Wimbledon and Morden on the south, are directly connected by the urban electric railways with the centre of London. The lines were constructed by various companies, but control was exercised by the Underground Electric Railways company, which erected a great power house at Chelsea in 1904–05, over all the urban lines excepting those belonging to the trunk systems and the Metropolitan company, which had its power house at Neasden. By June 30, 1939, the route mileage worked by the Metropolitan and District systems was 113 mi. and by the "tubes" 96 mi.

London Passenger Transport Board.—In course of time London transport grew to be so complex and was provided by so many different companies that it became apparent that some form of unified control was needed if the best service was to be provided. The London Passenger Transport board was, therefore, constituted in 1933, "to secure the provision of an adequate and properly co-ordinated system of transport" within the London area, and was required to conduct its undertakings "in such a manner and for such fares and charges . . . as to secure that (its) revenues should be sufficient to defray all charges which are . . . required to be defrayed out of the revenues of the board." In the period 1933–34 there were transferred to the board 5 railway, 17 tramway and 135 bus and coach undertakings, the new undertaking being the largest system of urban transport in the world, serving an area of 1,986 sq.mi. with a population of about 9,500,000. The act of 1933 under which the board was set up also provided for the establishment of a standing joint committee of representatives of the board and the four main-line railway companies and for the creation of a pool of passenger receipts less operating allowances, so that in effect all the means of local passenger transport within the board's area could be treated as a unified system with a common financial interest. Thus a consolidated and unified transport system succeeded a complex and diverse one.

The board itself consists of seven members, two of whom are required to have had not less than six years local government experience in the area. The act further states that members must "have had wide experience, and have shown capacity in transport, industrial, commercial or financial matters or in the conduct of public affairs." The board is appointed by a body known as the appointing trustees, convened for the purpose by the minister of transport. This consists of the chairman of the L.C.C., a representative of the London Home Counties traffic advisory committee, the chairman of the Committee of London Clearing Bankers, the president of the Law society, and the president of the Institute of Chartered Accountants in England and Wales.

The board's first task was to complete the £10,000,000 program of improvements begun by the former companies, but plans were soon made for a further scheme, in conjunction with the main-line railways, involving the construction of 25 mi. of track extensions, the electrification of about 83 mi. of the L.N.E. and G.W. railways, the construction of 13 new stations and the remodelling of 70 existing stations. This program will raise the route mileage of lines owned by the board from 174 to 191 mi. and the route mileage run over by the board's trains from 209 to 275 mi., while through services will be provided to the west central and City areas from such outlying places as Ruislip, Denham, Loughton and Epping. Work was begun in 1936 and was to have been completed in 1941, but had to be suspended during World War II, though by 1943 two of the five new "tube" sections had been opened, namely, Baker street to Finchley road, connecting with the Metropolitan line, and the Northern line extension to East Finchley.

Some idea of the vast extent of the system may be gained from the following facts, as of June 30, 1939, the longest through "surface" line was from Liverpool street to Aylesbury (42 mi.), the longest "tube" line was from Cockfosters to Uxbridge (32 mi.), and the District line service from Ealing to Upminster was 27 mi. in length; the board's vehicles work 3,093 route miles of services (about 3,150 mi. on completion of present plans) and in the year 1938–39 carried over 3,872,000,000 passengers, the railways' share being 563,000,000, of whom about 50,000,000 used Piccadilly Circus station annually, a world record. Other interesting details are —the deepest station is Hampstead, 181 ft. below ground; the longest continuous tunnel is that between Morden and Golders Green, 16½ mi.; and the escalator at Leicester Square station, 180⅓ ft. long, with a vertical drop of 80¾ ft., is the longest in the world.

During World War II the "tubes" were extensively used as air raid shelters. In 1941 about 16,000,000 persons were accommodated at 79 underground stations. Approximately 8½ mi. of three-tier bunks, 7,600 in all, were installed on platforms and in subways, the short spur from Strand to Aldwych being permanently closed to traffic. At night food trains were sent round, and 11 tons of food were distributed nightly during raids. There were also 124 underground canteens. (*See* also *Tramways, Omnibuses* below.)

Tramways.—Tramways were introduced in London in 1860, the first line running from Marble Arch to Paddington, via Bayswater road. In 1905 electric traction appeared, but the surface tramway system of London could never be complete, as, within an area roughly represented by the boroughs of Chelsea, Kensington and Fulham, the city of Westminster and a considerable district north thereof, and the city of London, the existing streets could not accommodate tram lines along with other traffic over any great distance consecutively, and in point of fact there were never more than a few lines, beyond the Embankment line from Blackfriars bridge to Westminster bridge, which connects with the southern system, and the line running south from Islington, using the shallow-level subway under Kingsway and connecting with the Embankment line. The northern, western and eastern outskirts and London south of the Thames, however, came to be extensively served. Most of the lines were in the possession of the London county council when London Transport took over in 1933. Electric traction and (generally) underground transmission are used; but the tramway lines seriously congest the thoroughfares for other traffic, and the tramways, however necessary, do not pay in competition with omnibuses. In consequence, they began to be replaced by trolley buses in May 1931, and the conversion would have been completed by 1941 under the L.P.T.B.'s five-year scheme had it not been for the outbreak of World War II. By June 30, 1939, the tramway route mileage was 135 mi. and that of the trolley bus system was 236 mi. The complete conversion will raise the latter mileage to 362. During the war a number of tram routes were converted, and with the exception of two isolated cases the whole of the present (1943) tramway system comprises the area from the Embankment to south of the Thames. From the Embankment tram routes run to Greenwich, Woolwich, Abbey Wood, Lewisham, Lee Green, Eltham, Catford, Downham, New Cross, Camberwell, Brixton, Streatham, Croydon, Purley, Clapham, Balham, Tooting, Wimbledon, Battersea and Clapham Junction. In the year ended June 30, 1939, passengers carried by the trams and trolley buses numbered 1,086,738,072.

Omnibuses.—The first omnibus began operation between the Bank and Paddington on July 4, 1829, and accommodated 18 persons. In 1850 men were allowed to ride on top. The first motor omnibus ran from Victoria to Charing Cross in 1897. In 1905 and following years these vehicles began to a large extent to supplant horse traction, though the last horse bus was not withdrawn until 1916. The first covered-top omnibus was introduced in 1925. The principal company was the London General Omnibus company, founded 1855, but as time went on the number of its competitors grew, until after World War I scores of "pirate" companies, as they were called, were operating in cut-throat competition. The service provided was, however, very extensive, embracing the principal streets throughout the county and extending far beyond its boundaries—to Leatherhead, Windsor, St. Albans, Watford, etc. All the services were consolidated under the L.P.T.B., and by June 30, 1939, the route mileage worked by the board's 6,389 buses and coaches was 2,513 mi., while the number of passengers carried in the year 1938–39 was 2,222,695,228. The service consists of two main divisions—the town (red vehicles, mostly double-decker) and the country (green vehicles), the Green Line. In recent years many buses have been converted to diesel operation to reduce running costs.

Cabs.—"Hackney coaches" for hire are first mentioned in 1625, when they were kept at inns, and numbered 20. The horse-drawn "hansom," a two-wheeled vehicle so named after its inventor (1834), and the "four-wheeler" or "growler," began to be superseded by motor cabs about the same time as the omnibuses, and in 1907 many motor cabs provided with taximeters ("taxicabs") were put into service. In Jan. 1939, there were 7,500 "taxis" in Greater London. In August the number had fallen to 7,300 and by Oct. 1943 there were only 4,500 owing to the wartime gasoline shortage. Horse-drawn cabs are now mainly a novelty.

Thames Steamers.—A local passenger steamboat service on the Thames suffers from the disadvantage that the river does not provide the shortest route between points at any great distance apart, and that the main thoroughfares between east and west do not, as a rule, touch its banks, so that passengers along those thoroughfares are not tempted to use it as a channel of communication. High pier dues, moreover, contributed to the decline of the traffic, and attempts to overcome the disinclination of passengers to use the river except for pleasure show a record of failure. Steamboats were worked by various companies from 1840 until 1902. In 1904 the L.C.C. obtained powers to undertake the service and in June 1905 one was opened, only to be closed, a financial failure, in Oct. 1907. So matters rested until 1934, when the London and Home Counties traffic advisory committee reported after holding an inquiry that there was no evidence of a strong public demand for a river service and that having one would not relieve land transport pressure. During World War II, however, an emergency service was run from Westminster to Woolwich as an alternative means of transport between the places on the Thames where normal road and rail services had been affected by enemy action. It began operating on Sept. 13 and closed Nov. 11, 1940.

Traffic Problem.—One of the most serious administrative problems met with in London is that of locomotion, especially in the regulation of traffic in the principal thoroughfares and at the busiest crossings. The police have powers of control over vehicles and exercise them admirably; their work in this respect is a constant source of wonder to foreign visitors. But this control does not meet the problem of actually lessening the number of vehicles in the main arteries of traffic. Some idea of the volume of traffic and the delays is obtained from the fact that the seven most important intersections carry from 48,000 to 80,000 vehicles in 12 hours. In order of *traffic volume* these are Hyde Park corner. Trafalgar square (65,000), Marble Arch, Piccadilly circus, Chatham place (north end of Blackfriars bridge), Piccadilly (between Berkeley and Bond streets) and Victoria station (Vauxhall Bridge road and Ebury street). The seven most important intersections from the point of view of *delay* are Ludgate circus, Hyde Park corner, Trafalgar square, Elephant and Castle (36,000), Mansion House, Piccadilly (as above) and Piccadilly circus. The interesting point is, however, that the 80,000 vehicles using Hyde Park corner accumulate only 1,000 hours delay in the 12 hours compared with 1,200 hours accumulated by the 43,000 vehicles using Ludgate circus. In the narrow streets of the City, congestion is often exceedingly severe, and is aggravated when any main street is under repair, and diversion of traffic through narrow side streets becomes necessary. A "round-about" movement of traffic, first introduced at Trafalgar square in 1926, and supplemented by the use of "one-way" streets, alleviated the delay caused by crossing streams of vehicles, with great success in some instances, but not in all. The installation of traffic-operated automatic lights also considerably improved matters.

In 1903 a royal commission was appointed to consider the whole question of locomotion and transport in London, and it reported in 1905 (blue-book, Cd. 2,597, contains its general conclusions). One of its recommendations was that a traffic board should be established for London; and a London and Home Counties traffic advisory committee was appointed under the London Traffic act, 1924, to advise the ministry of transport (which had come into existence since the date of the royal commission). Its jurisdiction covers an area of 1,820 sq.mi., known as the London Traffic area. (The Metropolitan Traffic area for the licensing of public service vehicles is 2,415 sq.mi.) The emergence of new problems associated with the development of motor traffic diverted attention from some of the commission's recommendations as to the construction of new thoroughfares, and public attention was focused upon two main aspects of this problem: (*a*) the construction of arterial roads from the outer parts of London, continuing or connecting with certain of the trunk roads of the country; (*b*) the provision of more adequate communications north and south across the Thames. As for (*a*) it is mainly owing to the great post-World War I arterial road works (principally outside the county) that the London traffic situation is not far worse. Chief among these roads are Eastern and Western avenues, the North and South Circular roads, the Barnet, Watford and Kingston by-passes and the London-Southend road. An important improvement, for which powers were obtained in 1936, is the extension of West Cromwell road (Kensington) to the county boundary, thence to join up with the Great Chertsey road, the Great West road and the North Circular road. The completion of this scheme will provide a valuable traffic outlet to the west and southwest. Outstanding examples of radial routes are the Shooter's Hill by-pass and the Eltham by-pass (Sidcup road). But traffic within inner London has far to travel under congested conditions before it can escape by these channels. The alleviation of these ills is assisted by the widening of key bottle-neck sections, such as Notting Hill Gate, Horseferry road and Kensington High street, and the introduction of roundabouts, as at Vauxhall Cross, the junction of five important roads, where a large central island was laid out. The river-crossings which have come most closely under scrutiny are those at Charing Cross and near St. Paul's cathedral. The substitution of a road-bridge for the railway bridge at Charing Cross (or preferably the provision of a bridge serving both purposes), after being under discussion at least from 1904, was brought to a conclusion about 1937 when, following a report of the traffic advisory committee (June 1936), the L.C.C. pointed out that the scheme the committee favoured would cost £32,500,000. Its death blow was Sir Charles Bressey's opinion that other projects already being negotiated would give better value for the money and that the bridge scheme would itself probably aggravate traffic congestion on the south side of the river.

The bridges within the City of London, as distinct from those within the county, are London, Southwark (rebuilt), Blackfriars and Tower bridges. They are in the immediate care of the Bridge House Estates committee, a committee of the City corporation which takes its name from the "bridge house," mentioned as early as 1272 as the administrative centre for the property connected with London bridge, including the houses and shops upon the former bridge. Rents, tolls, etc., were the source of the committee's income. Proposals from this committee and from other quarters for a new road bridge over the river below St. Paul's cathedral, with new streets giving access to it, have been brought forward from time to time since 1852; they have encountered opposition from commercial interests, inevitable in so crowded an area, and from the authorities of St. Paul's cathedral, who fear the effects of additional vibration. The corporation was authorized to build a bridge by act of parliament in 1911, but World War I deferred the work, and an extension of time was granted in 1921. The question was still in abeyance in 1935. Improvements carried out on bridges under the county council are outlined on p. 349. (See *Report of Royal Commission on Cross River Traffic in London, 1926,* and *Highway Development Survey, 1937, Greater London,* Bressey Report.)

Post Office.—The General Post Office lies in the centre of the city on either side of the street called St. Martin's le Grand. The oldest portion of the buildings, Ionic in style, was designed by Sir Robert Smirke and erected in 1829. The headquarters of the parcels department are at Mount Pleasant, Clerkenwell; those of the post office savings bank at Blythe road, West Kensington, those of the money order department in Manor Gardens, Holloway, and those of the London telephone service at Faraday building, Queen Victoria street. An electric tube railway, completed in 1927 and the only one of its kind in the world, runs from the eastern district sorting office in Whitechapel to Paddington railway station, connecting with Liverpool Street station (L.N.E.R.) and the City delivery and parcels offices. It is 6½ mi. long and is operated from without, the trains carrying no men; 30,000 bags of mail are carried daily and the annual number of train miles is 1,700,000. The postal area of 234 sq.mi. is divided into ten districts, commonly designated by initials, and many subdistricts, designated by numerals (which it is customary to employ in writing addresses). The area excludes part of Woolwich within the county, but extends considerably beyond the county boundaries in other directions. About 50,000,000 letters are posted in London weekly, of which 21,000,000 are for the provinces.

Telephones.—The first London telephone exchange was opened in Aug. 1879 by "The Telephone Company." In the following year it amalgamated with the rival Edison Telephone company to form the United Telephone company, which introduced the first all-night service in London at Heddon street and Westminster exchanges in 1885, intended specially for the use of members of parliament. Four years later, on May 1, this company combined with the National Telephone company, which had been formed in 1881 and which gave its name to the new organization. This gradually absorbed rival concerns, and in 1894 the post office, through the telegraph, was its only competitor.

It was inevitable, however, that the post office should eventually absorb all its rivals, since the government, shortly after the formation of the United company, succeeded in obtaining a legal judgment that a telephone was a "telegraph" within the meaning of the Telegraph acts. Telephone conversations were, therefore, strictly within the province of the postmaster-general. This decision, combined with public complaints about the service, led first to the introduction of a separate system of exchanges and lines by the post office and finally to the post office's acquisition of the National system, which took place on Dec. 31, 1911, at a price later settled at £12,500,000.

The London telephone area in 1943 covered about 1,200 sq.mi., and extended from Welwyn in the north to Reigate in the south and from Gravesend in the east to Staines in the west. The toll exchange gave immediate connection, outside that area, with places as far as Letchworth, Buckingham, Newbury, Brighton, Margate and Aldeburgh. Beyond these limits the trunk system operated. Although the post office opened its first public automatic exchange at Epsom, Surrey, in 1912, the first in London were Bishopsgate, Holborn and Sloane, which were opened in the summer of 1927.

The District Messengers company affords facilities through local offices for the use of special messengers.

POPULATION, PUBLIC HEALTH, ETC.

The population of Greater London in 1938 was 8,700,000. Area of administrative county is 117 sq.mi.

The following table gives comparisons between certain census returns for Greater London and its chief component parts, namely, the City, the administrative county and Outer London (*i.e.,* the zone outside the county boundary but inside Greater London). All the figures before those of 1921 are adjusted to these areas.

Year	City	County	Outer London	Greater London
1841	123,563	1,825,714	286,067	2,235,344
1881	50,569	3,779,728	936,364	4,766,661
1921	13,709	4,484,523	2,995,678	7,480,201
1931	10,996	4,397,003	3,806,939	8,203,942
1938	8,780	4,062,800	4,637,200	8,700,000

In the above table it will be noticed that the population of Greater London has been increasing steadily and that since 1921 a decline in the population of the administrative county has for the first time been added to the long decline in that of the City. The increase in the whole London area since 1921 has taken place, therefore, entirely outside the county boundary, and of this increase the most striking feature is the rapid growth, particularly since 1931, of Outer London. In fact, this area of only 576 sq.mi., showed an increase in population in the 17-year period 1921–38 almost equal to that of the whole of the remainder of England and Wales, the figures for each being 1,641,522 and 1,686,479 respectively. Thus there have been two distinct population movements, one outward from the centre and one inward from the provinces. The outward movement was, however, desirable, since the density in the administrative county was in places high, *e.g.,* Southwark, with about 150 persons per acre, but if adequate accommodation under proper conditions is to be provided in the future for the migrating inhabitants of the county in the space surrounding it, then the inward flow from the provinces must be diverted to other areas.

As the population of London has been increasing, so has its character been changing. For centuries London has been one of the greatest seaports of the world and a great centre of commerce, but never before had it been a centre of manufacturing industry in the way it was becoming up to the outbreak of World War II; and a great part of the new development was in the outer ring. One effect of this trend was to raise the proportion of the population born outside the area, through immigration that was to a great extent industrial in character. At the outbreak of World War II about half the population of Greater London and a considerably higher proportion of that of Outer London were foreign to them.

The birth-rate, which averaged 35.4 per thousand in 1861–80 and 30.3 in 1891–1900, had fallen to 13.4 in 1937. The death-rate (23.4 per thousand in 1861–80, 19.2 in 1891–1900), fell to 12.7 in 1937. The deaths of infants under one year old were 60 per thousand births. In 1937 the lowest death-rates among the metropolitan boroughs were returned by Lewisham (10.9), Woolwich (11.1), Hackney (11.2), and the City (11.5). The highest rate was 14.6 in Finsbury, followed by Chelsea and Southwark with 14.1 each.

GENERAL VIEWS OF LONDON

1. Fleet street looking toward St. Paul's cathedral. Here is the publishing centre of London
2. Regent street, looking north. This street is one of the busiest in London and, especially in the vicinity of Piccadilly circus, is the capital's fashionable shopping centre
3. St. James's palace, built by King Henry VIII. It was the royal residence from the reign of William III until 1809, when it was almost completely destroyed by fire.
4. Aerial view of Trafalgar square, named in commemoration of Admiral Nelson's victory at Trafalgar, with the Nelson monument at the right. The National gallery (*see* fig. 6) is on the left and beyond it, the Church of St. Martin's-in-the-Fields. Charing Cross station and the Strand may be seen at the top of the picture
5. Looking down Piccadilly to Piccadilly circus (at top of picture), an irregularly shaped circus at the junction of several important streets. The curved street at the upper left is Regent street
6. The north side of Trafalgar square, occupied by the National Gallery and the National Portrait gallery. The Church of St. Martin's-in-the-Fields is at the right

VIEWS OF THE THAMES AND LUDGATE CIRCUS

1. Scene taken at night from Lambeth bridge, showing the Houses of Parliament, with Westminster Abbey in the left centre. In the distance, at the right, is seen Westminster Bridge, which crosses the Thames below the Houses of Parliament
2. Aerial view of the Thames, and Tower Bridge which was built at a cost of £1,500,000 and opened in 1894. The central span is 200 feet long; those on either side with chain suspension, 270 feet each. A raised footway, 142 feet above high water, is reached by stairs in the Gothic towers. The central portion of the roadway consists of bascules which can be raised to admit the passage of vessels
3. View of Ludgate Hill, showing St. Paul's Cathedral at the top and Ludgate Circus in the foreground

Housing.—It was not until the royal commission's report of 1884–85 on housing that public opinion became aroused to the necessity for action in the eradication of slums, and in 1890 was passed the Housing of the Working Classes act, the foundation of modern housing legislation, which consolidated the powers for dealing with unhealthful areas, of which there were about 200 under the county council, and for erecting new dwellings. At the turn of the century the metropolitan and borough councils began to provide flats and housing in addition to those replacing clearances, but progress was slow until after World War I. After 1919, however, enormous strides were made, due on the one hand to government demands and on the other to state aid to local authorities and subsidies and guarantees to private enterprise. The metropolitan and borough councils provided 12,692 new dwellings between 1889 and 1919, but in the following two years the L.C.C. alone built 9,430 new houses. Only a small proportion of this building represented slum clearance, attention having been directed toward the more pressing problem of additional housing, which in large part was provided in housing estates in the suburbs. The best known of these is the Becontree estate of 2,784 ac. in Essex, with a population of about 120,000 in 26,000 houses, the largest municipal housing estate in the world. Of the total area, 500 ac. have been reserved for open spaces, including a central area of 118 ac. Other estates are St. Helier (40,000 people in over 9,000 dwellings) and Downham (over 7,000 houses), while the White City estate of block dwellings is planned for 10,000 persons.

In June 1934, state aid for additional housing came to an end, since under the 1933 act government financial assistance was to be applied chiefly toward slum clearance, building to be by private enterprise, though under guaranteed mortgage loans if necessary. But by March 1938 the position was that 74,465 additional dwellings had been provided by the county council, the City and the metropolitan boroughs.

Slum Clearance.—In the meanwhile progress was being made in slum clearance and rehousing, though slowly until 1930, when an act was passed enabling the council to proceed on a bigger scale by giving it power to declare "improvement areas" and by so doing requiring owners of premises to make them sanitary or, if that was impossible, have them demolished by the borough council, who could provide new accommodation for people thus displaced. Five areas involving 11,000 persons were cleared under these powers and the rehousing was undertaken by the local authorities. In 1934 a scheme to clear all the London slums in 10 years, involving the displacement of about 250,000 people and costing nearly £35,000,000, was begun by adopting a three-year program for clearing 132 ac. affecting over 80,000 persons. Further progress was facilitated the following year by a new housing act which granted greater powers, whereby the council could clear and replan large areas ("redevelopment areas"). In July 1938 a single area of 46 ac., housing about 4,700 persons, was being dealt with.

Under the same act a new attack on overcrowding was begun. A survey completed in 1936 showed that about 71,000 families were living in overcrowded conditions in London, an average of 7 families in 100. Woolwich (under 3%) had least overcrowding and Shoreditch (over 17%) most. It was estimated that 24,000 dwellings would be required to abate this condition and by March 1938 the council had provided 2,363.

Slum clearance and rehousing, as distinct from additional housing and the abatement of overcrowding, may be summarized thus —between 1919 and March 1938 orders were confirmed for the clearance of 135 insanitary areas occupied by more than 127,000 persons. About 12,500 premises were demolished, displacing about 88,000 persons, and 16,132 dwellings were built for rehousing, of which 15,580 were in flats. The total expenditure was £12,000,000. During the same period the City and the metropolitan boroughs completed or had in hand schemes displacing 54,809 persons and erected 7,614 new dwellings for rehousing.

The achievement of the county council far exceeds any work of the kind previously carried out. At the end of March 1940 it owned and managed about 98,500 dwellings, occupied by about 424,000 persons, and its capital expenditure on dwellings and housing estates had exceeded £60,000,000. The rate of subsequent development was uncertain, owing to the destruction caused by World War II, which affected not only dwellings, of which about 1,500,000 were damaged, but also other properties that would have to be included in further building schemes.

Sanitation.—The London county council is a central sanitary authority; the City and metropolitan boroughs are sanitary districts, and the corporation and borough councils are local sanitary authorities. The county council deals directly with matters where uniformity of administration is essential, *e.g.*, main drainage, housing of working classes, infant life protection, common lodging-houses and shelters, and contagious diseases of animals. With a further view to uniformity it has certain powers of supervision and control over local authorities, and can make by-laws respecting construction of local sewers, sanitary conveniences, offensive trades, slaughter-houses and dairies, and prevention of nuisances outside the jurisdiction of local authorities.

The first act providing for a commission of sewers in London dates from 1531. Various works of a more or less imperfect character were carried out, such as the bridging over in 1637 of the river Fleet, which as early as 1307 had become inaccessible to shipping through the accumulation of filth. Scavengers were employed in early times, and sewage was received into wells and pumped into the kennels (channels) of the streets. A system of main drainage was inaugurated by the Commissioners of Sewers in 1849, but their work proceeded very slowly. It was carried on more effectively by the Metropolitan Board of Works (1856–88), and was transferred in 1889 to the newly created London county council, who completed and improved the system, which covers the county of London, Willesden, Tottenham, Wood Green, West Ham, Brent area (Willesden), Leyton, Walthamstow, Ilford, Barking and Penge and parts of Acton, Croydon, Beckenham, Hornsey and East Ham. There are actually two distinct systems, north and south of the Thames, having separate outfall works on the north and south banks of the river, at Barking and Crossness. In 1937 there were 420 mi. of main sewers vested in the council, excluding street sewers and sewers outside the county area draining into the main system. There are about 2,500 mi. of streets in the county, and the London main drainage area is about 160 sq.mi. The sanitary authorities are concerned only with the supervision of house drainage, and the construction and maintenance of local sewers discharging into the main system. The Thames and the Lea Conservancies have powers to guard against the pollution of the rivers.

Hospitals.—Until consolidated under the county council on April 1, 1930, the hospital services of London, excluding the voluntary hospitals (*see* below), were divided between the 25 boards of guardians and the Metropolitan Asylums board (established in 1867 as a poor law authority), and amounted, really, to a hospital branch of the poor law. Sickness of a general character was treated in the poor law institutions, while insanity and infectious diseases came under the jurisdiction of the asylums board. In course of time, and more rapidly in the asylums board hospitals, the poor law requirements were relaxed, as ideas regarding public health broadened, so that the sick poor, as distinct from the destitute, came to be treated.

The new doctrine was given effect by the Local Government act of 1929, under which the council was empowered to provide hospitals and was required to separate institutional treatment of the sick from the poor law administration as soon as possible. At the same time all the hospitals and institutions of the boards of guardians (abolished) and the asylums board were transferred to the council. These amounted to 140 hospitals, schools and other institutions—75,000 beds and about 180,000 people in receipt of relief.

A survey of the transferred poor law institutions revealed the necessity for a reclassification of the chronically sick and their separation from the able-bodied. As a result, 12 of the mixed institutions were selected for use as hospitals for the chronically sick and placed under the control of the Central Public Health committee, which was formed to undertake all the public health work of the council. (Some time later this committee was divided into the Hospitals and Medical Services committee and the Housing and Public Health committee.) After this transference the committee's control extended to the general hospitals, comprising 29 hospitals (formerly poor law infirmaries) containing 18,074 beds, the 12 institutions previously mentioned, containing 9,401 beds, and 2 colonies for sane epileptics containing 809 beds, in addition to the special hospitals of the asylums board, which comprised in the main 18 hospitals for infectious diseases, 9 for tuberculosis and 5 children's institutions. There were also the board's laboratories and land and river ambulance services.

The council immediately embarked upon a comprehensive program of hospital improvement and enlargement and a start was made to "appropriate" various hospitals, *i.e.,* to declare which of them would no longer be poor law hospitals. By mid–1932, 60 had thus been transferred, but after April 1938, all the council's hospitals, acute, chronic and special, were administered under its public health powers. About £3,000,000 had been spent by mid-1938 on improvements, well seen in Lambeth and Hackney hospitals, and in 1937 the council decided to build at Tooting, in the grounds of St. Benedict's hospital, a new hospital of 600 beds, the first to be built under its new power. Further provision for medical education was made by the establishment at Hammersmith hospital by the council, in co-operation with the ministry of health and London university, of a post-graduate medical school, which was opened by King George V in May 1935.

The county council in 1944 maintained 10 mental hospitals, 77 general and special hospitals, and an ambulance service of 173 vehicles, besides 13 institutions (workhouses), 2 emergency nurseries, 3 homes for the aged, 1 receiving home for children, 1 residential training centre, 2 hostels and 5 casual wards.

At the end of 1936 there were 107 voluntary hospitals, *i.e.,* hospitals not under public management, in the London county area, containing 15,443 beds. Some control over them is exercised by the King Edward's Hospital fund through its power of giving or withholding grants, for which voluntary hospitals and convalescent homes within a radius of 11 mi. of St. Paul's cathedral may apply. By the Public Health (London) act, 1936, the London county council may also grant funds to these hospitals, if by so doing it maintains or extends the efficiency of the hospital accommodation in the county. Most of London's best known hospitals are voluntary hospitals, such as St. Bartholomew's, the oldest, founded by Rahere in 1123, St. Thomas's (1200), Guy's (1724), St. George's (1733) and St. Mary's (1845); the London hospital (1740), with 865 beds in 1937, is the largest in the country.

There are several regular funds in London for the support of voluntary hospitals. The chief is the King Edward's Hospital fund (mentioned above), founded in 1897 and incorporated in 1907, with which the League of Mercy co-operates in the collection of small subscriptions. The Metropolitan Hospital Sunday fund (1873) draws the greater part of its revenue from collections in churches. The Hospital Saturday fund (1873) is made up chiefly of small sums collected in places of business, etc. The British Charities association (1923) raises money mostly by prize competitions and similar schemes. The Voluntary Hospitals commission, founded to administer a government grant of £500,000 in 1921, was later put on a permanent basis as a link between the government and the committees of the voluntary hospitals. The Medical Research council (1920) is in charge of government research funds.

To care for the anticipated large number of civilian casualties as a result of air raids in World War II, an emergency hospital scheme on a national scale was set up under an Emergency Medical Service division created in the ministry of health. Hospitals remained under their peace-time administration, but their work was controlled by the E.M.S. London was divided into 9 sectors (6 north and 3 south of the Thames), each with one or more teaching hospitals at its apex and stretching out to base hospitals up to 50 mi. away. At the outbreak of war 71,600 beds out of 98,000 in the London E.M.S. region were reserved for E.M.S. cases, an accommodation made possible by the discharge of patients or their removal to hospitals outside the danger area. During the period Aug. 1940–May 1941, air raids seriously damaged 43 voluntary hospitals and 30 others suffered, while only four or five county council hospitals escaped. Top floors had to be closed and work carried on in basements. By the end of 1941 the nine sectors had available 68,500 casualty beds, of which about 36,000 were in casualty receiving or advanced base hospitals. (*See* also PUBLIC HEALTH.)

Water Supply.—In the 12th century London was supplied with water from local streams and wells, of which Holy well, Clerk's well (Clerkenwell) and St. Clement's well, near St. Clement's Inn, were examples. In 1236 the magistrates purchased the liberty to convey the waters of the Tyburn from Paddington to the City by leaden pipes, and a great conduit was erected in West Cheap in 1285. Other conduits were subsequently built (*cf.* Conduit street off Bond street, Lamb's Conduit street, Bloomsbury); and water was also supplied by the company of water-bearers in leathern panniers borne by horses. In 1582 Peter Moris, a Dutchman, erected a "forcier" on an arch of London bridge, which he rented for 10s. per annum for 500 years. His works succeeded and increased, and continued in his family till 1701, when a company took over the lease. Other forciers had been set up, and in 1609, on an act of 1605, Sir Hugh Myddelton undertook the task of supplying reservoirs at Clerkenwell through the New river from springs near Ware, Hertfordshire; and these were opened in 1613. In 1630 a scheme to bring water from Hoddesdon on the Lea was promoted by aid of a lottery licensed by Charles I. The Chelsea Water company opened its supply from the Thames in 1721; the Lambeth waterworks were erected in 1783; the Vauxhall company was established in 1805, the West Middlesex, near Hammersmith, and the East London on the river Lea in 1806, the Kent on the Ravensbourne (Deptford) in 1810, the Grand Junction in 1811, and the Southwark (which amalgamated with the Vauxhall) in 1822.

For many years proposals to amalgamate the working of the companies and displace them by a central public authority were put forward, until in 1902 the Metropolis Water act constituted the Metropolitan Water board to purchase and carry on the undertakings of the eight then existing companies, and of certain local authorities. It consists of 66 members, appointed by the London county council (14), the City of London (2), the City of Westminster (2), the other metropolitan boroughs (27), the county councils of Middlesex, Hertfordshire, Essex, Kent and Surrey, the borough of West Ham, various groups of other boroughs and urban districts, and the Thames and the Lea Conservancies. June 24, 1904, was the date fixed on which control passed to the board and by 1943 it was the largest water company in the world. It serves an area of 576 sq.mi. (42 mi. from N. to S. and 34 mi. from E. to W.) and the area and capacity of the combined reservoirs are about 2,700 ac. and 20,000,000,000 gal. respectively. Roughly 60% of the water supplied by the board is taken from the Thames, next in importance being the Lea and New rivers. The principal reservoir is the Queen Mary reservoir at Littleton, Middlesex, which is the largest artificial reservoir in the world, with an area of 723 ac. and a capacity when full of 6,750,000,000 gal. The average amount of water supplied daily by the board was 293,500,000 gal. in 1942 and there were then 8,275 mi. of water pipes.

Public baths and washhouses are provided by local authorities under various acts between 1846 and 1896, which have been adopted by all the borough councils.

Lighting.—From 1416, citizens were obliged to hang out candles between certain hours on dark nights to illuminate the streets. An act of parliament enforced this in 1661; in 1684 Edward Heming, the inventor of oil lamps, obtained a licence to supply public lights; and in 1736 the corporation took the matter in hand, levying a rate. Gaslighting was introduced on one side of Pall Mall in 1809, though it is said that Golden Lane Brewery and portions of Beech and Whitecross streets were lit by gas in 1807. In 1810 the Gas Light and Coke company received a charter, and developed gaslighting in Westminster. There are now three principal companies within the county, the Gas Light and Coke, South Metropolitan and Commercial, though certain other companies supply some of the outlying districts.

The Metropolitan Board of Works, and the commissioners of sewers in the City began experiments with electric light, which was introduced in 1881 at the Royal Exchange and neighbourhood. At the close of the 19th and the beginning of the 20th century a large number of electric light companies came into existence, and some of the metropolitan borough councils, and local authorities within Greater London also undertook the supply. Under the Electricity Supply Act of 1926, the London and Home Counties joint electrical authority, composed of representatives of the county councils and the electrical undertakings, was formed, and made responsible for the supply over an area of 1,841 sq.mi., stretching from Guildford to Gravesend and from Hertford to Reigate. A large new power station was constructed at Chiswick. Battersea power station belongs to the Central Electricity board.

Fire.—In 1832 the fire insurance companies united to maintain a small fire brigade, and continued to do so until 1866. The brigade was confined to the central part of the metropolis; for the rest, the parochial authorities had charge of protection from fire. The central brigade came under the control of the Metropolitan Board of Works and was taken over by the county council in 1889, when it consisted of 48 steam engines, 78 manual engines, 146 fire escapes, and about 30 mi. of hose. In 1880 alarms had been introduced on the "open circuit" system, which remained as standard until 1938, when the council decided to replace it by a "closed circuit" system. Appliances for fighting riverside fires had been in existence for more than 25 years when the county council took over, but until 1900, when the first modern fireboat made its appearance, fire-engine rafts manoeuvred by tugs were used. In 1935 a more powerful type of boat, having a pumping capacity of 3,000 gal. a minute, was introduced. The famous brass helmets of the London firemen, which were provided first by Captain Shaw (later Sir Eyre Massey Shaw), commander of the brigade at the time of its transference to the council, are now obsolete, and in about 1935 began steadily to be replaced by a new type composed of a cork and canvas compound. This step was made necessary by the electrical risks encountered in a modern burning building. By 1938 the equipment mainly used by the brigade consisted of 56 "dual-purpose" engines, *i.e.*, machines combining a pump and a 50-ft. escape, 73 pumps (enclosed and otherwise), 20 escape vans (being replaced by dual-purpose engines), and 15 river craft. There were also 14 turntable ladders, about half being fitted with pumps, and 65 mi. of hose. In Oct. 1937 the first enclosed dual-purpose engine was introduced. It carried a steel escape, the first to be used by the brigade.

The headquarters of the brigade were formerly in Southwark Bridge road, but in July 1937 they were transferred to a new building, constituting both a land and river station, on the south bank of the Thames near Lambeth bridge. This accommodated the central administrative offices and the living quarters of the chief officer and 12 other officers. In 1888 the brigade consisted of 581 men, but 50 years later had risen to 2,562 persons. Only about 2% of the applicants for membership are recruited, owing to the high standard of physical fitness required. The cost of the brigade is borne mostly by the London ratepayers, but contributions are received from the government and the tariff insurance companies, who also maintain a salvage corps.

The chief development during World War II was the formation, on Aug. 18, 1941, as a wartime measure, of the National Fire Service under the Fire Services (Emergency Provisions) act, 1941, which transferred the whole fire brigade resources of the country from local to government control, London being constituted a region itself. The new organization embodied the professional and part-time brigades and the auxiliary fire services. By the spring of 1942 personnel totalled about 212,000, including 100,000 part-time men. Facilities for training had been extended, equipment brought up-to-date, and many local brigade buildings enlarged and improved. A large number of sites of bombed buildings had been converted into reservoirs and many more steel water tanks erected in the streets. The new service is considered to have more than justified itself, especially as regards its flexibility of operation.

Cemeteries.—The administrative authorities of cemeteries for the county are the borough councils and the City corporation and private companies. The large cemetery at Brompton is the property of the government. Kensal Green cemetery, the burial-place of many famous persons, is of great extent, but several large cemeteries outside the metropolis have come into use. Such are that of the London Necropolis company at Brookwood, near Woking, Surrey, and that of the parishes of St. Mary Abbots, Kensington, and St. George, Hanover square, at Hanwell, Middlesex. Crematoria are provided at Golder's Green, Norwood, Ilford (for the city of London), and Brookwood.

EDUCATION AND RECREATION

Education.—The British and Foreign School society (1808) and the National society (1811), together with the Ragged Schools Union (1844) were the only special organizations providing for the education of the poor until 1870, but in that year, when the London School board was created, more than half the child population of London had no school to attend. Under the Education (London) act, 1903, which was passed in pursuance of the system, put into operation by the Education act, 1902, of bringing general education within the scope of municipal government, the board's activities were transferred (1904) to the county council, which at the same time was given the responsibility of maintaining the voluntary schools.

By then the board had running a sound system of elementary education, and provision had been made for every child in need of education, while compulsory attendance had been enforced in 1876. In all there were transferred to the control of the council 521 board schools, with an average attendance of 485,000 students; 438 voluntary schools, with 175,000 students; special schools containing 5,000 blind, deaf and defective children; 356 domestic economy centres and 196 manual training centres; 373 evening schools, with 145,000 students, and 9 industrial schools.

Organized higher technical education was slower in coming and did not get under way until the formation in 1893 of the Technical Education board, under the county council, which was, therefore, from the first the authority for such education. It found a woeful lack of instruction in chemistry, electricity, art and technical subjects, but during its 11 years' existence did much to improve matters, partly through grants to existing voluntary technical institutions and partly through conducting centres itself. With the help of the parochial charities the number of polytechnics and technical institutes was raised from 8 to 26, day classes were increased threefold and the student hours of evening students fourfold. There were also established the Central School of Arts and the London Day Training college (since 1932 the Institute of Education), besides many science lecture rooms, laboratories, and workshops, while a scheme of scholarships to link elementary and secondary education was set up.

Provision for the foundation of polytechnics was made under the City of London Parochial Charities act, 1883, the model institution being that of Quintin Hogg, which had been opened in Regent street the previous year. Polytechnics give instruction in general knowledge and special crafts and trades and usually have art schools attached. In 1880 the City and Guilds of London institute was formed for the advancement of technical education, but before that time little had been done to promote such instruction, though useful lectures and examinations were held by the Science and Art department, founded in 1853.

The unification of educational control enabled the county council to proceed with a co-ordinated program to develop a complete system. This is now done through a succession of three-year plans, under which a forward movement is assured, and improvements are carried out as they relate to an ordered scheme. Prominent among the steps that have been taken by the council are—the improvement of teachers through the raising of qualifications, higher salaries, and promotion only through merit, besides the provision of refresher courses and a special library; the great increase in the number of scholarships connecting elementary with secondary education; and the creation of central and junior technical schools.

After 1907 only teachers holding certificates were eligible for the council's elementary schools, while secondary school teachers were normally required to have a university degree. The appointment of head teachers and principals is made by the education committee or its teaching staff subcommittee. Teachers for non-provided schools (*see* below) are selected by the school managers. The council maintains two training colleges for elementary school teachers, one for men specializing in handicrafts, and one providing courses in physical education. Special lecture courses are also held, and were attended in 1937 by about 37,000 teachers. The work of teachers was greatly facilitated by a reduction in the size of classes, which were limited to 40 students in senior and 48 in infants' departments.

Elementary schools are of two kinds—those that are provided by the council and those that are not, the latter being known as non-provided schools. These, however, are maintained by the council except for the buildings, which belong to managers who usually represent some religious body. The education given in both sorts of schools is the same, and in 1943 there were in all 892 elementary schools under the council, attended by 428,000 pupils. This represented a fall of 52,000 in attendance from the 1937 figure, the reduction being due to evacuation during World War II.

Compulsory attendance at school begins at the age of five, but before then children may be sent to nursery schools or babies' classes, where instruction is confined to training in good habits. There were about 20 nursery schools in 1937, but the number subsequently increased, and during World War II many residential nursery schools were established outside the London area for evacuated children.

The separation of primary and post-primary education was advanced by means of the "central" schools, established by the council in 1911. These were a development of the "higher-grade" schools set up by the school board in 1898, but in future were to provide a general education with a commercial or technical bias. At the end of March 1938 there were 87 central schools attended by about 31,700 students. At the same time there were 212 senior departments with over 73,300 pupils. These departments, or schools, originated in 1924 and were to secure that elementary school children over 11 years should have the advantage of spending their later school life in places expressly organized for them. The aim is to set up all the senior departments as separate schools.

The scholarship scheme is very extensive and in 1938 about 60% of the pupils in the secondary schools held some form of award. Scholarships are open, in the first place, to children of 11 years, taking them to the secondary schools, and from there they may proceed by means of further awards to a university, technical college or other institution providing advanced teaching. There are also technical and art scholarships and evening exhibitions for those in employment. The total number of scholarships, exhibitions and free places held in 1937 was about 28,000.

A number of secondary schools was already in existence when the county council became London education authority, many of them ancient foundations and some already receiving aid from the Technical Education board. The act of 1903, however, obliged the council "to supply, or aid the supply of, education other than elementary," and to do this effectively it soon became apparent that more secondary schools were needed. The council therefore founded many new ones, which were known as "maintained" schools, the rest being "aided" schools. In 1937 the former contained about 12,200 places and the latter about 22,000.

Technical and continued education includes both vocational and non-vocational studies at nearly 250 institutes of various kinds, comprising polytechnics, technical and trade schools, schools of art, day continuation schools and evening institutes. The evening institutes and all the day continuation schools but one are maintained by the council. Some of the technical schools and schools of art are maintained, while others receive aid, all the polytechnics being aided. During 1936–37 the total enrolment for technical and continued education was more than 250,000 and the number of student-hours worked reached 26,000,000.

In the technical schools evening classes are mainly for adults, but full-time day courses are provided in the form of junior technical schools, the first of which was established in 1904. Senior technical courses are available to students over 16 years. The day continuation schools came under the Education act of 1918 and are for students of 14 to 18 years of age. The courses are definitely vocational.

The present organization of evening institutes dates from 1913, when the whole system of evening education was overhauled and co-ordinated. The junior institutes are for students under 18 and the senior for those above that age. There are also institutes devoted to instruction in particular subjects, such as the St. Bride's Foundation institute, near Fleet street, for the printing trade, the School of Building at Brixton and the Poplar School of Engineering and Navigation. Classes are sometimes arranged for employees of particular firms. The evening institutes include senior and junior commercial and technical, literary and men's and women's institutes.

The educational system provides special schools for the defective. In 1943 there were under the council 110 schools (including open-air schools) for the blind, deaf and physically and mentally defective, some of which are outside the county, 10 residential homes (for children over three for whom indoor relief is required) and 11 hospital schools, which are attended by children undergoing prolonged treatment in the council's hospitals. The foundation of these special schools dates from 1874, when the school board established education for the blind and deaf. Eighteen years later came centres for helping the mentally and physically defective. These schools were legalized by the acts of 1893 and 1899, and by 1938 the enrolment was 534 blind, 486 deaf, 2,611 mentally defective and 2,522 physically defective children.

Philanthropic Institutions.—The labours of the clergy in the poorer parts of London, such as the "East End," Southwark, Bermondsey, St. Pancras and North Kensington, lie largely in the direction of social reform, and churches and missions have been established and are maintained by colleges, schools and other bodies. There are, further, "settlements" where members of the various bodies may reside in order to devote themselves to philanthropical work; and these include clubs, recreation rooms and other institutions for the use of the poor. Such are the Oxford house, Bethnal Green; the Cambridge house, Camberwell road; Toynbee hall, Whitechapel; Mansfield house, Canning Town; the Robert Browning settlement, Southwark; and the Passmore Edwards settlement, St. Pancras. There are also several women's settlements of a similar character. The People's palace, Mile End road, opened in 1887 as a recreative and an educational institution, suffered a disastrous fire in 1931. Its educational side now centres in Queen Mary college, formerly known as East London college.

Public Schools.—In early times the priories and other religious houses had generally grammar schools attached to them. Those at St. Peter's, Westminster and St. Paul's attained a fame which has survived, while other similar foundations lapsed, such as St. Anthony's (Threadneedle street, City), at which Sir Thomas More, Archbishop Whitgift and many other men of eminence received education. Certain of the schools were re-endowed after the dissolution of the monasteries. St. Peter's college or Westminster school (*see* WESTMINSTER) is unique among English public schools of the highest rank in maintaining its original situation in London. Other early metropolitan foundations have been moved in accordance with modern tendencies either into the country or to sites aloof from the heart of London. Thus Charterhouse school, part of the foundation of Sir Thomas Sutton (1611), was moved (1872) from Finsbury to Godalming, Surrey; St. Paul's school (1509) occupies modern buildings at Hammersmith since 1884, and Christ's hospital (1553) has been at Horsham, Sussex, since 1902. Of other schools, Merchant Taylors' was founded by the company of that name in 1561, and occupied the premises vacated by Charterhouse school from 1875 to 1933, when it moved to Sandy Lodge, near Rickmansworth. The Mercers' school, Holborn, originally attached to the hospital of St. Thomas of Acon, was refounded in 1447. It was taken over by the Mercers' company in 1542 and was transferred to Barnard's Inn in 1894. The City of London school (1442), refounded in Milk street, Cheapside, by the City corporation in 1835, occupies modern buildings on the Victoria embankment. Dulwich college originates in a licence granted in 1619 to Edward Alleyn to found a college in Dulwich. Under an act of 1857 two schools were constituted—Dulwich, or the Upper school, and Alleyn's, or the Lower school. St. Olave's and St. Saviour's Grammar school received its charter in 1561 and since 1896 has been in new buildings in Bermondsey.

London University.—The University of London was incorporated by royal charter in 1836, as an examining body for conferring degrees, but only those who had studied at an "approved institution" were admitted to examination. Under the charter of 1858, however, the examinations (other than medical) were thrown open to anyone from the British Isles and the empire. This charter also admitted graduates to the university government and conferred on them the right to assemble in convocation. A supplemental charter of 1878 admitted women to degree examinations, and London was thus the first university in the kingdom to do so. The university was also the first in the country to found a faculty of science, which it did in 1859.

Under the University of London act, 1900, the university was reorganized as both a teaching and an examining body, and there were set up an academic council to control teaching and research, a council for external students to control external examinations, and an extension board to supervise university extension work. It was further provided that teaching should be carried on in colleges, which in future were known as schools of the university, and research institutions were admitted as schools. An advisory service for external students was set up in 1924, whereby they were provided with complete schemes of reading by teachers of the university.

In 1929 revised statutes came into force. These had been drawn up by commissioners appointed for the purpose under the University of London act, 1926. The most important changes were the creation of a court (on which the L.C.C. has two representatives) to control finances; a collegiate council, consisting of the heads of the schools, whose duties included the co-ordination of the work of the schools and the organization and extension of social facilities for students; and the grouping of matriculation and schools examinations under one council. The senate is the supreme governing and executive body in all academic matters.

From 1835–55 the university occupied rooms in Marlborough house and then moved to Burlington house, where it remained until 1870, when it moved to a building in Burlington gardens later occupied by the Civil Service commissioners. From 1900–36 the university headquarters were in the Imperial institute in South Kensington, but in that year the administrative offices were moved to the new senate house and library in Bloomsbury. This site was acquired in 1927 with the help of a gift of £400,000 from the Rockefeller foundation and it was hoped that eventually it would accommodate all the university departments, several of which moved in after 1937. During World War II the buildings were occupied by the ministry of information.

Colleges incorporated in the university are University and King's colleges, and schools include King's college theological department and three other theological colleges, Queen Mary college, the London School of Economics, Royal Holloway college and Bedford college, the Institute of Education (formerly the London Day Training college), the Imperial College of Science and Technology, the South Eastern Agricultural college, King's College of Household and Social Science, various medical colleges and institutes, including the London School of Hygiene and Tropical Medicine and the Lister Institute of Preventive Medicine, and the medical schools of 12 hospitals. Important foundations are the Institute of Historical Research (1920) and the Courtauld Institute of Art (opened in 1932). A university observatory was founded in 1929 at Mill Hill, Hendon.

Other Educational Institutions.—The board of education directly administers the following educational institutions—the Victoria and Albert museum, South Kensington, with its branch at Bethnal Green, from both of which objects are lent to various institutions for educational purposes; the Geological Survey of the United Kingdom and the Museum of Practical Geology, South Kensington; the Solar Physics observatory, South Kensington; and the Royal College of Art, South Kensington. At Gresham college, Basinghall street, City, founded in 1597 by Sir Thomas Gresham, and moved to its present site in 1843, lectures are given in the principal branches of science, law, divinity, medicine, etc.

Some further important establishments and institutions may be tabulated here:—

Architecture.—The Royal Institute of British Architects, Conduit street, conducts examinations and awards diplomas.

Education.—The College of Preceptors, Bloomsbury, conducts examinations of persons engaged in education and awards diplomas.

Law.—The Inns of Court are four—Middle Temple, Inner Temple, Lincoln's Inn, Gray's Inn. A joint board of examiners examines students previous to admission. The Council of Legal Education superintends the education and subsequent examination of students. (*See* INNS OF COURT AND CHANCERY.) The Law society is the superintending body for examination and admission in the case of solicitors.

Medical.—The Royal College of Physicians is in Pall Mall East, and the Royal College of Surgeons is in Lincoln's Inn Fields. The Society of Apothecaries is in Water lane, City. The Royal College of Veterinary Surgeons is in Red Lion square, and the Royal Veterinary college at Camden Town.

Military and Naval.—The Royal Military academy is at Woolwich; the Royal Naval college at Greenwich.

Music.—The principal educational institutions are—the Royal Academy of Music, York gate, Marylebone road; the Royal College of Music, South Kensington; Guildhall school, City, near the Victoria embankment; London college, Great Marlborough street; Trinity college, Mandeville place; and the Royal College of Organists, Kensington Gore.

Scientific Societies.—Burlington house, in Piccadilly, built in 1872 on the site of a mansion of the earls of Burlington, houses adapted to the needs of the Royal society, the Chemical, Geological, Linnaean and Royal Astronomical societies, the Society of Antiquaries and the British Association for the Advancement of Science. The Society of Arts, John street, Adelphi, was established in 1754 for the encouragement of arts, manufactures and commerce. The Royal institution, Albemarle street, was founded in 1799, maintains a library and laboratories and promotes research in connection with the experimental sciences. The Royal Geographical society, occupying a building in Kensington Gore, maintains a map-room open to the public, holds lectures by prominent explorers and geographers, and takes a leading part in the promotion of geographical discovery. The London society, Lancaster house, St. James's, was founded in 1912 to stimulate interest in the development of London. The Royal Horticultural society maintains gardens at Wisley, Surrey, and has an exhibition hall in Vincent square, Westminster. The exhibitions of the Royal Agricultural society are held at Park Royal, near Willesden. The Zoological society maintains a magnificent collection of living specimens in the Zoological Gardens, Regent's park, a popular resort.

Museums, Art Galleries, Libraries.—In the British museum, London possesses one of the most celebrated collections in the world, originated in 1753 by the purchase of Sir Hans Sloane's collection, and library by the government. The great building in Bloomsbury (1828–52) with its massive Ionic portico, houses the collections of antiquities, coins, books, manuscripts and drawings, and contains the reading-rooms for the use of readers. The natural history branch was removed to a building at South Kensington (the Natural History museum) in 1881, where the zoological, botanical and mineralogical exhibits are kept. Close to this museum is the Victoria and Albert museum for which an extension of buildings, from a fine design by Sir Aston Webb, was begun in 1899. Here are collections of pictures and drawings, including the Raphael cartoons, objects of art of every description, including Japanese, Chinese and Persian collections, and an Indian section. The Science museum, near by, has divisions of industrial and mechanical engineering, transport in all its branches, and scientific instruments. In the vicinity, also, is the fine building of the Imperial institute, founded in 1887 as an exhibition to illustrate the resources of all parts of the empire, as well as an institution for the furtherance of imperial intercourse. The London museum, in Lancaster house, St. James's (1914; previously in Kensington palace) illustrates the antiquities and history of London. Other museums are Sir John Soane's collection in Lincoln's Inn Fields and the Museum of Practical Geology, South Kensington, while the scientific societies have libraries and in some cases collections of a specialized character, such as the museums of the Royal College of Surgeons, the Royal Architectural society, the Wellcome Historical Medical museum and the Parkes Sanitary museum. Among permanent art collections the first place is taken by the National gallery in Trafalgar square. This magnificent collection was originated in 1824, and the building dates from 1838, but has been more than once enlarged. The building of the National Portrait gallery, adjoining it, dates from 1896, but the nucleus of the collection was formed in 1858. The munificence of Sir Henry Tate provided the gallery, commonly named after him, by the Thames near Vauxhall bridge, which contains the national collection of British art. The Wallace collection of paintings and objects of art, in Hertford house, Manchester square, was bequeathed to the nation by the widow of Sir Richard Wallace in 1897. Of the periodical art exhibitions that of the Royal academy is most noteworthy. It is held annually at Burlington house from the first Monday in May to the first Monday in August. It consists mainly of paintings, but includes a few drawings and examples of sculpture. There are many art galleries in and about Bond street and Piccadilly, Regent street and Pall Mall. An industrial museum was opened in Horseferry road by the home office in 1927. The Imperial War museum in Lambeth road was founded in 1917.

Municipal provision of public libraries under acts of 1892 and 1893 is general throughout London, and these institutions are exceedingly popular for purposes both of reference and of loan. The London county council administers the Horniman museum at Forest Hill, Lewisham. The City corporation maintains the fine Guildhall library and museum. Besides the government reference libraries at the British museum and South Kensington there are other such libraries, of a specialized character, as at the patent office and the record office. Among lending libraries should be noticed the London library in St. James's square, Pall Mall.

Theatres and Places of Entertainment.—The principal London theatres and music halls lie between Piccadilly and Temple Bar, and High Holborn and Victoria street, the majority being in Shaftesbury avenue, the Haymarket, the neighbourhood of Charing Cross and the Strand. The Covent Garden theatre is the principal home of grand opera; the chief halls devoted mainly to concerts are the Royal Albert hall, close to the South Kensington museums, and, formerly, Queen's hall in Langham place, Regent street. This was destroyed in World War II. Among other popular places of entertainment may be mentioned the new Earl's Court exhibition, rebuilt 1936–37 and covering about 19 ac. It has iceskating, and with Olympia hall, Hammersmith road, is used for such purposes as military tournaments, motorcar "shows," "ideal home" exhibitions and the like; the celebrated waxwork exhibition of Madame Tussaud in Marylebone road, burned in 1925, restored, and again damaged in World War II; and the Agricultural hall, Islington, where agricultural and other exhibitions are held. Theatres, music halls, concert halls, cinematograph theatres and so forth, are licensed by the county council, except that the licence for stage plays is granted by the lord chamberlain under the Theatres act, 1843. The council provides for inspection of places of entertainment in respect of precautions against fire, structural safety, etc. The principal clubs are in and about Piccadilly and Pall Mall. (*See* CLUBS.)

(O. J. R. H.; X.)

Parks.—St. James's park, Green park, Hyde park and Kensington gardens (which, with Regent's park, Richmond, Bushey and Greenwich parks, and Kew gardens are royal parks), stretch in an irregular belt for nearly 3 mi. between Whitehall and Kensington. St. James's park was transformed from marshy land into a deer park, bowling green and tennis court by Henry VIII, extended and laid out as a pleasure garden by Charles II, and rearranged according to the designs of John Nash in 1827–29. Its lake, the broad Mall leading up to Buckingham palace, and the proximity of the government buildings in Whitehall, combine to beautify it. St. James's park is continued between the Mall and Piccadilly by the Green park. Hyde park, to the west, belonged originally to the manor of Hyde, which was attached to Westminster abbey, but was taken by Henry VIII on the dissolution of the monasteries. Two of its gateways are noteworthy, namely that at Hyde Park corner at the southeast and the Marble Arch at the northeast. The first was built in 1828 from designs of Decimus Burton, and comprises three arches with a frieze above the central arch copied from that of the Parthenon at Athens, now in the British museum. The Marble Arch was intended as a monument to Nelson; it was erected by John Nash in 1828 in front of Buckingham palace, and was moved to its present site in 1851. In 1908 this corner of the park was cut to give additional accommodation for the heavy traffic between Oxford street, Edgware road and Park lane, and the Marble Arch was left isolated. Hyde park and Kensington gardens between them contain a lake 1,500 yd. in length, known in its park portion as the Serpentine and in the gardens portion as the Long Water; from the bridge which marks the division one of the finest prospects in London is seen, extending to the distant towers of Westminster, and on the north bank of the Serpentine is the bird sanctuary with Epstein's "Rima" memorial to W. H. Hudson. Since the 17th century this park has been one of the most favoured resorts of fashionable society, and at the height of the "season," from May to the end of July, its drives present a brilliant scene. In the 17th and 18th centuries it was a favourite duelling ground, and in the present day it is not infrequently the scene of political and other popular demonstrations

FIG. 1.—THE QUADRANT, REGENT STREET, AS IT APPEARED NEAR THE MIDDLE OF THE 19TH CENTURY. THE COLONNADE WAS REMOVED IN 1848

(as is also Trafalgar square), while the neighbourhood of Marble Arch is the resort of orators on social and religious topics. Kensington gardens were originally attached to Kensington palace, but were subsequently much extended; they are specially favoured by children, for here is the famous Round pond, and in 1912 Sir G. Frampton's statue of "Peter Pan" was placed here. They were magnificently timbered, containing plantations of rare shrubs and flowering trees. Regent's park, mainly in the borough of Marylebone, owes its preservation to George IV, who, when regent, intended to build a palace here, and had the park laid out by John

Nash in 1812. The other most notable open spaces wholly or partly within the county are: Hampstead heath in the northwest, a high-lying tract, preserved to a great extent in its natural state, which, with the adjoining Parliament hill, Ken wood and Golders Hill park, covers some 850 ac.; and in the southwest Wimbledon common and Putney heath (together 1,200 ac.) and the royal demesne of Richmond park (2,358 ac.), which from its higher parts commands a wonderful view up the rich valley of the Thames. The east, south and north are not lacking in open spaces, the chief of which are—Victoria park (217 ac.), in the northeast; Greenwich park (188 ac.), Blackheath (267 ac.) and Woolwich commons in the southeast, and Battersea park (200 ac.), and Wandsworth (183 ac.) and Tooting Bec (217 ac.) commons in the south; but there is an extensive inner area where at most only small gardens and squares break the continuity of buildings, and where, in some cases, old churchyards serve as public grounds. The L.C.C. maintains, in all, 104 open spaces of 6,690 ac., excluding the "greenbelt," which came into being following an offer by the L.C.C. in 1935 to assist county and borough councils to buy or otherwise preserve important land on the outskirts of the London area. The council has set aside £2,000,000 for this purpose and in 1943 over 20,000 ac. had been acquired. Grants towards the acquisition of a further 55,000 ac. have been approved.

Sports Grounds.—Among many sports grounds, the two best known cricket grounds are Lord's, near Regent's park (M.C.C.—Marylebone Cricket club—and Middlesex county matches, Oxford *v.* Cambridge university matches, Eton *v.* Harrow school matches, etc.), and the Oval in Kennington (Surrey county matches, etc.). At these two grounds there also take place any "test" matches played in London by teams representing England against overseas sides. International Rugby football matches (among others) are played at Twickenham; and the final ties of the English association football cup, of late years, at Wembley stadium, the vast arena originally erected in connection with the British Empire exhibition (1924–25). (O. J. R. H.; H. Or.; X.)

GOVERNMENT

Vestries.—The middle of the 19th century found the whole local administration of London still of a mediaeval character. Moreover, as complete reform had always been resisted, homogeneity was wanting. Greater London (in the sense in which that name might then have been applied) was governed by the inhabitants of each parish in vestry assembled, save that in some instances parishes had elected select vestries under the provisions of the Vestries act, 1831. In neither case had the vestry powers of town management. To meet the needs of particular localities, commissioners or trustees having such powers had been from time to time created by local acts. In 1855 these local acts numbered 250, administered by not less than 300 bodies either self-elected, or elected for life, or both, and therefore in no degree responsible to the ratepayers. There were two bodies having jurisdiction over the whole metropolis except the City, namely, the officers appointed under the Metropolitan Building act of 1844, and the Metropolitan Commissioners of Sewers, appointed under the Commissioners of Sewers act, 1848. Neither was responsible to the ratepayers.

Metropolitan Board of Works.—To remedy this chaotic state of affairs, the Metropolis Management act, 1855, was passed. Under that act a vestry elected by the ratepayers of the parish was established for each parish in the metropolis outside the City. The vestries for larger parishes were constituted by the local authorities; smaller parishes were grouped under district boards. A central body, the Metropolitan Board of Works, having jurisdiction over the whole metropolis (including the City) was also established, the members of which were elected by the common council of the City, the vestries and district boards, and the previously established local board of Woolwich (*q.v.*). The area of the metropolis for local government purposes was for the first time defined. The Metropolitan Board of Works was given certain powers of supervision over the vestries and district boards, and became the authority for main drainage and for the administration of the Building acts, and subsequently had many additional powers and duties conferred upon it. The vestries and district boards became the authorities for local drainage, paving, lighting, repairing and maintaining streets, and for the removal of nuisances, etc.

London County Council.—An objection to the Metropolitan Board of Works soon became manifest, inasmuch as the system of election was indirect. Moreover, enquiry by a royal commission disclosed the inefficiency of the board in certain respects, and also indicated the existence of corruption. Reform followed immediately. In 1888 the Local Government act, dealing with the area of the metropolis as a separate county, created the London county council as the central administrative body, possessing not only the powers of an ordinary county council, but also extensive powers of town management, transferred to it from the abolished board of works. Here, then, was the central body, under their direct control, which inhabitants of London had hitherto lacked. Under the Local Government act, 1929, the council's powers were extended through the transference to it in 1930 of the poor law administration, viz., the 25 boards of guardians, the Metropolitan Asylums board, the four boards of school district managers and the Central (Unemployed) Body. The council consists of 124 councillors elected triennially by the ratepayers, and 20 aldermen elected by the councillors and holding office for six years. A chairman, vice-chairman and deputy-chairman are elected in council. In 1935 the chairman became "right honourable." The first woman chairman was Mrs. Eveline M. Lowe, chairman 1939–40.

Metropolitan Boroughs.—The question of subsidiary councils remained to be settled after the act of 1888. The wealthier metropolitan parishes became discontented with the form of local government to which they remained subject, and in 1897 Kensington and Westminster petitioned to be created boroughs by the grant of charters under the Municipal Corporation acts. Instead, the London Government act of 1899 was evolved. It brought into existence the 28 metropolitan boroughs, so that the county of London may be regarded from the administrative standpoint as consisting of 29 contiguous towns, counting the City of London. One of these, Westminster, became later a city in itself. As regards the distribution of powers and duties between the county council and the borough councils, and the constitution and working of each, the underlying principle may be briefly indicated as giving all powers and duties which require uniformity of action throughout the whole of London to the county council, and powers and duties that can be locally administered to the borough councils. Primarily the borough councils are street and local sanitary authorities. Under the act of 1929 some minor powers were transferred to them from the L.C.C. They are the first authorities for assessing the annual value on which money required for local expenditure is raised and they are the rate-collecting authorities. Councils consist of a mayor and aldermen and councillors in proportion as one to six. In all, there are 1,604 members, 35 to 70 on each council. (*See* separate article on each borough.) Elections are triennial.

Corporation of the City of London.—The legislation of 1855, 1888 and 1899 left the government of the small area of the City in the hands of an unreformed corporation. Here the mediaeval system, in spite of any anomalies with respect to modern conditions, has resisted reform, and no other municipal body shares the traditions and peculiar dignity of the City corporation. This consists of a lord mayor, 25 aldermen and 206 common councilmen, forming the Court of Common Council, which is the principal administrative body. Its scope may be briefly indicated as including (*a*) duties exercised elsewhere by the borough councils, and by the London county council (although that body is by no means powerless within the City boundaries); and (*b*) peculiar duties such as control of markets and police. The City corporation also maintains several parks, mostly outside London, such as Epping Forest, Burnham Beeches, Coulsdon commons, West Ham park, Highgate woods, etc. The election of common councilmen, whose institution dates from the reign of Edward I, takes place annually, the electors being the ratepayers, divided among the 25 wards of the City. An alderman (*q.v.*) of each ward (save that the wards of Cripplegate Within and Without share one) is elected for life. The lord mayor is now elected by the court of aldermen from two aldermen nominated in the court of common hall by the livery, an electorate drawn from the members of the ancient trade guilds or livery companies (*q.v.*), which, through their control over the several trades or manufactures, had formerly an influence over the government of the city which from the time of Edward III was paramount.

Finance, Rating, etc.—Before 1899 the duties of overseers in London had been performed by most diverse bodies. In that year the new borough councils were constituted in every case the overseers within their respective boroughs, except that the town clerk of each borough performs the duties of overseers with respect to the registration of electors. Again, with regard to rates, there were till 1899 three or four different rates leviable in each parish. These are now consolidated into a single rate, called the general rate. Every precept sent by an authority in London for the purpose of obtaining money which has ultimately to be raised out of a rate within a borough is sent to the council of the borough. The metropolitan borough councils make one general rate, which includes the amount necessary to meet their own expenditure, as well as to meet the demands of the county council and the Metropolitan police. The total amount of rates raised in 1935–36 was £31,613,960, representing an average rate of 10*s.* 9.4*d.* in the pound (calculated on the basis of the net produce of a rate of a penny in the pound). Of this 8*s.* 1.3*d.* in a pound was levied centrally, 8*s.* 0.5*d.* for county purposes (London county council and Metropolitan police) and .8*d.* for local services (London county council grants to local authorities). The remainder, 2*s.* 8.1*d.* in the pound, was levied locally by the City corporation and the metropolitan borough councils.

The total expenditure of the London county council, borough councils, and other local authorities, in 1935–36 was £63,201,413, when payments included twice had been deducted. Receipts in aid were £19,398,558, and exchequer grants were £12,948,972, leaving £30,853,883 to be raised by rates (the amount actually raised was £31,613,959). This expenditure was divided among the following bodies:—London county council, £35,494,397; Metropolitan police (proportion), £5,327,086; City of London corporation, £2,431,053; Metropolitan borough councils, £15,855,621; other authorities, £4,093,256. Of the county council expenditure £13,696,493 went to health services; £13,476,286 to educational services and £3,271,262 to public assistance. The "other authorities" are the City Mental Hospital committee (£56,018) the Metropolitan Water board (£4,011,639) and the Borough Market (Southwark) Trustees (£25,599). A revaluation of properties is made every five years. In spite of attempts at equalization, rates still remain very unequal in London, and varied in 1935–36 from 9*s.* 6*d.* in the £ in Westminster, to 17*s.* 4*d.* in Poplar, though the latter rate had fallen from 25*s.* in 1927–28. The government at one time was compelled to intervene in the financial administration of this borough, which was convicted of extravagance and laxity.

Besides the annual expenditure of the various authorities, large sums have been borrowed to defray the cost of works of a permanent nature. The debt of London, like that of other municipalities, has considerably increased and shows a tendency to go on increasing, although certain safeguards against too ready borrowing have been imposed. Every local authority has to obtain the sanction of some higher authority before raising a loan, and there are, in addition, certain statutory limits of borrowing. Metropolitan borough councils have to obtain the sanction of the L.C.C. to their loans, with the exception of those for electrical works, for which the sanction of the Electricity commissioners is required, and those for a few services for which sanction is asked of the minister of health. The county council itself has to obtain (since 1891) the sanction of parliament. This is done annually by means of a Money act, put forward as a private bill. The means of borrowing are not specified in the act, but are through the creation and issue of consolidated stocks and bonds; the employment of the moneys of the Consolidated Loan fund (*i.e.,* the general sinking fund for the redemption of stock); the issue of London County bills; and temporary loans. Power also exists to issue terminable annuities and obtain mortgages. Under the L.C.C. (Money) act, 1936, the powers to use moneys of the Consolidated Loans fund were extended to superannuation, insurance, reserve and similar funds, while the Housing act, 1935, gave powers to make like use of moneys of the housing repairs fund. The debt of the county council in March 1937 was approximately £80,350,000.

Non-administrative Arrangements.—The Local Government act of 1888 dealt with the metropolis for non-administrative purposes as it did for administrative, that is to say, as a separate county. The arrangements of quarter-sessions, justices, coroners, sheriffs, etc., were thus brought into line with other counties, except in so far as the ordinary organization is modified by the existence of the central criminal court, the Metropolitan police, police courts and magistrates, and a paid chairman of quarter-sessions. The powers of the governing body of the City, moreover, are as peculiar in this direction as in that of municipal administration, and the act left the City as a county of a city practically unchanged. Thus the lord mayor and aldermen possess judicial authority, and the police of London are divided into two separate bodies, the Metropolitan and the City police. (*See* POLICE.)

The chief courts for the trial of criminal cases are the central criminal court and the court of quarter-sessions. The central criminal court, taking the place of the provincial assizes, was established by an act of 1834. There are 12 sessions annually, under the lord mayor, aldermen and judges. They were formerly held in the "Old Bailey" sessions-house, but a fine new building from designs of E. W. Mountford took the place of this in 1906. There are 4 general quarter-sessions and various adjourned quarter-sessions totalling 20 meetings annually. General quarter-sessions are held at Newington causeway. The separate court of the lord mayor and aldermen is held at the Guildhall. The Metropolitan police courts became 13 in number with the closing of Westminster court in 1942. The police courts of the city are held at the Mansion House, the lord mayor or an alderman sitting as magistrate, and at the Guildhall, where the aldermen preside in rotation. The prisons within the metropolis are Brixton, Holloway, Pentonville, Wandsworth and Wormwood Scrubbs. There are 12 coroners' districts, 16 petty sessional divisions, and 14 county court districts, including the City in each case. The boundaries of these divisions do not correspond with each other, or with the police divisions, or with the borough or parish boundaries. The registration county of London coincides with the administrative.

Parliamentary Representation.—London returns 62 members to parliament. Each division of each borough, or each borough where not divided, returns one member, save that the City of London returns two members.

Ecclesiastical Divisions and Denominations.—The diocese of London, founded in 314, covers the cities of London and Westminster, the county of Middlesex and the boroughs of the county of London north of the Thames. In the diocese are the bishoprics suffragan of Fulham, Kensington, Stepney and Willesden. The bishopric of Southwark was created in 1904, having been previously a bishopric suffragan in the diocese of Rochester. It contains the bishoprics suffragan of Woolwich and Kingston-upon-Thames. Westminster is the seat of the Roman Catholic archbishopric in England, and Southwark is a bishopric. Among the numerous chapels of dissenting bodies there may be mentioned the City temple, Congregational, on Holborn viaduct (burned out in World War II); the Metropolitan tabernacle, Baptist, in Southwark (also burned out), the creation of which was the outcome of the labours of the famous preacher Charles Spurgeon (d. 1892); and Wesley's chapel, City road, in the graveyard of which is the tomb of John Wesley; his house, which adjoins the chapel, being open as a memorial museum. In 1903 the Wesleyans acquired the site of the Royal aquarium, near Westminster abbey, for the erection of a central hall. The Great Synagogue of the Jews is in St. James's place, Aldgate. The headquarters of the Salvation Army are in Queen Victoria street, City. There are numerous foreign churches, among which may be mentioned the

French Protestant churches in Monmouth road, Bayswater and Soho square; the Greek church of St. Sophia, Moscow road, Bayswater; and the German Evangelical church in Montpelier place, Brompton road. (O. J. R. H.; X.)

PORT AND COMMERCE

The forces which led to the development of the port of London and which continue to operate arise primarily from its geographical position and physical advantages. It is situated on a broad deep tidal river with a current sufficient to keep up a natural scour which maintains the channel, yet not too fast to prevent the safe navigation of the largest vessels.

Another contributing cause to London's commercial advancement was the adoption of the system of bonded warehouses first introduced by Walpole in 1733 but not legalized until 1803. But no factor has contributed so much to the port's prosperity as the enormous expansion of British colonies and possessions during the last three centuries. Goods coming to London which are identified with empire expansion include wool, sugar, rubber, tea, refrigerated meat, furniture woods, provisions, metals, rum, spices, ivory and ostrich feathers. Among the products of countries outside the empire sold in the London markets are soft wood (deals), gasoline, tobacco, cigars, silk, wine and brandy. The total value of the imports of all classes of merchandise from overseas in 1936 was £353,067,978, representing 42% of the total for Great Britain and Northern Ireland. The value of goods imported for transshipment under bond was £16,751,596. While the port has attracted an unparaleled import trade, its export trade though very extensive is second to that of Liverpool, amounting in 1936 to £120,455,240 as against £130,270,495 at Liverpool, these figures excluding the value of exports of imported merchandise, which in the case of London was £36,213,195. London is the largest manufacturing city in Great Britain and a large percentage of its manufactures are shipped at the London docks, but Liverpool has the advantage of contiguity to the cotton, woollen and steel manufactories of the north, and offers better facilities for their shipments than London.

The sum total of foreign imports and exports of the port of London for the year 1936 was £473,523,218, the highest in the kingdom. Besides the foreign trade, London has the largest coastwise trade of any port in Britain, the principal commodity carried being coal.

The following are the particulars of the net registered tonnage of shipping entering and leaving the port during 1936:

	Foreign	*Coastwise*	*Total*
Arrived	22,385,652	8,482,729	30,868,381
Departed . . .	20,136,125	11,146,804	31,282,929

These figures represent 20.4% of the total tonnage for Great Britain.

A feature of modern London has been the industrialization of Outer London, particularly in the northwest and west, the new industries being for the most part highly mechanized. Out of the 25 aircraft factories existing in 1935, for instance, 12 were in or near London and a further five were in the southeastern counties. Moreover, some of the most important electrical firms, one of the largest motor car manufacturers, and the only manufacturers of large scale cold storage equipment in the country have been established in the London area. The flood of lighter manufacturing industries concentrating in Outer London brought in its wake other industries and services required by the vastly increased population. One of the chief causes of this development has been the vast size of London itself, which made the city the finest market in Europe, if not in the world, for manufacturers and distributors of consumption goods, and so provided an almost irresistible attraction to new ventures. One result, however, has been to take earning power away from other parts of the country. This is evidenced by the enormous growth of the port of London, which in the period 1913–1935 increased its foreign trade by over 14%, while the principal west coast ports lost about 11% of theirs. To some extent the decline in the latter ports was due to the loss of the export coal trade, but this would not apply to Liverpool, where conditions were very difficult for some years before World War II, nor would it entirely account for the heavy loss of the South Wales ports. It is clear, therefore, that between the two world wars the tendency for the control of overseas trade to be concentrated in London increased, and this tended to bring to the London area, for distribution in the rest of the country, trade which had formerly gone to the chief west coast ports.

Administration.—The administration of the port of London has undergone many changes in the course of its history. In its earliest days the port was governed by the crown. With the Norman conquest, the City corporation obtained the recognition of certain rights as the conservators of the Thames, which enabled the corporation to collect revenues without any responsibility for guardianship of the interests of the port. A third stage was inaugurated with the accession of Elizabeth in 1558 when a number of privately owned quays were given the monopoly of landing dutiable goods. Another stage was reached in 1799 when William Pitt established three systems of docks built by companies which were privileged to accommodate particular classes of trade for 21 years. On the expiry of that period, the port was thrown open for a general competition of facilities between the docks and river wharfingers. On March 31, 1909, under the powers of an act of parliament passed on the initiative of D. Lloyd George, the Port of London authority commenced its career by assuming the functions of the Thames conservancy in the lower river and those of the old dock companies in the docks with the special duty of improving the accommodation in the port.

The authority is a board of 28 members. Seventeen of them are elected by payers of dues, by wharfingers and owners of river craft, 1 by wharfingers only and the remainder are appointed by the admiralty (1), the ministry of transport (2), the City corporation (2), the London county council (4) and Trinity House (1). Labour has two representatives. The authority's jurisdiction in the river extends from Teddington lock down to an imaginary line drawn from Warden point in Kent to Havengore creek in Essex. This line is 50 mi. below London bridge and 69 mi. from Teddington lock. On this part of the river, the authority is the conservator. It controls the licensing of all erections on the river banks, the regulation of the navigation of the river, the prevention of pollution, and the licensing of lightermen and their craft. The control of the lighting and buoying of the river as well as of pilotage is in the hands of Trinity House.

After 1909 the river channel was deepened and widened. From the Nore to Cold Harbour point, there is a channel of 1,000-ft. width with a minimum depth of 30 ft. at low water spring tides. From Cold Harbour point to the Royal Albert dock, the channel is 600 ft. wide with a depth of 27 ft. An addition of from 17 to 21 ft. must be made to the above figures of depth to ascertain the depth of water available at high water.

In the docks, the authority, as the successors of the dock companies, furnishes every class of accommodation, except storage for mineral oils and explosives. At the upper docks, the authority undertakes the discharging of ships, whereas at the lower docks, shipowners discharge their own ships, the only exception being bulk grain for which the authority provides floating elevators and carries out the work with its own staff. The actual loading of ships is not performed by the authority, its only service to export goods being the handling of such cargo as passes over the dock quays. The most important functions of the authority in the docks are connected with operations on goods stored in its warehouses and intended for sale in the wholesale markets of the City. In the year ending March 31, 1937, the Port of London authority received 1,077,926 tons of goods for warehousing and the stock of goods in the warehouses at that date was 553,287 tons. In addition 1,228,166 tons of goods were landed for immediate delivery. Of export goods, 728,813 tons were received for shipment from the dock quays during the same period. The length of dock quays in the port is about 45½ mi. The largest lock at the King George V dock has a length of 800 ft. and a width of 100 ft. The lock at the Tilbury dock was opened in 1929 and is 1,000 ft. long, with a width of 110 ft. The equipment of the docks of London has been greatly improved by the Port of

London authority especially in regard to dry docks, electric cranes and railways.

Besides the accommodation of the authority, facilities are provided on the river side by private wharfingers both for shipping and for the warehousing of goods. The tonnage of shipping using riverside accommodation forms about 38% of the total and consists mostly of colliers, continental and coastwise traffic and oil tankers.

Markets.—Sales of goods in the wholesale markets of London are effected at various centres in the city and are based upon either inspection at the warehouse of storage or upon samples supplied by the port authority or the private warehouse keepers. Wool is sold at the Wool exchange in Coleman street and grain at the Corn exchange in Mark lane. The Commercial sale rooms in Mincing lane are devoted to tea, rubber, sugar, wines, spirits and other foreign and colonial produce. The Coal exchange is in Lower Thames street. The Hop exchange and the Metal exchange are in the Borough and Whittington avenue respectively.

There are some markets in London controlled by the City corporation. These include the central markets in Smithfield for meat, poultry and provisions, Billingsgate market for fish, and Spitalfields for vegetables. Leadenhall market is a retail market, chiefly for meat and poultry. The Covent Garden market, which is the chief market in the metropolis for vegetables, fruit and flowers, is the property of private owners.

London's predominance as a port has been the foundation of its predominance as a financial centre of the world. For a description of the financial system of London *see* the various articles dealing with banking and insurance. (J. G. Br.; X.)

HISTORY

The Origin of London.—The few facts available indicate that London first rose out of complete obscurity early after the Roman occupation of Britain, in the 1st century of the Christian era. Its geographical position was the determining factor. A British *oppidum,* or stronghold, of the Catuvellauni that became Roman Verulam and is today St. Albans was sheltered behind the Middlesex forest when Julius Caesar, having landed in Kent in 54 B.C., made his raid. Upon that he marched, crossing the Thames at some point that remains uncertain. Caesar makes no mention of London. The inference is that London did not exist. A British trackway, and later the Roman Watling street, from the Kentish ports to Verulam forded the Thames at Westminster. In A.D. 5 Cunobelin, or Cymbeline, succeeded to the throne of the confederated tribes in southern Britain. Early he transferred his seat of government to what became Roman Camulodunum (Colchester). London's site was well placed for the service of both cities. The Thames at this point greatly narrowed, twin hills rose upon the left bank, and there was easy access from the sea. The belief now widely held is that London's emergence was due to its service as a landing stage, or bridgehead, for continental trade with Britain.

When London appears in history it is not as a capital. Tacitus, who wrote early in the 2nd century, refers to it as having been in A.D. 61 a place much frequented by merchants. The name London is not Roman, but Celtic, and the Romans adopted it in their own Londinium. A coin of Cunobelin and a few late Celtic objects have been recovered in city excavations and the Thames bed. Evidence of a pre-Roman settlement, whether a trading or fishing village, is, however, extremely vague. Fragments of Arretine and British pottery found in the area are regarded, not as pre-conquest objects, but as survivals of types into the Roman era.

Roman London.—Aulus Plautius, a general of the emperor Claudius, landed in Britain with Roman troops in A.D. 43. With the fall next year of British Colchester and St. Albans, the whole of southeast Britain after no long interval passed under Roman domination. From Dion Cassius's enigmatical statement (early 3rd century) there was already at the invasion a bridge, "a little above the mouth of the river." The evidence is much stronger that the Romans at some later date themselves constructed a bridge joining London, on the northern bank, with Southwark. This must, indeed, have become a necessity for them. Close by Old London bridge wooden piles, many thousands of Roman coins, medallions and quantities of broken tile and pottery have been found in the Thames bed. What survives of the Roman city is now buried at depths of from 12 ft. to 19 ft. below the ground surface.

The first actual knowledge of London comes with its destruction in A.D. 61, when the Roman governor, Suetonius, retired and Boudicca's (Boadicea's) hordes sacked the city and massacred the remaining inhabitants. A crushing victory over the British restored Roman authority, which thereafter endured in London and in England for three-and-a-half centuries.

The Romans cast a wall about the city, with a ditch beyond. Massive fragments of the wall remain. Its thickness at the base is about 8 ft., the height being unknown. It consists of a core of rubble faced with Kentish rag-stone, with bonding tiles at regular intervals, and a chamfered footing of sandstone outward. It is structurally the same wherever found, was evidently carried out as a single undertaking, and evidence now available from silt and deposit against the wall where the Wallbrook entered the City indicates that it was built in the 1st century, after Boudicca's ravages were repaired. Burials imply that the first Roman city was a small rectangle about Cornhill. The area walled, 324 acres, is immense, much greater than that of any other Roman town in Britain, and equalled by few in the world-empire. Londinium's importance is attested not only thereby, but by the fact that from it the chief Roman roads radiated, linking up the most distant areas of the province with London. Excavations at Newgate in 1908 definitely established a Roman gateway there. Other original gates were probably at or near Aldgate, Aldersgate and opening upon the river bridge. Ludgate has been considered a Saxon postern; but the discovery in 1927 of a Roman cemetery, with urn burials, in Shoe lane, by the side of Fleet street, strengthens the belief that Ludgate, too, was Roman. Late in the Roman occupation, probably 4th century, the wall was strengthened by bastions, of which there are examples underground at Newgate, at St. Giles Cripplegate (mediaeval above the surface) and beneath the vestry of Allhallows, London Wall.

Not a column of any building has been left standing in historical times, and in a city without stone, which had to be brought in from distant parts of Kent and Surrey, it is likely that the Roman houses were largely of brick or timber construction. The city wall is Londinium's greatest monument. Remains of very thick walls with an apsidal structure found in 1881 beneath Leadenhall market have been believed to disclose the basilica and forum; an amphitheatre has been conjectured; the spade has uncovered evidence of riverside wharves; but no definite indication of the street plan of Roman London is to be traced in the modern city.

London Stone, a fragment of which is fixed in the exterior wall of St. Swithin's church, Cannon street, has been deemed a *milliarium,* marking a starting point for the measurement of distances along the Roman roads; but there is no actual evidence of its purpose.

Abundant relics in sculptured altars and tombs, bronzes, tesselated pavements, hypocausts, pottery, domestic utensils and articles of apparel attest a very high state of culture that Roman London attained. Guildhall museum, the London museum and the British museum have rich collections of these. Remains of a Roman house are preserved undisturbed beneath the Coal exchange at Billingsgate. Christianity was introduced late in the 3rd century, but its records are very meagre. Restitutus is named as a bishop of London at the Council of Arles in A.D. 313.

The political history of Roman London remains vague. Although it became a chief city and centre of administration it did not receive the superior title Augusta until A.D. 368. Information is available concerning the province, but it is curious that London is rarely linked with it. Hadrian presumably passed through on his visit to Britain in A.D. 122; the wonderful bronze head of this emperor, of colossal size, that was dredged from the Thames bed near London bridge and is now in the British museum, is the most perfect example of Roman art found in Britain. After Boudicca's ravages, there is no mention of London by any classical author till late in the 3rd century, and what little is known is derived solely from archaeology. London, then possessing a mint, appears again in record after the revolt of Carausius and his murder by Allectus, when the Frankish seamen and mercenaries of the last named were trapped in the city in A.D. 296. Its sacking was stayed by the timely arrival of Constantius Chlorus and his fleet. A Roman boat, preserved in the London museum, was recovered from the Thames mud at Lambeth where today the county hall stands, and is conjectured to have been a craft in Allectus's fleet sunk in the fight; coins of both Carausius and Allectus were associated with the find.

Following a peaceful period, the last half-century of the Roman occupation was much disturbed. London was in jeopardy on several occasions after A.D. 360 from raids by Picts and Scots, augmented by Northern races from overseas, who ultimately penetrated as far south as Kent. The Roman general Theodosius, sent by the emperor Valentinian, cleared them from southern Britain, and in A.D. 368 he made a triumphal entry into London. Near the end of this century internal troubles were almost continuous; and early in the 5th century Rome, in grave peril herself, withdrew her legions from Britain.

Saxon and Danish.—Thereafter the "dark centuries" descend, and London completely disappears from record. Of its fate nothing is known. The "Anglo-Saxon Chronicle" is not silent for those years. It tells of piratical raids upon the English coasts by Saxons and Franks, and battles with the invaders and bloodshed and destruction, and the fact that nothing is related of London tends to support the belief that there was nothing to relate—that the city was depopulated. Even the name of London has no mention till about 597, when Pope Gregory sent Augustine to teach pagan Britain Christianity, expecting that he would found a see at London, though for sufficient reasons his choice first fell upon Canterbury, in Kent.

Mellitus was despatched by Augustine to London to become its bishop in 604, and on its re-emergence at this date London was the tribal capital of the East Saxons, whose kingdom was subordinate to the power of the kings of Kent. Already recurrent invasions had resulted in a considerable Saxon settlement in Britain, but the newcomers were not by choice town-dwellers. Sebert was then king in London, and Mellitus appears to have been well received. With Sebert's death in 616, and that of his overlord, Ethelbert of Kent, the East Saxons relapsed into paganism. The bishop fled; and though after an interval Cedd (633) and Wine (665) are mentioned as bishops, and laboured to restore Christianity, it was in the period of Earconwald, who about 675 was appointed by Archbishop Theodore as "bishop of the East Saxons in the city of London," that the faith was firmly re-established. Bede gives Ethelbert as the builder of the first cathedral of St. Paul's, and in the years of returned heathenism it is to be presumed that his fabric was destroyed.

Names of successive bishops occur; a London mint was founded in the 7th century; but there is little light thrown into the darkness in which London was engulfed till Bede, writing about 730, draws an unexpected picture of London as the "mart of many nations resorting to it by sea and land." The overlordship of the kingdom of the East Saxons passed successively from Kent to Wessex, to Northumbria, to Mercia, back to Wessex, and again to Mercia, all of which indicates a period of considerable disturbance. London, "a royal town," was under Coenwulf the capital of Mercia in 796, and so remained until in 827 the Saxon kingdoms became united under Egbert, king of Wessex, who established his authority over all England.

The 9th century was an active period of Danish raids which were to disturb England for a century and a half. London frequently recurs in the brief incisive passages of the "Anglo-Saxon Chronicle." A fight with the Danes, with great slaughter, occurred in 839; in the mid-century the city appears to have been intermittently in Danish hands; and it was the Danes whom Alfred attacked when in 886 he occupied London (*gesette Lundun burg*—presumably restored its ruinous defenses). A governor for London was found in Ethelred, and in the more restful period it enjoyed while England was under Alfred's strong rule London's overseas commerce developed, and the city and port rose to a place of first importance in the kingdom. Evil days returned after Alfred's death in 899.

The tangled record of London in the 10th century is one of repeated raids by the warlike Scandinavians. While the surrounding country was harried and plundered, London for the greater part maintained its independence. The city had thrice been destroyed by fire in the 7th and 8th centuries, and was again burned in 982. Olaf and Sweyn, with 94 ships, besieged it in 994, but the Londoners offered stout and successful resistance. "In wrath and sorrow" the invaders sailed away. The first decade of the 11th century witnessed several attacks, and in 1009 the city was in great jeopardy from the invading army of the Norse earl, Thurkhill. "Glory be to God," says the pious chronicler, "it yet standeth sound." A gallant defense against the Danes was maintained in 1013, but later that year the city fell to Sweyn. Independence was restored under Ethelred, who on Sweyn's death next year was elected king by the English. King Olaf of Norway gave his aid to them, and one of the most charming of Icelandic sagas describes a battle fought at London bridge.

On Ethelred's death in 1016, the gemot in London chose his son, Edmund Ironside, as king, though the country outside London had accepted Sweyn's son, Canute. London was again besieged; the citizens repulsed successive attacks, and under Edmund reconquered the neighbouring country. Edmund's reign, however, lasted but seven months, and on his death all England acknowledged Canute as king. The Londoners had no alternative but to "make a truce with the army and buy themselves a peace."

London paid tribute to Canute of £10,500, a sum that indicates its importance and, despite the constant hostilities, its wealth, for it represented one-eighth of the payment made by the whole of England. Under that farsighted monarch peace was assured, London's commerce rapidly developed, and the city definitely established its predominant position in national affairs.

A renewed period of unrest followed Canute's death in 1035. Edward, afterwards known as the Confessor, was chosen king in 1042 by the people assembled in London. In his reign Norman influence strongly permeated the government. Duke William of Normandy paid England a visit, and according to his subsequent claim, Edward's oath that he should succeed to the kingdom was confirmed by the gemot of London, but evidence of this is wanting. The election of Harold as king at the Confessor's death in Jan. 1066 was a denial of Duke William's pretensions. London sent its hosts to the field of Hastings on Oct. 14, where they fought under the leadership of Ansgar the Stallar, guarding the king's person and standard. In this place of peril it is probable that few of them survived the defeat and rout. William wasted the country through which his army passed, but purposely avoided London, though a detached force of Normans burned Southwark. His march brought William to Berkhamsted, where he camped, and there in December, two months after his victory, he received from a representative body of ecclesiastics and eldermen the submission of London.

Norman and Plantagenet.—Norman London starts with a definite act, the grant by the Conqueror to the citizens of a charter. A narrow strip of parchment 6 in. in length, it bears no date. In 1927 A. H. Thomas, clerk of the records at Guildhall, skilfully pieced together fragments of a wax seal originally attached to the document, and it proved to be King William's second great seal; but all probabilities suggest that the grant was made at Berkhamsted or in London immediately after the submission, the formal warrant being delayed. The charter is remarkable in its terms:

William, King, greets William, Bishop, and Gosfregth, Portreeve, and all the burgesses within London, French and English, friendly. And I give you to know that I will that ye both be worthy of all those laws that ye were worthy of in King Edward's day. And I will that every child be his father's heir after his father's day, and I will not suffer that any man offer you any wrong. God keep you.

Thus early London possessed a government in which the secular authority of the portreeve combined with the ecclesiastical authority of the bishop. No new powers were given. The citizens were confirmed in the enjoyment of their laws, which were the growth of many years. The king was their sole overlord, and would suffer none to wrong them. London's privileged position, dependent upon no man save the king, became a basis of its commercial pre-eminence.

The Anglo-Saxon laws to which King William assented had raised London to equality with a shire. It had rights beyond the walls. Its folk-moot, or general assembly, was an ancient institution, enjoying powers to discuss and decide matters that were essential to the welfare of the community. In the 10th century there is mention of the Hustings of London—the equivalent of a shire court—which in modified form still survives. There is much to suggest that the sheriff presided. It transacted a large part of the work for which the folk-moot had become too cumbersome a body. The Norman portreeve doubtless was the successor of the Saxon reeve, and Dr. Round has shown that Gosfregth (or Gosfrid), to whom among others the Conqueror's charter to London is addressed, was Geoffrey de Mandeville, the sheriff. The charter, moreover, bears testimony to the large proportion of Normans resident in London. In the state of settled security that followed, the ranks of these oversea traders were largely augmented.

So long as William reigned, both the king and London kept the pact.

It was less honoured by William Rufus, who oppressed the people by building his great hall at Westminster, strengthening the Tower of London (*q.v.*) erected by his predecessor at the water gate, and in the repair of the Thames bridge that floods had mostly carried away. Fire in 1087 destroyed St. Paul's and a large part of the city.

London supported the election of Henry I to the throne, and from this king obtained a charter of liberties that is of outstanding importance, though it did not become really effective till King John, when encountering supreme difficulties in conflict with his rebellious subjects, was forced to recapitulate its provisions. The citizens of London were given the county of Middlesex at farm, and they were to appoint from among themselves one who would be sheriff over it. Elsewhere the sheriff (shire-reeve) was, and for centuries has remained, a royal officer appointed by the king; his concern was with the collection of revenues, the profits of justice and the military organization of the shire. The delegation of the royal authority to election by the citizens marks the unique position which London attained.

London enlarged its pretensions when, on Stephen's appearance as a claimant to the English throne in 1135, the citizens asserted that it was their right and special privilege, on occasion of the king's decease, to provide another in his place, and they proceeded to election. Later, when Stephen was held prisoner for Matilda, after the battle of Lincoln, the Londoners appeared by a delegation of leading men, refused to enter into debate and demanded that their lord the king be released. A revolt of the Londoners finally drove Matilda from the kingdom.

MIDDLE AGES: RISE OF THE MAYORALTY

The rise of London's mayoralty is associated with the reign of Richard I, and more especially those years when John (afterwards king) acted as regent during the monarch's absence on the crusades. Then was definitely established the rule by a mayor, to whose side was drawn a body of aldermen and councilmen, which has endured till this day. London thus became the first municipal corporation in England, and upon its model 28 mediaeval towns afterwards drafted their charters.

The corporation of the City of London has greater antiquity than the English parliament. It is not of English origin. The model is French, and the French title *maire* remains for the chief ruler. To the citizens the idea of a commune was not new. They had claimed to be such when they demanded Stephen's release. No public recognition of London citizens as constituting a body corporate is, however, to be traced. In France and Flanders this trend towards corporate life had rapidly developed in the chief centres of mercantile activity, notably Rouen; and London, with its large trading activities, was not slow to profit by the example.

Not for the first time in her history, nor the last, the crown's difficulty was London's opportunity. Longchamp's tyrannical administration of England as the appointed representative of the absent king, Richard I, brought him into fierce conflict with John, the king's brother, who championed the popular cause. In the resulting deadlock, the London citizens made the acceptance by John of their "commune" the price of their support. The chroniclers tell that on Oct. 8, 1191, the barons of the realm and the citizens of London met in St. Paul's, deposed Longchamp from office and recognized John as head of the kingdom. Immediately thereafter John formally granted the commune, and took oath before all assembled to maintain the dignities of the city.

Of events that preceded this remarkable change in London government nothing is known, and some historians have conjectured a revolt in the city. Formidable obstacles to corporate administration were to be found in the existence of many sokes, or private territorial liberties, each with its separate jurisdiction.

It is not till two years later (1193) that mention occurs of the first mayor, Henry FitzAilwyn. He held the office till his death in 1212. Much remains obscure. Certain aldermen, when they appear in subsequent jurisdiction, were territorial magnates, representatives of the wards which they held in personal possession; and there are many indications that they exercised powers anterior to the creation of the mayoralty. It is probable that from their body were derived the "more discreet men of the city" who were called into council. Certainly by the reign of Edward I the aldermen had become the main administrative body, as for centuries they remained. Every mayor down the ages has been chosen from the aldermen, and is so chosen today. With the institution of London's mayor the portreeve disappears, and the sheriff falls back into a secondary place.

King John's charter to London of 1215 granted to the citizens the right to elect their mayor from among themselves annually, directing that they should present their choice to the sovereign or his minister for the royal approval. From the "ridings" to Westminster for this purpose originated the Lord Mayor's show, which survives as the most popular of London's pageants.

The mayor of London was one of the treasurers of Richard I's ransom. In John's reign of misgovernment, the city espoused the cause of the barons, whom they admitted within the walls and supported with men and money. Robert FitzWalter, the Castellain of London and owner of Baynards castle, the city's western fortress by the river, was chosen leader of the barons. Both the mayor of London and FitzWalter are named in Magna Carta among those charged to see that the terms of the great charter were strictly carried out. Incidentally those terms specifically preserved the city's privileges and customs.

The long period covered by the reigns of Henry III and Edward I is made notable in civic history by the various occasions upon which the city was "taken into the King's hands," its mayor being arbitrarily displaced from office, and a royal warden appointed. London always supported the popular cause against tyrannical kings. A body of Londoners fought against Henry III under Simon de Montfort's banner at the battle of Lewes in 1264. For a period of five years (1265–70) Henry III ruled London by his *custos,* as did Edward I for 13 years (1285–98).

Thirteenth and Fourteenth Century London.—London records become much more full in the 13th century, especially its later years. Chroniclers' narratives are supplemented by contemporary City archives (now in part printed) such as the Letter Books which begin under Edward I, the rolls of the mayor's court and Hustings court, and citizens' wills enrolled in the latter. From these is derived information of the trading and social activities of the citizens, and—still very imperfectly—of the panorama that the town presented. London ranged along the Thames-side, nowhere extending far back from the water, having a small outpost on the opposite bank at Southwark. A London custumal lays emphasis upon "the many folk of the city, and they are housed close together and are more crowded early and late than other people are"—the common condition of any walled town.

Of the houses, some knowledge is derived from specifications still extant. The merchants lived in timber-framed dwellings.

FitzAilwyn, the first mayor, gave to London that assize which is honoured as the first building act. It aimed at protection against fires, which frequently devastated the city. Thatch was prohibited for roofs, party walls were to be of stone, though for centuries after this provision was ignored. Many citizens' houses carried a solar, or sleeping-room above. A building agreement of 1384 provides for an important dwelling in timber of three stories, to have a hall, 40 ft. by 24 ft. parlour, kitchen, buttery and cellars, with storehouses adjoining. More sumptuous dwellings than this were built for nobles and the richest merchants.

London when the mayoralty was set up was already spreading out beyond the city wall into the western liberty, where many ecclesiastics had their town hostels. The Knights Templars migrated from Holborn to the Thames-side, where they had raised their Round church by 1189. The greatest enterprise for London's development undertaken in the middle ages was the construction of the first stone bridge to replace the earlier successive wooden structures. Old London bridge is customarily dated from King John, in whose reign it was completed, and it served the city till 1832, when it was taken down. Peter of Colechurch began the work in 1176; he died during its progress; and it took more than 30 years to complete. The bridge consisted of 19 arches and a drawbridge, the largest span being 30 ft.; the original breadth above the stonework was 20 ft. This was widened in later centuries. It bore houses from early times, partly overhanging the water and supported by struts.

Although the chief city and commercial capital of England, London city since Canute has never been the political capital. Alfred and other Anglo-Saxon rulers of England made Winchester their capital; the Confessor's royal palace was at Westminster. When Winchester ceased to have that use, in the 12th century, the kings established themselves at Westminster, where William Rufus had begun the building of a great Norman palace, of which Westminster hall survives as a glorious relic. The royal courts of justice and the exchequer became established at Westminster, where later the parliaments assembled in the abbey chapter-house and at St. Stephen's chapel. Henry VIII built Bridewell, in the City's western liberty, and Henry VII lodged at Baynards castle; but no king of England chose to live permanently in London.

Lacking the royal palace and most offices of state, London's greatest buildings throughout the middle ages, as was to be expected, were those of the church. The Guildhall vied with some of these in spaciousness, but the existing Guildhall was not built till the early 15th century. It stood alone, and about it were ecclesiastical buildings of unsurpassed splendour. Old St. Paul's was, when erected, not only England's greatest cathedral; it was the greatest in Europe. Its wooden steeple, destroyed in Queen Elizabeth's reign (1561), rose as high as the present cross, and was accounted a world's wonder. St. Martin-le-Grand, of Saxon origin, had been refounded by William the Conqueror. Rahere's priory and hospital of St. Bartholomew, Smithfield, was founded in 1123. What remains of the church, a fragment notable for its beautiful late Norman work, is merely the chancel and transepts and the restored Lady chapel; all the vast nave has gone. Conventual houses within the city or upon its confines included the priory of Holy Trinity, just within Aldgate, of which no trace remains; the nunnery of St. Helen's, Bishopsgate, the nuns' nave forming part of the existing church; the abbey of the Poor Clares (Minoresses), a fragment of which survives in one wall of the old church of Holy Trinity, Minories; St. Mary Grace, east of Tower hill; the Carthusian monastery, today's Charterhouse; the priory of St. Mary Overy, Southwark, represented by Southwark cathedral; and the priories at Bermondsey and Clerkenwell and the Augustinian nunnery of Holywell, in Shoreditch, and St. Mary Spital.

The coming of the friars in the 13th century had marked influence upon London's life in the middle ages, and was destined to give to the city many imposing religious buildings. They came in poverty, and for many years their work was amongst the poor and the outcast. First to arrive in England were the Dominicans, in 1221. From their settlement in Holborn they moved down, in 1276, to the Thames-side district still known as Blackfriars, having obtained authority from King Edward I to pull down the city wall from Ludgate to the river and in its rebuilding to enclose their precinct. The Franciscans reached London in 1224, and established themselves within Newgate. The Carmelites (1241) built their house in Fleet street. Last of the chief mendicant orders were the Austin Friars (1253). Of all their buildings there remained only the nave of Austin Friars church and this was completely destroyed in World War II. For more than 300 years it was used by the Dutch Protestant congregation.

Wealth came to these religious orders, and with its accumulations they raised churches which were the largest in London, rivalled only by the cathedral. The arrogant magnificence of the Blackfriars' church, its "gay glittering glas glowing as the sun," provoked bitter denunciation in Piers Plowman's verse. The Franciscan (Greyfriars) church, begun in 1306 under royal patronage, was largest of all. Two English Queens, Margaret, second wife of King Edward I, and Isabella, wife of his successor, were interred there.

The normal peace of the city was twice broken by risings: first, the peasants' revolt under Wat Tyler (*q.v.*) in 1381, and secondly, Jack Cade's (*q.v.*) rebellion in 1450.

Throughout the middle ages the trades and crafts of London were highly organized in a guild system, the memory of which is perpetuated in the existing city livery companies, though their powers have long since lapsed, and today their energies and funds are mostly devoted to educational and philanthropic purposes. Fellowships of craftsmen are traced back to a remote past, and in the late 13th and the 14th centuries many of these obtained incorporation for the better development of the industries. The weavers had royal permission as early as Henry I to hold their guild; Henry II in 1160 imposed fines upon no fewer than 18 London guilds for having been set up without the king's licence. Membership of a guild, which gave the coveted city freedom, became almost universal.

London enjoyed a great and increasing trade. It was by far the most populous city in England, needing large imports to meet its own wants, and it was also a principal distributing centre for the country. Vessels drew up at the little Thames ports of Queenhithe and Billingsgate, and the receipt and storage of continental goods further necessitated the provision of many wharves along the river. The Hansa merchants were settled in London by 1157. As late in the 14th century the fairs in the country began to lose their original importance, the bulk of commerce fell to the London merchants, many of whom, like Richard Whittington, the famous mayor, John Pounteney, John Philpot and other mayors, made great fortunes. The cloth industry in the 15th century also created a large export trade from London. The accumulation of so much of the nation's wealth in the capital enabled London to finance the wars of Edward III and Henry V for the conquest of France.

The long internecine struggles of the Wars of the Roses had no marked effect upon London. Disillusioned by the mismanagement of affairs and costly extravagance under the Lancastrian king, Henry VI, London transferred its allegiance to the Yorkist Edward IV, with whom the mediaeval period ended.

LONDON TO THE FIRE

Tudor London.—The significance of the Tudor period in London history lies in the vast changes that the Reformation brought about in the aspect of the capital, and in its social and economic life. Henry VIII found the city crowded with majestic ecclesiastical buildings, fruits of the piety and artistic skill of preceding centuries. Large numbers of these he left in ruins or converted to secular uses, when not actually razed to the ground, and the scars remained in Elizabeth's reign. The great conventual houses of the monastic orders and of the friars were the first to fall. Amid the vast destruction the citizens were able to save much for their permanent advantage. Rahere's Priory of St. Bartholomew was wholly destroyed save for the parts of the church still in parochial use and the attached medical hospital, of which Henry figures as the refounder. St. Thomas's hospital by London bridge, on the Southwark side (removed in the 19th century to Lambeth) was also refounded under the same royal patronage, as was Bethlehem hospital for the insane. City livery companies, the Mercers and the Leathersellers among them, obtained halls for themselves from the spoils of the church.

In the short reign of Henry's son, Edward VI, the Greyfriars buildings at Newgate, mostly left standing, were converted into Christ's hospital for the maintenance and education of poor children. The derelict Bridewell royal palace was in like manner given to the citizens as a house of correction for rogues, vagabonds and refractory city apprentices, and the training of boys for industry.

By the suppression of the monastic houses London was faced anew with urgent problems of the relief of the poor, to which the religious brotherhoods had largely ministered, and the education of the young. Henry's methods of treating the first were chiefly oppressive, and it was not until Elizabeth's last years that the first workable Poor Law act was instituted. The rise of the merchant class to greater power and social prestige was an outstanding feature of the Tudor epoch, and nowhere was more strongly evidenced than in the City of London. Elizabeth's reign was marked by many efforts to establish grammar schools. To the enterprise of London merchant citizens is due the foundation of such famous public schools as Rugby, Oundle and Tonbridge. London also owes Charterhouse, St. Paul's (to which Dean Colet devoted part of his fortune inherited from his father, a City mercer), the City of London school, and the Merchant Taylors' and Mercers' schools to the munificence of the citizens.

Twice during the Tudor epoch the City of London became the scene of armed risings against the crown. In 1554 Sir Thomas Wyat's rebellion against Queen Mary collapsed when, after the march of his followers from Kingston-on-Thames, he found the city gate at Ludgate closed to keep him out. The earl of Essex's effort against Queen Elizabeth in 1601, made from his house at Temple Bar, had no promise of success. In each case the citizens withheld their support.

Mary's accession was subjected to brief delay by the plot to place on the throne Lady Jane Grey, the queen of the nine days' reign. The mayor abstained from attending at Cheapside at the proclamation of Jane, which was received with coldness—"few or none said 'God save her'"—but was present with the recorder and many aldermen when on July 11, 1553, Mary was proclaimed queen at the same place.

London, always intensely patriotic in national movements, rallied to the side of Elizabeth for defense against the Spanish Armada, sending a large contingent of armed men to Tilbury. In prosperous years under the queen the population greatly increased. The City and liberties became closely built upon the dispossessed lands of the ecclesiastics, and the beginnings are detected of a "trek" outwards by substantial merchants to pleasant country houses beyond its confines. Maps and views by Van den Wyngaerde (1550), Braun and Hogenberg (1572–73), and Ralph Agas' map a little later for the first time give an adequate pictorial representation of London, showing a considerable extension of the town westward towards Westminster, especially by large houses built by ecclesiastics and nobles by the Thames front.

Stuart London.—A Scottish monarch stepped up to the throne as King James I of England in 1603. There came in his train the first large migration of Scots to London. It continued in succeeding centuries, and by their characteristic enterprise, industry and ability the capital has largely benefited both in commerce and in culture. Inigo Jones began under James and Charles I, to introduce town planning; but the first experiments at Covent Garden and Lincoln's Inn Fields had made small progress when the Civil War intervened. Two notable civic enterprises mark James I's reign. First was the New River scheme, which gave to the capital a much-needed supply of pure water. It was in origin a City corporation project, carried out, when the corporation did nothing, by Hugh Myddelton, a wealthy citizen, with financial assistance from the king. The second enterprise was the plantation of the Irish province of Ulster, and its development by funds raised by the London livery companies. The link survives in the Irish society.

London history under Charles I is chiefly that of struggles with the king, whose financial expedients of forced loans, ship money, tonnage and poundage estranged the City. Monopolies and trade restrictions further incensed the merchants, and Charles had few friends in London when the Civil War became inevitable. The five members whom the king attempted to arrest in the house of commons on Jan. 4, 1642, on accusation of treason, took refuge in the City. "The birds are flown," he remarked, looking round the benches; and next day he went in person to Guildhall to demand their surrender. Again he met with no success, and as he left the council chamber cries of "Privileges of parliament!" rang in his ears. London became the natural capital of the king's enemies.

It was but once in military peril, in Nov. 1642, when three weeks after the opening battle at Edgehill Charles and his army, moving south, occupied Brentford 9 mi. distant. At Turnham Green the king found Lord Essex's troops, augmented by a large body of Londoners, arrayed against him, and after a reconnaissance he retired to Reading and Oxford. London saw nothing of the king until his trial and execution at Westminster in Jan. 1649.

Cromwell's Protectorate witnessed the readmission of Jews. They had been banished from the kingdom by Edward I in 1292, and for three-and-a-half centuries thereafter, very rarely is a Jewish name found. A small but definite settlement of Spanish and Portuguese Jews in London occurred in Charles I's reign, refugees from the terrors of the Inquisition, who crossed from the Netherlands *via* Amsterdam. Charles no doubt found them useful in his financial negotiations with Amsterdam. Cromwell utilized them in his secret service, giving "endenization" to their leader, Antonio Fernandez Carvajal (*q.v.*), thus making him the first English Jew. A conference, at which Rabbi Menasseh Ben Israel was the chief spokesman, was held at Whitehall in 1655, with the ultimate result of wresting an admission that English laws did not forbid the settlement of Jews. A synagogue was opened undisguised at Creechurch lane in the City in 1657, and a burial ground obtained at Mile End.

REBUILDING OF THE CITY

The Great Plague in 1665.—London suffered two vast calamities early after Charles II's restoration, by the great plague in 1665, followed by the great fire next year. Bubonic plague had scourged London for centuries. It is an error to regard the great plague of 1665 as an isolated event, or as a foreign importation. It began in London's suburb of St. Giles-in-the-Fields. Comparatively few deaths occurred in the walled city. The greatest devastation was in the town's outskirts, at Stepney, Shoreditch, Clerkenwell, Cripplegate, St. Giles's and Westminster, quarters wherein the poor were densely crowded. It was known as "the poor's plague."

The king and court fled from London in June, and did not return till the following February; parliament kept a short session at Oxford, where a legal term was held, lasting a few days only. The duke of Albemarle alone among Charles's ministers remained in London, and with the assistance of magistrates whom the king directed to stay exercised authority in the out-parishes, the lord mayor (Sir John Lawrence) accepting responsibility for the City. Defoe's vivid narrative in his *Journal of the Plague Year* is valuable as a picture of the time, but is historically inaccurate by reason of his assumption that the lord mayor's orders were faithfully carried out, which was not the case. The bills returned 97,306 deaths in London in 1665; 68,596 were attributed to plague.

The Great Fire.—Plague had not actually disappeared from London when the great fire occurred. A baker's shop in Pudding lane, near London bridge, was alight about one o'clock on the morning of Sunday, Sept. 2. The flames spread among crowded wooden houses down to the Thames wharves, whereon were stored quantities of inflammable goods. The water-wheel by the bridge was early destroyed, and thereby the water supply to neighbouring parts of the City was cut off. In the night the fire burned up into the City, and in the afternoon of the second day was raging about the Royal exchange, Lombard street and Cornhill, among the dwellings and shops of the richest brokers and merchants.

A wind blew freshly throughout three of the four days that London burned, always driving the flames farther into the City. By midnight on Monday, the second day, vast destruction had been done in an area that spread for nearly a mile along the river front, and in its northward extension the fire involved the whole of Cornhill, the Poultry, and was at the entrance of Cheapside. About the waterside much of the City lay dead and blackened, and the fire at night assumed the form of that huge "bow of flame" which so greatly impressed the diarist Pepys. Fire appliances consisted of iron hooks on poles for pulling down the burning wooden houses, axes and ladders, the only means of projecting water being brass hand-squirts worked by three men.

The king displaced the irresolute lord mayor (Sir Thomas Bludworth) from supreme authority, which he gave to James, duke of York; soldiers and dockyardsmen were sent in. Nearly half the walled City was burning by Tuesday morning. That third day the Guildhall was alight, the custom house and Royal exchange were destroyed, and late that night fire broke out on the roof of St. Paul's and ultimately left the great Gothic cathedral in ruins. In its onward rush the fire burned through Cheapside and reached London's northern wall at Cripplegate, and westward passed the wall at Newgate and Ludgate, and burned the larger part of the liberty, extending to Holborn bridge and throughout the length of Fleet street to within a few houses of Temple Bar. The wind falling during the night, the fire made but small advance on the fourth day, when save in a few isolated places it burned itself out.

The City surveyors' return shows concisely the extent of the calamity:—Area of the City burned, 273 ac. within the walls, 63 ac. without the walls; 87 parish churches, besides chapels, burned; 13,200 houses burned in over 400 streets and courts. Only one-fifth of the walled city was left standing.

Reconstruction.—With undaunted courage the citizens faced the vast task of rebuilding their city. Sir Christopher Wren and John Evelyn devised model plans, but amid the resulting distress and in the absence of any national contribution these could not be carried out, and the mediaeval street plan was retained. The Rebuilding act of 1667 directed that brick and stone only should be used. Four types of houses alone were to be permitted, for which specifications were given. A brick-built city slowly arose that was orderly in design, and in marked contrast to the picturesque jumble of gabled dwellings that it superseded. A few main streets were widened and straightened. Forty-four City companies' halls had been burned, and these, with the custom house and Royal exchange, were first rebuilt. Repairs to the Guildhall lasted till 1675. Four years after the fire construction began of ten of Wren's churches; the 51 churches rebuilt were not completed when the century ended. St. Paul's was finished in 1712.

No other single event exerted such influence upon the city's future and the welfare of its inhabitants as the great fire. The Reformation destroyed the predominating ecclesiastical character that London had maintained throughout the middle ages; the fire made the City within the lord mayor's jurisdiction the main commercial centre that it has since been. Under the first Stuart kings the nobility, moving out from the City, created a fashionable west-end at Covent Garden and Lincoln's Inn Fields; loyalists returned with King Charles II built themselves houses farther west. At the close of the reign Aldersgate street alone in the City remained a place of fashionable residence.

After the fire London for the first time was given a central sanitary authority. Municipal service hardly existed. Lighting such as the streets enjoyed, by candles exposed in horn lanterns before the house fronts, it was the duty of individual householders to provide; they formed the watch (police); there was no public control of drainage; repair of the street surface to the centre line and cleansing of the streets were obligations cast upon residents, each man before his own house. A Sewers act of 1671 gave to London in perpetuity a public body called the commissioners of sewers, nominated by the corporation, with power to raise a rate, and to this body was confided the laying out, repair, drainage and cleansing of the City streets.

For the last time a king of England sought to curtail the City of London's ancient liberties and franchises, by proceedings under the writ *Quo warranto,* which resulted in 1683 in various aldermen and officers being ejected, and for a few years their places, together with the mayoralty, were filled by royal nominees. The legality of the proceedings was never acknowledged; it became known only later that two of the King's Bench judges who favoured the City's cause were arbitrarily removed before judgment. Charles died on Feb. 6, 1685, and in the crisis of King James II's short reign that followed full restitution was made of the City's liberties.

On the flight of King James II from London in Dec. 1688, lords spiritual and temporal came to Guildhall as a place of greatest security, and there drew up the Declaration of Allegiance to the prince of Orange. The common council voted an address welcoming the prince. It was significant of the City's great position and prestige, that to the authoritative assembly which met after William of Orange's arrival in London he summoned not only the members of past parliaments, but also the lord mayor, the aldermen, and 50 representatives of the common council.

The characters of the successive Georges did little to endear them to the populace, among which was a not inconsiderable Jacobite faction. But London, with its vast commercial and financial interests, had everything to gain by settled government and order, and in the crises provoked by the Jacobite risings of 1715 and 1745 gave its weighty support to the throne. Later there came a distinct cleavage between the corporation and the court party. The only statue to a lord mayor that the City has raised in Guildhall is to William Beckford, and beneath it is set out in golden letters the strong, if still courteous, remonstrance that he addressed to King George III, touching a violated right of election.

The mayoralty in a struggle with the house of commons performed conspicuous service in advancing the liberty of the press. Parliament held publication of its debates to be a breach of privilege. In March 1771, certain printers abandoned the subterfuge of giving fictitious names, date and place, and reported the debates openly. Thereupon a messenger armed with the speaker's warrant arrested Miller, the printer of the *Evening Post,* in the City. Aldermen John Wilkes and Oliver declared the warrant illegal, released Miller and placed the messenger under arrest and bond. Brass Crosby, the lord mayor, upheld the City's franchise to execute the laws within its jurisdiction. Great processions of citizens accompanied Crosby and Oliver (Wilkes was not molested) to the house of commons, by which, after having been heard, they were committed to custody in the Tower. The prorogation of parliament six weeks later set them free, when the full common council, gowned, with the City officers and a multitude of people, attended at the Tower gates to receive the mayor and alderman, and escorted them amid tumultuous enthusiasm to the Mansion house. At night the city was illuminated. Thereafter the ban upon reporting the debates was tacitly withdrawn.

Vast destruction was done in London during the Gordon riots in June 1780, which followed upon the act of parliament for relieving Roman Catholics of certain disabilities. The disorders were finally put down by the soldiers, with 285 dead by musket fire and 173 wounded civilian prisoners. Such was the official return, but the actual casualties were believed to exceed 700.

London lost its character as a walled city by the demolition in 1760–66 of the last City gates and the last sections of the wall. This was but a small part of the change that the Georgian era brought about. Before the century ended the historic area of the lord mayor's jurisdiction distinguished today by the name of "the City," was left embedded as the small nucleus of a capital that spread for miles distant on every side.

The Thames had been from time immemorial the chief highway for communications about the town and for the passage of heavy merchandise. Pepys, the diarist, records many occasions on which he took boat at the stairs for Westminster and Lambeth and to Deptford dockyard. In Queen Anne's reign the world of fashion largely adopted the sedan chair. The bridge between the City and Southwark stood alone until 1750, when an additional bridge crossing the Thames at Westminster was opened, followed 19 years later by a third bridge at Blackfriars.

Architecture in the capital underwent considerable development at the hands of Chambers, Soane, Gibbs, Kent, the brothers Adam—who gave the Adelphi in the Strand—and the elder and younger Dance. Important buildings of the period are Somerset house, its river front then washed by the tide; the Bank of England, of which Soane's finely conceived encircling wall remains in the reconstruction; the Mansion house, the Horse Guards and Lansdowne house. Bloomsbury was laid out in garden squares which today bear their Georgian names, and set an example to builders farther west from which London has greatly benefited. The signs that after the great fire had been placed flat on the house fronts were withdrawn in the middle 18th century, when the numbering of houses was introduced. Oil lamps gave better lighting to the streets, though it was not until 1736 that street lighting was accepted as a municipal duty. In turn these gave place to gas, introduced in 1807, and to electricity.

Recent Developments.—After Queen Victoria's accession in 1837 the City was almost wholly given up to commerce. New streets opened out its congestion, but the larger developments were in the West End. Regent street, the West End's principal shopping thoroughfare, was part of the ambitious project of the prince who became King George IV. The advent of railways gave additional impetus to the extension of the metropolis; and in 1851 the Great Exhibition, held in Hyde Park, set the example of international exhibitions to other nations, added largely to the trade of the country, and made the capital itself far better known to foreign visitors.

The larger part of the City has been newly built in stone, but brick and concrete predominate outside its limits, the former being largely used for blocks of flats and the latter for commercial buildings. London made a worthy contribution both in men and treasure to World War I and for the first time since the days of William the Conqueror was attacked by forces from overseas. Air-raids by zeppelin and aeroplane took place at intervals from May 31, 1915, to May 20, 1918; 355 incendiary and 567 explosive bombs were dropped in the City, completely destroying 174 buildings, seriously damaging 617 others, killing 524 persons and injuring 1,264, and doing damage to the estimated value of £2,042,000.

The figures for World War I are trifling compared with those for World War II. In the 11 months from Sept. 1940, to the end of July 1941, for instance, it is computed that between 45,000 and 50,000 bombs were dropped on the London region, of a total weight of roughly 7,500 tons, excluding incendiary bombs. Close on 10,000 persons were killed and 17,000 seriously wounded. Bombing continued for 57 successive nights (Sept. 7–Nov. 2, inclusive) and roughly 20,000 bombs were dropped in this period. During the two years 1940–41 about 10,000 tons of bombs were dropped. The second great fire of London occurred on the night of Dec. 29–30, 1940, when more than 100 aeroplanes showered incendiary bombs on the City. Some 1,500 fires were started, including six conflagrations and 16 major fires. A large area round St. Paul's cathedral was laid waste, the Guildhall was all but gutted, eight Wren churches suffered seriously and the Law Courts and the Tower were hit. During the previous September great fires had also been caused in the docks and the more eastern part of the City. On the night of April 16–17, 1941, the houses of parliament, the Law Courts and St. Paul's were hit, while on May 10–11 the commons chamber of parliament was destroyed and Westminster abbey, Westminster hall, the British museum, the Law Courts again, the war office, the mint, the Mansion House and again the Tower were hit. Five of the halls of City companies were destroyed and many famous churches were damaged.

In the months that followed the air raids diminished, until in 1942 and 1943 there were long periods when no raids took place; few planes penetrated the extensive balloon barrage and the progressively improving anti-aircraft defenses. In the final reckoning, therefore, the bulk of the damage, amounting to hundreds of thousands of buildings, if houses are included, and to millions of pounds in value, will be found to have been caused during 1940–41.

The corporation of the City of London is now surrounded by 28 municipal boroughs (including the City of Westminster) and an inhabited area of some 700 square miles.

Bibliography.—Much information concerning the earliest period is contained in the Roman and Anglo-Saxon sections of *Victoria County History of London*, vol. i. (1909); W. Lethaby's *Londinium* (1923), for architecture; W. Page's *London: Its Origin, etc.* (1923), which carries the history through Norman times; *London*, vol. iii. (1928) of the Historical Monuments Commission; and Prof. Haverfield's works, particularly *Journal of Roman Studies*, vol. i. Sir G. L. Gomme, in *The Governance of London* (1907), *London*, and other books, has striven to find an unbroken link between the historic City and London of the Romans.

For the middle ages sources are very numerous. Liebermann's *Gesetze der Angelsachsen* contains many London records of early date. J. H. Round's *Geoffrey de Mandeville* (1896) and *The Commune of London* (1899), and Miss Bateson's "A London Municipal Collection of the Reign of John," in *English Historical Review*, vol. xvii., must be read for Norman London and the rise of the mayoralty. The City corporation has published many of its muniments, which remain the basis of civic history. Included in these are the following edited by H. T. Riley: *Munimenta Gildhallae* (1859, Rolls Series), which contains the *Liber Albus*, written in 1419, and the *Liber Custumarum* (an English translation of the first-named printed in 1861); *Chronicles of the Mayor and Sheriffs of London*, 1180–1274 (1863) and translations of the *Liber de Antiques Legibus;* and *French Chronicle of London*, 1259–1343 (1844–46, Camden Society); and *Memorials of London and London Life in the 13th, 14th and 15th Centuries* (1868), the last a selection of documents from the records known as the City Letter Books. Complete Calendars of these Letter Books from A to L—Edward I. to Henry VII.—have been edited by R. R. Sharpe (1899–1912), who also has edited the *Hustings Wills* (1889–90) and early *Coroner's Rolls*. Other archives at Guildhall, edited by A. H. Thomas, are *Plea and Memoranda Rolls*, 1323–64 (1926) and *Early Records of the Mayor's Court*, 1298–1307 (1924). Full translations of the City's charters are given in W. de G. Birch's *Historical Charters and Constitutional Documents of the City of London* (1887).

John Stow's *Surveigh of London* (1598, 1603) edited by C. L. Kingsford (1908), invaluable for its pictures of London in the Elizabethan age, is a basis of much knowledge of earlier times. It also contains the first written description of London, by Fitzstephen in the year 1174. Kingsford's *Chronicles of London* (1905) brings together chronicles written between 1200 and 1516. H. B. Wheatley's *The Story of London* (Mediaeval Towns series, 1904) and W. J. Loftie's *A History of London* (1883) cover the period. Accounts of trade and craft guilds are contained in W. Herbert's *Twelve Great Livery Companies of London* (1837); W. C. Hazlitt, *Livery Companies* (1892); G. Unwin, *Gilds and Companies of London* (1918). Many of the Companies have published their separate histories.

London's religious houses and ecclesiastical affairs are dealt with in detail by the *Victoria County History of London*, vol. i., and Dugdale's *Monasticon;* and the parishes till 1700 by Newcourt's *Repertorium*, and its continuation, G. Hennessy's *Novum Repertorium* (1898). A. B. Beaven's *Aldermen of the City of London* (1908–13) is a full record of that body. W. G. Bell's *Great Plague in London in 1665* (1924) and *Great Fire of London* (1920) give accounts of the two catastrophes based on recent research. Dr. Reginald Sharpe's *London and the Kingdom* (1894–95), written from the civic archives, is an admirable exposition of the City's political history. The London Topographical Society has published facsimiles of early London maps. Views of typical buildings of past ages are given in J. T. Smith's *Ancient Topography of London* (1815), J. W. Archer's *Vestiges of Old London* (1851) and P. Norman's *London Vanished and Vanishing* (1905). Many of the larger historical buildings still standing and certain parishes are the subject of monographs by the London Survey committee.

General histories of London begin with Stow. J. Howel's *Londinopolis* (1657) is Stow's book with additions, and it is largely augmented in J. Strype's edition of 1720, a standard work, and subsequent issues. Other histories of wide scope are Maitland's *London* (1739); T. Pennant's *London* (1790); J. P. Malcolm's *Londinium Redivivum* (1803); T. Allan, *History and Antiquities of London* (1827–29); Sir W. Besant's *Survey of London* (1902–08); and notably H. P. Wheatley and Cunningham's *London Past and Present* (1891). *The Times* "Book of the City of London" (1928), by various authors, presents the results of recent scholarship. For outer London, D. Lyson's *Environs of London* (1792–1811) is authoritative, and much information is given by W. Thornbury and E. Walford's *Old and New London* and *Greater London* (1873–78).

Among recent works may be mentioned—G. H. Cunningham, *London* (1927), for buildings and historical monuments; *An Encyclopaedia of London* (1937); *New Survey of London Life and Labour* (9 vols., 1930–35); W. A. Robson, *The Government and Misgovernment of London* (1939); Sir G. Gibbon and R. W. Bell, *History of the London County Council, 1889–1939* (1939); J. M. Richards (ed.), *The Bombed Buildings of Britain* (1942), pp. 5–80. The catalogue of the Members' Library, L.C.C., vol. I, is devoted to London history and topography. The publications of the L.C.C. should be consulted. (W. G. B.; X.)

LONDON, a village of Ohio, U.S.A., 25 mi. W. by S. of Columbus; the county seat of Madison county. It is on federal highway 42 and is served by the Big Four and the Pennsylvania railways. The population in 1920 was 4,080; it was 4,141 in 1930 and 4,697 in 1940 by the federal census. London was settled about 1811.

LONDON, CONFERENCES OF. Many important international conferences have been held in London during the 19th and 20th centuries. The first, in June 1814, was the outcome of the visit of the Allied sovereigns to the prince regent after the downfall of Napoleon, the opportunity being used to effect some of the settlements agreed upon in the first treaty of Paris, notably the conditions attached to the erection of the kingdom of the United Netherlands. From 1815 onwards, too, diplomatists of the Allies accredited to Great Britain formed a conference in London for the purpose of discussing measures for the suppression of the slave trade and of the Barbary pirates.

Greece.—In 1827 a conference met in London to attempt to settle the affairs of Greece. This conference (the first international gathering to be usually thus described) met on July 12, 1827, and sat till 1832. It was attended only by the representatives of the three powers which had signed the treaty of London (July 6, 1827), *i.e.*, France, Great Britain and Russia. The treaty of London of May 7, 1832, however, which established the kingdom of Greece, with Prince Otto of Bavaria as king, was signed also by Baron de Cetto on behalf of the king of Bavaria.

Belgium.—In 1830, while this conference was still in session, the insurrection of the Belgians against the king of the Netherlands led to the summoning of another conference in London, to deal with the dangerous situation thus created. The personnel of both conferences was in part the same, both France and Russia being represented in both by their ambassadors, Talleyrand and Matuszewicz, while Palmerston, when he succeeded Aberdeen as foreign secretary, presided at the Greek conference and also, from the fourth session onwards, over that on the Belgian question. But in the latter Austria, Prussia and Holland were also represented. This conference first met on Nov. 4, 1830, and there were in all 70 sessions. After the independence of Belgium had been recognized and Leopold of Coburg had been elected king (June 4, 1831) a Belgian plenipotentiary was also admitted. On Oct. 1, 1832, Austria, Prussia and Russia having refused to agree to the French proposal to coerce the Dutch king into accepting the 24 articles embodied in the treaty of Nov. 15, 1831, the conference virtually broke up, the further proceedings being conducted by the representatives of France and Great Britain. These ended on May 21, 1833, with the signature of a convention between the two powers and Holland, providing for the non-renewal of hostilities and freedom of navigation on the Scheldt and Meuse. Thus matters remained till 1839 when, the king of Holland having at last consented to recognize the inevitable, the plenipotentiaries of all the five powers met in London to sign with those of

Holland, on April 7/19, a treaty to which the 24 Articles of Nov. 15, 1831, were annexed (*see* BELGIUM).

Schleswig-Holstein and Luxembourg.—In 1848 the war between Prussia and Denmark over the Schleswig-Holstein Question (*q.v.*) led to the assembling of an international conference in London. It met after the pressure of the Powers had forced Prussia to conclude the truce of Malmö (Aug. 26) and resulted in the peace signed at Berlin on July 2, 1850, which left the main problems unsolved. By the protocol signed on May 8, 1852, the conference settled the succession to the Danish throne and the duchies of Schleswig and Holstein on Christian of Glücksburg.

In 1864, during the war between the two great German Powers and Denmark Great Britain invited the signatories of the Protocol of 1852 to a conference in London, with a view to a settlement. The conference met on April 25, immediately after the storming of the Düppel lines; but, owing to Bismarck's skilful diplomacy, it broke up on June 25 without having effected anything.

In 1867 an important international conference met in London, at the instance of the king of the Netherlands, to deal with the situation in regard to Luxembourg created by the war of 1866 and the consequent dissolution of the old German Confederation. The conference consisted primarily of the representatives of the States signatory of the treaty of 1839, by which the status of the grand duchy of Luxembourg had been determined, *i.e.,* Austria, Belgium, France, Great Britain, Holland-Luxembourg, Prussia and Russia, but on the motion of Lord Stanley, who presided, the Italian ambassador was also invited to assist. The conference resulted in the Treaty of London of May 11, 1867, by the terms of which the Prussian troops, which had garrisoned the city of Luxembourg since 1815, were to be withdrawn and the fortress demolished. On the motion of the Prussian plenipotentiary, Count Bernstorff, a clause was introduced placing the neutrality of Luxembourg under the guarantee of the signatory Powers.

Russia.—In 1871, during the Franco-German War, the denunciation by Russia of the Black Sea clauses of the Treaty of Paris of 1856 led to the assembling of a conference in London, in order to regularize the situation thus created by a revision of the treaty of 1856, so far as regarded the neutralization of the Black sea, the Straits of the Dardanelles and Bosphorus, and the navigation of the Danube. The conference, which sat from January to March, and was attended by the representatives of North Germany, Austria-Hungary, Great Britain, Italy, Russia and Turkey, while revising the treaty in accordance with Russia's wishes, asserted the principle of the inviolability of treaties (*see* TREATIES).

Treaty of Berlin.—In 1883 a conference sat in London (Feb. 8–March 10) to consider the execution of Arts. 54 and 55 of the Treaty of Berlin of July 13, 1878, concerning the navigation of the Danube (*q.v.*). It was attended by representatives of all the Powers which had signed the Berlin treaty, and those of the other riverain States (*i.e.,* Serbia and Rumania) which had not signed the treaty were invited to attend, but without a deliberative voice. Bulgaria, as a vassal state, was represented by the Turkish delegate. Rumania refused to accept these conditions, but the Serbian plenipotentiary attended the sessions.

Egypt.—In 1885 a conference between the great Powers and Turkey was held in London to deal with the situation arising out of the financial crisis in Egypt. The result was the signature, in March, of what is known as the London Convention, the terms of which were embodied in a khedivial decree and, with some modifications, remained for 20 years the organic law governing the administration of the finances of Egypt (*q.v.*).

In 1887, in response to an invitation issued by the British Government on July 2, an international conference met in London to deal with the question of sugar bounties. The debates led up to the convention of Aug. 30, 1888, which was signed by all the representatives except the French. It was, however, never ratified.

Naval Conference.—In 1908, at the invitation of the British Government an international naval conference met in London to attempt a settlement of those questions regarding contraband, blockade, etc., which had been raised at the second Hague Conference. The conference met on Dec. 4, 1908 and continued in session until Feb. 26, 1909, the outcome of its labours being the Declaration of London. This Declaration was never ratified.

The Balkans.—In 1912 and 1913 conferences were held in London to arrange terms of peace between Turkey and the Allied Balkan States, Bulgaria, Greece, Montenegro and Serbia. The conference, which was attended by representatives of the belligerent states, was opened on Dec. 16, 1912, by the British foreign secretary, but was suspended without result on Jan. 6. It met again on May 30, 1913, the outcome being the Treaty of London signed on the same day. The conference was dissolved on June 9, and its work was rendered abortive by the outbreak, immediately afterwards, of the second Balkan war.

Post-war Conferences.—In 1921–1922 four conferences of Allied statesmen were held in London, to adjust matters arising out of the peace treaties which ended the World War. The first met from Feb. 21 to March 14, 1921, and carried on alternately two sets of negotiations, one with the Athens, Constantinople and Angora Governments on the near Eastern question (*see* TURKEY), the other with the German Minister for Foreign Affairs, Dr. Simons, on the subject of reparations. The result in both cases was failure. The conference was hardly over before the Greeks launched a new offensive against the Turkish Nationalists, while the unacceptable counter-proposals made by Dr. Simons to the demands put forward by the Allies at the Paris Conference of Jan. 24–30 led, early in March, to fresh sanctions being taken against Germany (occupation of Düsseldorf, etc.).

On April 29 the Allied statesmen, after a preliminary meeting at Lympne on the 23rd and 24th, met again in London to decide what was to be done in view of the expected default of Germany in the matter of the payment of the first installment of reparations due, under Art. 235 of the Treaty of Versailles, on April 30. New sanctions against Germany were discussed. But the Reparations Commission having on April 27 declared an estimate of Germany's total liability, the Allied statesmen made this the basis of a "schedule of Payments describing the Time and Manner for securing and discharging the entire Obligation of Germany for Reparation under Articles 231, 232 and 233 of the Treaty of Versailles." This document was sent to Berlin on May 5, with an ultimatum, and on the 11th the German Government accepted the Allies' terms.

In 1922, owing to the failure of the German Government to carry out the above agreement, the Allied statesmen again met in conference in London, from Aug. 7 to Aug. 14. At this meeting M. Poincaré, as conditions precedent to granting Germany a moratorium, put forward proposals for "productive guarantees," which he attempted to carry out after the Franco-Belgian occupation of the Ruhr district in 1923. An irreconcilable difference of opinion having arisen as to the effectiveness of such measures, the conference broke up without reaching any decision. The conference held in London later in the year for the same purpose met with no better result. At this meeting, which lasted from Dec. 9 to Dec. 11, M. Poincaré again put forward his proposal for "productive guarantees." As in this matter, as in other respects, no agreement could be reached between the French and British representatives, the conference was adjourned (*see* REPARATIONS).

(W. A. P.)

LONDON AND NORTH EASTERN RAILWAY COMPANY, THE, is the second largest railway company in Great Britain, incorporating the former Great Central, Great Eastern, Great Northern, Hull and Barnsley, North Eastern, North British and Great North of Scotland companies. It has a total mileage of 6,349 miles which covers the whole of eastern England, and East and West Scotland between the Thames and Moray Firth.

High speed streamlined trains run as follows: "Coronation"—London (King's Cross) and Edinburgh (6 hours); "Silver Jubilee"— London (King's Cross) and Newcastle (4 hours); "West Riding Limited"—London (King's Cross) and Leeds and Bradford. Restaurant car expresses, including the "Flying Scotsman", run between London (King's Cross) and the North of England and Scotland; London (Marylebone) and the Midlands and Liverpool; London (Liverpool Street) and the Eastern Counties. Sleeping car services operate between London (King's Cross) and the North of England and Scotland. Fast freight services operate between most stations on the system.

The company employs approximately 170,000 people, owns 2,500 stations and goods depots, and is the largest dock owning railway company in the world. Its property includes docks at Grimsby, Immingham, Hull, Middlesbrough, the Hartlepools, Silloth, Burntisland, Methil, Alloa and Bo'ness.

The company's rolling stock includes 6,500 locomotives, 20,000 passenger vehicles, and 260,000 goods and mineral wagons. Its annual traffic figures are 262,000,000 passengers, 101,000,000 tons of merchandise and minerals, and 2,750,000 head of livestock.

The London and North Eastern Railway also owns 33 steamships and operates services between Harwich and Hook of Holland, Antwerp and Zeebrugge and is associated with the operation of services between Humber and Continental ports. Three train ferries are worked between Harwich and Zeebrugge. (G. Do.)

LONDONDERRY, EARLS AND MARQUESSES OF. The 1st earl of Londonderry was Thomas Ridgeway (*c.* 1565–1631), a Devon man, who was treasurer in Ireland from 1606 to 1616 and was engaged in the plantation of Ulster. Ridgeway was made a baronet in 1611, Baron Ridgeway in 1616 and earl of Londonderry in 1623. The Ridgeways held the earldom until March 1714, when Robert, the 4th earl, died without sons. In 1726 Robert's son-in-law, Thomas Pitt (*c.* 1688–1729), son of Thomas Pitt, "Diamond Pitt," governor at Madras and uncle of the great earl of Chatham, was created earl of Londonderry, the earldom again becoming extinct when his younger son Ridgeway, the 3rd earl of this line, died unmarried in Jan. 1765. In 1796 Robert Stewart (1739–1821), of Mount Stewart, Co. Down, was made earl of Londonderry in the Irish peerage. He had been created Baron Londonderry in 1789 and Viscount Castlereagh in 1795; in 1816 he was advanced to the rank of marquess of Londonderry. The 3rd marquess married the heiress of the Vane-Tempests and took the name of Vane instead of Stewart; the 5th marquess called himself Vane-Tempest and the 6th marquess Vane-Tempest-Stewart.

LONDONDERRY, CHARLES STEWART HENRY VANE-TEMPEST-STEWART, 7TH MARQUESS OF (1878–), British statesman, born in London on May 13, 1878, was the son of Charles Stewart Vane-Tempest-Stewart (b. 1852, *see* LONDONDERRY, CHARLES WILLIAM STEWART [VANE]). Educated at Eton and Sandhurst, he entered the House of Commons in 1906 as Unionist member for Maidstone. From 1914–19 he served in the World War, being twice mentioned in despatches. Made a privy councillor for Ireland in 1918 and a K.G. in 1919, in 1920–21 he was under-secretary for air, and minister of education for Northern Ireland, 1921–26. He was first commissioner of works, 1928–29 and 1931, and air minister from 1931 to 1935, in which year he was leader of the House of Lords.

LONDONDERRY, CHARLES WILLIAM STEWART (VANE), 3RD MARQUESS OF (1778–1854), British soldier and diplomatist, was the son of the 1st marquess by a second marriage with the daughter of the 1st Earl Camden. He entered the army and served in the Netherlands (1794) on the Rhine and Danube (1795), in the Irish rebellion (1798), and Holland (1799), rising to be colonel. He was elected M.P. for Kerry and became under-secretary for war under his half-brother Castlereagh in 1807. In 1808 he was given a cavalry command in the Peninsula. In 1809, and in the campaigns of 1810–1811, as major-general, he served under Wellington in the Peninsula as his adjutant-general, and was at the capture of Ciudad Rodrigo, but at the beginning of 1812 he was invalided home. Castlereagh (*see* LONDONDERRY, ROBERT STEWART) then sent him to Berlin as minister, to represent Great Britain in the allied British, Russian and Prussian armies and he played an important part in the subsequent fighting, while ably seconding Castlereagh's diplomacy. In 1814 he was made a peer as Baron Stewart, and later in the year was appointed ambassador at Vienna, and was a member of the important congresses which followed. In 1822 Castlereagh's death made him 3rd marquess of Londonderry, and shortly afterwards, disagreeing with Canning, he resigned, being created Earl Vane (1823), and for some years lived quietly in England. In 1835 he was for a short time ambassador at St. Petersburg. In 1852, after the death of Wellington, he received the order of the Garter. He died on March 6, 1854. He was twice married, first in 1808 to the daughter of the earl of Darnley, and secondly in 1819 to the heiress of Sir Harry Vane-Tempest, when he assumed the name of Vane. Frederick William Robert (1805–72), his son by the first marriage, became 4th marquess; and on the latter's death in 1872, George Henry (1821–84), the eldest son by the second marriage, after succeeding as Earl Vane (according to the patent of 1823), became 5th marquess. In 1884 he was succeeded as 6th marquess by his son Charles Stewart Vane-Tempest-Stewart (1852–1915), a prominent Conservative politician, who was viceroy of Ireland (1886–89), chairman of the London School Board (1895–97), postmaster-general (1900–02), president of the Board of Education (1902–05) and lord president of the Council (1903–05). He was a prominent leader of the opposition to the Home Rule Bill of 1912, and was one of the first to sign the Ulster Covenant, Sept. 28, 1912. He died at Stockton-on-Tees, on Feb. 8, 1915.

LONDONDERRY, ROBERT STEWART, 2ND MARQUESS OF (1769–1822), British statesman, was the eldest son of Robert Stewart of Ballylawn Castle, in Donegal, and Mount Stewart in Down, an Ulster landowner, of kin to the Galloway Stewarts, who became baron, viscount, earl and marquess in the peerage of Ireland. The son, known in history as Lord Castlereagh, was born on June 18, in the same year as Napoleon and Wellington. His mother was Lady Sarah Seymour, daughter of the earl of Hertford. He went from Armagh school to St. John's College, Cambridge, but left at the end of his first year. With Lord Downshire, then holding sway over the County Down, Lord Stewart had a standing feud, and he put forward his son, in July 1790, for one of the seats. Young Stewart was returned, but at a vast cost to his family, when he was barely twenty-one. He took his seat in the Irish House of Commons at the same time as his friend, Arthur Wellesley, M.P. for Trim, but sat later for two close boroughs in England, still remaining member for Down at College Green.

From 1796, when his father became an earl, he took the courtesy title of Viscount Castlereagh, and becoming keeper of the privy seal in Ireland, he acted as chief secretary, during the prolonged absence of Pelham, from February 1797. Castlereagh's conviction was that, in presence of threatened invasion and rebellion, Ireland could only be made safe by union with Great Britain. In Lord Camden, as afterwards in Lord Cornwallis, Castlereagh found a congenial chief. Though his favour with these statesmen was jealously viewed both by the Irish oligarchy and by the English politicians who wished to keep the machine of Irish administration in their own hands. Pitt was doubtful of the expediency of making an Irishman chief secretary, but his view was changed by the influence of Cornwallis. In suppressing Lord Edward Fitzgerald's conspiracy, and the rebellion which followed in 1798, Castlereagh's vigilance and firmness were effective. The various forces which feared the consequence of the Union, coalesced against him in Dublin. Even there Castlereagh, though defeated in a first campaign (1799), impressed Pitt with his ability and tact. With Cornwallis he joined in holding out, during the second Union campaign (1800), the prospect of emancipation to the Roman Catholics.

When the Act of Union was carried through the Irish parliament, in the summer of 1800, Castlereagh's official connection with Ireland practically ended. Before the Imperial Parliament met he urged upon Pitt the measures which he and Cornwallis thought requisite to make the Union effective. But the king flatly refused to sanction emancipation, and Pitt and his cabinet made way for the Addington administration. Thereupon Castlereagh resigned, with Cornwallis. He took his seat at Westminster for Down, the constituency he had represented for ten years in Dublin. The leadership of an Irish party was offered to him, but he declined so to limit his political activity. His father accepted, at Portland's request, an Irish marquessate, on the understanding that in the future he or his heirs might claim the same rank in the Imperial legislature; so that Castlereagh was able to sit in the

House of Commons as Marquess in 1821–22.

In 1802, Castlereagh, at Pitt's suggestion, became president of the Board of Control in the Addington cabinet. He had, though not in office, taken charge of Irish measures under Addington, including the repression of the Rebellion Bill, and the temporary suspension of the Habeas Corpus in 1801, and he continued to advocate Catholic relief, tithe reform, state payment of Catholic and dissenting clergy and "the steady application of authority in support of the laws." To Lord Wellesley's Indian policy he gave a staunch support, warmly recognized by the governor-general. On Pitt's return to office (May 1804), Castlereagh retained his post, and, next year, he took over the duties of secretary for war and the colonies. His house became a meeting-place of the party; and his influence in parliament grew. After Pitt's death his colleagues failed to form a cabinet able to face the combination known as "All the Talents," and Castlereagh acquiesced in the resignation. But to the foreign policy of the Fox-Grenville ministry and its conduct of the war he was always opposed.

In 1807 Castlereagh returned to the War Office under Portland, but grave difficulties arose, though Canning at the Foreign Office was then thoroughly at one with him. The operations to avert the ruin of the coalition at Friedland came too late. The Tsar Alexander believed that England would no longer concern herself with the Continental struggle, and Friedland was followed by Tilsit. The seizure of the Danish squadron at Copenhagen, and the measures taken to rescue the fleets of Portugal and Sweden from Napoleon, crushed a combination as menacing as that defeated at Trafalgar. The expedition to Portugal, though Castlereagh's influence was able only to secure Arthur Wellesley a secondary part at first, soon dwarfed other issues. In the debates on the Convention of Cintra, Castlereagh defended Wellesley against parliamentary attacks. Early in 1809, Castlereagh secured his friend's appointment as commander-in-chief of the second Portuguese expedition.

Disagreement with Canning.—Meanwhile a breach arose between Castlereagh and Canning. Canning was not openly opposed to the Walcheren expedition, and on the Peninsular question he mainly differed from Castlereagh and Wellington in fixing his hopes on national enthusiasm and popular uprisings. Castlereagh's proposal of action in the Netherlands was for a *coup de main*, under strict conditions of celerity and secrecy, as Antwerp was unable to make any adequate defence. But the expedition, planned at the end of March, did not reach Walcheren till the end of July 1809; and more time was lost, until sickness in the army necessitated its withdrawal in September. Public opinion threw the whole blame upon Castlereagh, who then found that his colleagues had determined on his removal six months earlier. Castlereagh held himself justified in sending a challenge to the original author, as he held, of a disloyal intrigue against a colleague. In the subsequent duel Canning was wounded and the rivals simultaneously resigned. Though Wellington's retreat after Talavera had been included, with the disasters of the Corunna and Walcheren campaigns, in the censures on Castlereagh, and though ministers were often depressed and doubtful, Castlereagh never lost faith in Wellington's genius. Lord Wellesley's resignation in 1812, when the Whigs failed to come to terms with the regent, led to Castlereagh's return to office as foreign secretary (March 1812). The assassination of Percival soon threw upon him the leadership of the House of Commons, and this double burden he continued to bear during the rest of his life.

The Duel with Napoleon.—From March 1812 to July 1822 Castlereagh's biography is, in truth, the history of England. He set himself at once to meet Napoleon's designs in northern Europe, where Russia was preparing for her life-and-death struggle. Castlereagh wisely rejected Napoleon's insincere overtures for peace. After the Moscow *débâcle* Napoleon's fate was affected not only by Wellington's progress in Spain, but by the attitude of the northern powers and by the action of Turkey, due to Castlereagh's opportune disclosure to the Porte of the scheme of partition at Tilsit. The British subsidies to the Allies were largely increased as the operations of 1813 developed, but all Castlereagh's skill was needed to keep the Coalition together. The Allied powers were willing, even after Leipzig, to treat with France on the basis of restoring her "natural frontiers"—the Rhine, the Alps and the Pyrenees; but Castlereagh protested. Early in 1814 his colleagues, who needed him in the House of Commons, reluctantly consented to his visit to the allied headquarters. The Great Alliance showed signs of weakness and division. Austria was holding back; Prussia had almost broken away; above all, the ambiguous conduct of Alexander bred alarm and doubt. Napoleon's military genius, confronting a hesitant and divided enemy, was at its best. Castlereagh strove to keep the Allies together, to give no excuse for those separate arrangements upon which Napoleon was reckoning, to assert no selfish policy for England, to be tied by no theoretical consistency. At the Châtillon conferences England was represented by others, but Castlereagh was present with supreme authority over all. He declined to commit his country either to a blank refusal to negotiate with Napoleon or to the advocacy of a Bourbon restoration. He insisted on the return of France within her ancient limits as the basis of a settlement. Even before the Châtillon conference was dissolved (March 18), Castlereagh saw that Caulaincourt's efforts would never bend Napoleon's will. The Allies adopted his view and signed the treaty of Chaumont (March 1), "my treaty," as Castlereagh called it, with an unusual touch of personal pride. At Bar-sur-Aube, when at a council of all the representatives of the powers the retreat of the allied armies was discussed, Bernadotte, playing a waiting game in Holland, was unwilling to reinforce Blücher, then in a dangerous position, by the Russian and Prussian divisions of Winzingerode and Bülow, temporarily placed under his orders. Castlereagh, without consulting the Cabinet at home, threatened the withdrawal of the British subsidy. Bernadotte gave in. Blücher was reinforced by the two divisions; the battle of Laon was fought and won, and the allies occupied the French capital. In April 1814 Castlereagh arrived in Paris. He did not like Napoleon's position at Elba, close to the French coast, and he summoned Wellington from the south to the embassy in Paris.

His appointment as British representative at Vienna, where the congress was to meet in September, was foreseen. At Vienna he realized at once that the ambition of Russia might be as formidable to Europe and to Great Britain as that of Napoleon. His aim had been to rescue Europe from military domination; and when he realized the ambitions of Russia and Prussia, he did not hesitate to take a new line. He brought about the secret treaty (Jan. 3, 1815) between Great Britain, Austria, and France, directed against the plans of Russia in Poland and of Prussia in Saxony. Through Castlereagh's efforts, the Polish and Saxon questions were settled on the basis of compromise. The threat of Russian interference in the Low Countries was dropped.

Castlereagh had come home for a short visit (Feb. 1815), at the urgent request of the cabinet, just before Napoleon escaped from Elba. The shock revived the Great Alliance under the compact of Chaumont. Napoleon promptly published the secret treaty which Castlereagh had concluded with Metternich and Talleyrand. But Russia and Prussia, though much displeased, dared not weaken the Alliance. British subsidies were again poured out like water. After Waterloo, Castlereagh successfully urged Napoleon's removal to St. Helena.

Peace and the Holy Alliance.—Some of the continental powers demanded fines and cessions that would have crushed France; but in November a peace was finally concluded, mainly by Castlereagh's endeavours, minimizing the penalties exacted, and abandoning on England's part the whole of her share of the indemnity. Castlereagh's policy, impressed upon British representatives abroad, was "to turn the confidence Great Britain inspired to the account of peace, by exercising a conciliatory influence in Europe." Brougham's action, at the end of 1815, denouncing the Holy Alliance, even in its early form, was calculated to embarrass England, though she was no party to what Castlereagh described as a "piece of sublime mysticism and nonsense."

While he saw no reason in this for breaking up the Grand Alliance, which he looked upon as a convenient organ of diplomatic intercourse and as essential for the maintenance of peace, he agreed with Wellington that to attempt to crush France, as the Prussians desired, or to keep her in a perpetual condition of tutelage under a European concert from which she herself should be excluded, would be to invite the very disaster which it was the object of the Alliance to avoid. It was not till Metternich's idea of extending the scope of the Alliance, by using it to crush "the revolution" wherever it should raise its head, began to take shape, from the conference of Aix-la-Chapelle (1818) onward, that Great Britain's separation from her continental allies became inevitable. Against this policy of the reactionary powers Castlereagh from the first vigorously protested. As little was he prepared to accept the visionary schemes of the emperor Alexander for founding an effective "confederation of Europe" upon the inclusive basis of the Holy Alliance (*see* ALEXANDER I. of Russia).

Home Politics.—Meanwhile financial troubles at home, complicated by the resumption of cash payments in 1819, led to acute social tension. "Peterloo" and the "Six Acts" were furiously denounced. Throughout, Castlereagh maintained his ascendancy in the House of Commons, though he had few colleagues who were capable of standing up against Brougham. Canning, indeed, had returned to office and had defended the "Six Acts," but Castlereagh bore the whole burden of parliamentary leadership, as well as the responsibilities of the Foreign Office. In 1821, on Sidmouth's retirement, he assumed the duties of the Home Office. The policy of "intervention," with which Great Britain had consistently refused to identify herself, had been proclaimed to the world by the famous Troppau Protocol, signed by Russia, Austria and Prussia (*see* TROPPAU, CONGRESS OF). The immediate occasion was the revolution at Naples, where the egregious Spanish constitution of 1812 had been forced on the king by a military rising. Castlereagh was prepared to allow the intervention of Austria, if she considered her rights under the treaty of 1813 violated, or her position as an Italian Power imperilled. But he protested against the general claim, embodied in the Protocol, of the European powers to interfere, uninvited, in the internal concerns of sovereign states.

THE EASTERN QUESTION

To Troppau, accordingly, no British plenipotentiary was sent, since the outcome of the conferences was a foregone conclusion; though Lord Stewart came from Vienna to watch the course of events. At Laibach an attempt to revive the Troppau proposals was defeated by the firm opposition of Stewart; but a renewal of the struggle at Verona in the autumn of 1822 was certain. Castlereagh, now marquess of Londonderry, was again to be the British representative, and he drew up for himself instructions that were handed over unaltered by Canning, his successor at the Foreign Office, to the new plenipotentiary, Wellington. In the threatened intervention of the continental powers in Spain, as in their earlier action towards Naples and Sardinia, England refused to take part. The Spanish revolutionary movement, Castlereagh wrote, "was a matter with which, in the opinion of the English cabinet, no foreign power had the smallest right to interfere." Before, however, the question of intervention in Spain had reached its most critical stage the development of the Greek insurrection against the Ottoman government brought up the Eastern Question in an acute form, which profoundly modified the relations of the powers within the Alliance, and again drew Metternich and Castlereagh together in common dread of an isolated attack by Russia upon Turkey. A visit of King George IV. to Hanover, in October 1821, was made the occasion of a meeting between Castlereagh and Metternich, with whom he joined in taking advantage of the emperor Alexander's devotion to the principles of the Alliance to prevent his taking an independent line in the Eastern Question. It was, indeed, the belief that this question would be discussed at the congress that led Castlereagh to agree to be present at Verona; and in his *Instructions* he foreshadowed the policy afterwards carried out by Canning, pointing out that the development of the war had made the recognition of the belligerent rights of the Greeks inevitable, and quoting the precedent of the Spanish American colonies as exactly applicable.

The Tragic End.—The tragic ending of Castlereagh's strenuous life was near; and the credit of carrying out the policy foreshadowed in the *Instructions* was to fall to Canning. During the session of 1822 Wellington warned Dr. Bankhead that Castlereagh was unwell, and, perhaps, mentally disordered. Bankhead went down to North Cray and took due precautions. Castlereagh's razors were taken away, but a penknife was forgotten in a drawer, and with this he cut his throat (Aug. 12, 1822). The testimony of statesmen of all parties to Castlereagh's gifts and charm is in strong contrast with the flood of calumny poured out upon his memory by those who knew him not.

BIBLIOGRAPHY.—Castlereagh's correspondence and papers were published by his brother and successor (1850–53) in 12 volumes. *See* also Sir Archibald Alison's *Biography* (3 vols., 1861); and lives by Lady Londonderry 1904, and A. Hassall (1909). For an account of his post-war diplomacy *see* C. K. Webster, *The Foreign Policy of Castlereagh 1815–22* (1925).

LONDONDERRY, a county of Northern Ireland, bounded north by the Atlantic, west by Lough Foyle and Donegal, east by Antrim and Lough Neagh, and south by Tyrone. The area is 523,432 acres, or 817.9 sq.mi. Pop. (1937) exclusive of Londonderry county borough is 94,923. Old Red sandstone and Lower Carboniferous sandstone overlie old rocks in the south and east, meeting the igneous "green rocks" of Tyrone, and the granite intrusive in them, at the north end of Slieve Gallion. Triassic sandstone covers the lower slope of Slieve Gallion on the south-east towards Moneymore, and rises above the Carboniferous sandstone from Dungiven northward. At Moneymore the western scarp of the White Limestone (Chalk) and the overlying basalt of the great plateaus dip down eastward under Lough Neagh. The basalt scarp, protecting chalk and patches of Liassic and Rhaetic strata, rises to 1,260 ft. in Benevenagh north of Limavady. A raised shelf with post-glacial marine clays forms the flat land west of Limavady. Haematite has been mined on the south flank of Slieve Gallion. The principal river is the Roe, which flows northward from the borders of Tyrone into Lough Foyle below Newton-Limavady. Farther west the Faughan also falls into Lough Foyle, and the river Foyle passes through a small portion of the county near its north-western boundary. In the south-east the Moyola falls into Lough Neagh, and the Lower Bann from Lough Neagh forms for some distance its eastern boundary with Antrim. The only lake in the county is Lough Finn on the borders of Tyrone, but Lough Neagh forms about 6 mi. of its south-eastern boundary. Castlerock, Downhill, Magilligan and Portstewart are seaside resorts.

Early inhabitants were the O'Cathans or O'Catrans, who were tributary to the O'Neills. Towards the close of the reign of Elizabeth the county was seized and received the name of Coleraine, having that town for its capital. In 1609, after the confiscation of the estates of the O'Neills, the citizens of London obtained possession of the towns of Londonderry and Coleraine and adjoining lands, 60 acres out of every 1,000 being assigned for church lands. The common council of London elected a body of twenty-six for its management, who in 1613 were incorporated as the Irish Society, and retained possession of the towns of Londonderry and Coleraine. Their estates were sequestrated by James I, and in 1637 the charter of the Irish Society was cancelled. Cromwell restored the society to its former position, and Charles II granted it a new charter. In the insurrection of 1641 many towns and villages were burned. There are several stone circles, and a large number of artificial caves. The horned cairn at Ballybriest is 100 ft. long by 50 ft. broad. Of the castles erected by the English, those of Dungiven and Muff are largely reconstructed. The ruins of Dungiven Priory, founded *c.* 1100, are notable as containing perhaps the most beautiful sepulchral monument in Ulster, that to an O'Cahan chieftain.

The excessive rainfall and the cold and uncertain climate are unfavourable for agriculture. Along the seacoast there is a district of red clay formed by the decomposition of sandstone, and near the mouth of the Roe is a tract of marl. The staple manufacture of the county is linen. The manufacture of coarse earthenware is also carried on, and there are large distilleries and breweries and some saltworks. Coleraine is the headquarters for salmon and eel fisheries on the Bann. The deep-sea and coast fisheries are centred at Moville in Co. Donegal. The city of Londonderry is an important railway centre. The L.M.S.R. (N.C.C.) main line reaches it by way of Coleraine and the north coast of the county, and the same railway serves the eastern part of the county. The Great Northern railway reaches Londonderry from the south, and the city is also the starting point of the Londonderry and Lough Swilly railway. The county contains one county and one municipal borough and two urban and four rural districts, as well as four Poor Law unions. Londonderry (including borough of Londonderry) returns 5 members to the parliament of Northern Ireland and 1 member to the United Kingdom parliament.

LONDONDERRY or DERRY, a city, county and parliamentary borough, and the chief town of Co. Londonderry, Northern Ireland, 4 mi. from the junction of the river Foyle with Lough Foyle, and 95 mi. N.N.W. of Belfast. Pop. (1937) 47,813. Area, 3.44 sq.mi. Derry, the original name of Londonderry, is derived from *Doire,* the "place of oaks." It owes its origin to the monastery founded by Columba about 546. With the bishopric which arose in connection with this foundation, that of Raphoe was amalgamated in 1834. From the 9th to the 11th century the town was frequently taken by the Danes, but they were finally driven from it by Murtagh O'Brien about the beginning of the 12th century. In 1311 it was granted by Edward II to Richard de Burgh. After the Irish Society of London obtained possession of it, it was incorporated in 1613 under the name of Londonderry. The fortifications, begun in 1600, were completed in 1618. In 1688 Derry had become the stronghold of the Protestants of the north. In April 1689 it was besieged by the forces of James II but was relieved in July.

The city stands on an eminence rising abruptly from the west side of the river to a height of about 120 ft. It is surrounded by an ancient rampart about a mile in circumference, having seven gates and several bastions, but buildings extend beyond this boundary and across the river, over which is the Craigavon road and railway bridge, opened in 1933 and the largest in Ulster, being 1,200 ft. long by 40 ft. wide. The summit of the hill, at the centre of the town, is occupied by a quadrangular area, known as the Diamond, from which the main streets diverge. Some old houses with high pyramidal gables remain but are much modernized. The Protestant cathedral of St. Columba, in Perpendicular style (1633), was enlarged and restored in 1887. The spire was rebuilt in 1802. The bishop's palace (1716) occupies the site of the abbey founded by Columba. The abbot of this monastery, on being made bishop, erected in 1164 Temple More or the "Great Church," one of the finest buildings in Ireland previous to the Anglo-Norman invasion. It was demolished in 1600. There is a Roman Catholic cathedral (*c.* 1870) dedicated to St. Eugenius. Educational establishments include Magee University college (1865), formerly M'Crea Magee college, the first in Ireland to admit women. It was affiliated to Dublin University in 1909. Foyle college, a boys' school, dates from 1617. About 5 mi. W. of the city is the Grianan of Aileach, consisting of three concentric ramparts and an interior fortification of stone.

The staple industry of Londonderry is the manufacture of shirts and collars, and there are also iron foundries, sawmills, box and yeast factories; while pork curing, biscuitmaking and shipbuilding are carried on. The borough returns one member to the United Kingdom parliament and two members to that of N. Ireland. The salmon fishery on the Foyle is valuable.

LONDON GENERAL OMNIBUS CO., LTD. This British joint stock company was founded in Paris in 1855 and commenced operations in London in 1856. The passing of the Stage Carriage Act of 1832 had produced a boom in omnibus business and led to a congestion of many services. The London General Omnibus Co., Ltd., purchased 600 of the omnibuses in service and paid the proprietors £250,000 for the right to work them on the established routes. A scheme of fare reduction and extended service was at once initiated and a prize of £100 was offered for an improved new type of omnibus, which was promptly nicknamed the "knifeboard" owing to the arrangement of its outside seats. In 1880 the London Road Car company began work and introduced omnibuses with the so-called garden seats; the removal of the staircase to the rear of this type of omnibus marks the inception of the modern omnibus. It was not until 1904 that the first motor omnibus of the London General Omnibus Co., Ltd., was licensed to work between Kennington and Victoria. In 1908 the London General Omnibus Co., Ltd., was amalgamated with the London Road Car company and the Vanguard company.

The London General Omnibus Co., Ltd., still continued to run horse-drawn omnibuses, the maximum number of these vehicles operated being 1,418 in 1905, with a stud of nearly 18,000 horses. The last horse-drawn omnibus operated between London bridge and Moorgate street until Oct. 1911.

In Jan. 1912 the company passed under the control of the Underground Electric Railways Company of London, Ltd. From then onwards, the company began operating the omnibuses of other companies, the Metropolitan Steam Omnibus Co., Ltd., from Oct. 1912; Tramways (M.E.T.) Omnibus company from Jan. 1913, the Gearless Motor Omnibus Co., Ltd., from April 1913 and the Southern from Aug. 1913. Working arrangements were entered into with many other companies, and in 1926, the company acquired an interest in the small independent concerns which had begun work in 1922.

Under the powers conferred by the London Electric Railway Facilities Act of 1915, an agreement was entered into by the company with the City and South London, Central London, London Electric and Metropolitan District railways as to the payment into a common fund after meeting revenue liabilities of any surplus which might remain. In 1933 the company was merged in the London Passenger Transport Board. (L. C. M.)

LONDON MIDLAND AND SCOTTISH RAILWAY, British railway company, was formed on Jan. 1, 1923, by amalgamation, under the Railways Act of 1921, of the London and North Western, Midland, Lancashire and Yorkshire, Caledonian, and Glasgow and South Western and other railway companies. The system includes the Liverpool and Manchester Railway upon which in 1829 the famous "Rocket" demonstrated the practicability of the steam locomotive and originated the modern railway. The capital expenditure of the company amounts to £459,000,000 and it owns 6,842 mi. of line, the total length of track including sidings being 19,246 mi., serving 5,300 stations and 3,700 connections with private sidings of traders. Its working stock includes 7,600 locomotives, 24,000 carriages and 280,000 wagons, and on road services it employs 3,500 motor vehicles and 7,400 horses with 18,200 vehicles. Other assets include 40 steamers, 25 docks with quays upwards of 92,000 ft. in length, 535 mi. of canals and 29 hotels. Extending from London by two main lines through the industrial area of England to the extreme north of Scotland it is the largest of the British railways and in 1938 carried 434,000,000 passengers, 124,000,000 tons of goods and minerals and 5,500,000 head of livestock, representing approximately 7,500,000,000 passenger miles and 6,800,000,000 ton miles. The net revenue from all sources in 1938 amounted to 11,000,000 pounds, and this distributed to 323,000 stockholders represented an average return of 2.63% upon the capital invested by them. The number of employees of all grades was 233,000 in 1938, their remuneration being 41,000,000 pounds.

Recent developments include streamlining of locomotives, softening of water for locomotive purposes, colour light signalling, electrification of the Wirral Railway, provision of Scientific Research Laboratory and Staff College at Derby, co-operation with Omnibus and other Road Transport companies, operation of Air Services in conjunction with other main line companies.

LONDON NAVAL CONFERENCE, 1930, THE. The work of limitation of naval armaments has advanced slowly since the close of World War I. The first real achievement came at the Washington Conference of 1921–22, where the five principal Naval Powers, who eight years later were to meet in London, conferred. There they succeeded in setting limits to the total displacement tonnages of the categories of capital ships and aircraft-carriers to be possessed by each of them on a certain date, and also in establishing a maximum unit tonnage, gun calibre and age limit for vessels in each of these categories. When the delegates endeavoured to agree concerning the limitation of smaller fighting vessels—cruisers, destroyers and submarines—they failed. The building of these categories was left unrestricted, except that a maximum unit tonnage and gun calibre for cruisers was fixed.

The failure to reach an agreement on auxiliary craft was due mainly to the difficulty of settling on tonnage figures in the various categories acceptable to all the five Powers. But it became evident in subsequent discussions (which came to a head at the meetings of the Preparatory Disarmament Commission at Geneva early in 1927) that the difference of opinion between the naval powers was not simply one on the particular figures which should be entered for each of them in a programme limiting every category of ship, but also on the general principles on which that programme should be constructed. The French, supported by the Italians, advocated limitation by "global tonnage", meaning that only the tonnage for the whole of a fleet should be limited, and that within this total a Power could allot what tonnage it liked to each category. The British, with the support of the United States representatives, urged that not only should the maximum total tonnage for each fleet be fixed, but that it should be agreed how this total was to be divided between the categories.

There were thus two major problems left unsolved by the Washington Treaty and subsequent discussions, and they were still unsettled when the Powers met in London in January 1930. There was the issue of the general principle on which limitation programmes should be constructed and the question of agreeing, whatever principle was adopted, on actual figures for limiting the building of auxiliary craft.

Between March 1927 and 1929 there were separate attempts at solving, at least partially, each of these problems. First the British Empire, the United States and Japan endeavoured at the Three Power Conference in Geneva late in 1927 to reach an agreement on actual figures for the limitation of every class of fighting ship in their own navies. Their discussions failed, because the United States and the British Empire could not agree about cruisers. The root of their trouble was that whereas the need of the former was for 10,000 ton cruisers mounted with 8 inch guns (the maximum permitted under the Washington Treaty) the latter required a larger number of smaller cruisers armed with 6 inch guns. The two Powers had agreed in the most friendly spirit that parity should exist between them, but could not discover a strict mathematical equality in cruiser strengths which would give each of them different numbers of different kinds of ships. This Anglo-American cruiser problem was a difficult obstacle to a complete agreement which the discussions immediately preceding and at the London Conference had to clear away.

Secondly, after the breakdown of the Geneva Conference there were conversations in particular between Great Britain and France with a view to reaching an agreement on the "global" versus "category" tonnages controversy. This resulted in the ill-fated Anglo-French compromise proposals of 1928. These were virtually dead from the moment it became known that they were unacceptable to the United States Government. They were rejected in Washington principally because they proposed restrictions in the building of cruisers carrying 8 inch guns but not of cruisers armed with smaller guns. As the former was the type required by the United States, their Government could not consent to the limitation of this type whilst no limit was set to ships more useful to other Powers.

These failures were a serious set-back to the movement for Naval limitation. Above all they led to strained relations between the United States and Great Britain, when confidence and co-operation between them, as being the two principal Naval Powers, were essential to the work. Their differences were still on the cruiser problem, and it was clearly of vital importance that the matter should be settled between them before there was any hope of tackling successfully the two other outstanding questions between the five Powers. That was the position when Mr. Hoover became President of the United States.

This sketch of the history of the problem is essential to an understanding of what the negotiations preceding and during the Naval Conference achieved.

The Yard Stick.—A way out of the Anglo-American difficulty was indicated in a speech made by Mr. Gibson, the representative of the new American administration, during the meetings of the Preparatory Commission at Geneva in April 1929. He proposed that in estimating equivalent naval strengths other factors than unit displacement tonnages should be considered. In the case of categories in which there were marked variations as to unit characteristics, the age of ships and the calibres of their guns might also be taken into account. Here was a method—known as "the yard stick"—of calculating parity between the cruiser fleets of the United States and Great Britain even though they differed in the numbers, tonnages and gun calibres of their ships. The American fleet might contain a larger number of 8 inch gun cruisers whilst the British possessed a still greater preponderance of the smaller ships. The fruitless search after strict mathematical parity could be abandoned.

The two Governments lost no time in exploring the possibilities of this method, and their efforts ended successfully. In June conversations commenced between General Dawes, the new Ambassador of the United States in London, and Mr. Ramsay MacDonald, who had become Prime Minister ten days previously. Their informal negotiations were continued for three months, at the end of which time the difference of opinion between their Governments as to how their cruiser fleets might be limited so as to achieve parity whilst allowing variety, had been reduced to a minimum. But for a matter of 30,000 tons the two Governments were indeed agreed on programmes for the limitation of every category of ship in their two navies. But they never lost sight of the fact that the United States and Great Britain alone could not solve the Naval limitation problem. Their conversations were a preliminary to a conference of the five Washington Treaty Powers, the summoning of which had been in the minds of President Hoover and Mr. MacDonald ever since they faced the Naval problem in the summer. Therefore their negotiations were not intended to reach an agreement which they would present as a *fait accompli* to be accepted or rejected in its entirety by the other three Powers. The understanding between them was a provisional one, to liquidate the Anglo-American cruiser difficulty and to form a basis for negotiations between all the five Powers together. The other interested Governments were at each stage informed of the progress of their negotiations.

The Conference Meets.—On October 7th invitations to a Naval Conference to meet in London in January 1930 were sent with the authority of both Governments to the French, Italian and Japanese Governments, and not many days later were accepted. Meanwhile Mr. MacDonald had sailed for the United States, on a visit to the President which still further strengthened the confidence and friendliness between the two great English-speaking peoples, a deplorable lack of which had previously threatened to destroy the work for Naval disarmament. On his return to London conversations with the three other Governments were commenced, with a view to disposing of any preliminary difficulties.

The London Naval Conference was opened by His Majesty King George V. on January 21st, 1930. Although it was called a Five Power Conference, there were actually twice that number of delegations attending it, for five British Dominion Governments sent delegates to co-operate with the United Kingdom Delegation in discussions of vital importance to the Navy which protects them as a whole. The Conference sat until April 22nd, when the London Naval Treaty was signed by all the delegates.

The Conference's work would have been comparatively simple had it been a meeting of only the three Geneva Conference Powers. Recognising the complications which would be introduced if it were a gathering of the five Washington Conference Powers, President Hoover and Mr. MacDonald had considered whether the easier task should not be finished first, but they came to the conclusion that the London Conference should be one of the five Powers. When it met, forebodings of difficulty proved correct.

It became clear that the five Powers did not form one unified group; indeed, that though there were five Powers represented there were really two groups, so to speak, of three Powers each. One group consisted of the United States, Great Britain and Japan, and became known as the High Seas Group; the other, which was called the Continental Group, consisted of France, Italy and, again, Great Britain. In each Group the first two Powers could, strictly from their own geographical point of view, consider their Naval affairs independently of discussion in the other Group; but Great Britain was interested in the proposals of both Groups; and from the point of view of securing a Five Power Treaty it was necessary that the conclusions of both Groups should be combined into a harmonious whole. This was not easy to achieve. No differences existed, for instance, amongst members of the High Seas Group on the question of limitation by categories, and a Conference confined to them would have engaged simply in programme making, a task which had already been simplified for them by the almost complete Anglo-American agreement on cruisers. But France and Italy were advocates of the principle of limitation by global tonnage, so that the Conference was divided on and had to face immediately this problem. At the London Conference a compromise on this question was reached. This agreement was not included in the text of the Treaty, for the Italian Delegation had declared that they would only be prepared to accept it if the question of the ratio of naval strength between all the contracting parties were first settled, a condition which was not satisfied. Nevertheless in principle and on its merits all the Delegations did agree to the compromise which was reached on this previously baffling question, and accordingly Mr. MacDonald as President of the Conference reported its details in a letter to the Chairman of the Preparatory Commission at Geneva, to whose work it would clearly be of extreme value. The agreement provides that in practice the Powers should accept programmes which limit their warship building category by category, though it allows a slight transfer between certain categories. A complete Five Power agreement, which is embodied in the Treaty, was also reached upon such matters as definitions, rules for replacement, rules for scrapping, etc.

Parity.—To this achievement was added an agreement on actual programmes between the three Principal Powers. France and Italy were unable to join in this section (Part III) of the Treaty owing to a particular difficulty which the Conference at the time of its adjournment had been unable to dissolve. As the United States and Great Britain had agreed on parity between themselves, so Italy claimed Naval parity with the strongest Continental European Naval Power, which meant France. The Washington Treaty had recognised parity between France and Italy in capital ships and aircraft-carriers, and the Italian Delegation in London asked that the principle should be extended to other categories. The French did not agree, and therefore no figures for either country are included in Part III of the London Treaty. But hope of settling this question has not been abandoned. So far as negotiations on the point were concerned, the Conference was only adjourned and conversations have since been proceeding with a view to settling the Franco-Italian difficulty.

As for the members of the High Seas Group, the United States and Great Britain had already agreed that parity in each category of ships should exist between them. Japan, whose capital ship and aircraft-carrier tonnages had been fixed in the Washington Treaty at 60% of the strengths of each of the other two Powers, put forward in London a claim for an increased ratio in the various classes of auxiliary ships. In the negotiations all difficulties between the Three Powers were composed, and they were able to sign an agreement which for the first time limits the building of cruisers, destroyers and submarines of all types. Thus limitation was extended far beyond the Washington Treaty provisions. Nor was the extension confined to categories not covered by that Treaty. With regard to capital shipbuilding restriction was carried a stage further than it had been left in 1922. The following are the principal provisions of the London Treaty concerning specific programmes.

The Washington Treaty provided for a maximum capital ship replacement tonnage of 525,000 (15 units) each for the United States and the British Empire, 315,000 tons (9 units) for Japan and 175,000 for France and for Italy; these figures as to numbers of units to be reached by 1936 and as total tonnages by 1942. At the time of the London Conference the first three Powers still had ships in excess of these figures, the British Empire possessing 20, the United States 18 and Japan 10 ships. The London Treaty decided that the surplus ships, instead of being retained until 1936 should be rendered unfit for warlike service within eighteen months after the coming into effect of the Treaty. Moreover, the Washington Treaty would have permitted further building for replacement of older capital ships before 1936. Great Britain and the United States, for instance, could each have completed five new battleships and commenced a further five by then. The London Treaty withdrew these provisions and declared a battleship "holiday" until 1936, except that France and Italy retained their right to build up to the tonnage, which they do not now possess, allowed them under the Washington Treaty. Apart from the great economies which this "holiday" means for the three principal Naval Powers, it will give time before the next Naval Conference for a thorough consideration of the question of the future of the capital ship.

With regard to aircraft-carriers the position was left practically as it had been by the Washington Treaty, except that carriers of less than 10,000 tons, which were previously not subject to limitation, are now taken into account. The figures agreed upon for the cruiser, destroyer and submarine fleets of the three Powers are as follows, an Anglo-American effort to persuade the Conference to agree to the total abolition of the submarine having failed:

British Commonwealth of Nations.

		Tons
8-inch gun cruisers	15 units	146,800
6-inch gun cruisers		192,200
Destroyers		150,000
Submarines		52,700
Total		541,700

United States.

		Tons
8-inch gun cruisers	18 units	180,000
6-inch gun cruisers		143,500
Destroyers		150,000
Submarines		52,700
Total		526,200

Japan.

		Tons
8-inch gun cruisers	12 units	108,400
6-inch gun cruisers		100,450
Destroyers		105,500
Submarines		52,700
Total		367,050

The United States undertake not to complete more than fifteen 8-inch cruisers before 1935. It is open to the United States Government, moreover, instead of building to the figures entered for itself, to adopt a programme almost exactly identical with that fixed for Great Britain. The three Navies are to be brought within these strengths by December 31st, 1936, before which date it is agreed that a further Naval Conference shall be held to decide what regulation is to follow that. Meanwhile, since Great Britain cannot be indifferent to the size of the auxiliary fleets of European Powers, which for the present remain unrestricted, a clause in Part III of the Treaty provides that an alteration in the figures can be made on notification by one Power to the other two that in its opinion expansion is necessary to meet the requirements of national security consequent on new construction by a Power not bound by Part III of the Treaty. The other two Powers would then be entitled to make proportionate increases. But it is hoped that this clause need never be operated.

In addition all the five Powers reached an agreement strictly limiting the use of the submarine, ensuring its compliance with the rules generally recognised to be applicable to all surface vessels.

The London Naval Conference set out to achieve limitation of every category of ship in the largest Navies, and, if possible, reductions in them as well. Reduction did not necessarily mean a reduction in the size of existing fleets. If the Conference could produce reductions in the programmes for expanding those fleets which the various Powers had already in project—programmes which would have been put into effect in the next few years but for a new Treaty of limitation—the Conference would have achieved its second object. The Conference did succeed in doing this. It also succeeded in actually reducing the existing fleets of all the three Powers in the categories of battleships, destroyers and submarines. But even had the Conference failed in these respects and achieved limitation alone, it would have been a signal contribution to confidence, disarmament and peace between nations. For one of the most fruitful causes of international distrust and war in the past has been competition in building up armaments. Agreed limitation stops that competition. In naval armaments competition had recommenced seriously after the breakdown of the Geneva Conference, but so far, at any rate, as the United States, Great Britain and Japan are concerned, the London Naval Treaty has ended it. Thus the Treaty starts a new era between those naval Powers in which their relations are free from the distrust bred from hostile shipbuilding. The nations can take advantage of this during the next few years to improve the security offered by political machinery for settling international disputes, in which case the naval powers would, it is hoped, be induced at their next Conference to make further reductions in their naval forces. Thus disarmament will come stage by stage. The chief practical achievement of the London Treaty is that it calls a halt at certain figures to the building of every kind of war vessel, and it is for future Conferences to bring those armament figures lower and lower until they reach negligible proportions.

(J. R. M.; H. L. STI.)

LONDON PRIDE: *see* SAXIFRAGE.

LONDON UNIVERSITY. Sir Thomas Gresham in the 16th century laid down a noble plan for a university in London, but for various reasons it failed and the present university may be said to have had its origin with the foundation in 1827 of the non-sectarian University college, which, in the hope and expectation of receiving a charter empowering it to grant degrees, bore for some time the title of University of London. This was followed by the foundation, as a Church of England institution, of King's college, which received a charter of incorporation in 1829. The movement to grant a charter to University college was bitterly opposed and finally in 1836 two charters were granted, one incorporating University college and the other setting up a new body with examining functions and degree-giving powers, and known as the University of London. In the first instance students from University and King's colleges only were admissible to examinations for degrees, but the list of colleges was rapidly expanded by supplementary charters, until by the middle of the century its degrees, except in medicine, were thrown open to all candidates who cared to present themselves for examination, irrespective of their place of education. In 1878 a further charter was granted making all degrees, etc., open to women on equal terms with men.

Reorganization.—Various proposals were put forward from time to time for the establishment of a teaching university in London, and after two royal commissions had reported on the matter the university was re-constituted in 1900 in accordance with the University of London Act of 1898.

The work of the University of London as reconstituted by the Act of 1898 falls into three main divisions: (1) teaching and research, carried on by professors and other university teachers in the colleges and schools of the university, the students of which, if matriculated, are known as internal students; (2) the examination of other students ("external students"), principally from institutions not forming part of the university, *e.g.*, provincial universities and private students; and (3) university extension.

In addition to the colleges and institutions which under the act were affiliated as schools of the university other teaching institutions have been added, and research institutions have been added under a statute which empowered the senate to admit institutions for purposes of research. The institutions belonging to or affiliated to the university in which teaching and research are carried on include University college, King's college, Goldsmiths' college (*see* below), the Imperial college of science and technology, Royal Holloway college, Bedford college, East London college, the London school of economics, Westfield college, Birkbeck college, the London Day Training college, the School of Oriental studies, the Medical schools of the twelve great London hospitals, four theological colleges, the London school of hygiene and tropical medicine, and a number of other institutions admitted as research institutions. There are also the Institute of Historical Research (*see* below), the Galton laboratory for eugenics, and the Bartlett school of architecture housed at University college.

By the University college Transfer Act of 1905 that college and its property and trust funds, except such as belonged to or were held in trust for University college hospital and its medical school and the boys' school carried on by the college, were transferred to the university as from June 1, 1907. The college is managed by a committee appointed by the senate. By a similar act, King's college Transfer Act of 1908, the property, etc., of that college in faculties other than in the faculty of theology was transferred to the university as from Jan. 1, 1910. The act also provides for the separate government of King's college hospital medical school and King's college hospital.

In 1905 the Goldsmiths' company gave to the university their institute at New Cross with 4½ acres of unoccupied land. The institute, now named Goldsmiths' college, is a large and successful training college for teachers. In 1921 funds were raised for the establishment of an institute of historical research and in July of that year the present (temporary) building was opened as a centre for the post-graduate study of history.

Great progress has been made in all branches of the work of the university since its reconstitution. Research has been promoted by scholarships, the establishment of research funds, by a publication fund to facilitate the production of learned and scientific works, and the creation of research degrees. The number of university professors in 1928 was 181, of readers 85, and other teachers 815. The number of matriculated students pursuing degree courses in the university (internal students) was over 9,000.

The number of external students has doubled since the reconstitution of the university. The number examined in 1927 was 6,689.

The university extension board, in addition to extending university extension work, conducts the inspection and examination of schools and arranges vacation courses for foreign students. A joint committee of the board and the Workers' Educational Association has developed a scheme of university tutorial classes for working people.

Constitutional Changes.—In 1909 a royal commission on the university under the chairmanship of R. B. (afterwards Lord) Haldane was appointed with very wide terms of reference. Its final report was published in 1913 and in the same year a departmental committee was set up to report as to the steps necessary to give effect to the commission's recommendations. Soon after the outbreak of the World War the committee abandoned its sittings and, although some of the recommendations of the commission were brought into effect administratively, no action was taken on its recommendations as to the constitution of the university until 1924. In that year another departmental committee was appointed to consider the "Haldane" report and to indicate what were the principal changes now needed in the constitution of the university. That committee reported in 1926.

The most important of their recommendations are two: the first is the creation of a small body composed (as to its majority) of representatives of the senate, with representatives of the Crown and London county council which is to control finance and to be the channel for all public grants to the university and its schools. The second is the constitution of a new body known as the collegiate council consisting of the heads of the greater colleges who will together with the representatives of the faculties and convocation make up the senate.

By the University of London Act of 1926 a body of commissioners was appointed to make statutes in general accordance with the recommendations in the report, subject to any modifications which might appear expedient. Draft statutes were published, if approved, to become operative in 1929.

Provision is made for the financial body (to be known as the court) referred to above, but the senate is to remain the supreme governing body in academic matters. It will be advised by five standing committees: (1) the academic council, elected by the faculties and concerned with the teaching work of the university; (2) the external council, composed principally of representatives elected by the graduates and concerned with external students; (3) the collegiate council, referred to above; (4) the university extension and tutorial classes council; and (5) the matriculation and schools examination council.

University Headquarters.—Up to the reconstitution of 1900 the senate had occupied buildings in Burlington gardens but soon after these were given up and the senate accepted in their place a portion of the premises of the Imperial Institute at South Kensington. These have, however, proved unsuitable in many respects and the Haldane commission recommended that the university should obtain for the use of the senate, its administrative staff, the library, and for the development of the social and corporate life of the university, permanent buildings of appropriate design, adequate and apt for the purpose, conveniently situated and bearing its own name. In 1912 efforts had been made to acquire a site for the purpose in Bloomsbury but for various reasons the project was abandoned. In 1920 the Government offered to the university for its use and that of King's college a site of about 11½ acres north of the British Museum. The offer was subject to a condition that King's college should surrender to the Crown the lease (held on a nominal rent) of its premises in the Strand to which condition the authorities of the college were unable to agree. The offer accordingly expired and the Government resold the site to the vendor.

The position was one which caused the senate some concern since in anticipation that the university would become the owner of the site some university institutions had been erected on it. In 1927, largely with the assistance of a munificent benefaction from the Rockefeller Trustees, the senate were able to repurchase the site free of any conditions. The question of the development of the site is now (1928) under consideration; obviously a good deal of money will be necessary to create a centre worthy of the University of the capital of the British Empire.

Bibliography.—University publications:—*Calendar; Historical Record 1836–1912* (includes texts of Charters, Acts of Parliament, etc.); *Historical Record* (second issue) *1836–1926* (includes historical introduction, particulars of trusts and benefactions, etc.). LONE STAR ROUTE HIGHWAY, an American highway about 1,190 m. long, connecting the Great Lakes with the Gulf of Mexico. Starting at Chicago, Ill., it passes through the agricultural centre of that State to St. Louis, Mo., and thence follows the valley of the Mississippi river on its western side to Lake Charles, La. The roadway is paved through Illinois and in and out of Little Rock, Ark.; the balance is either improved or graded. Other cities served by the highway are Poplar Bluff, Mo., Little Rock, Ark. and Alexandria, La.

LONG, CRAWFORD WILLIAMSON (1815–1878), American physician, was born at Danielsville, Ga., on Nov. 1, 1815. He graduated at Franklin college, Ga., and secured his medical education at Transylvania university and the University of Pennsylvania. After finishing his course he spent 18 months in New York city hospitals observing and performing surgical operations. In 1841 he returned to Jefferson, Ga., to open his practice and there, on March 30, 1842, he administered ether to a patient before removing a tumour from the neck, the first recorded use of an anaesthetic in surgery. Dr. Long performed at least eight other operations with the use of ether before 1849, when he published an account of his discovery in the *Southern Medical and Surgical Journal.* He died at Athens, Ga., on June 16, 1878.

See C. T. Jackson, "First Practical Use of Ether in Surgical Operations," *Boston Medical and Surgical Journal* (April 11, 1861); George Fory, *Crawford Williamson Long* (1886); Charles Johnson, "Dr. Crawford Long," in the *Illinois Medical Journal* (Aug. 1917); J. Jackson, *Dr. Crawford W. Long* (1919); "Crawford W. Long," 69th Cong., 1st Sess., *Sen. Doc. No. 160* (1926); F. L. Taylor, *Crawford Williamson Long* (1928).

LONG, HUEY PIERCE (1893–1935), U.S.A. Senator, was born Aug. 30, 1893, at Winnfield, La., where he secured a public education. He studied law at Oklahoma and Tulane universities but, after a brief trial of private practice, turned to politics. Rapidly advancing from membership on the La. Railroad Commission (1918–21) and the Public Service Commission (1921–28) to the governor's chair (1928–32) and finally to the United States Senate (1931–), Long became undisputed "leader" of the backcountry of Louisiana (*q.v.*). Long's filibustering activity in the Senate and his third party threat for the 1936 elections were only removed by his assassination by a victim of his own autocracy.

LONG, WALTER HUME LONG, 1st Viscount (1854–1924), English politician, was born at Bath on July 13, 1854. He was educated at Harrow and Christ Church, Oxford. He entered parliament in 1880 as Conservative member for North Wilts, and sat in the House of Commons till he was created a peer in May 1921, though he changed his constituency several times. He obtained office early, and showed administrative power and common sense as parliamentary secretary to the Local Government Board (1886–92), president of the board of agriculture (1895–1900) and president of the Local Government Board (1900–05).

In March 1905 Long was chosen by Balfour to succeed Wyndham, after the latter's breach with Irish Unionism, as chief secretary for Ireland. The impression which he produced in Ireland in the few months before Balfour's resignation was so considerable that he, an Englishman, was returned to Parliament in the general election of 1906 for a Dublin seat. When Balfour resigned the leadership of the Conservative party, Nov. 1911, Long was the candidate of its more conservative branch, but, with his rival, Austen Chamberlain, stood aside in favour of Bonar Law. He joined the first Coalition Ministry in 1915 as president of the Local Government Board, and the second Coalition in 1916 as colonial secretary. He sponsored the Franchise bill (1918) granting the vote to women over 30. In 1919–21 he served as first lord of the Admiralty and was created Viscount Long of Wraxall in 1921. He died on Sept. 26, 1924 at Rood Ashton, Wiltshire.

LONG. A buyer or holder of securities is said to be "long" of the market or "long" of stock if he has more of a particular security than he has contracts to deliver. The longs are usually those who have bought expecting a rise in prices, and are commonly included among those known as "bulls" (*q.v.*). The opposite term, "short," is applied to one who has contracted to deliver more of a certain security than he holds. The shorts are principally those who have "sold short" in anticipation of a drop in prices, in which event they will buy at the lower price for delivery. They are often included among those known as "bears" (*q.v.*).

LONG BEACH, a city of Los Angeles county, California, U.S.A., on San Pedro bay, 20 mi. S. of Los Angeles; a recreation resort and an important industrial and commercial centre. It is served by the Pacific Electric, the Southern Pacific and the Union Pacific railways, and has a well equipped municipal airport of 749·6 ac., 4½ mi. from the business district. The land area is 30·97 sq.mi. The population was 2,252 in 1900; 142,032 in 1930 and 164,271 in 1940. In front of the city lies Catalina island, which protects it from violent storms. There is a wide beach, more than 7 mi. long. A fine harbour, with a depth of 40 ft. and 25 sq.mi. of anchorage for naval and merchant ships, makes Long Beach an important defence base. It has an inside channel connecting with Los Angeles harbour. The federal government and the two municipalities co-operate in port development. Within the city and its environs is the Signal hill oil field (6,500 ac.).

producing 43,446 bbl. daily in 1941. The city owns about one-sixth of the field. Long Beach harbour district also owns 1,860 ac. of oil land, with a daily production of 47,922 bbl. in 1941. The combined fields produce 49,000,000 cu.ft. of gas per day, giving an abundant supply of natural gas. Harbour and city revenue from oil royalties in 1940 totalled $1,800,000. Manufacturing establishments include an automobile assembly plant, an aircraft factory, a vegetable oil refinery, other oil refineries and fish, vegetable and fruit canneries. Output for 1940 was $50,000,000. Bank clearings for 1940 were $196,986,091 and the assessed value of property was $233,811,265. Bank deposits (1940) totalled $73,930,788.

LONG BRANCH, a city of Monmouth county, N. J., U.S.A., on the eastern or long branch of the Shrewsbury river and the Atlantic coast, 30 mi. S. of New York city. It is served by the Central of New Jersey, the New York and Long Branch, and the Pennsylvania railways, and by steamboats to New York. The population was 13,521 in 1920 (17.8% foreign-born white) and 1940, 17,408. Long Branch is one of the oldest of American seaside resorts. It is situated on a bluff which rises abruptly 20 to 35 ft. from the beach. Along the edge of the bluff runs Ocean ave. (60 ft. wide) now part of a continuous highway connecting the resorts which edge this section of the Jersey coast (from Highlands on the north to Point Pleasant at the mouth of the Manasquan river). In a cottage in Elberon (the south part of the city) Gen. Grant spent many summers, and in another, President Garfield died in 1881. Fort Monmouth, 4 mi. N.W., is an important army post, the headquarters of the Signal school and the radio laboratories. The city was chartered in 1904.

LONGCHAMP, WILLIAM (d. 1197), chancellor of England and bishop of Ely, entered public life at the close of Henry II's reign as official to the king's son Geoffrey, for the archdeaconry of Rouen. Henry II, who disliked him, called him the "son of two traitors." He soon deserted Geoffrey for Richard, who made him chancellor of the duchy of Aquitaine. As Richard's envoy, in Paris, he defeated Henry II's attempt to make peace with Philip Augustus (1189). On Richard's accession William became chancellor of the kingdom and bishop of Ely. When Richard left England (Dec. 1189), he put the tower of London in his hands and chose him to share with Hugh de Puiset, the great bishop of Durham, the office of chief justiciar. William immediately quarrelled with Hugh, and by April 1190 had ousted him from office. In June 1190 he received a commission as legate from Pope Celestine.

John returned to England in 1191; he and his adherents were immediately involved in disputes with William. At last (June 1191) Geoffrey, archbishop of York and William's earliest benefactor, was violently arrested by William's subordinates on landing at Dover. They exceeded their orders, which were to prevent the archbishop from entering England until he had sworn fealty to Richard. This outrage was made a pretext for a general rising against William, whose legatine commission had now expired, and whose power was balanced by the presence of the archbishop of Rouen, Walter Coutances, with a commission from the king. William shut himself up in the Tower, but he was forced to surrender his castles and expelled from the kingdom. In 1193 he joined Richard in Germany. Richard employed Longchamp in confidential and diplomatic missions in Germany, in France and at Rome. He died in Jan. 1197.

LONGCLOTH, a plain cotton cloth originally made in comparatively long pieces. The name was applied particularly to cloth made in India. Longcloth, which is now commonly bleached, comprehends a number of various qualities. It is heavier than cambric, and finer than medium or Mexican. As it is used principally for underclothing and shirts, most of the longcloth sold in Great Britain passes through the hands of the shirt and underclothing manufacturers, who sell to the shopkeepers, though there is still a considerable if decreasing retail trade in piece-goods. The lower kinds of longcloth, which are made from American cotton correspond in quality to the better kinds of "shirting" made for the east, but the best longcloths are made from Egyptian cotton, and are fine and fairly costly goods.

LONG EATON, an urban district of Derbyshire, England, 10 mi. E.S.E. of Derby, on the L.M.S. railway. Pop. (1938) 26,120. Area, 5.6 sq.mi. The church of St. Lawrence has Norman portions, and an arch and window apparently of pre-Conquest date. There are lace manufactures and railway carriage works. To the north is the township of Sandiacre, where the church has a noteworthy Decorated chancel and Norman and early English portions.

LONGEVITY, or length of days, is the prolongation of life to or beyond the standard duration. Generally speaking there is a rough correspondence between the bodily bulk and the span of life; thus the imagines of ephemerids or dayflies after an hour or two of "aerial life devoted to love" die, whereas the tortoise may survive for one or even two centuries; but this relation is not absolute, parrots, ravens, and geese live longer than many larger birds and than most mammals (Mitchell); some fish, such as salmon (100 years), carp (150) and pike (200), have a longevity contrasting with the 30 years of horses. Trees are constructed on an entirely different plan from that underlying the complex higher animals, and are thus endowed with a kind of potential immortality. The section of the trunk of a mammoth tree (*Sequoia gigantea*) in the Natural History Museum, South Kensington, showing 1,335 rings, might have been as many years old.

Death, the termination of life, is avoided in the protozoa by the division of the individual into two, which thus start afresh, so that, as Weismann long ago argued, the organism is immortal. But in the higher grades of the animal kingdom such rejuvenation is impossible, and the processes of senescence and death must be regarded as the penalty to be paid for their higher differentiation; they are dependent for their term of life on an inherited physico-chemical constitution, and are thus, like a clock, set for a definite period. After the time of Aristotle, the vital cycle has been thought to be a multiple of the period of growth; Francis Bacon considered that as a rule animals should live eight times, Flourens five times, as long as they take to reach maturity; in the case of man both Buffon and Flourens, though on rather different grounds, estimated that 100 years is the physiological duration of life, and this has been widely accepted, in spite of the psalmist's "three score years and ten," with perhaps a sorrowful extension to four score.

In more modern times the number of reputed centenarians has been shown by critical enquiry to be much in excess of the real figure, and that the ages popularly ascribed to Henry Jenkins (169), Thomas Parr (152), Katherine, Countess of Desmond (140), and many of the 1,712 centenarians in James Easton's list covering the years A.D. 66 to 1799 cannot be accepted as authentic. Fallacies easily creep in and memories and records fail; thus in the census of 1911 the excess of persons alive over 91 and the deficit of those between 85 and 90 could only be explained by exaggeration of their age by old people.

It is desirable to distinguish clearly between the concept of the life span and that of the average length of life. The former term is best reserved to denote the extreme limit of life characteristic of the species, say a little more than 100 years in the case of man. On the other hand, the term *average length of life* is applied to a figure computed from a life table; it measures the average number of years lived by the individuals of a large cohort of persons passing from birth to death in accordance with the mortality exhibited in the life table. The average length of life, so defined, is also often spoken of as the expectation of life at birth. Similarly, the average number of years lived beyond a given age, such as age 30 for example, is called the expectation of life at that age. While the life span has probably changed little, if at all, in all historic time, the average length of life has been greatly extended, especially in modern times. So, *e.g.*, the average length of life, as given by the registrar-general for England and Wales in 1838–54, was 39.91 years for males and 41.85 years for females; by 1937, the latest year for which a life table is available (1947), the corresponding figures were 60.18 and 64.40 years. The expectation of life at later ages, that is to say the average after-lifetime; also shows improvement; thus in 1854, males at the age of 60 had an expectation of 13.53 years, females an expectation of 14.34 years. The corresponding figures for 1937 were 14.32 and 16.48 years. In the United States, the expectation of life at birth for both sexes combined in the white population in 1901 was 48.23 for males and 51.08 for females; by 1944, these figures had risen to 63.55 and 68.95 years respectively. The gain has been chiefly in the childhood ages. It is due in large part to the success gained in the treatment, and even more in the prevention, of infectious diseases. The diseases characteristic of middle life and advanced age—the so-called degenerative diseases, especially those associated with hardening of the arteries—have so far yielded little to efforts of control.

Presumably if all were placed under similar environmental circumstances, there would be certain racial differences in longevity. This statement is hardly capable of definite test, since the more outstanding racial differences in different parts of the world cannot be separated from accompanying environmental differences. As to sex differences, in all civilized countries females have a lower mortality than males at most ages of life. Figures for the last census year, 1940, in the United States show that if deaths from causes connected with childbirth are excluded, the difference in favour of female mortality extends to all ages of life. An interesting observation by Graham Bell, in his analysis of the Hyde genealogy, dealing with 8,972 persons and dating from the 17th century, shows that, in this group at least, the proportion of those living long increased with size of family up to families containing nine and ten children, and then fell in the case of still larger families. It also appeared that the first born lived as long as subsequent children, and that children born between four and eight years after their parents' marriage were on the average longer lived than those born earlier or later.

Heredity.—The two great factors influencing the length of life are heredity and environment in its broadest sense; for obvious reasons it is impossible to disentangle them and ascertain what share each of these two factors contributes. That longevity well beyond the average tends to run in families seems to be well established. To this topic an important contribution has been made by the late Raymond Pearl in a book under joint authorship with his daughter, Ruth DeWitt Pearl, entitled *The Ancestry of the Long-Lived.* A most striking example of apparently hereditary longevity quoted by these authors is that of a group of seven persons, grandparents, parents and son, whose aggregate age at death was no less than 699 years; at that, two of them died by accident. Another significant investigation of inheritance of longevity, conducted on the basis of records of insurance companies by Louis I. Dublin and Herbert Marks, showed very clearly how longevity of parents favourably influences the longevity of offspring.

Inborn vitality may counteract the evil influences of unhealthy environment and bad habits, such as overcrowding in towns and alcoholism, and so explain the occasional longevity of those who have lived in most unfavourable circumstances; *e.g.*, the contrast between two aged brothers, one a confirmed toper, the other a total abstainer. Of the hereditary factors innate vitality of the nervous and the circulatory systems are the most important; the nervous system decides the mental disposition and the reactions of the body as a whole. Cazalis' aphorism "Man is as old as his arteries" expresses the advantage of possessing a circulatory system which does not degenerate readily, harden into the condition of arteriosclerosis, or show an excessive blood pressure; for it is well known that the members of some families tend to die about the age of 60 from apoplexy, heart or kidney disease, the latter being often the result of arterial disease in the kidneys.

Environment.—One way in which environmental conditions affect longevity is through diseases contracted in the course of life. It has been stated that only those who have escaped illness up to the age of 60 years are likely to reach extreme old age, but nearly half of the 824 persons between the ages 80 and 100, analysed by Sir George Humphry, had passed through a severe illness, in many of them an acute infection. An acute illness may be the apparent starting point of old age and senescence, especially if sufficient time for convalescence is not allowed. It has been suggested that the deteriorating influence of malaria on individuals may, by its mass effect, account, in some degree at any rate, for the decadence of Magna Graecia (W. H. S. Jones). Functional activity, mental and bodily, plays an important part in postponing the advent of morbid old age, and there is more danger of rusting out than of wearing out, provided the body is healthy and the mind free from worry. The advanced ages of many dignitaries of the Church and the bench and of prime ministers, though many of these may be supermen, point to the beneficial influence of long-continued activity. Among painters Giovanni Bellini, Michelangelo, and Sidney Cooper worked up to nearly their death, and Titian was painting with "incomparable steadiness of hand" when cut off by the plague at the age of 99. The same retention of productivity was seen in Voltaire, Littré, Anatole France, Goethe, von Ranke, and Frederick Harrison. The members of the Académie Française are long-lived, and thus doubly justify their title of "the immortals." Retirement, often looked forward to in early life, is a source of danger, as it may bring with it cessation from activity.

The majority of centenarians have been small eaters, and several aphorisms point to the evil, if slow, effect of being a good trencherman, such as Montaigne's "Man does not die, he kills himself" and the forcible proverb "You dig your grave with your teeth." Overfeeding by overworking the resources of the body leads to metabolic disease, such as diabetes mellitus, and to arterial, heart and kidney affections, which are preceded often by long periods of latency during which the individual flatters himself on his vigour, but in which his arterial blood pressure is unduly high. During World War I it was observed that in certain countries the death rate from diabetes was reduced, and this has been attributed to dietary curtailment. Poverty, within limits, is an advantage inasmuch as it removes the dangers of excessive eating, particularly of meat, after the body has reached maturity. The beneficial effects of a meagre dietary were set forth by the noble Venetian Luigi Cornaro (1467–1566), by Metchnikoff, Henry Thompson the surgeon, Hermann Weber, and many others who practised their own precepts. With regard to the influence of alcohol there can be no doubt, as the actuarial reports of life assurance companies amply prove, that excess is harmful.

It is true that Raymond Pearl's statistical enquiry into over 5,000 lives at Baltimore showed that "a moderate use of alcohol does not tend to shorten life." But what constitutes moderation is open to question.

Prolongation of life towards its limits may be healthy or attended by morbid manifestations. Healthy or normal old age is attended by diminution in functional activity which corresponds with the characteristic changes of atrophy and involution in the structure of organs and tissues and of a diminished area of the capillary blood vessels. With the waning of sexual power the mind becomes calmer and more philosophic, so that the limitations of activity are more cheerfully accepted; but fatigue is more readily produced, memory, especially for names, becomes less agile, and will power, like the gait, becomes less certain. The mental outlook is largely determined by that of the individual in the past, happy and kindly, or pessimistic and uncharitable. Often there is a tendency to ego-centricity and to nervous apprehension, as the preacher (Koheleth) in Ecclesiastes said "Fears shall be in the way." It may be pointed out that the glands of internal secretion become old with the rest of the body, not that their atrophy causes old age. For it has been thought that senescence results from failure of the thyroid, and especially of the interstitial cells of the testes, and experiments and operations by Steinach and Voronoff to supplement this want have been followed by dramatic, if temporary, rejuvenation, which in animals at least cannot be explained by suggestion; but that life is thus prolonged as well as being made to burn more brightly remains to be proved in the case of man.

It is hard to draw a sharp line of demarcation between normal old age (senescence), with its limitations due to atrophic changes in the body, on the one hand, and on the other hand the manifestations in the elderly resulting from past infections and diseases (senility). Physiological old age, that is freedom from any pathological change, is agreed to be rare, and it has been said by Terence, Cicero, Sanctorius, and often since that old age is itself a disease.

Eli Metchnikoff attributed the senile accompaniments of advanced years to pathological and preventable causes, especially poisons produced by bacteria in the large intestine, these toxins causing degeneration of the bodily cells which are eaten up by more resistant cells called macrophages; this hypothesis has been much discussed.

That disease may produce the picture of morbid old age prematurely is well established, and in the remarkable but rare condition of progeria this occurs in childhood. The various parts of the body do not all grow old at the same time, but when these changes are much more advanced in a vital organ, especially the brain, than elsewhere, the proper harmony of the system is so disturbed that the condition becomes pathological, and then instead of a happy, healthy and pleasant old age there is the picture of incapacity, pain and misery so that existence becomes a burden to the individual and to his family.

Some diseases are especially prone to attack the aged, though they are not entirely confined to the evening of life. The chief diseases mainly concentrated in later life are diabetes, cancer and the cardiovascular-renal group. This last is closely related to arteriosclerosis which may affect various parts of the body, such as the kidneys, the brain and the heart.

The acute fevers, such as measles, typhoid, scarlet fever and diphtheria, rarely attack the old, probably because immunity has gradually been acquired, but pneumonia and erysipelas are exceptions to this rule, and pneumonia, with but few symptoms, often proves to be the last straw in breaking the feeble thread of existence.

LONGFELLOW, HENRY WADSWORTH (1807–1882), American poet, was born in Portland (Me.), on Feb. 27, 1807, of a family for generations domiciled in New England. After studying at a private school and at the Portland academy, he entered Bowdoin college, graduating there in 1825. Even as a boy he wrote prose and verse for newspapers and magazines, and showed an interest in native themes for literature and a talent for imitation of other poets, notably Bryant. He longed to be a man of letters, though his father disapproved. In 1826 he went to Europe to prepare himself to teach at Bowdoin, and when he returned in 1829 he was elected professor of modern languages and librarian of the college. In 1831 he married Mary Storer Potter of Portland, a former schoolmate. In connection with his work as a teacher he did some text-book writing, translating, and editing of foreign texts, and wrote several essays on French, Italian and Spanish languages and literature. His *Outre-Mer,* a book of European sketches, came out in 1835, showing strongly Irving's influence though based on Longfellow's impressions during his first visit to the Old World. In 1834 he was offered the Smith professorship of modern languages at Harvard, then vacated by George Ticknor. He accepted and went abroad to study. After pleasant months in England, Sweden and Denmark, he met tragedy for the first time when Mrs. Longfellow died in Rotterdam, on Nov. 29, 1835.

He went alone to Germany and Switzerland, coming to Cambridge to begin his work at Harvard in Dec. 1836. After a few months he took rooms at the historic Craigie House, which later became his own, and is now celebrated as the Longfellow House. His *Hyperion,* a prose romance, appeared in 1839, as did *Voices of the Night,* a volume of poems which won general favour and praise even from such critics as Poe. At Harvard he lectured on French, Spanish, Italian and German, apparently with success. In 1841 his *Ballads and other Poems* increased his celebrity as a poet. He was in Europe for part of the next year, and on the journey home prepared his *Poems of Slavery* (1842), his one considerable excursion into the field of contemporary social and political debate. Hawthorne wrote to him: "I never was more surprised than at your writing poems about slavery. . . . You have never poetized a practical subject hitherto." It is significant that, although Longfellow heartily opposed slavery, the ardent abolitionists found his anti-slavery verse "perfect dish-water beside Whittier's." Margaret Fuller called *Poems of Slavery* "the thinnest of all Mr. Longfellow's thin books" and said, "The subject would warrant a deeper tone." In 1843, he married Frances Elizabeth Appleton, of Boston. *The Spanish Student,* a poetic drama, came out in book form in 1843; *The Belfry of Bruges,* another volume of verse, in 1846, and *Evangeline,* interesting as his first long poem on an American theme and as one of the better known compositions in English hexameters, in 1847. A novel, *Kavanagh,* praised by Emerson but not otherwise distinguished, was issued in 1849; and in 1850 still another book of verse, *The Seaside and the Fireside,* was added to the list of his publications.

By 1854 he found teaching a burden, and resigned from Harvard, turning his whole attention to poetry. Eight other volumes of short poems, most famous of which is his *Tales of a Wayside Inn* (1863), were printed before his death. *Hiawatha* came out in 1855. It attempted to weave together the legends and traditions of the American Indians. The metre, trochaic dimeter, was suggested by the Finnish *Kalevala.* In 1858 he used hexameters for another American theme, *The Courtship of Miles Standish.* The two most ambitious works of his later life were his translation of Dante's *Divina Commedia,* and his *Christus,* a trilogy, which he planned as his greatest achievement. He had begun to translate Dante in 1843. *Christus,* too, he began early. Though the whole poem did not appear till 1872, its three parts, *The Golden Legend,* a re-working of a mediaeval tale, *The New England Tragedies,* two dramas of Puritan America, and *The Divine Tragedy,* had already appeared as separate works.

His second wife died on July 10, 1861, as the result of a tragic accident, and the poem of Longfellow's which is most successful in conveying the effect of deep emotion, his *Cross of Snow,* resulted from this bereavement. He did not print it; he seems always to have felt that frank expression of his personal feeling was not for the public eye. In 1868 he went to Europe, where he was hailed as a celebrity. Among the honours conferred on him were degrees of LL.D. from Cambridge and D.C.L. from Oxford, and election to membership in the Royal Spanish Academy. He died on March 24, 1882, and in 1884 a memorial to him was unveiled in Westminster Abbey. He was the first American poet to be commemorated there.

His fame in his own day was greater than that attained by any American poet prior to his time. It was based on the extraordinary popularity of his work, which was read not only by all classes in the United States but generally in England, and was translated into many languages to meet the demand for it in other countries. Longfellow's kindliness and charm, his unfailing generosity toward the thousands who visited his house in Cambridge, besieged him with requests for autographs, and heaped his desk with correspondence, contributed toward making him a national hero.

Longfellow's facility in remembering and reproducing what he had read gives an imitative quality and a too bookish flavour to much of his verse, though he was never the downright plagiarist Poe called him. But, though his writing rarely reflects current American concerns and though he cherished the romantic past, he believed definitely that there should be a truly American literature, not distinguished by its mere difference from English but by its authors' willingness to write "naturally, to write from their own feelings and impressions, from the influence of what they see around them." He was a good story-teller, and this has endeared him to children and to beginners in the appreciation of poetry.

Longfellow is still probably as much read as any American poet, even by those who do not come to know his verse in school. Barred from the company of the few great universal poets of the world, his work has virtues which are not ordinarily found in the merely mediocre. Much is summed up in the words of William Dean Howells, who refused to prophesy as to Longfellow's future place in literature, but remarked, "I am sure that with Tennyson and Browning he fully shared in the expression of an age which more completely than any former age got itself said by its poets."

BIBLIOGRAPHY.—*See* the Riverside edition of Longfellow's *Works* (Boston, 1886). The most complete biography is Samuel Longfellow's *Life of Henry Wadsworth Longfellow with Extracts from his Journals and Correspondence* (Boston, 1891). For bibliography *see* L. S. Livingston, *Bibliography of the . . . Writings of Henry Wadsworth Longfellow* (1908). Of the shorter biographies that by T. W. Higginson (1902) is the best; H. S. Gorman's *A Victorian American* (1926), the most recent. P. Morin's *Les Sources de l'Oeuvre de Henry Wadsworth Longfellow* (1913) is a useful study. For a friend's description of the poet, *see* W. D. Howell's *Literary Friends and Acquaintance* (1900). Brief essays and criticisms are numerous; *see,* for example, Paul Elmer More in *Shelburne Essays,* vol. v. (1908); Bliss Perry in *Park Street Papers* (Boston, 1908); and his "Longfellow and Hawthorne" in *Bowdoin College Bulletin* (Sept. 1925); E. C. Stedman in *Poets of America* (Boston, 1885); and W. P. Trent in *Longfellow and Other Essays* (1910). (K. B. M.)

LONG FIVES. This game, though played on a tennis court, bears but a slight resemblance to tennis, but is nevertheless a valuable form of preparatory practice. The game is 8 or 11 points, each stroke won counting one point to the winner. The server gives 3 points in 8, or 4 points in 11 to the striker-out. There are no chases. The winning openings count as at tennis. If a ball be struck into any other gallery or opening, it may be counted, by arrangement, either as a "let" (the rest being annulled) or against the striker; a similar arrangement is made for balls that make any chase on the hazard-side, or a chase of the last gallery on the service-side.

LONGFORD, a county of Eire, bounded northwest by Leitrim, northeast by Cavan, east and south by Westmeath and west by Lough Ree and Roscommon. The area is 257,935 acres, or about 403 sq.mi. Pop. (1936) 37,847.

The Silurian axis of Newry reaches the north of the county, where Lough Gowna lies upon it. Anticlinals bring up Old Red Sandstone at Longford town and Ardagh, above the Carboniferous Limestone plain, in which Lough Ree forms a characteristic lake, with signs of extension by solution along its shores. Marble of fine quality has been raised. In the north indications of iron are abundant, and there are also traces of lead. The principal rivers are the Camlin, which rises near Granard and flows past Longford to the Shannon, and the Inny, which entering the county from Westmeath crosses its southern corner and falls into Lough Ree. Lough Ree is partly included in Longford. The other principal lakes are Lough Gowna, Derrylough, Lough Drum and Lough Bannow.

The early name of Longford was Annaly or Analé, a principality of the O'Farrels. Then included in Meath, it was granted by Henry II. to Hugh de Lacy, who planted an English colony. On the division of Meath into two counties in 1543, Annaly was included in Westmeath, but in 1569 it was made shire ground under the name of Longford.

The chief rath is called the Moat of Granard. There are monastic remains at Ardagh, a former bishopric, Longford, Moydow and on several of the islands of Lough Ree. The principal castles are those of Rathcline near Lanesborough, and Ballymahon on the Inny. Oliver Goldsmith was born at Pallas, a village near Ballymahon, in this county; and at Edgeworthstown lived the family of the novelist Maria Edgeworth.

The climate is moist and cold, and there is much marsh and bog. The soil in the southern districts resting on the limestone is a deep loam well adapted for pasture, but in the north it is often poor. Oats and potatoes are the principal crops. The Great Southern line from Mullingar to Sligo crosses the county by way of the county town of Longford; and the Cavan branch touches the extreme east.

The Royal canal enters the county in the south at Abbeyshrule, and joins the Shannon near Cloondara. The constituency of Longford-Athlone returns three members to Dáil Eireann.

LONGFORD, the county town of Co. Longford, Eire, on the river Camlin, 75 mi. W.N.W. of Dublin by rail. Pop. (1936) 3,807. The principal building is St. Mel's Roman Catholic cathedral for the diocese of Ardagh. Trade is in grain, butter and bacon. There are corn-mills, a spool factory and tanneries. The ancient name of the town was Athfada, and here a monastery is said to have been founded by St. Idus, a disciple of St. Patrick. The town obtained a fair and market from James I. and a charter of incorporation from Charles II.

LONGHI, PIETRO (1702–1785), Venetian painter, celebrated for his little pictures of satiric *genre,* was born in Venice. He was a pupil of Antonio Balestra and Giuseppe Maria Crespi at Bologna. He has very aptly been called the Goldoni of painting, and Mariette said of him "Il devint un autre Watteau." Most of his paintings are in the public collections of Venice. The Brera collection, Milan, owns several examples of his work. They are generally on a small scale, but the staircase of the Palazzo Grassi-Stucky, now Sina, on the Canal Grande in Venice, is decorated by him with seven frescoes, representing carnival scenes. In England the National Gallery owns "The Exhibition of a Rhinoceros in an Arena," a "Domestic Group" and "The Fortune Teller"; two *genre* pictures are at Hampton Court palace. Many of his works have been engraved by Alessandro Longhi, Bartolozzi Cattini, Faldoni and others.

His son, ALESSANDRO LONGHI (1733–1813), was a famous portrait painter and engraver. He studied painting under the Venetian portraitist, Giuseppe Nogari, as he himself states in his book on Venetian painters, *Compendio delle Vite dei Pittori Veneziani Istorici più rinomati del presente secolo, con suoi ritratti dal naturale, delineati ed incisi* (Venice, 1762). Portraits painted by Alessandro have in recent times been attributed to his famous father, who was never mentioned in his own days as a portraitist. In 1766 an academy of painters was founded at Venice. The majority of Venetian painters belonged to it, among them the two Longhi—father and son. In the list of its members Pietro is described as a figure painter only; his son Alessandro, however, is entered as a portrait painter.

See J. P. Richter, *Mond Collection* (1910).

LONGINUS, CASSIUS (*c.* A.D. 213–273), Greek rhetorician and philosophical critic, surnamed PHILOLOGUS. The origin of his gentile name Cassius is unknown; it can only be conjectured that he adopted it from a Roman patron. He was perhaps a native of Emesa (Homs) in Syria, the birthplace of his uncle Fronto the rhetorician. He studied at Alexandria under Origen the heathen, and taught for 30 years at Athens. Longinus upheld, in opposition to Plotinus, the doctrine that the Platonic ideas existed outside the divine Νοῦς (*ὅτι ἔξω τοῦ νοῦ ὑφέστηκε τὰ νοητά*: *see* F. Überweg, *Grundriss der Geschichte der Philosophie,* 9th ed., 1903, i. § 72). Plotinus, after reading his treatise Περὶ ἀρχῶν (*On First Principles*), remarked that Longinus might be a scholar (*φιλόλογος*), but that he was no philosopher (*φιλόσοφος*). The reputation which Longinus acquired by his learning was immense; he is described by Porphyry as "the first of critics," and by Eunapius as "a living library and a walking museum" or encyclopaedia. During a visit to the East he became teacher in Greek, and subsequently chief counsellor in state affairs, to Zenobia, queen of Palmyra. It was by his advice that she endeavoured to regain her independence; Aurelian, however, crushed the attempt, and while Zenobia was led captive to Rome to grace Aurelian's triumph, Longinus paid the forfeit of his life.

Longinus was the author of a large number of works, nearly all of which have perished. Among those mentioned by Suïdas are *Quaestiones Homericae, An Homerus fuerit philosophus, Problemata Homeri et solutiones, Atticorum vocabulorum editiones duae;* the most important of his philological works, Φιλόλογοι ὁμιλίαι (*Philological Discourses*) consisting of at least 21 books, is omitted. A considerable fragment of the Περὶ τέλους (*De finibus, On the Chief End*) is preserved in the *Life of Plotinus* by Porphyry (§ 20). Under his name there are also extant Prolegomena to the *Encheiridion* of Hephaestion on metre (printed in R. Westphal, *Scriptores Metrici Graeci,* i. 1866) and the fragment of a treatise on rhetoric (L. Spengel, *Rhetores Graeci,* i. pp. 299–320), inserted in the middle of a similar treatise by Apsines. It gives brief practical hints on invention, arrangement, style, memory and other things useful to the student.

It is as the reputed author of the well-known and remarkable work Περὶ ὕψους (generally, but inadequately, rendered *On the Sublime*) that Longinus is best known. Modern scholars, however, with few exceptions, are agreed that it cannot with any certainty be ascribed to him, and that the question of authorship cannot be determined (*see* Introduction to Roberts's edition).

The alternative author, Dionysius, of the mss. has been variously identified with the rhetorician and historian Dionysius of Halicarnassus, the Atticist Aelius Dionysius of Halicarnassus, Dionysius Atticus of Pergamum, Dionysius of Miletus. Dr. W. R. Roberts (Class. Ass. Proceedings, 1928) concludes on an unidentified Greek man of letters who probably lived at Rome not more than 30 or 40 years after the birth of Christ. Wilamowitz-Möllendorff also gives his date as about A.D. 40.

The rendering *On the Sublime* implies more than is intended by the Greek Περὶ ὕψους ("impressiveness in style," Jebb). Nothing abnormal, such as is associated with the word "sublime," is the subject of discussion; it is rather a treatise on style. According to the author's own definitions, "sublimity is a certain distinction and excellence in expression," "sublimity consists in elevation," "sublimity is the echo (or expression) of a great soul" (*see* note in Roberts).

The treatise is especially valuable for the numerous quotations from classical authors, above all, for the preservation of the famous fragment of Sappho, the ode to Anactoria, beginning

φαίνεταί μοι κῆνος ἴσος θεοῖσιν,

imitated by Catullus (li.) *Ad Lesbiam,*

"Ille mi par esse deo videtur."

"Its main object is to point out the essential elements of an impressive style which, avoiding all tumidity, puerility, affectation and bad taste, finds its inspiration in grandeur of thought and intensity of feeling, and its expression in nobility of diction and in skilfully ordered composition" (Sandys).

A full bibliography of this subject will be found in the edition by W. Rhys Roberts (2nd ed. 1909), with introduction, analysis, translation and appendices. *See* also W. R. Roberts' introduction to *Demetrius on Style* in *Aristotle: the Poetics* (ed. with Eng. trans. by W. Hamilton Fyfe, 1927); F. Marx, *Wiener Studien* (xx. 1898) and F. Kaikel, *Hermes* (xxxiv., 1899), who respectively advocate and reject the claims of Longinus, and J. E. Sandys, *History of Classical Scholarship* (2nd ed. 1906). The number of translations in all the languages of Europe is large, including the famous one by Boileau. A text and translation was published by A. O. Prickard (1907–08).

LONG ISLAND, a fragment of the North American continent extending 118 m. east-north-east from the mouth of the Hudson river, U.S.A. It roughly parallels the south shore of Connecticut from which it is separated by Long Island sound (115 m. long) and lies south-east of the mainland of New York State of which it is a part. The island is from 12 to 23 m. wide and has an area of 1,682 sq.m. The east end is divided into two narrow peninsulas (the northern culminating in Orient point about 25 m. long, the southern ending in Montauk point, the eastern extremity of the island, about 40 m. long) by three bays, Great Peconic, Little Peconic (in which lies Shelter island) and Gardiners (in which lies Gardiners island). The north shore is broken in its western half by Flushing bay, Little Neck bay, Manhasset bay, Cold Spring Harbor, Huntington bay, Smithtown bay and Port Jefferson. The south shore has Jamaica bay with many low islands and nearly cut off from the ocean by the narrow spit of Rockaway beach; the ill-defined Great South bay, which is separated from the Atlantic by the narrow Long beach, Jones beach and Oak Island beach, and by the long peninsula called Fire island or Great South beach. Still farther east is Shinnecock bay, about 10 m. long and cut off from the ocean by a narrow beach.

Physiography, climate and location have combined to make Long Island one of the richest and most important garden spots in the United States. The hills of glacial moraine and much of the outwash plains of the southern half of the island, covered for centuries with forest mould, offer a rich soil to the husbandman. A mild, maritime climate brings the spring earlier and holds the autumn later than in the continental interior at the same latitude. New York city offers a market without equal in America. Long Island agriculture of the 17th and 18th centuries was characterized by the self-sufficient farm. Toward the end of the 18th century some farmers began selling their surplus crops in New York. Connection with this market was by wagons from the farms at the western end of the island and by small coasting boats from the homesteads of the north shore. Two events in the first half of the 19th century established Long Island agriculture on its modern basis. In 1825 the completion of the Erie canal gave New York city a connection with the continental interior and allowed a swift development which made it the metropolis of North America. In 1844 the Long Island railroad was completed to Greenport.

The growth of New York and the completion of the railroad caused the general farms to be turned into market gardens, cultivated intensively. The change did not come at once. For a time, after the Civil War, Queens and western Suffolk counties comprised an important milk-producing region. As the urban market increased, however, the land became too valuable for grazing, and truck farming became the dominant industry.

In 1935, according to the figures of the farm census for that year, the farming land of Long Island was roughly valued at $90,000,000. Kings county, across the East river from Manhattan, had 42 farms with a total of 117 ac. under cultivation. Queens county had 292 farms with a total acreage of 2,234 where market gardening was conducted with profit. Nassau county, the next political division to the east, had 614 farms with an acreage of 27,895. Suffolk county, covering the remainder of the island to the east, is chiefly agricultural with 2,220 farms with 123,351 ac. The product of the farms and market gardens is sold in New York city.

Fishing Industries.—Whaling was the first important maritime industry. So far as Long Island was concerned the fishery had its origin in the 17th century at East Hampton and Southampton. Early in the 19th century Sag Harbor became the chief Long Island whaling port. The village, dependent almost solely upon whaling, prospered in the golden age of the fishery and suffered heavily when whaling swiftly declined after the middle of the century. Throughout most of the 19th century the menhaden fishery flourished along the southern shore and in Peconic bay. Before the end of the 18th century, the Blue Point oyster bed in Great South bay had been discovered and was being worked, and in 1855 New York State permitted the leasing of sea-bottom, which was not part of a natural bed, for the purpose of establishing oyster farms. Oystering under the new conditions became one of the important industries, not only of Great South bay, but of Peconic bay, and some of the north shore harbours. Scallop fishing is also an enterprise of some importance in Peconic bay. Throughout the history of the island, deep-sea fishing—for cod, mackerel, bluefish, sea bass, weakfish, etc.—has supported many Long Island families.

Manufactures.—The chief manufacturing enterprises of the first half of the 19th century were those supplying the needs of the maritime industries. Cooperages and rope walks characterized Sag Harbor in the whaling days. The building of ships and boats became an important industry at Port Jefferson and other north shore towns located near good timber. The development of oystering on a large scale made a new demand for boats and for repair work. More important was the growth of summer colonies on the shores. The making, repairing, and storing during the winter of pleasure-craft became and has remained an important industry. Here and there, as at Patchogue and Sag Harbor, other manufacturing industries sprang up. Today Brooklyn and Queens boroughs are among the most important industrial centres in the United States. The two boroughs had in 1939, 6,454 industrial establishments, with 187,907 employees and produced goods valued at $1,304,010,119. Among the more important industries were automobile, shoe, silk, candy, printing, rubber, food-stuff, sugar, soap, iron and steel, paint and varnish and motion pictures. The factors causing this great industrial development at the western end of Long Island are not far to seek. Nearly 30% of the buying power of the United States lies within 100 m. of New York city. Land on Long Island is cheaper than in Manhattan, yet it is near the water front and close to the important trans-Atlantic lines.

Long Island as a Playground.—The growth of New York has caused the development of Long Island for recreational purposes. In the first decade of the 19th century Far Rockaway became a watering place for New York's *élite*. After the Civil War, with the increase of railroad facilities great estates began to be developed. Southampton became a second Newport. Camps, like Camp Carey of the New York Boys' Club, appeared. Coney Island, pioneer of American amusement parks, flourished. And all the while the city grew eastward.

Improved transportation made it possible for millions to escape for a few hours or days from the crowded streets to the quiet shore or countryside. Under the leadership of Governor Alfred E. Smith, the development of parks on Long Island began. By 1941, as a result of the activities of the Long Island State Park commission, some 10,000 ac. had been set aside as state parks. Some, like those at Fire island, Montauk, and Wading river, are on the shore. Deer Range park on Great South bay is well stocked with deer and other wild animals. In Nassau county, New York city has turned over more than 2,000 ac. containing lakes no longer used as reservoirs, where boating, bathing and fishing are possible. In 1928 a parkway scheme was undertaken to make it easy for the people to reach their playgrounds. The park commission hopes and plans to bring the area of Long Island State parks up to 40,000 acres. Long Island, on the edge of the largest American city, has become one of the most important of American playgrounds.

Early History.—At the time of the first settlement by the whites, the island was occupied by numerous small tribes of Indians whose former existence is now commemorated by such names as "Montauk" Point, "Shinnecock" hills, "Manhasset" bay, etc. The territory of Long Island was included in the grant of 1620 by James I. to the Plymouth Company and in 1635 was conveyed to William Alexander, earl of Stirling. The conflicting claims of English and Dutch were the subject of the treaty concluded at Hartford, Conn., in 1650, by which the Dutch were to hold everything west of Oyster bay, the English everything east—a provision which failed to settle the boundary dispute. In 1674 by the treaty of Westminster, Long Island became a part of the British colony of New York.

The Dutch settlements on the west end of the island were more important ethnically than historically. The "Five Dutch Towns" were: Nieuw Amersfoord (after 1801 officially called Flatlands) on Jamaica bay, where the first settlement was made about 1623 and the first grant in 1636; Midwout (later Vlackte-Bosch and Flatbush), settled between 1645 and 1650 and having in 1654 the first Dutch church; Nieuw Utrecht, settled soon after 1650 and incorporated in 1660; Breuckelen (now Brooklyn), which was settled a little before its organization as a town in 1646; and Boswijck (Bushwick), first settled by Swedes and Norwegians and incorporated in 1660.

Apparently the earliest English settlement was at Hempstead in 1640 by colonists from Lynn, Mass., but they were immediately driven out by the Dutch. In 1643 another English settlement was made at Hempstead by men from Stamford, Conn., who in 1644 secured a patent from Gov. Keift of New Netherland. In 1645 Keift granted land at Gravesend to Lady Deborah Moody, who had settled there about 1643. The Connecticut towns were as follow: Southampton, settled in 1640 by the Lynn men driven out of Hempstead by the Dutch, and in 1644–64 was under the Connecticut jurisdiction; and Southold (the "South Hold of New Haven"), which had a church and a code of law court based on the "cotton code." The colony joined New Haven in 1648, in which year the colony of Forretts (now Shelter) island also submitted to New Haven. Oyster bay and Easthampton were settled by people from Lynn in 1640 and 1648, respectively. Newton, subsequently named Hastings, was settled in 1652 and was annexed to Connecticut in 1662. Other early settlements were Huntington (1653), Jamaica (1657), Brookhaven (1655) and Smithtown (patented in 1677).

Battle of Long Island, 1776.—The interest of this battle lies in the fact that it was the first engagement in the campaign of 1776 (*see* AMERICAN REVOLUTION) and was expected in England to be decisive of the contest in the colonies. After the evacuation of Boston (March 1776), Lord Howe moved against New York city, which he thought would afford a better base of operations for the future. The Americans undertook its defence although recognizing the difficulties in the case, as the bay and rivers adjoining would enable the British fleet to co-operate effectively with the army. To protect his left flank Washington was forced to throw a portion of his troops over to the Long Island side of the East river; they fortified themselves there on the site of the present Borough of Brooklyn. Lord Howe, who had encamped on Staten Island at the entrance to the harbour, determined to attack this isolated left wing, and on Aug. 22 landed at Gravesend bay, Long Island, with about 20,000 men. The Americans maintained strong outposts in the wooded hills in advance of their fortified lines. On the morning of the 27th Howe, after four days' reconnaissance, attacked these posts with three columns, the left and centre delivering the holding attack, and the right and strongest column turning the enemy's left by a détour. Howe himself, accompanied by Generals (Sir H.) Clinton and Lord Cornwallis, led the turning movement, which came upon the rear of the enemy at the moment when they were engaged with the two other columns. By noon the Americans had been driven back into the Brooklyn lines in considerable confusion, and with the loss of about half their number. This constituted the battle. The completeness of the British victory was due to the neglect of the Americans in guarding the left of their outposts. Howe has been criticized for not immediately assaulting the American works, which he might have carried on the evening of the battle. In view of the fact that he had only defeated a small portion of the American forces, and that the works were of considerable strength, he decided to make a formal siege, and Washington took advantage of the delay in operations to retreat across the river to New York on the night of the 29th. This successful movement repaired to some extent the bad moral effect of the defeat of the 27th in the American camp. In the engagement of Long Island Washington lost about 1,200 prisoners and 30 guns, and 400 killed and wounded; of the latter the British lost nearly the same number.

See Thomas Warren Field, "The Battle of Long Island," *Long Island Hist. Soc. Memoirs*, vol. ii. (1869); and Charles Francis Adams, "The Battle of Long Island," *Amer. Hist. Rev.*, vol. i., p. 650–670 (1896). (C. F. A.)

LONG ISLAND CITY, formerly a city of Queens county, New York, U.S.A. and since 1898 a part of the Borough of Queens, New York city. It has a river front, on East river and Long Island sound, of 10 miles. The first settlement within the limits of what subsequently became Long Island City was made in 1640 by a Dutch blacksmith, Hendrick Harmensen, who soon afterward was murdered by an Indian. Other settlers, both Dutch and English, soon followed, and established detached villages, which became known at Hunter's Point, Blissville, Astoria, Ravenswood, Dutch Kills, Middleton and Steinway. In 1853 this group of villages, by that time virtually one community, was called Long Island City, and it was formally incorporated under that name in 1870. It is the principal industrial area of Queens borough and ranks in number of plants among the first 20 communities of the United States. The industrial pay roll equals that of San Francisco, Calif. Food products lead and aircraft, shoes, paints, plastics, motion pictures and metal goods are other important products. The Sunnyside yards contain the country's largest Pullman storage space and busiest railway express depot. Astoria is the chief retail and residential section with 130,000 of the 240,000 population.

Railroad and vehicular tunnels and bridges linking it to Manhattan just across the East river, and near by La Guardia airport, enhance its industrial advantages.

See J. S. Kelsey, *History of Long Island City* (Long Island City, 1896); B. F. Thompson, *History of Long Island* (1918); and R. H. Gabriel, *The Evolution of Long Island* (1921).

LONGITUDE, the angle which the terrestrial meridian from the pole through a point on the earth's surface makes with some standard meridian, commonly that of Greenwich. It is equal to the difference between local time on the standard meridian, and at the place defined, one hour of time corresponding to 15° difference of longitude. Formerly each nation took its own capital or principal observatory as the standard meridian from which longitudes were measured. Another system had a meridian passing through or near the island of Ferro, defined as 20° W. of Paris, as the standard. While the system of counting from the capital of the country is still used for some purposes, the meridian of Greenwich has been used for nautical and international calculations since the Washington Meridian Conference of 1884. In astronomy, the longitude of a celestial body is the distance of its projection upon the ecliptic from the vernal equinox, counted in the direction west to east from 0° to 360°.

LONGLEY, CHARLES THOMAS (1794–1868), archbishop of Canterbury, was born at Rochester, and educated at Westminster and Oxford. He was ordained in 1818. He was headmaster of Harrow School (1829–36), bishop of Ripon (1836–56), bishop of Durham (1856–60), archbishop of York (1860–62), and archbishop of Canterbury (1862–68). The chief event of his primacy was the meeting at Lambeth, in 1867, of the first Pan-Anglican conference of British, colonial and foreign bishops (*see* LAMBETH CONFERENCES). He died on Oct. 27, 1868, at Addington Park, near Croydon.

LONGMANS, a firm of English publishers. The founder, Thomas Longman (1) (1699–1755), was the son of Ezekiel Longman, a gentleman of Bristol. Thomas was apprenticed in 1716 to John Osborn, a London bookseller. He married Osborn's daughter, and in 1724 purchased the goods of William Taylor, the first publisher of *Robinson Crusoe,* for £2,282 9s. 6d. Taylor's two shops in Paternoster Row were known respectively as the Black Swan and the Ship. Osborn, who afterwards entered into partnership with his son-in-law, held one-sixth of the shares in Ephraim Chambers's *Cyclopaedia of the Arts and Sciences,* and Thomas Longman was one of the six booksellers who undertook the responsibility of Samuel Johnson's *Dictionary.* In 1754 Thomas Longman took his nephew into partnership, the title of the firm becoming T. and T. Longman.

Upon the death of his uncle in 1755, Thomas Longman (2) became sole proprietor. He had three sons. Of these, Thomas Norton Longman (3) succeeded to the business. In 1794 Owen Rees became a partner, and Thomas Brown, who was for many years after 1811 a partner, entered the house as an apprentice. He published the works of Wordsworth, Coleridge, Southey and Scott. In 1824 the title of the firm was changed to Longman, Hurst, Rees, Orme, Brown & Green. In 1814 arrangements were made with Thomas Moore for the publication of *Lalla Rookh,* for which he received £3,000; and when Archibald Constable failed in 1826, Longmans became the proprietors of the *Edinburgh Review.*

Thomas Norton Longman (3) died on Aug. 29, 1842, leaving his two sons, Thomas (4) and William Longman in control. They first published Macaulay's *Lays of Ancient Rome,* which was followed in 1849 by the issue of the first two volumes of his *History of England,* which in a few years had a sale of 40,000 copies. Both brothers had literary talent; Thomas Longman edited a beautifully illustrated edition of the New Testament, and William Longman wrote a *History of the Three Cathedrals dedicated to St. Paul* (1869) and a work on the *History of the Life and Times of Edward III.* (1873). In 1890 they incorporated all the publications of the firm of Rivington, established in 1711. The family control of the firm (now Longmans, Green & Co.) was continued by Thomas Norton Longman (5), son of Thomas Longman (4).

LONGMONT, a city of Boulder county, Colorado, U.S.A., 35 mi. N. by W. of Denver, and 32 mi. E. of the Rocky Mountain National park; at an altitude of 4,950 ft. Longs peak is visible in the distance. Longmont is on federal highway 87, and is served by the Burlington, the Colorado and Southern, and Great Western railways. Pop., 6,029 in 1930; 7,406 in 1940. It is a trading and shipping point for the fertile irrigated region around it, and has an immense beet-sugar factory, large flour mills and vegetable canneries. Gold and lignite coal are mined near by.

LONGOMONTANUS (or LONGBERG), **CHRISTIAN SEVERIN** (1562–1647), Danish astronomer, was born at Longberg in Jutland, Denmark, on Oct. 4, 1562. The appellation Longomontanus was a Latinized form of the name of his birthplace. In 1577 he ran away to Viborg, where he attended the grammar-school, defraying his expenses by manual labour, and went to Copenhagen in 1588 with a high reputation for learning and ability. Engaged by Tycho Brahe in 1589 as his assistant in his great astronomical observatory of Uraniborg, he rendered him invaluable services there during eight years. He quitted the island of Hveen with his master, but obtained his discharge at Copenhagen on June 1, 1597, for the purpose of studying at some German universities. He rejoined Tycho at Prague in January 1600, and having completed the Tychonic lunar theory, turned homeward again in August. He visited Frauenburg, where Copernicus had made his observations, took a master's degree at Rostock, and at Copenhagen found a patron in Christian Friis, chancellor of Denmark, who gave him employment in his household. Appointed in 1603 rector of the school of Viborg, he was elected two years later to a professorship in the university of Copenhagen, and his promotion to the chair of mathematics ensued in 1607. This post he held till his death, on Oct. 8, 1647.

He inaugurated, at Copenhagen in 1632, the erection of a stately astronomical tower, but did not live to witness its completion. Christian IV. of Denmark, to whom he dedicated his *Astronomia Danica,* an exposition of the Tychonic system of the world, conferred upon him the canonry of Lunden in Schleswig.

The following is a list of his more important works in mathematics and astronomy: *Systematis Mathematici,* etc. (1611); *Cyclometria e Lunulis reciproce demonstrata,* etc. (1612); *Disputatio de Eclipsibus* (1616); *Astronomia Danica,* etc. (1622); *Disputationes quatuor Astrologicae* (1622); *Pentas Problematum Philosophiae* (1623); *De Chronolabio Historico, seu de Tempore Disputationes tres* (1627); *Geometriae quaesita XIII. de Cyclometria rationali et vera* (1631); *Inventio Quadraturae Circuli* (1634); *Disputatio de Matheseos Indole* (1636); *Coronis Problematica ex Mysteriis trium Numerorum* (1637); *Problemata duo Geometrici* (1638); *Problema contra Paulum Guldinum de Circuli Mensura* (1638); *Introductio in Theatrum Astronomicum* (1639); *Rotundi in Plano,* etc. (1644); *Admiranda Operatio trium Numerorum* 6, 7, 8, etc. (1645); *Caput tertium Libri primi de absoluta Mensura Rotundi plani,* etc. (1646).

Hoeffer, *Hist. de l'astronomie,* p. 391; J. Mädler, *Geschichte der Himmelskunde,* i. 195; J. F. Weidler, *Hist. Astronomiae,* p. 451.

LONG PRIMER, a printing type, in size larger than bourgeois and smaller than small pica. It is also known as 10-point. The term describes size only, and does not indicate any particular design. The following passage is printed in long primer:

> "Until well into the 19th century types were cast in small hand moulds, the output from which was about 400 letters an hour by a skilled worker."

This size of type is among those most frequently used in book printing. (*See* PRINTING TYPE.)

LONGS PEAK, a peak of the Front Range in Boulder county, Colorado. It is the 14th highest summit in the State, attaining an elevation of 14,255 ft. above sea-level. The peak was named in honour of Major S. H. Long who, in 1820, led an exploring party into the valleys of the South Platte and the Arkansas and made the first official report of the existence of the peak.

LONGSTREET, JAMES (1821–1904), American soldier, lieutenant general in the Confederate army, was born on Jan. 8, 1821, in Edgefield district, S.C., and graduated from West Point in 1842. He was severely wounded in the Mexican war, and received two brevets for gallantry. In 1861, having attained the rank of major, he resigned when his state seceded, and became a brigadier general in the Confederate army. In this rank he fought at the first battle of Bull Run, and at the head of a division in the Peninsular campaign and the Seven Days. This division later became the nucleus of the 1st corps, army of northern Virginia, which was commanded throughout the war by Longstreet, and took part in the second battle of Bull Run, Antietam and Fredericksburg. Most of the corps was absent in North Carolina when the battle of Chancellorsville took place, but Longstreet, now a lieutenant general, returned to Lee in time to take part in the campaign of Gettysburg. In Sept. 1863 he took part in the great battle of Chickamauga. In November he commanded the unsuccessful expedition against Knoxville. In 1864 he rejoined Lee's army in Virginia, and on May 6 arrived upon the field of the Wilderness as the Confederate right had been turned and routed. His attack was a model of impetuosity and skill, and drove the enemy back until their entire force upon that flank was in confusion. At this critical moment, as Longstreet in person, at the head of fresh troops, was pushing the attack in the forest he was fired upon by mistake by his own men and desperately wounded. This mischance stayed the Confederate assault for two hours, and enabled the enemy to provide effective means to meet it. In Oct. 1864 he resumed command of his corps, which he retained until the surrender, although paralyzed in his right arm.

During the period of Reconstruction, Longstreet's attitude toward the political problem, and the discussion of certain military incidents, notably the responsibility for the Gettysburg failure, brought the general into extreme unpopularity. His admiration for General Grant, and his loyalty to the Republican party accentuated the ill-feeling of the southern people. But in time his services in former days were recalled, and he became once more "General Lee's war-horse" to his old soldiers and the people of the south.

He held several civil offices, among them that of minister to Turkey under Grant, and that of commissioner of Pacific railways under Presidents McKinley and Roosevelt. In 1896 he published *From Manassas to Appomattox*, and in his later years he prepared an account of Gettysburg, which was published soon after his death, with notes and reminiscences of his whole military career. He died at Gainesville, Ga., on Jan. 2, 1904.

See Helen D. Longstreet, *Lee and Longstreet at High Tide* (1904), also Sir F. Maurice, *Statesmen and War* and *Robert E. Lee*.

LONGTON, a former market town of Stoke-on-Trent municipal county and parliamentary borough, Staffordshire, England. In 1910 it amalgamated with neighbouring towns to form the municipal borough of Stoke-on-Trent (*q.v.*) which in 1925 became a city.

LONGUEVILLE, ANNE GENEVIEVE, DUCHESSE DE (1619–1679), was the only daughter of Henri de Bourbon, Prince de Condé, and the sister of Louis, the great Condé (*q.v.*). She was the guiding spirit of the first Fronde, (*q.v.*) when she brought over Armand, Prince de Conti, her second brother, and her husband to the malcontents, but she failed to attract Condé himself, whose loyalty to the court overthrew the first Fronde.

The second Fronde was largely her work, and in it she played the most prominent part in attracting to the rebels first Condé and later Turenne. After the war she became more and more Jansenist in opinion.

In her house Antoine Arnauld, Pierre Nicole (*qq.v.*) and De Lane were protected. Her letters to the pope are part of the history of PORT ROYAL (*q.v.*), and as long as she lived the nuns of Port Royal des Champs were left in safety.

As her health failed she hardly ever left the convent of the Carmelites in which she had been educated. On her death in 1679 she was buried with great splendour by her brother Condé, and her heart, as she had directed, was sent to the nuns of Port Royal des Champs.

The chief authority for Madame de Longueville's life is a little book in two volumes by Villefore the Jansenist, published in 1738. Victor Cousin has devoted four volumes to her, which, though immensely diffuse, give a vivid picture of her time. *See* also Sainte-Beuve, *Portraits of Women* (tr. 1891). Her connection with Port Royal should be studied in Arnauld's *Memoirs*, and in the different histories of that institution. *See* also Hugh Noel Williams, *A Princess of Intrigue, Anne Geneviève de Bourbon, Duchesse de Longueville, and her Times* (1908).

LONGUS, Greek romancer, author of *Daphnis and Chloë*. All that can be said about him is that he probably lived at the end of the 2nd or the beginning of the 3rd century A.D. Even the name attributed to the author may be a misreading of the title of the work.

Longus's style is rhetorical, his shepherds and shepherdesses are wholly conventional, but he has imparted human interest to a purely fanciful picture. As an analysis of feeling *Daphnis and Chloë* makes a nearer approach to the modern novel than its chief rival among Greek erotic romances, the *Aethiopica* of Heliodorus, which is remarkable mainly for the ingenious succession of incidents. Daphnis and Chloë, two children found by shepherds, grow up together, nourishing a mutual love which neither suspects. The development of this simple passion forms the chief interest, and the only notable incident is the abduction of Chloë by a pirate. The two lovers eventually discover their parents and marry.

See J. Dunlop, *History of Prose Fiction* (1888), and especially E. Rohde, *Der griechische Roman* (1900). Longus found an incomparable translator in Jacques Amyot, bishop of Auxerre, whose French version, as revised by Paul Louis Courier, is better known than the original. It appeared in 1559, 39 years before the publication of the Greek text at Florence by Columbani. The chief subsequent editions are those by G. Jungermann (1605), J. B. de Villoison (1778, the first standard text with commentary), A. Coraes (Coray) (1802), P. L. Courier (1810, with a newly discovered passage), E. Seiler (1835), R. Hercher (1858), N. Piccolos (Paris, 1866) and Kiefer (Leipzig, 1904), W. D. Lowe (Cambridge, 1908). A. J. Pons's edition (1878) of Courier's version contains an exhaustive bibliography. There are English translations by G. Thorneley (1733, reprinted 1893), C. V. Le Grice (1803); R. Smith (in Bohn's *Classical Library*), and the rare Elizabethan version by Angel Day from Amyot's translation (ed. J. Jacobs in *Tudor Library*, 1890).

LONGVIEW, a city of eastern Texas, on federal highway 80, near the Sabine river; the county seat of Gregg county. It is served by the Santa Fe, the Texas and Pacific and Missouri Pacific railways. Pop. (1930) 5,036; (1940) 13,758. The city was founded in 1871 and incorporated in 1882.

LONGWY, a fortified town of northeastern France in the department of Meurthe-et-Moselle, 89 mi. N.N.W. of Nancy by rail. Pop. (1936) 6,024. It is situated on a plateau overlooking the Chiers, a right-bank affluent of the Meuse, near the frontiers of Belgium and Luxembourg. Longwy (*Longus vicus*) came into the possession of the French in 1678 and was at once fortified by Vauban. It was captured by the Prussians in 1792, 1815 and 1871. It comprises an upper and a lower town; the former, on a hill, 390 ft. above the Chiers valley, commands the Luxembourg road, and is fortified. The 17th-century church has a high square tower and the hôtel de ville dates from 1730.

LÖNNROT, ELIAS (1802–1884), Finnish philologist and discoverer of the *Kalevala*, was born at Nyland, Finland, on April 9, 1802. He entered the university of Åbo in 1822, and qualified as a physician.

As early as 1827, he had begun to publish contributions to the study of the ancient Finnish language, and to collect the national ballads and folk-lore. In 1833 he settled as a doctor in the country district of Kajana, and began to travel throughout Finland and the adjoining Russian provinces, collecting songs and legends. In this way he was able to put together the great epic of Finland, the *Kalevala*, the first edition of which he published in 1835; he continued to add to it, and in 1849 issued a larger and completer text.

Lönnrot also published an important collection (1840) of the *Kanteletar*, or folk-songs of ancient Finland, which he had taken down from oral tradition; and the *Proverbs of Finland* (1842). In 1853 Lönnrot succeeded Castrén as lecturer on the Finnish language and literature at the Helsingfors high school; he retired in 1862. He died on March 19, 1884.

LONSDALE, EARLS OF. This English earldom is held by the ancient family of Lowther, which traces its descent to Sir Hugh Lowther, who flourished in the reign of Edward I. Sir Hugh's descendant Sir Richard Lowther (1529–1607) received Mary queen of Scots on her flight into England in 1568, and in the two following years was concerned with his brother Gerard in attempts to release her from captivity. He was sheriff of

Cumberland and lord warden of the west marches. Sir Richard's eldest son, Sir Christopher Lowther (d. 1617), was the ancestor of the later Lowthers, and another son, Sir Gerard Lowther (d. 1624), was judge of the common pleas in Ireland.

One of Sir Christopher's descendants was Sir John Lowther, Bart. (d. 1706), the founder of the trade of Whitehaven, and another was John Lowther (1655–1700), who was created Viscount Lonsdale in 1696. Before this creation John had succeeded his grandfather, another Sir John Lowther (d. 1675), as a baronet. In 1690 he was first lord of the treasury, and he was lord privy seal from March 1699 until his death in July 1700.

James Lowther, 1st earl of Lonsdale (1736–1802), was descended from Sir Christopher Lowther; through his mother, James was a great-grandson of the 1st Viscount Lonsdale. From 1757 to 1784 he was a member of parliament, exercising enormous influence on elections in the north of England on account of his great wealth, and controlling nine seats in the house of commons, where his nominees were known as "Sir James's ninepins." In 1784 Lowther was created earl of Lonsdale and in 1797 Viscount Lowther with an extended remainder.

The earldom became extinct in 1802, but was revived in 1807, and William Lowther (1757–1844), a cousin of James Lowther, was created the 1st earl of Lonsdale after the earldom was revived. He was succeeded by his eldest son, William Lowther II (1787–1872), upon whose death a nephew, Henry Lowther (1818–76), became the 3rd earl. St. George Henry Lowther (1855–82), son of Henry Lowther, and 4th earl, was succeeded by his brother, Hugh Cecil Lowther, 5th earl of Lonsdale. He died on April 13, 1944.

LONSDALE, WILLIAM (1794–1871), English geologist and palaeontologist, born at Bath on Sept. 9, 1794, was educated for the army, and in 1810 was gazetted as ensign in the 4th (King's Own) regiment. He served in the Peninsular War at the battles of Salamanca and Waterloo, for both of which he received medals; and he retired as lieutenant. At his home at Batheaston he collected a series of rocks and fossils which he presented to the Literary and Scientific Institution of Bath. He became the first honorary curator of the natural history department of the museum.

He was assistant secretary and curator of the Geological society of London at Somerset House from 1829 to 1842. In 1829 Lonsdale read before the society an important paper "On the Oolitic District of Bath" (*Trans. Geol. Soc.* ser. 2, vol. iii), the results of a survey begun in 1827; later he was engaged in a survey of the Oolitic strata of Gloucestershire (1832), and he laid down on the one-inch ordnance maps the boundaries of the various geological formations.

He became the highest authority in England on corals, and he described fossil forms from the Tertiary and Cretaceous strata of North America and from the older strata of Britain and Russia. In 1837 he suggested from a study of the fossils of the South Devon limestones that they would prove to be of an age intermediate between the Carboniferous and Silurian systems. This suggestion was adopted by Sedgwick and Murchison in 1839, and may be regarded as the basis on which they founded the Devonian system.

Lonsdale's paper, "Notes on the Age of the Limestones of South Devonshire" (read 1840), was published in the same volume of the *Transactions of the Geological Society* (ser. 2, vol. v) with Sedgwick and Murchison's famous paper "On the Physical Structure of Devonshire." Lonsdale died at Bristol on Nov. 11, 1871.

LONS-LE-SAUNIER, a town of E. France, capital of the department of Jura, 76 mi. N.N.E. of Lyons on the P.L.M. Ry., on which it is a junction for Chalon-sur-Saône, Dôle, Besançon and Champagnole. Pop. (1936) 14,593. The town is on both sides of the river Vallière and is surrounded by the vine-clad hills of the western Jura.

Lons-le-Saunier, known as *Ledo* in the time of the Gauls, was fortified by the Romans, who added the surname *Salinarius* to the Gallic name. An object of contention owing to the value of its salt, it belonged for a long time during the mediaeval period to the house of Chalon. It was burned in 1364 by the English, and again in 1637, when it was seized by the duke of Longueville for Louis XIII. It became definitely French in 1674. There the meeting between Ney and Napoleon took place, on the latter's return from Elba in 1815.

The town owes its name to the salt mines of Montmorot, its western suburb, which have been used from early times. The church of St. Désiré (12th and 15th centuries), has a huge Romanesque crypt. The town is the seat of a prefect and of a court of assizes, and there are tribunals of first instance and of commerce and a chamber of commerce. There are sodio-chlorinated mineral waters. The principal industry of the place is the manufacture of sparkling wines.

LOO, formerly called "Lanterloo" (Fr. *lanturlu,* the refrain of a popular 17th century song), a game of cards, invariably played for a stake. The players may number from five to about nine, each for himself. The pack of 52 cards is used.

In the simplest form of the game, three cards are dealt to each player, and the next is turned for trump. Eldest hand leads, and one-third of the pool goes to the winner of each trick. The pool is formed by antes before each deal, and may be increased by payments for *loo* (failure to win a trick) and fines for irregularities.

Among the features added to this base are found:

1. Turn of a card for trump is deferred until the first time any hand fails to follow suit. The trump then fixed affects the winning of the current and any subsequent tricks.

2. The first pool is a *single,* three counters put in by dealer alone. The players who are looed pay three counters each to the next pool, making it a *double.*

An extra hand called the *miss* is dealt at the right of the next dealer. Each player in turn, eldest hand first, must *pass, stand* or take the miss if it is still available. The player who takes the miss discards his original hand. After the miss is taken, the remaining players must pass or stand. All who pass throw in their cards; all who stand must play. Dealer must take the miss if no other does, playing for himself or "for the pool" (in which case his winnings if any remain in the next pool). The pool is divided, one-third for each trick. Players looed contribute to the next pool. Whenever the pool is cleared, the next deal is a *single,* otherwise the *doubles* continue.

3. The first dealer (eldest hand of those who stand) must lead the ace of trumps if he has it, or the king if the ace was previously turned for trump. The leader is also bound to lead a trump if he has two. Each player must *head* a trick if able, by playing higher in the suit led, by trumping if void of the suit led, or by playing a higher trump than any previously played to the trick.

4. A player dealt a *flush* wins the pool without play. A flush is three trumps.

5. The penalty for loo is to double the current pool. This variant, unlimited loo, has caused some considerable fortunes to change hands.

6. The hand may be five cards instead of three.

7. The turned trump may be taken up by the dealer in place of a discard.

8. *Pam,* the knave of clubs, is always the highest trump. It may be used as a "wild card" to complete a *flush* or a *blaze.* A flush is five trumps; a blaze is five court cards. The holder of either wins the pool without play.

9. Pam may be withheld on a trump lead, and must be withheld if the leader of the trump ace says, "Pam be civil!"

See J. Warren, *Rules for Three Card Loo* (1820); *The Laws of Loo of the Blenheim Club* (London, 1866).

LOOE, a seaport and market town of Cornwall, England, 17 mi. by sea W. of Plymouth. Pop. (est. 1938) 3,088. It is divided by the river into East Looe and West Looe; and is so sheltered by the surrounding hills that myrtles, geraniums, fuchsias and other delicate plants flourish at all seasons in the open air. Its lanes are narrow, steep and winding; many of the houses are entered by wooden staircases. Area of urban district 2.6 sq.mi.

The harbourage was probably the original cause of settlement. At the time of the Domesday Survey East Looe was assessed under Pendrym, which was of the king's demesne and West Looe under Hamelin's manor of Trelowia. In the 14th century the former manor was held by the family of Bodrugan; the latter by that of Dauney. In 1237 Henry Bodrugan received the grant of a market on Fridays and a fair at Michaelmas in his manor of Pendrym. In 1301 East Looe was granted a market and fair, and other privileges. Otto Bodrugan in 1320 granted the burgesses the privilege of electing their own portreeve and controlling the trade of the town. A charter of incorporation was granted in 1587 under which the common council was to consist of a mayor and 8 chief burgesses. There was to be a court of record, a market on Saturdays and fairs at Michaelmas and Candlemas. In 1685 James II provided that there should be a mayor and 11 aldermen, 36 free burgesses, 4 fairs and a court of pie powder. East Looe was governed under this charter until 1885. West Looe (known also as Porpighan or Porbuan), was constituted a free borough by a charter ratified in 1325. There were to be a market on Wednesdays and a fair at Michaelmas. Upon the attainder of the earl of Devon in 1539 the borough fell to the crown and was annexed to the duchy. In 1574 a charter of incorporation was granted providing for a mayor and 11 burgesses, also for a market on Wednesdays and two fairs. West Looe continued to be administered under this charter until 1869. Looe was second only to Fowey as a port in the 15th century. It furnished 20 ships for the siege of Calais. Of the markets and fairs only the markets on Wednesdays and Saturdays and a fair on May 6 remain.

The parish church of St. Martin, 1 mi. outside the town, has a Norman doorway and font. The ancient chapel of St. Nicholas in West Looe was restored in 1862; in the old town hall is preserved the ancient pillory. A considerable export trade in copper, tin and granite was formerly carried on; grain, granite, fish and clay are now exported; while timber, coal, limestone and manure are imported. There are also thriving fisheries, the Looe fishermen being particularly expert with the seine on a rocky bottom.

LOOFAH: *see* LUFFA.

LOOM. A machine for weaving fabrics by intersecting the longitudinal threads, the "warp," *i.e.,* "that which is thrown across," with the transverse threads, the "weft," *i.e.,* "that which is woven." (*See* WEAVING.)

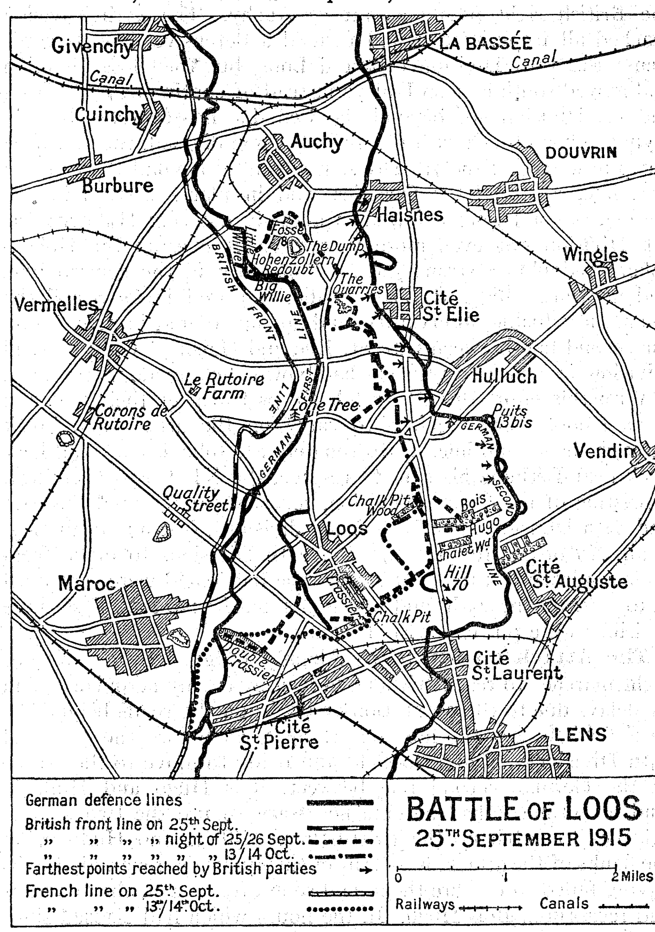
LOON, largest municipality in rank of population of the island and province of Bohol, Philippine Islands, on the extreme west coast. Pop. (1939) 28,799. It is picturesquely situated on the west slope of a hill and is reached from the sea by steps cut in the rocks. The harbour is in a sheltered bay on the north side of the place. Agriculture and livestock raising are the principal industries. The chief products are coconuts, maguey, tobacco, cotton and maize (corn). Cebuano, a dialect of Bisayan, is the principal vernacular. Of the inhabitants aged 6 to 19 inclusive, 26.3% in 1939 attended school; of the population aged 10 years and over, 34.4% was literate.

LOON, any of several primitive, large, fish-eating diving birds constituting the genus *Gavia* and order Gaviiformes, inhabiting circumpolar northern regions. The common loon or great northern diver (*G. immer*), 32 in., occurs from Arctic coasts to northern United States, has an iridescent black head, white-spotted black back and wings and white under parts; the lesser loon (*G. i. elasson*) occurs in the Dakotas and perhaps nearby regions. The smaller European black-throated diver (*G. arctica*) occurs in northern Europe and Scotland, with *G. a. suschkini* in western Siberia, the green-throated loon (*G. a. viridigularis*) on the coast of northeastern Siberia and western Alaska, and the Pacific loon (*G. a. pacifica*) from Point Barrow and the Alaska peninsula east to Southampton Island. The red-throated loon (*G. stellata*) ranges from Arctic coasts to Sweden, northern Russia, Kamchatka, the Aleutians and southern Canada. The yellow-billed loon (*G. adamsii*) is found on Arctic coasts from eastern Siberia to the Mackenzie Delta of northern Canada. The loon dives at the flash of a gun, swims long distances under water, has gooselike flight and is nearly helpless on land because the short powerful legs are so far back at rear end of body. The smooth head and slender, dagger bill distinguish it from near-related water birds. Two mottled olive eggs are laid on a mass of soggy vegetation. (*See* DIVER.) (G. F. Ss.)

LOOS, THE BATTLE OF (Sept. 25–Oct. 19, 1915), is the name given to the actions fought by the British in the great Allied offensive in France in the autumn of 1915.

The French Plan.—The plan elaborated by Gen. Joffre was to attack on both sides the great salient formed by the German front in France: on the right in Champagne with the French II. and IV. Armies, the main effort; and on the left in Artois with the X. Army. He hoped by these two operations to cut off the enemy troops in the salient and get astride their communications. He asked that the British should co-operate by attacking in Artois on the left of the X. Army. This army was commanded by Gen. D'Urbal and in the group of armies under Gen. Foch. Field-Marshal Sir John French was opposed to committing his troops to battle until the spring following, by which time further reinforcements and more guns and ammunition would have arrived. The B.E.F. had suffered very heavy losses at Neuve Chapelle, Second Ypres, Aubers and Festubert earlier in the year; had recently taken over a considerable portion of the French front with the newly-formed III. Army; the Territorial and New Army divisions recently sent to France required more training; and the force possessed very few heavy guns and was woefully short of ammunition and equipment for trench warfare.

In view of the German successes in Russia and the necessity for assisting France to the utmost, the British Government felt compelled to abandon the natural policy of waiting until such time as sufficient munitions could be prepared and the newly raised forces were ready before taking the offensive. Sir John French was therefore given definite orders to co-operate with the French. The I. Army under Gen. Sir. D. Haig, was selected to carry out the attack. Both Sir John French and Gen. Haig were opposed to attacking in the area between Lens and the La Bassée canal, as Gen. Foch required; for it involved advancing



over very unfavourable ground, open, but dotted with coal mines and mining villages: whilst Lens and its suburbs formed one vast industrial town. They suggested an objective further north. This proposal was overruled.

The Employment of Gas.—Whilst the British leaders were doing their best, against their better judgment, to prepare the offensive at a spot not of their own selection and with totally inadequate artillery, the first consignment of chlorine gas arrived, for trial. Its use seemed to promise a chance of surprise and provide a solution of the problem of attack with inadequate means. A sufficient supply of gas was manufactured and preparations were made to employ it. After four days' bombardment, during the later part of which the weather was unsuitable for flying and observation, on Sept. 25 the offensive was begun simultaneously in Champagne (30 French divisions) and Artois (17 French and nine—later 12—British divisions), whilst diversions were made at other parts of the line: by the British near Givenchy, Neuve Chapelle and Hooge; by the Belgians near Nieuport; and by the navy on the coast. On the British front gas and smoke were discharged for 40min. preceding the assault, which took place at 6:30 A.M. The French X. Army did not leave its trenches until 12:45 P.M. and even then the Allied contingents in Artois were not shoulder to shoulder, for between them opposite Lens was left a passive front of 3m. held by a French Territorial division.

The Assault on Sept. 25.—The British assault was made by the 47th (2nd London Territorial), 15th (Scottish, of the New Army), and 1st Divisions of the IV. Corps (Rawlinson), and the 7th, 9th (Scottish, of the New Army) and 2nd Divisions of the I. Corps (Gough). Although the wind was very feeble, and on the front of the 2nd Division unfavourable so that the gas and smoke blew back, considerable success was obtained by the British. The German defences comprised two separate positions (*see* sketch) disposed on the great rolling plain in which the spurs of the Artois plateau sink down. In spite of insufficient bombardment, the German front line position was overrun from the British right nearly as far as Auchy. The 47th Division reached all its objectives and formed a defensive flank towards Lens; the 15th Division captured Loos, but then lost direction and moved south-east on Hill 70 instead of continuing eastwards; the 1st Division got beyond the Lens-La Bassée road, but, in trying to keep touch with the 15th, became divided, thus creating a gap in its front; the 7th Division advanced beyond the German first line, captured the Quarries, and in places arrived at the German second line, a few men actually entering Hulluch; the 9th Division was even more successful: it overran the Hohenzollern redoubt, a strong independent work in the general line, and its wings, Big and Little Willie, captured Fosse 8 and the Dump, a valuable observatory, and got up to, and in places into, the second line between Cité St. Elie and Haisnes. Only the 2nd Division, in whose area the gas had blown back, made no progress.

With this effort the IV. and I. Corps had shot their bolt and fresh troops were required to carry on the attack and break through the second line. Unfortunately Sir John French had kept back near Béthune his general reserve, the XI. Corps (Haking), consisting of the Guards Division, recently formed, and the 21st and 24th Divisions, two New Army divisions, just out from England. No orders for the 21st and 24th Divisions to move from their rendezvous 5 to 8 miles from the battlefield were sent until 9:30 A.M. on the 25th, and it was not until 1:20 P.M. that these divisions were put under Sir D. Haig.

The Attack on Sept. 26.—Already fatigued by a series of night marches to reach Béthune unseen by enemy aeroplanes, and by delays due to the congestion of traffic on the roads behind the battlefield, it was the morning of Sept. 26 before the 21st and 24th Divisions were on the field and ready to move to the attack of the German second line between Bois Hugo and Hulluch. And meantime it had become necessary to use the two leading brigades to patch up the British line. Hill 70 and Hulluch, on the flanks of the attack, were still in enemy hands, renewed attacks having failed to capture them, and soon after 9 A.M. the Germans had recaptured Bois Hugo. In the hours which had elapsed since the original attack, they had recovered from their surprise, brought up reinforcements and strengthened their second line. During the night of the 25th–26th and early morning of the 26th they made counter-attacks on both flanks of the line gained by the British in the first advance and recovered part of the lost ground.

The attack of the four remaining brigades of the two divisions at 11 A.M. against the intact second line was a failure, though some units actually reached the wire entanglement in front of it. Eventually the men, new to war, having done all that was possible, began to stream back. The Guards Division was brought up to fill the gap in the line that their retirement caused, and the 3rd Cavalry Division to stiffen the defence near Loos village. The French X. Army, having no gas, had less success than the British; but its persistent attacks, against the crest of Vimy Ridge by Gen. Foch's orders, caused the Germans to divert the Guard Corps from the British to the French front.

After Sept. 26 the fighting became desultory and degenerated into trench warfare, and on the 30th the French offensives, both in Champagne (where also no success had been achieved) and Artois, were formally stopped in order to prepare for another combined effort. Delays brought about by bad weather, enemy interference with the preparations and enemy counter-attacks, led to postponement after postponement.

The Last Phase.—Finally a renewed French attack in Champagne was made on Nov. 6, a French attack in Artois on Nov. 11, and a British (fresh divisions, the 12th, 28th and 46th having arrived) on the 13th, with no result but heavy casualties. Trench fighting, particularly round the Hohenzollern Redoubt, went on for several days longer, and then both sides settled down to winter conditions. The fighting of the year had but proved that, with the guns and munitions then available, the defence was still stronger than the attack. The British losses in the battle of Loos included three divisional commanders killed (Maj.-Gen. Sir T. Capper, G. H. Thesiger and F. D. V. Wing) and 2,407 officers and 57,985 other ranks killed, wounded and missing, and were probably three times as heavy as those of the enemy.

See *History of the Great War Based on Official Documents,* "Military Operations France and Belgium, 1915," vol. ii. (1928, where there is a bibl.); *Les Armées Françaises dans la Grande Guerre,* tome iii. (1922); M. Schwarte, *Ed., Der grosse Krieg, 1914–1918,* vol. ii. (1921–25). (J. E. E.)

LOOSESTRIFE, the common name of any plant of the genus *Lysimachia* of the family Primulaceae. The Eurasian *L. vulgaris,* an erect plant, 2 to 4 ft. high, is common on river banks in England; the branched stem bears tapering leaves in pairs or whorls, and terminal panicles of rather large deep yellow flowers. *L. nemorum,* yellow pimpernel or wood loosestrife, a low-growing plant with slender spreading stem and yellow flowers standing singly in the leaf-axils, is frequent in England. *L. Nummularia* is the well known creeping jenny or moneywort, a larger plant with widely creeping stem, pairs of shining leaves and large solitary yellow flowers; it is found on banks of rivers and damp woods, and is a common rockery plant. Purple loosestrife, *Lythrum Salicaria,* belongs to a different family, Lythraceae. It is a handsome plant growing 2 to 6 ft. high on river banks and ditches with a branched stem bearing whorls of narrow pointed stalkless leaves and ending in tall tapering spikes of beautiful rose-purple flowers. The flowers are trimorphic, that is to say, exist in three forms which differ in the relative length of the styles and stamens and are known as long-styled, mid-styled and short-styled forms respectively; the size and colour of the pollen also differ. These differences are important in the pollination of the flower, making self-fertilization next to impossible. (*See* POLLINATION.)

LOPE DE VEGA: *see* VEGA CARPIO, LOPE FELIX DE.

LOPES, FERNAO (1380?–1460?) (FERNAM LOPEZ), the patriarch of Portuguese historians, was appointed keeper of the royal archives, then housed in the castle of St. George in Lisbon, by King John I. in Nov. 1418. He acted as private secretary to the Infantes D. Duarte and D. Fernando, and when the former ascended the throne he charged Lopes, by a letter of March 19, 1434, with the work of "putting into chronicles the stories of the kings of old time as well as the great and lofty actions of the most virtuous king my lord and father" (John I.). King Alphonso V. confirmed him in his post by a letter of June 3, 1449, and in 1454, after 36 years' service in the archives and 20 as chronicler he resigned in favour of Gomes Eannes de Zurara. The modern historian Herculano says, "there is not only history in the chronicles of Fernão Lopes, there is poetry and drama as well; there is the middle age with its faith, its enthusiasm, its love of glory." Lopes has been called the Portuguese Froissart, and that rare gift, the power of making their subjects live, is common to the two writers; indeed, had the former written in a better-known language, there can be little doubt that the general opinion of critics would have confirmed that of Robert Southey, who called Lopes "beyond all comparison the best chronicler of any age or nation." He had an excellent subject and his scenes are full of dramatic detail. He is a picturesque chronicler and he is a national historian. Lopes composed a general chronicle of the kingdom, which almost certainly served as a foundation for the chronicles of Ruy de Pina. Lopes prepared himself for his work with care and diligence by a study of the archives belonging to municipalities, monasteries and churches, both in Portugal and Spain. He is usually a trustworthy guide in facts and charms the reader by the naïve simplicity of his style.

BIBLIOGRAPHY.—Extant works of Lopes are: *Chronica de D. João I.* (1644; part 1, ed. Braamcamp Freire, 1915); *Chronica de D. Pedro I.*, in vol. iv. of the *Collecção de Livros Ineditos da Historia Portugueza* (1816); *Chronica de D. Fernando,* published in the same volume.

LÓPEZ, CARLOS ANTONIO (1790–1862), ruler of Paraguay, was born at Asunción on Nov. 4, 1790, and was educated in the ecclesiastical seminary of that city. He attracted the hostility of the dictator, Francia, and was forced to keep in hiding for several years. He acquired, however, so unusual a knowledge of law and governmental affairs that, on Francia's death in 1840, he obtained an almost undisputed control of the Paraguayan State, which he maintained uninterruptedly until his death on Sept. 10, 1862. He was successively secretary of the ruling military *junta* (1840–41), one of the two consuls (1841–44) and president with dictatorial powers (1844–62) by successive elections for ten and three years, and in 1857 again for ten years, with power to nominate his own successor. Though nominally a president acting under a republican Constitution, he ruled despotically. His government was in general directed with wise energy towards developing the material resources and strengthening the military power of the country. His jealousy of foreign approach several times involved him in diplomatic disputes with Brazil, England and the United States, which nearly resulted in war, but each time he succeeded in extricating himself by skilful evasions.

LÓPEZ, FRANCISCO SOLANO (1827–1870), dictator of Paraguay, eldest son of Carlos Antonio López, was born near Asunción on July 24, 1827. With very little education he was made commander-in-chief of the Paraguayan army in his 18th year. In 1854 he was sent as Paraguayan minister to Europe, where he spent nearly two years, imbibed much of the militaristic spirit which marked his career, and placed orders for munitions and supplies. On his father's death in 1862 he assumed the government as vice-president and called a congress on Oct. 16 which elected him president, virtually dictator, for ten years. In 1864 he demanded that Brazil abandon her armed interference in a revolution in Uruguay. No attention being paid to his demand, he seized a Brazilian merchant steamer in the harbour of Asunción, and threw into prison the Brazilian governor of the province of Matto Grosso who was on board. In the following month (Dec. 1864) he sent a force to invade Matto Grosso. He next sought to send an army to the relief of the Uruguayan Government against the revolutionary aspirant Flores, who was supported by Brazilian troops. The refusal of the Argentine president, Mitre, to allow this force to cross the intervening province of Corrientes, was seized upon by López as an occasion for war with the Argentine Republic. A congress bestowed upon López the title of marshal, with extraordinary war powers, and on April 13, 1865, he declared war on Argentina and summarily announced the annexation of the provinces of Corrientes and Entre Ríos. Flores, meantime, had been successful in Uruguay, and now Brazil and Uruguay joined Argentina in declaring war on Paraguay on May 1, 1865. The war, known as the War of the Triple Alliance, which lasted until April 1, 1870, was carried on with a swelling tide of disasters to López. (*See* PARAGUAY.) In 1868, conceiving that a conspiracy had been formed against his life in Asunción, he ordered several hundred of the leading citizens to be seized and executed. He suffered defeat after defeat until he was at last driven with a mere handful of troops to the northern frontier of Paraguay where he was killed on April 1, 1870, at the Aquidaban river. López's attempt to make himself arbiter of the La Plata region so nearly destroyed Paraguay that the country has not yet recovered from the shock.

Washburn, *History of Paraguay* (Boston, 1871); Cecilio Báez, "La guerra y la tiranía de López," *Revista Chilena,* vol. xvi. (1923); A. Rebaudi, *Un tirano de Sudamerica* (Buenos Aires, 1925); A. Zinny, *Historia de governantes del Paraguay, 1535–1887* (Buenos Aires, 1887). (W. B. P.)

LÓPEZ DE AYALA, DON PEDRO, (1332–1407), Spanish statesman, historian and poet, was born at Vittoria in 1332. He first came into prominence at the court of Pedro the Cruel, whose cause he finally deserted; he greatly distinguished himself in subsequent campaigns, during which he was twice made prisoner, by the Black Prince at Nájera (1367) and by the Portuguese at Aljubarrota (1385). A favourite of Henry II. and John I. of Castile, he was made grand chancellor of the realm by Henry III. in 1398.

Ayala was one of the most cultivated Spaniards of his time, at once historian, translator and poet. Of his many works, the most important are his chronicles of the four kings of Castile during whose reigns he lived; they give a generally accurate account of scenes and events, most of which he had witnessed. In addition, he also wrote a long satirical and didactic poem, interesting as a picture of his personal experiences and of contemporary morality.

The first part of his chronicle, covering only the reign of Pedro the Cruel, was printed at Seville in 1495; the first complete edition was printed in 1779–80 in the collection of *Crónicas Españolas,* under the auspices of the Spanish Royal Academy of History. Ayala died at Calahorra in 1407.

BIBLIOGRAPHY.—*See* Rafael Floranes, "Vida literaria de Pedro López de Ayala," in the *Documentos inéditos para la historia de España,* vol. xix. and xx.; F. W. Schirrmacher, "Über die Glaubwürdigkeit der Chronik Ayalas," in *Geschichte von Spanien* (Berlin, 1902), vol. v. pp. 510–32.

LÓPEZ DE GÓMARA, FRANCISCO (1511–1557), Spanish historian, author of the *Primera y Segunda Parte de la historia general de las Indias* . . . (1552), a panegyric of Cortés written in a pleasing style by a literary artist.

He was educated at the university of Alcalá, where he took orders. Soon after 1540 he entered the household of the famous Cortés who supplied him with most of the material for his *Historia* and also with information which the historian used in his *Crónica de la conquista da Nueva España.* While the novel matter and the attractive style enchanted the Spanish public, the unmeasured laudations of Cortés at the expense of his lieutenants and companions brought about a violent reaction and both works were forbidden on Nov. 17, 1553.

LOPHIODONTIDAE, a family of extinct mammals allied to the tapirs and rhinoceroses (*qq.v.*). They lived in Europe during the Eocene epoch. (*See* PERISSODACTYLA.)

LOP-NOR or **LOB-NOR,** a lake of Central Asia, in the Gobi Desert, between the Astin-tagh (Altyn-tagh) on the south and the Kuruk-tagh on the north. Previous to 1876 it was placed in nearly all maps at 42° 30′ N., a position which agreed with the accounts and the maps of ancient Chinese geographers. In the year mentioned the Russian explorer Przhevalsky discovered two closely connected lake-basins, Kara-buran and Kara-koshun, fully one degree farther south, and considerably east of the site of the old Lop-nor, which lake-basins he nevertheless regarded as being identical with the old Lop-nor of the Chinese. But the water they contained he pronounced to be fresh water. This identification was disputed by von Richthofen, on the ground that the Lop-nor, the "Salt Lake" of the Chinese geographers, could not be filled with fresh water; moreover, being the final gathering basin of the desert stream, the Tarim, it was bound to be salt, more especially as the lake had no outflow. Przhevalsky visited the Lop-nor region again in 1885, and adhered to his opinion. But ten years later it was explored anew by Dr. Sven Hedin, who ascertained that the Tarim empties part of its waters into another lake, or rather string of lakes (Avullu-köl, Kara-köl, Tayek-köl and Arka-köl), which *are* situated in 42° 30′ N., and thus so far justified the views of von Richthofen, and confirmed the Chinese accounts. At the same time he advanced reasons for believing that Przhevalsky's lake-basins, the southern Lop-nor, are of quite recent origin—indeed, he fixed upon 1720 as the probably approximate date of their formation, a date which von Richthofen would alter to 1750. Besides this, Sven Hedin argued that there exists a close inter-relation between the northern Lop-nor lakes and the southern Lop-nor lakes, so that as the water in the one group increases, it decreases to the same proportion and volume in the other. He also argued that the four lakes of northern Lop-nor are slowly moving westwards under the incessant impetus of wind and sandstorm (*buran*). These conclusions were afterwards controverted by the Russian traveller, P. K. Kozlov, who visited the Lop-nor region in 1893–1894—that is, before Dr. Sven Hedin's examination. He practically only reiterated Przhevalsky's contention, that the ancient Chinese maps were erroneously drawn, and that the Kara-koshun, in spite of the freshness of its water, was the old Lop-nor, *the* Salt Lake *par excellence* of the Chinese. Finally, Sven Hedin, following up the course of the Kum-darya, discovered—at the foot of the Kuruk-tagh, and at the E. (lowest) extremity of the now desiccated Kuruk-darya, with traces of dead forest and other vegetation beside it and beside the river bed—the basin of a desiccated salt lake, which he holds to be the true ancient Lop-nor of the Chinese geographers, and at the same time he found that the Kara-koshun or Lop-nor of Przhevalsky had extended towards the north, but shrunk on the south. Thus the old Lop-nor no longer exists, but in place of it there are a number of much smaller lakes of newer formation. It may fairly be inferred that, owing to the uniform level of the region, the sluggish flow of the Tarim, its unceasing tendency to divide and reunite, conjoined with the violence and persistency of the winds (mostly from the east and northeast), and the rapid and dense growth of the reed-beds in the shallow marshes, the drainage waters of the Tarim basin gather now in greater volume in one depression, and now in another. This view derives support from the extreme shallowness of the lakes.

See Delmar Morgan's translation of Przhevalsky's *From Kuja across the Tian-shan to Lop-nor* (London, 1879); Von Richthofen's "Bemerkungen zu den Ergebnissen von Oberst-Leutenant Prjewalskis Reise nach dem Lop-nor" in *Verhandl. der Gesch. f. Erdkunde zu Berlin* (1878), pp. 121 *seq.*; Sven Hedin's *Scientific Results of a Journey in Central Asia, 1899–1902* (vols. i and ii, Stockholm, 1905–06), where Kozlov's share of the controversy is summarized. (*Cf.* ii, 270–280.)

LOQUAT, JAPANESE PLUM or Japanese Medlar, known botanically as *Eriobotrya japonica*, small evergreen tree belonging to the family Rosaceae, with large, thick, oval-oblong leaves borne near the ends of the branches, and dark green above with a felt of rusty hairs on the lower face. The fruit is pear-shaped, yellow, about 1½ in. long and contains large stony seeds; it has an agreeable acid flavour. The plant is a native of China and Japan, but is widely grown for its fruit and as a decorative plant. It is a familiar object in the Mediterranean region, in the southern and Pacific coast states of the U.S.A., as well as many parts of South America. It in no way resembles the European medlar (*Mespilus germanica*). (*See* Medlar.)

LORAIN, a city of Lorain county, Ohio, U.S.A., on Lake Erie, at the mouth of the Black river, 28 mi. W. by S. of Cleveland. It is served by the Baltimore and Ohio, the Lake Terminal, the Lorain and West Virginia and the Nickel Plate railways and by interurban bus lines and lake freighters. The population was 44,512 in 1930, and 44,125 in 1940, 18% foreign-born white, by federal census. It is a port of entry and has a fine harbour. The commerce of the port averages close to 5,000,000 tons (largely incoming iron ore and shipments of coal received by rail) valued at $25,000,000. There is a limited fishing industry. The city has steel works employing 9,000 men, shipbuilding yards employing 900, railroad shops and other important manufacturing industries with an aggregate pay roll of over $25,000,000 a year. Bank clearings in 1940 were $11,716,383 and the assessed valuation of property in 1940 was $74,000,000. A Moravian mission was established here in 1787–88, and a trading post in 1807, but permanent settlement began several years later. In 1836 the village was incorporated as Charleston; in 1874 the present name was adopted; and in 1896 Lorain became a city.

LORALAI, a town and district of Baluchistan, in India. The town, which is situated 4,700 ft. above the sea, 35 mi. by road from the railway station of Harnai, was occupied as a military station in 1886 and still serves as a military cantonment. Pop. (1941) 3,419. The District of Loralai was formed in 1903. It consists of a series of long, narrow valleys, hemmed in by rugged mountains, and bordered E. by Dera Ghazi Khan district of the Punjab. Area 7,375 sq.mi.; pop. (1941) 83,685, of whom the majority are Afghans. The principal crops are wheat and millet; but the chief wealth of the inhabitants is derived from their herds of cattle, sheep and goats.

LORANTHACEAE, the mistletoe family, containing 36 genera and 600 species. All the members of this dicotyledonous family are parasitic plants with green leaves. The only British species is *Viscum album*, the mistletoe (*q.v.*). In the United States the family is represented by about six species of *Phoradendron* (American mistletoe) and some eight species of *Arceuthobium* (pine mistletoe). For a treatment of the genera *see* A. Engler and K. Krause, "Loranthaceae," *Die Natürlichen Pflanzenfamilien*, ed. 2, 16b: 98-203, fig. 48-102. (1935).

LORCA, a town of eastern Spain, in the province of Murcia, on the right bank of the river Sangonera and on the Murcia-Baza railway. Pop. (1940) 24,491 (mun., 69,639). It occupies a height crowned by a mediaeval fortress, among the foothills of the Sierra del Caño.

Lorca is the Roman *Eliocroca* (perhaps also the *Ilorci* of Pliny, *N.H.* iii 3) and the Moorish *Lurka*. It was the key of Murcia during the Moorish wars and was frequently taken and retaken. In 1802, by the bursting of the reservoir known as the Pantano de Puentes, the district adjoining the river, the Barrio de San Cristobal, was completely ruined. In 1810 Lorca suffered greatly from the French invasion. In 1886 the Pantano, which was one of the largest European reservoirs, being formed by a dam 800 ft. long and 160 ft. high, was rebuilt. There is an important trade in agricultural products and livestock, as well as manufactures of woollen stuffs, leather, chemicals and porcelain.

LORCH, a town in the Prussian province of Hesse-Nassau, Germany, on the right bank of the Rhine, 8 mi. below Rüdesheim by the railway Frankfort-on-Main-Wiesbaden-Cologne. Pop. (1933) 2,620. It has a Gothic church—St. Martin's—dating from the 14th century. The slopes of the hills descending to the Rhine are covered with vineyards, which produce excellent wine. In the neighbourhood is the ruined castle of Nollich.

LORCH, a town in the *Land* of Württemberg, Germany, on the Rems, 26 mi. E. of Stuttgart. Pop. (1933) 3,421. It possesses a 12th century Protestant church containing several tombs of the Hohenstaufen family. It manufactures cement, cardboard and furniture. On the Marienberg lying above the town stands the former Benedictine monastery of Lorch, founded about 1108 by Frederick of Hohenstaufen, and in 1563 converted into an Evangelical college, where Schiller passed a portion of his school days. The Roman *limes* began at Lorch and Roman remains have been found in the neighbourhood of the town.

LORD, in its primary sense, the head of a household, the master of those dependent on him for their daily bread; the word frequently occurs in this sense in the Bible, *cf.* Matt. xxiv, 45. As a term implying the ownership of property, "lord" survives in "lord of the manor" and "landlord." The chief applications are due to its use as the equivalent of Lat. *dominus*, Gr. κύριος and Fr. *seigneur;* thus in the Old Testament it represents *Yahweh*, Jehovah, and, in the New Testament κύριος as a title of Jesus Christ. It is not only a general word for a prince or sovereign, but also the common word for a feudal superior, and particularly for a feudal tenant holding directly of the king, a baron (*q.v.*), hence a peer of the realm, a member of the House of Lords, constituted of the lords temporal and the lords spiritual; this is the chief modern usage. The prefix "lord" is ordinarily used as a less formal alternative to the full title, whether held by right or by courtesy, of marquess, earl or viscount, and is always so used in the case of a baron (which in English usage is generally confined to the holder of a foreign title). Where the name is territorial the "of" is dropped, thus the marquess of A., but Lord A. The younger sons of dukes and marquesses have, by courtesy, the title of Lord prefixed to the Christian and surname, *e.g.*, Lord John Russell. In the case of bishops, the full and formal title of address is the Lord Bishop of A., whether he be a spiritual peer or not. Many high officials of the British Government have the word "lord" prefixed to their titles. (*See* CABINET, THE.) In certain cases the members of a board which has taken the place of an office of State are known as lords commissioners or, shortly, lords of the office in question, *e.g.*, lords of the treasury, civil or naval lords of the admiralty.

For lord lieutenant and lord mayor *see* LIEUTENANT and MAYOR. As the proper form of address, "my lord" is used not only to those members of the nobility to whom the title "Lord" is applicable, and to bishops, but also to all judges of the High Court in England, and of the Scottish and Irish Superior Courts, and to lord mayors and lord provosts (*see* also FORMS OF ADDRESS.)

LORD ADVOCATE, or king's advocate, the principal law-officer of the Crown in Scotland. His business is to act as a public prosecutor, and to plead in all causes that concern the Crown. He is the head of the administration of criminal justice, and thus his functions are of a far more extensive character than those of the English law-officers. He is aided by a solicitor-general and advocates-depute. The office seems to have been established about the beginning of the 16th century. Originally he could only prosecute with the concurrence of a private party; but in the year 1597 he was empowered to do so at his own instance. He has the privilege of pleading in court with his hat on.

LORD CHAMBERLAIN, in England, an important officer of the king's household, to be distinguished from the lord great chamberlain (*q.v.*). He is the second dignitary of the court, and is always a member of the government of the day (before 1782 the office carried cabinet rank), a peer and a privy councillor. He carries a white staff, and wears a golden or jewelled key, typical of the key of the palace, which is supposed to be in his charge, as the ensigns of his office. He is responsible for the necessary arrangements connected with State ceremonies, such as coronations and royal marriages, christenings and funerals; he examines the claims of those who desire to be presented at court; all invitations are sent out in his name by command of the sovereign, and at drawing-rooms and levees he stands next to the sovereign and announces the persons who are approaching the throne. It is also part of his duty to conduct the sovereign to and from his carriage. At one time he discharged some important political functions. The bedchamber, privy chamber and presence chamber, the wardrobe, the housekeeper's room, the guardroom and the chapels royal are in the lord chamberlain's department. He is regarded as chief officer of the royal household, and he has charge of a large number of appointments, such as those of the royal physicians, tradesmen and private attendants of the sovereign. All theatres in the cities of London and Westminster (except patent theatres), in certain of the London boroughs and in the towns of Windsor and Brighton, are licensed by him and he is also licenser of plays (*see* THEATRES, LAW RELATING TO).

The vice-chamberlain of the household is the lord chamberlain's assistant and deputy. He also is one of the ministry, a white-staff officer and the bearer of a key; and he is generally a peer or the son of a peer as well as a privy councillor. Next to the vice-chamberlain comes the groom of the stole, an office only in use during the reign of a king. He has the charge of the vestment called the stole worn by the sovereign on State occasions. In the lord chamberlain's department also are the master, assistant master, marshal of the ceremonies and deputy-marshal of the ceremonies, officers whose special function it is to enforce the observance of the *etiquette* of the court. The reception of foreign potentates and ambassadors is under their particular care, and they assist in the ordering of all entertainments and festivities at the palace. The gentleman usher of the black rod—the black rod which he carries being the ensign of his office—is the principal usher of the court and kingdom. He is one of the original functionaries of the order of the Garter, and is in constant attendance on the House of Lords, from whom, either personally or by his deputy, the yeoman usher of the black rod, it is part of his duty to carry messages and summonses to the House of Commons. There are six lords and six grooms "in waiting" who attend on the sovereign throughout the year and whose terms of attendance are of a fortnight's or three weeks' duration at a time. Usually "extra" lords and grooms in waiting are nominated by the sovereign, who, however, are unpaid and have no regular duties. Among the serjeants-at-arms there are two to whom special duties are assigned: the one attending the speaker in the House of Commons, and the other attending the lord chancellor in the House of Lords, carrying their maces and executing their orders. The comptroller and examiner of accounts, the paymaster of the household, the licenser of plays, the dean and subdean of the chapels royal, the clerk and deputy clerks of the closet, the groom of the robes, the pages of the backstairs, of the chamber and of the presence, the poet laureate, the royal physicians and surgeons, chaplains, painters and sculptors, librarians and musicians, etc., are all under the superintendence of the lord chamberlain of the household.

The queen consort's household is also in the department of the lord chamberlain of the household. It comprises a lord chamberlain, a vice-chamberlain and treasurer, equerry and the various ladies of the royal household, a groom and a clerk of the robes. The ladies of the household are the mistress of the robes, the ladies of the bedchamber, the bedchamber women and the maids of honour. The mistress of the robes in some measure occupies the position of the groom of the stole. She is the only lady of the court who comes into office and goes out with the administration. She is always a duchess, and attends the queen consort at all State ceremonies and entertainments, but is never in permanent residence at the palace. Since the great "bedchamber question" of 1839 the settled practice has been for all the ladies of the court except the mistress of the robes to receive and continue in their appointments independently of the political connections of their husbands, fathers and brothers. The ladies of the bedchamber share the personal attendance on the queen consort throughout the year. Of these there are eight, always peeresses, and each is in waiting for a fortnight or three weeks at a time. But the women of the bedchamber, of whom there are also eight, appear only at court ceremonies and entertainments according to a roster annually issued under the authority of the lord chamberlain of the queen consort. They are usually the daughters of peers or the wives of the sons of peers. The eight maids of honour have the same terms of waiting as the ladies of the bedchamber. They are commonly if not always the daughters or granddaughters of peers.

LORD CHIEF JUSTICE OF ENGLAND is the head of the king's bench division of the high court of justice and next in rank to the lord chancellor. He is *ex officio* a member of the court of appeal, and is appointed by the Crown on nomination of the prime minister. This title was conferred upon him by the Judicature Act, 1873, by which the court of queen's bench became one of the divisions of the queen's bench division. It may be traced to that of the first minister of the Crown under the Norman and Angevin kings—*capitalis Angliae justiciarius* (*see* JUSTICIARIUS CAPITALIS ANGLIAE). He is now the only judicial officer entitled to wear the collar of SS, formerly worn by the chief justices of the three common law courts. His salary is £8,000 a year.

LORD GREAT CHAMBERLAIN, in England, a functionary who must be carefully distinguished from the lord chamberlain; he is one of the great officers of State, whose office dates from Norman times; and the only one who still holds it under a creation of that period. As his name implies, he was specially connected by his duties with the king's chamber (*camera curie*); but this phrase was also used to denote the king's privy purse, and the chamberlain may be considered as originally the financial officer of the household. But as he was always a great baron, deputies performed his financial work, and his functions became, as they are now, mainly ceremonial, though the emblem of his office is still a key. The office had been held by Robert Malet, son of a leading companion of the Conqueror, but he was forfeited by Henry I., who, in 1133, gave the great chamberlainship to Aubrey de Vere and his heirs, earls of Oxford, who, with some intermissions, held the office till 1779 when it passed to the coheiresses of Lord Willoughby d'Eresby. The office is now vested jointly in Lord Ancaster, Lord Cholmondeley and Lord Carrington and their heirs.

The lord great chamberlain has charge of the palace of Westminster, especially of the House of Lords, in which he has an office; and when the sovereign opens parliament in person he is responsible for the arrangements. At the opening or closing of the session of parliament by the sovereign in person he disposes of the sword of State to be carried by any peer he may select, and walks himself in the procession on the right of the sword of State, a little before it and next to the sovereign. He issues the tickets of admission on the same occasions. He assists at the introduction of all peers into the House of Lords on their creation, and at the homage of all bishops after their consecration. At coronations he emerges into special importance; he still asserts before the court of claims his archaic right to bring the king his "shirt, stockings and drawers" and to dress him on coronation day and to receive his ancient fees, which include the king's bed and "night robe." He also claims in error to serve the king with water before and after the banquet, which was the function of the "ewry," a distinct office held by the earls of Oxford. At the actual coronation ceremony he takes an active part in investing the king with the royal insignia.

See J. H. Round, "The Lord Great Chamberlain" (*Monthly Review*, June 1902) and "Notes on the Lord Great Chamberlain Case" (*Ancestor*, No. IV.). (J. H. R.)

LORD HIGH CHANCELLOR. The origin and early history of this official will be found under CHANCELLOR. The lord chancellor is not only head of the judiciary in England, but also a minister of State, taking precedence after the archbishop of Canterbury. The close connection of the chancellor and the chancery with all parts of the constitution accounts for the extraordinary range and variety of the chancellor's functions. They were summarized by Bentham as follows:—"He is (1) a single judge controlling in civil matters the several jurisdictions of the 12 great judges; (2) a necessary member of the cabinet, the chief and most constant adviser of the king in all matters of law; (3) the perpetual president of the highest of the two houses of legislature; (4) the absolute proprietor of a prodigious mass of ecclesiastical patronage; (5) the competitor of the minister for almost the whole patronage of the law; (6) the keeper of the great seal, a various, multifarious and indefinable office; (7) the possessor of a multitude of heterogeneous scraps of power too various to be enumerated." Nominated by the prime minister, he goes out of office with the party to which he is attached. As speaker or prolocutor of the House of Lords it is his principal function to put the question; he may take part in the debates, but cannot rule upon points of order. When the house sits for judicial business he is entitled to preside. He is a member of the court of appeal and when present presides. He is also president of the chancery division and a judge of the High Court of Justice. By the Act of Union (1705) one great seal was appointed to be kept for all public acts and so his authority extends to the whole of Britain, and the commissions of the peace for Scotland as well as for England issue from him. He is visitor of all hospitals and colleges of the king's foundation, patron of all the king's livings under the value of 20 marks—this was to enable him to reward the masters in chancery—guardian of all infants, idiots and lunatics, and superintendent of all charitable uses. Many of these functions are now committed to other departments or to the judges (*see* CHARITY; INFANT; INSANITY). His salary is £10,000 and his pension £5,000 per annum.

See Holdsworth, *Hist. Eng. Law* vol. i., ch. v.; Lord Campbell, *Lives of the Chancellors* (1845); J. B. Atlay, *The Victorian Chancellors* (1906). (H. H. L. B.)

LORD HIGH CONSTABLE, in England, the seventh of the great officers of State. His office is now called out of abeyance for coronations alone. The constable was originally the commander of the royal armies and the master of the horse. He was also, with the earl marshal, president of the court of chivalry. In feudal times martial law (*see* MILITARY LAW) was administered in the court of the constable and marshal. The constableship was granted by the empress Maud to Milo of Gloucester, and on the attainder of Edward Stafford, duke of Buckingham, in the reign of Henry VIII. it became merged in the Crown. The Lacys and Verduns were hereditary constables of Ireland from the 12th to the 14th century; and the Hays, earls of Erroll, have been hereditary constables of Scotland from early in the 14th century.

LORD HIGH STEWARD. The lord high steward of England, who must not be confused with the lord steward (*q.v.*), ranks as the first of the great officers of State. Appointments to this office are now made only for special occasions, such as the coronation of a sovereign or the trial of a peer by his peers. The history of the office is noteworthy. The household of the Norman and Angevin kings of England included certain domestics and officials styled dapifers, seneschals or stewards (the prototypes of the lord steward). At coronations, however, and great festivals it became the custom in England and elsewhere to appoint magnates of the first rank to discharge for the occasion these domestic functions. In accordance with this custom Henry II. appointed both Robert II., earl of Leicester, and Hugh Bigod, earl of Norfolk, to be his honorary hereditary stewards; and at the Christmas festival of 1186 the successors in title of these two earls are described as serving the king at the royal banqueting table. Subsequently the earls of Leicester bought out the rights of the earls of Norfolk for ten knights' fees.

The last of these earls of Leicester to inherit the hereditary stewardship was Simon V. de Montfort, upon whose death his forfeited estates were conferred on his son Edmund of Lancaster, who also obtained a grant of the stewardship, but only for life. Edmund was succeeded by Thomas, earl of Lancaster, who, upon his execution for treason, was succeeded in the earldom by his brother Henry. The subsequent earls and dukes of Lancaster were all recognized as stewards of England, the office apparently being treated as annexed to the earldom, or honour, of Leicester. Strictly speaking, none of the Lancasters after Thomas had any clear title either by grant or otherwise; such title as they had merged in the Crown when Henry IV. usurped the throne. Meanwhile the stewardship had increased in importance. On the accession of Edward III., Henry, earl of Lancaster, as president of the council, had superintended the coronation of the infant king; John of Gaunt did the same for the infant Richard II., and, as part of the duties involved, sat in the White Hall of Westminster to hear and determine the claims to perform coronation services. The claims were made by petition, and included, amongst others, the claim of Thomas of Woodstock to act as constable, the rival claims of John Dymock and Baldwin de Frevile to act as champion, and the claim of the barons of the cinque ports to carry a canopy over the king. Minutes of these proceedings, in which the duke is stated to have sat "as steward of England," were enrolled by his order. This is the origin of what is now called the court of claims. The precedent of Richard II. has been followed on all subsequent occasions, except that in modern times it has been the practice to appoint commissioners instead of a steward to superintend this court. In 1397 John of Gaunt created a notable precedent in support of the steward's claim to be supreme judge in parliament by presiding at the trial of the earl of Arundel and others.

When Henry IV. came to the throne he appointed his young son Thomas, afterwards duke of Clarence, to the office of steward. Clarence held the office until his death. He himself never acted as judge in parliament; but in 1415 he was appointed to preside at the judgment of peers delivered in Southampton against Richard, earl of Cambridge, and Lord Scrope of Masham, who had been previously tried by commissioners of oyer and terminer. No permanent steward was ever again created; but a steward was always appointed for coronations to perform the various ceremonial services associated with the office, and, until the court of claims was entrusted to commissioners, to preside over that court. Also, in the 15th century, it gradually became the custom to appoint a steward *pro hac vice* to preside at the trial, or at the proceedings upon the attainder, of a peer in parliament; and later, to preside over a court, called the court of the lord high steward, for the trial of peers when parliament was not sitting. To assist in establishing the latter court a precedent of 1400 appears to have been deliberately forged. This precedent is reported in the printed *Year-Book* of 1400, first published in 1553; it describes the trial of "the earl of H" for participation in the rebellion of that year, and gives details of procedure. John Holand, earl of Huntingdon, is undoubtedly the earl indicated, but the evidence is conclusive that he was murdered in Essex without any trial. The court of the lord high steward seems to have been first definitely instituted in 1499 for the trial of Edward Plantagenet, earl of Warwick; only two years earlier Lord Audley had been condemned by the court of chivalry, a very different and unpopular tribunal. The Warwick trial was most carefully schemed: the procedure, fundamentally dis-similar to that adopted in 1415, follows exactly the forged precedent; but the constitution of the court was plainly derived from the Southampton case. The record of the trial was consigned to a new repository (commonly but wrongly called the *Baga de Secretis*), which thenceforth became the regular place of custody for important state trials. Latterly, and possibly from its inception, this repository consisted of a closet with three locks, of which the keys were entrusted, one to the chief justice of England, another to the attorney-general and the third to the master of the Crown office, or coroner. Notwithstanding the irregular origin of the steward's court, for which Henry VII. must be held responsible, the validity of its jurisdiction cannot be questioned. The Warwick proceedings were confirmed by act of parliament, and ever since this court has been fully recognized as part of the English constitution.

For about a century and a half prior to the reign of James I. the criminal jurisdiction of parliament remained in abeyance, and bills of attainder were the vogue. The practice of appointing a steward on these occasions to execute judgment upon a peer was kept up till 1477—when George, duke of Clarence, was attainted—and then dropped. Under the Stuarts the criminal jurisdiction of parliament was again resorted to, and, when the proceedings against a peer were founded on indictment, the appointment of a steward followed as a matter of settled practice. The proper procedure in cases of impeachment had, on the contrary, never been defined. On the impeachment of Strafford the lords themselves appointed Arundel to be high steward. In Danby's case a commission under the great seal was issued in the common form adopted for the court of the steward; this was recalled, and the rule agreed to by a joint committee of both houses was that a steward for trials of peers upon impeachments was unnecessary. But, as such an office was obviously convenient, the lords petitioned for a steward; and a fresh commission was accordingly issued in an amended form, which recited the petition, and omitted words implying that the appointment was necessary. This precedent has been treated as settling the practice of parliament with regard to impeachments.

Of the proceedings against peers founded upon indictment very few trials antecedent to the revolution took place in parliament. The preference given to the steward's court was largely due to the practice, founded upon the Southampton case, of summoning only a few peers selected by the steward, a practice which made it easy for the king to secure a conviction. This arrangement has been partially abrogated by the Treason Act of William III., which in cases of treason and misprision of treason requires that all peers of parliament shall be summoned 20 days at least before every such trial. The steward's court also differed in certain other particulars from the high court of parliament. For example, it was ruled by Lord Chancellor Jeffreys, as steward at the trial of Lord Delamere, that, in trials of peers which take place during the recess of parliament in the steward's court, the steward is the judge of the court, the court is held before him, his warrant convenes the prisoner to the bar, his summons convenes the peers for the trial, and he is to determine by his sole authority all questions of law that arise in the course of the trial, but that he is to give no vote upon the issue of guilty or not guilty; during a session of parliament, on the contrary, all the peers are both triers and judges, and the steward is only the chairman of the court and gives his vote together with the other lords. Lord Delamere was tried in 1685 in the steward's court; since then all trials of peers have taken place before the lords in parliament. The most recent trial was that of Earl Russell in 1901, when Lord Chancellor Halsbury was made lord high steward. The steward is addressed as "his grace," he has a rod of office, and the commission appointing him is dissolved according to custom by breaking this rod.

A court of claims sat and a steward was appointed for the coronation of Edward VII.; and during the procession in Westminster Abbey the duke of Marlborough, as steward, carried "St. Edward's crown" in front of the bearer of the Bible (the bishop of London), who immediately preceded the king; this function of the steward is of modern origin. The steward's ancient and particular services at coronations are practically obsolete; the full ceremonies, processions from Westminster Hall and banquet in which he figured prominently were abandoned on the accession of William IV.

Bibliography.—For the early history of the steward *see* L. W. Vernon-Harcourt, *His Grace the Steward and Trial of Peers* (1907); for the later history of the office *see* Sir E. Coke, *Institutes* (1797); Cobbett and Howell, *State Trials* (1809, *seq.*); Sir M. Foster, *Crown Law* (1809); J. Hatsell, *Precedents of Proceedings in the House of Commons*, vol. iv. (1818); and S. M. Phillips, *State Trials* (1826). *See* also the various works on *Coronations* for the steward's services on these occasions. (L. W. V.-H.)

LORD HIGH TREASURER, in England, once the third great officer of state. The office was of Norman origin and dated from 1216. The duty of the treasurer originally was to act as keeper of the royal treasure at Winchester, while as officer of the exchequer he sat at Westminster to receive the accounts of the sheriffs, and appoint officers to collect the revenue. From the middle of the reign of Henry III. he became one of the chief officers of the Crown. He took an important part in the equitable jurisdiction of the exchequer, and was now styled lord high treasurer and treasurer of the exchequer. The first office was conferred by delivery of a white staff, the second by patent. On the death of Lord Salisbury in 1612 the office was put in commission; it was filled from time to time until 1714, when the duke of Shrewsbury resigned it; since that time it has always been in commission. (*See* Government Departments.) The Scottish treasury was merged with the English by the Act of Union, but the office of lord high treasurer for Ireland was continued until 1816.

LORD HOWE, an island of the southern Pacific ocean, lying about 31° 36′ S., 159° 5′ E., 436 mi. N.E. of Sydney. Pop. (1933) 161. It was discovered in 1788 and is a dependency of New South Wales. It measures about $5\frac{1}{2}$ mi. by 1 mi. (area, 5 sq.mi.), and is well wooded, reaching 2,840 ft. at the southern end. It is of volcanic formation, while there are coral reefs on the western shore. The palm seed industry is important. The name Lord Howe is given also to an islet of the Santa Cruz group, and to two islands, also known under other names—Mopiha, of the Society group, and Ongtong Java of the Solomon Islands.

LORD JUSTICE CLERK, in Scotland, the judge next in rank to the lord justice-general. He presides in civil cases in the second division of the court of session, and in the absence of the lord justice-general, presides in criminal cases in the court of justiciary. The justice clerk was originally not a judge at all, but simply clerk and legal assessor of the justice court. In course of time he was raised from the clerk's table to the bench, and by custom presided over the court in the absence of the justice-general. Up to 1672 his position was somewhat anomalous, as it was doubtful whether he was a clerk or a judge, but an act of that year, which suppressed the office of justice-depute, confirmed his position as a judge, forming him, with the justice-general and lords commissioners of justiciary, into the court of justiciary. The lord justice clerk is also one of the officers of State for Scotland, and one of the commissioners for keeping the Scottish regalia.

LORD JUSTICE-GENERAL, the highest judge in Scotland, head of the court of justiciary, called also the lord president, and as such head of the court of session and representative of the sovereign. The office of justice-general was for a considerable time a sinecure post held by one of the Scottish nobility, but by the Court of Session Act, 1830, it was enacted that, at the termination of the existing interest, the office should be united with that of lord president of the court of sessions, who then became presiding judge of the court of justiciary.

LORD KEEPER OF THE GREAT SEAL, in England, formerly a great officer of State. The great seal of England, which is affixed on all solemn occasions to documents expressing the pleasure of the sovereign, was first adopted by Edward the Confessor (*see* SEALS), and entrusted to a chancellor for keeping. The office of chancellor from the time of Becket onwards varied much in importance; the holder being an ecclesiastic, he was not only engaged in the business of his diocese, but sometimes was away from England. Consequently, it became not unusual to place the personal custody of the great seal in the hands of a keeper; this, too, was the practice followed during a temporary vacancy in the chancellorship. This office gradually developed into a permanent appointment, and the lord keeper acquired the right of discharging all the duties connected with the great seal. He was usually, though not necessarily, a peer, and held office during the king's pleasure; he was appointed merely by delivery of the seal, and not, like the chancellor, by patent. His status was definitely fixed (in the case of lord keeper Sir Nicholas Bacon) by an act of Elizabeth, which declared him entitled to the same powers and jurisdiction as the lord chancellor. Subsequently he was generally raised to the chancellorship, and retained the custody of the seal. The last lord keeper was Sir Robert Henley (afterwards Lord Northington), made chancellor on the accession of George III.

LORD MAYOR'S DAY, in England, Nov. 9, the date of the inauguration of the lord mayor of London, marked by a pageant known as the Lord Mayor's Show. The first of these pageants was held in 1215. The citizen chosen to be mayor was presented to the king or his justice for approval. The crowd of citizens who accompanied the mayor to Westminster developed into a yearly pageant. Until the 15th century the mayor either rode or walked to Westminster, but in 1453 Sir John Norman appears to have set a fashion of going by water. From 1639 to 1655 the show disappeared owing to Puritan opposition. With the Restoration the city pageant was revived. In 1711 an untoward accident befell the show, the mayor, Sir Gilbert Heathcote, being thrown by his horse. The next year a coach was provided for the chief magistrate. In 1757 this was superseded by a gilded and elaborately decorated equipage which was used till 1896, when a replica of it was built to replace it. The mediaeval procession, long traditional, has been succeeded by pageants illustrative of the empire, of seafaring and many other aspects of life.

LORD PRESIDENT OF THE COUNCIL, in England, one of the great officers of State, and a member of the ministry. It was only in 1679 that the office of lord president became permanent. Previously either the lord chancellor, the lord keeper of the seal, or some particular court official took formal direction of the Privy Council. In the reign of Charles I. a special lord president of the council was appointed, but in the following reign the office was left unfilled. The office was of considerable importance when the powers of the Privy Council, exercised through various committees, were of greater extent than at the present time. (*See* GOVERNMENT DEPARTMENTS.) The duties of the office are to preside on the infrequent meetings of the Privy Council, and to draw up the minutes of council upon subjects which do not belong to any other department of State. The office is very frequently held in conjunction with other ministerial offices. The lord president is appointed by a declaration made in council by the sovereign. He is invariably a member of the House of Lords, and is included in the cabinet.

LORD PRIVY SEAL, the officer in the British government who has custody of the Privy Seal. *See* SEALS.

LORDS JUSTICES OF APPEAL, in England, the ordinary judges of the court of appeal of the supreme court. Their number has been fixed at five and their salary is £5,000 a year. (*See* PRACTICE AND PROCEDURE.)

LORDS OF APPEAL IN ORDINARY, in England, certain persons (limited to seven), who, having held high judicial office or practised at the bar for not less than 15 years, sit as members of the House of Lords to adjudicate in cases before that house in its legal capacity, and also to aid the judicial committee of the Privy Council in hearing appeals. Of the six lords of appeal in ordinary one is usually appointed from the Irish bench or bar and one from Scotland. Their salary is £6,000 a year. They hold office on the same conditions as other judges, and take rank and sit and vote as barons during life. They are life peers only. The patent of a lord of appeal in ordinary differs from that of a baron in that he is not "created" but "nominated and appointed to be a lord of appeal in ordinary by the style of baron."

LORD STEWARD, in England, an important official of the king's household. He is always a member of the Government, a peer and a privy councillor. Up to 1782 the office was one of considerable political importance and carried cabinet rank. The lord steward receives his appointment from the sovereign in person, and bears a white staff. He is the first dignitary of the court. In the *Statutes of Eltham* he is called "the lord great master," but in the *Household Book* of Queen Elizabeth "the lord steward," as before and since. He presides at the Board of Green Cloth, a committee of the king's household, charged with the audit of its accounts. The board had also power to punish all offenders within the verge or jurisdiction of the palace. The name is derived from the green-covered table at which the transactions of the board were originally conducted. Under the lord steward are the treasurer and comptroller of the household, usually peers or the sons of peers and privy councillors, who sit at the Board of Green Cloth, carry white staves, and belong to the Ministry. But the duties which in theory belong to the lord steward, treasurer and comptroller of the household are in practice performed by the master of the household, who is a permanent officer and resides in the palace. He is a white-staff officer and a member of the Board of Green Cloth but not of the Ministry, and among other things he presides at the daily dinners of the suite in waiting on the sovereign. In his case history repeats itself. He is not named in the *Black Book* of Edward IV. or in the *Statutes* of Henry VIII., and is entered as "master of the household and clerk of the green cloth" in the *Household Book* of Queen Elizabeth. But he has superseded the lord steward of the household, as the lord steward of the household at one time superseded the lord high steward of England.

In the lord steward's department are the officials of the Board of Green Cloth, the coroner ("coroner of the verge"), and paymaster of the household, and the officers of the almonry. (*See* ALMONER.) The lord steward had formerly three courts besides the Board of Green Cloth under him. First, the lord steward's court, superseded (1541) by—second—the Marshalsea court, a court of record having jurisdiction, both civil and criminal, within the verge (the area within a radius of 12m. from where the sovereign is resident), and originally held for the purpose of administering justice between the domestic servants of the sovereign, "that they might not be drawn into other courts and their service lost." Its criminal jurisdiction had long fallen into disuse and its civil jurisdiction was abolished in 1849. Third, the palace court, created by letters patent in 1612 and renewed in 1665 with jurisdiction over all personal matters arising between parties within 12m. of Whitehall (the jurisdiction of the Marshalsea court, the City of London and Westminster Hall being excepted). It had no jurisdiction over the sovereign's household; nor were its suitors necessarily of the household. The privilege of practising before the palace court was limited to four counsel. It was abolished in 1849. The lord steward or his deputies formerly administered the oaths to the members of the House of Commons. In certain cases (messages from the sovereign under the sign-manual) "the lords with white staves" are the proper persons to bear communications between the sovereign and the houses of parliament.

Stephen, *Commentaries on the Laws of England* (18th ed., 1925); J. H. Hatsell, *Precedents of Proceedings in the House of Commons* (1818); T. E. May, *A Practical Treatise on the Law . . . and Usage of Parliament* (13th ed., 1921).

LORE, instruction, knowledge. The O.E. *lár,* and Ger. *Lehre,* represent the Old Teut. root, meaning to impart or receive knowledge, seen in "to learn." The word is frequently applied to the many traditional beliefs, stories, etc., connected with the body of knowledge concerning some special subject; *e.g.,* bird-lore, folklore (*q.v.*).

LOREBURN, ROBERT THRESHIE REID, 1ST EARL, cr. G.C.M.G. (1899) (1846–1923), British lawyer and politician, was born at Corfu on April 3, 1846, and was educated at Cheltenham and Balliol college, Oxford, where he won the Ireland scholarship in 1868. He was called to the bar in 1871, and in 1880 entered politics as Liberal M.P. for Hereford. In 1882 he became a Q.C. and, having in 1885 lost his seat at Hereford, represented Dumfries Burghs from 1886–1905. In 1894 he was for a few months solicitor-general and was knighted, and during 1894–95 was attorney-general. From 1899 to 1906 he was counsel to the University of Oxford. On the formation of Campbell-Bannerman's Government in 1905, Sir Robert Reid became lord chancellor, and was raised to the peerage as Baron Loreburn. The passage of the Court of Criminal Appeal Act (1907) was largely due to him. In 1912 he resigned on grounds of health. Lord Loreburn, who was created an earl in July 1911, published *Capture at Sea* (1913) and *How the War Came* (1919). He died without issue on Nov. 30, 1923, when the title became extinct.

LOREE, LEONOR FRESNEL (1858–1940), American railway president, son of William Mulford Loree, a millwright, was born in Fulton City, Ill., on April 23, 1858. After graduating at Rutgers college in 1877, he entered the service of the Pennsylvania railroad as a rodman. In 1879 he served in the U.S. army engineering corps and in 1881 as civil engineer for the Mexican National railway. Re-entering the employ of the Pennsylvania railroad in 1883, he served in engineering positions of increasing importance until 1889 when he was made a division superintendent, and in 1896 he rose to the position of general manager. In 1901 he was elected to a vice-presidency but resigned in the same year to become president of the Baltimore and Ohio railroad company, an office held until 1904 when he was chosen president of the Rock Island company. In 1907 he was elected president of the Delaware and Hudson company, a position in which he served for more than 30 years. He served also as a director of several other railways and in 1926 was made chairman of the board of the Missouri-Kansas-Texas railroad company. He invented the upper quadrant system of semaphore signalling, now standard on American railways; built the first high pressure locomotive; and made other improvements. In the effort to consolidate American railways into a limited number of systems in accordance with the policy formulated by Congress in 1920 he took an active and influential part. He also established the first organized railway police force. He wrote *Railroad Freight Transportation* (1922). (E. N. McG.)

LORELEI, a rock in the Rhine near St. Goar, which gives a remarkable echo (O.H.G. *Lur,* connected with modern Ger. *lauern,* "to lurk," "be on the watch for," and equivalent to elf, and *lai,* "a rock"). In the commonest form of the story the Lorelei is a maiden who threw herself into the Rhine in despair over a faithless lover, and became a siren whose voice lured fishermen to destruction. The tale is closely connected with the myth of Holda, queen of the elves. The man who sees her loses sight or reason, he who listens is condemned to wander with her for ever. In the 19th century the legend formed material for a number of songs, dramatic sketches, etc., enumerated by Dr. H. Seeliger in his *Loreleysage in Dichtung und Musik* (Leipzig-Reudnitz, 1898). The favourite poem with composers was Heine's beginning *Ich weiss nicht was soll es bedeuten,* the settings by Friedrich Silcher (from an old folk-song) and by Liszt being the most famous.

LORENTZ, HENDRIK ANTOON (1853–1928), Dutch physicist, was born at Arnheim on July 18, 1853. He studied at Leyden, where he was appointed professor of mathematical physics in 1878. In 1923 he became director of research at the Teyler institute, Haarlem. He remained honorary professor at Leyden, where he gave a weekly lecture on modern physics, which was usually reported for publication by one of the audience. He died at Haarlem on Feb. 4, 1928.

Lorentz's work in physics was very wide in its scope, but its central aim, it appears, was to arrive at some consistent theory for electricity, magnetism and light. He tried to explain these phenomena by assuming an ether which was at rest and had electrons either at rest or moving in it. A number of phenomena were successfully explained on this electron theory, but it failed to give an explanation of the negative result of the Michelson-Morley experiment. To overcome this difficulty Lorentz introduced the idea of "local time" in 1895. The connection between this and the Fitzgerald contraction was pointed out by Larmor, and in 1903 Lorentz extended his work and arrived at the "Lorentz transformation," which formed the basis of the restricted theory of relativity. Lorentz's earlier investigations were originally published in Dutch in the *Archives Néerlandaises* and consequently were not known to English physicists; Lord Rayleigh and Sir Oliver Lodge were largely responsible for the spread of his ideas in England. His first paper, published in 1875, dealt with the reflection and refraction of light by dielectrics and metals. In 1880 he published a memoir on the relation between the refractive index and the density of a medium. This was the first application of Maxwell's theory to a medium consisting of discrete molecules. Lorentz dealt with optical dispersion and tried to give an explanation on the assumption that it was due to resonant vibrations. This work was continued in his two well known memoirs, *La Théorie électromagnétique de Maxwell et son application aux corps mouvants* (1892) and *Versuch einer Theorie der electrischen und optischen Erscheinungen in bewegten Körpern* (1895). In the latter memoir he deals with the electrodynamic field of a system moving with uniform velocity. Lorentz gave an explanation of the Zeeman effect very soon after it was observed and predicted polarization effects which were verified later by experiment. He was also the author of a number of papers on gravitation theory, thermodynamics, radiation and kinetic theory.

Lorentz had a charming personality and kindly disposition. He spoke English, French and German fluently and he had the gift of clear exposition. He travelled and lectured extensively in Europe and America. He was a keen worker in the cause of international science and was chairman of the committee of intellectual co-operation set up by the League of Nations. Lorentz was an honorary or corresponding member of most scientific societies and received many medals and other honours. In 1902 he was awarded, with Zeeman, the Nobel prize for physics. The jubilee of his doctorate was celebrated by a *Festschrift* to which physicists of all countries contributed. The Lorentz Foundation was established to promote the advancement of theoretical physics.

BIBLIOGRAPHY.—Lorentz's works include *Abhandlungen über theoretische Physik* (vol. i., 1907); this contains some of his collected papers with comments and additions of previously unpublished work; *Theory of Electrons* (1909); *Differential and Integral Calculus* (1882); *Visible and Invisible Movements* (1901); *The Einstein Theory of Relativity* (1920); *Clerk Maxwell's Electromagnetic Theory* (1924). His lectures at Leyden university were published from 1919 onwards under his personal supervision with the title of *Lessons on Theoretical Physics.* (E. TR.)

LORENZ, ADOLF (1854–1946), Austrian surgeon, was born of poor parents at Vidnava, Silesia, on April 21, 1854. He studied at Vienna university where he afterward became a demonstrator and professor. He introduced the use of forcible manipulation for congenital dislocation of the hip joint and specialized on clubfoot and flatfoot. Important among his numerous publications are: *Die Lehre vom erebten Plattfusse* and *Über die operative Orthopädie des Klumpfusses.* He died in Vienna on Feb. 12, 1946.

LORENZAN, a small group of tribes of South American Indians, regarded, on very insufficient evidence, as constituting an independent linguistic stock. The Lorenzas live in Peru in the northern portion of the province of Junin, on the Palcazu, Piches and Chuchuras rivers (tributaries of the Pachitea). They are a timid people, going quite naked and are very little known.

See A. F. Chamberlain, "Sur quelques familles linguistiques . . . de l'Amérique du Sud," *J. Soc. Americanistes de Paris* (n.s.), vol. vii., pp. 178–202.

LORENZETTI, the name of two Italian painters of the first half of the 14th century. Their style combined the harmonious colour and expressive design of early Sienese masters with the naturalism of the Pisanos and of Giotto.

Ambrogio Lorenzetti (*c.* 1300–1348) was the younger and the more distinguished of the two brothers. Only five authentic works of his are in existence; they cover a period of 13 years. The frescoes representing scenes from the lives of St. Louis of Toulouse and of Franciscan martyrs, which he painted in 1331, in the chapter-house adjoining the church of San Francesco, are now in one of the choir chapels of that church. Ambrogio then worked in Florence and Cortona. Of an altarpiece, painted for the church of San Procato in Florence, four predella pieces with scenes from the life of St. Nicholas of Bari are in the Florence academy. From 1337–39 he was employed on the decoration of the Sala della Pace in the Palazzo Publico of Siena with four great allegorical pictures representing "Good Government," "Effects of Good Government," "Tyranny" and "Effects of Tyranny." The subject matter shows that the artist was a student of Aristotle's political philosophy, and bears out Vasari's statement that he was a philosopher and a man of distinction, who was interested in the government of his native town. The symbolical figures, especially those representing "Peace" and "Justice," are full of elegance and life, classical in conception. Here Sienese painting reached its climax. Among Ambrogio's later works are a "Presentation in the Temple," signed and dated 1342, painted for the Spedaletto of Mona Agnese and now in the Uffizi, Florence; and an "Annunciation" dated 1344 and also signed, in the Siena academy. As neither he nor his brother is mentioned after 1348 it is assumed that they died of the plague which that year devastated the city.

Pietro Lorenzetti (*c.* 1280–1348) elder brother of Ambrogio, called Pietro Laurati by Vasari, son of Lorenzo Laurati, was probably a pupil of Duccio. According to Vasari he worked in Florence, Pisa, Pistoia and Arezzo, as well as in his native town; he may have visited Assisi. The earliest work of which documentary evidence exists is the altarpiece of 1320 in S. Maria della Pieve at Arezzo. In 1328 he painted the Madonna for S. Ansano at Dofana outside Siena; and one year later the altarpiece for the church of the Carmine, of which the centrepiece is lost, and of which parts of the predella are in the Siena academy and in the Vatican gallery. We know from documentary evidence that in 1333 he painted a Madonna over one of the doors of the cathedral; and that two years later, in co-operation with his brother Ambrogio, he decorated the façade of the hospital of Santa Maria della Scala with scenes from the life of the Virgin. Unfortunately, both of these works have been destroyed. In 1340 he painted the "Madonna with Angels" for the church of San Francesco at Pistoia, which is in the Uffizi at Florence; in 1342 the "Nativity of the Virgin" in the Opera del Duomo, one of his most pleasant works. Both these pictures are signed. This closes the list of authenticated works.

The Siena gallery possesses a number of paintings which have been ascribed to the master on stylistic evidence. Among these the "Assumption" is the most important. To Pietro's early period is ascribed an altarpiece in the Academy of Florence representing St. Humility of Faenza, and scenes from her life. Two panels thereof are in the Berlin museum. This picture was painted for the convent at Vallombrosa in 1316. Moreover, Crowe and Cavalcaselle have attributed to him the frescoes of the Passion in the Lower church of San Francesco at Assisi and of the Crucifixion in San Francesco at Siena, a scene full of dramatic power. This attribution has been generally accepted; and on these works Pietro's fame as a great artist rests, for they are extremely fine and expressive paintings. The famous frescoes representing the "Triumph of Death," the "Last Judgment" and the "Hermits of the Thebaid," in the Campo Santo at Pisa, have also been ascribed to him by some authorities; they are sometimes given to a follower of the Lorenzetti.

Douglas, 1911); Langton-Douglas, *History of Siena* (1902); Raimond van Marle, *The Italian Schools of Painting,* ii. (1924). (I. A. R.)

LORENZO, MONACO, also called Don Lorenzo (*c.* 1370–*c.* 1425), Italian painter, was born at Siena. He took the vows of the Camaldolese order in 1391 and lived mostly at the monastery of Santa Maria degli Angeli, in Florence. His name as a layman was Piero di Giovanni del Popolo di San Michele de Bisdomini and a painter of that name was entered in the books of the guild of St. Luke at Florence in 1396. Lorenzo was in some respects an innovator in Florence, for he combined the rhythmic, graceful flow of line and decorative feeling of the Sienese school with the Florentine traditions of the followers of Giotto; in his later work he appears to be influenced by the realistic tendency of the Early Renaissance. The Uffizi in Florence contains a signed work by the master, "Coronation of the Virgin" with many figures, painted in 1413 for his convent, and later removed to a branch establishment near Certaldo. The National Gallery in London has another smaller version of the same subject; one of his most graceful altarpieces is the "Annunciation" in the Bartolini chapel in the church of S. Trinita at Florence. In the same chapel are late frescoes of the "Life of the Virgin," recently rescued from underneath a coat of whitewash. Another late work of the master is the "Adoration of the Magi" in the Uffizi. The master's feeling for decorative composition, his expressive line, and his originality come out well in his small predella pieces, as in the three small fragments at the Florence academy, representing the "Nativity," the "Life of a Hermit" and a stormy seascape, and in the two remarkable illuminations in the Berlin museums of the "Journey of the Three Kings" and the "Visitation."

LORETO, episcopal see and pilgrimage resort of the Marches, Italy, province of Ancona, 15 m. by rail S.S.E of Ancona. Pop. (1936) 3,310 (town), 7,081 (commune). It lies on the right bank of the Musone, on a hill-side commanding splendid views 341 ft. above sea-level. The town is a long narrow street, lined with shops for the sale of locally made cult-objects. The chief festival is held on Sept. 8, the Nativity of the Virgin. The principal buildings in the piazza are the college of the Jesuits, the Palazzo Apostolico (which contains a picture gallery with works of Lorenzo Lotto, Caracci, Magnasco, etc., a collection of majolica and a replica of the famous set of tapestries designed by Raphael for the Sistine chapel) and the cathedral church of the Holy House (Chiesa della Casa Santa), a Late Gothic structure begun under Paul II., and continued by Giuliano da Maiano, Giuliano da Sangallo Bramante and other architects who altered the original plan, which was revived in 1886 by Giuseppe Sacconi. The handsome façade of the church was completed under Sixtus V., who founded the episcopal see; his colossal statue stands in the middle of the flight of steps in front. Over the principal doorway is a life-size bronze statue of the Virgin and Child by Girolamo Lombardo; the three superb bronze doors executed at the latter end of the 16th century and under Paul V. (1605–1621) are also by Lombardo, his sons and his pupils, among them Tiburzio Vergelli, who also made the fine bronze font in the interior. The doors and hanging lamps of the Santa Casa are by the same artists. The richly decorated campanile, by Vanvitelli, is 250 ft. high. The principal bell, presented by Leo X, in 1516, weighs 11 tons. The interior of the church has mosaics by Domenichino and Guido Reni. In the sacristies on each side of the right transept are frescoes, on the right by Melozzo da Forlì, on the left by Luca Signorelli. In both are fine intarsias.

But the chief object of interest is the Holy House itself. It is of plain stone, 28 ft. by 12½ and 13½ ft. in height, with north door and west window; and a niche contains a small black image of the Virgin and Child, in Lebanon cedar, and richly adorned with jewels. St. Luke is alleged to have been the sculptor; its workmanship suggests the latter half of the 15th century. Around the Santa Casa is a lofty marble screen, designed by Bramante, and executed under Popes Leo X., Clement VII. and Paul III., by Andrea Sansovino, Girolamo Lombardo, Bandinelli, Guglielmo della Porta and others. The four sides represent the Annunciation, the Nativity, the Arrival of the Santa Casa at Loreto and the Nativity of the Virgin respectively.

The legend of the Holy House dates from the close of the crusading period. The house of Nazareth in which Mary had been born and brought up, had received the annunciation, and had lived during the childhood of Jesus and after His ascension, was converted into a church by the apostles. In 336 the empress Helena caused a basilica to be erected over it, in which worship continued until the fall of the kingdom of Jerusalem. Threatened with destruction by the Turks, it was carried by angels through the air and deposited (1291) in the first instance on a hill at Tersatto in Dalmatia, where an appearance of the Virgin and miraculous cures attested its sanctity, confirmed by investigations made at Nazareth by messengers from the governor of Dalmatia. In 1294 the angels carried it across the Adriatic to a wood near Recanati; from this wood (*lauretum*), the chapel derived the name which it still retains. From this spot it was afterwards (1295) removed to the present hill. Bulls in favour of the shrine at Loreto were issued by Pope Sixtus IV. in 1491 and by Julius II. in 1507, the last alluding to the translation of the house with some caution ("*ut pie creditur et fama est*"). There is, as a fact, documentary evidence for the existence of a church dedicated to the Virgin on the spot (*in fundo Laureti*) just a century before the date of its supposed translation. In the end of the 17th century Innocent XII. appointed a "*missa cum officio proprio*" for the feast of the Translation of the Holy House, and the feast is still enjoined in the Spanish Breviary as a "greater double" (Dec. 10). Benedict XV. declared the Madonna di Loreto to be the patron of aviators. (T. A.)

See also U. Chevalier, *Notre-Dame de Lorette* (Paris, 1906); A. Colasanti, *Loreto* (Bergamo, 1911, well illustrated).

LORETO, the largest and most easterly department in Peru (approximate area, 124,070 sq.mi., pop. [1940] 321,341), a partly undetermined tract in the level, forest-covered Amazonian plains east of the Andes, averaging 500 ft. above sea level. The territory north of the Amazon and east of the cordillera, long disputed with Ecuador, was involved in the Peru-Ecuador boundary war of 1941. A joint boundary commission was engaged (1943) in delineating the new boundary which will give most of the territory to Peru. Except for a few open areas such as the Pampa del Sacramento, the region is a continuous jungle whose only openings are the great tributaries of the Amazon, Pastaza, Tigre, Napo, Yavarí, Ucayali, Huallaga and Marañón. Indian tribes, speaking many languages, differing greatly in manners and customs, fish and hunt along the rivers of Amazonia and practice primitive agriculture much today as when Orellana first discovered the Amazon (*see* AMAZON). There are thousands of miles of navigable waterways on all the great tributaries with regular steamer or launch service at the few ports of call (*see* PERU). The only port or town of importance is Iquitos (*q.v.*), capital of the department and base for the Peruvian navy's small Amazon flotilla. There are no roads, but two trails from Iquitos to the Pacific coast, the northern, via Yurimaguas to Pacasmayo, the central, via the Pachitea and Chanchamayo rivers to Oroya and the Central railway.

Prior to the development of rubber plantations in the East Indies the chief industry in Loreto was the exploitation of wild rubber. With the outbreak of World War II this activity was revived and was heavily subsidized by the government of the United States.

Loreto abounds in plants used in making fabrics, for dyeing and tanning, oil and wax-bearing plants, food, aromatic, medicinal, narcotic and poisonous plants as well as vegetable ivory. Crops include cotton, tobacco, sugar, coffee, rice, bananas, yuca, *camotes*, cacao, vanilla, vegetables and fruits.

LORICATA, in zoology, a name applied to the order Crocodilian (*q.v.*), and to various other groups of animals, especially the armadillos.

LORIENT, a maritime town of western France, capital of an arrondissement in the department of Morbihan, on the right bank of the Scorff, at its confluence with the Blavet, 34 mi. W. by N. of Vannes by rail. Pop. (1936) 45,761.

Lorient took the place of Port Louis as the port of the Blavet. The latter stands on the site of an ancient hamlet fortified during the wars of the League and handed over by Philip Emmanuel, duke of Morcoeur, to the Spaniards. After the Treaty of Vervins it was restored to France, and received its name of Port Louis under Richelieu. Some Breton merchants trading with the Indies established themselves first at Port Louis, but in 1628 built their warehouses on the other bank. The Compagnie des Indes Orientales, created in 1664, took possession of these, giving them the name of l'Orient. The importance of the Compagnie des Indes waned after the English conquest of India, and in 1770 its property was ceded to the State. In 1782 the town was purchased by Louis XVI from its owners, the Rohan-Guéméné family.

The town is modern and regularly built. It is one of the five maritime prefectures in France and the first port for naval construction in the country. The naval port to the east of the town is formed by the channel of the Scorff, on the right bank of which the chief naval establishments are situated. A floating bridge connects the right bank with the peninsula of Caudan formed by the union of the Scorff and Blavet. Here are the shipbuilding yards. The commercial port to the south of the town consists of an outer tidal port protected by a jetty, and an inner dock, both lined by fine quays planted with trees. It separates the older part of the town, surrounded by fortifications from a newer quarter. The trade in fresh fish, sardines, oysters (which are reared near Lorient) and tinned vegetables is important, and the manufacture of basket-work, rope, nets, etc., tin-boxes and ice, and the preparation of preserved sardines and vegetables are carried on. The roadstead is the estuary of the Blavet accessible to the largest vessels; the entrance is 3 or 4 mi. S. from Lorient. In the middle of the channel is the granite rock of St. Michel, occupied by a powder magazine. Opposite it, on the right bank of the Blavet, is the mouth of the river Ter, with fish and oyster breeding establishments from which 10,000,000 oysters are annually obtained. The roadstead is provided with six lighthouses.

LORIMER, GEORGE HORACE (1868–1937), U.S. editor, was born at Louisville, Ky., Oct. 6, 1868. He attended the Mosely high school in Chicago, Colby college, and Yale university. After a short time in business in Chicago he became a newspaper reporter and correspondent. In 1897 he was literary editor of the *Saturday Evening Post,* and in 1899 editor-in-chief. The remarkable success of this periodical was largely caused by Mr. Lorimer's keen appreciation of the public taste, coupled with his ability to meet it. His *Letters from a Self-made Merchant to His Son* (1902), which attained great popularity, and *Old Gorgon Graham* (1904) are effective and interesting expositions of the philosophy of getting on. He continued his editorship until Jan. 1, 1937. He died at Wyncote, Pa., Oct. 22, 1937.

LORINER or **LORIMER,** one who makes bits and spurs and the metal mountings for saddles and bridles; the term is also applied to a worker in wrought iron and to a maker of small iron-ware. The word is now rarely used except as the name of one of the London livery companies. (*See* LIVERY COMPANIES.)

LORIS, a name applied to the Indo-Malay lemurs (*see* PRIMATES). Their soft fur, huge staring eyes, rudimentary tails and imperfectly developed index-fingers render lorises easy of recognition. The smallest is the slender loris (*Loris tardigradus*) of the forests of Madras and Ceylon, a creature smaller than a squirrel. The slow loris (*Nycticebus coucang*) is a heavier built and larger animal, ranging from eastern Bengal to Cochin China, the Malay Peninsula, Java, Borneo and Mindanao.

LORIS-MELIKOV, MICHAEL TARIELOVICH, COUNT (1826–1888), Russian statesman, son of an Armenian merchant, was born at Tiflis on Jan. 1, 1826, and educated in St. Petersburg, first in the Lazarev School of Oriental Languages, and afterwards in the Guard's Cadet Institute. He joined a hussar regiment, and in 1847 he was sent to the Caucasus, where he spent twenty years. He was governor of the Terek district from 1855 to 1876, and sought to educate the people so as to make possible the transition from military to civil government. In the Russo-Turkish War of 1877–78 he commanded a separate corps d'armée on the Turkish frontier in Asia Minor. After taking the fortress of Ardahan, he was repulsed by Mukhtar Pasha at Zevin, but subsequently defeated his opponent at Aladja Dagh, took Kars by storm, and laid siege to Erzerum. For these services he received the title of Count.

In 1879 he was appointed temporary governor-general of the region of the Lower Volga, to combat an outbreak of the plague. He was then transferred to the provinces of Central Russia to combat the Nihilists and Anarchists, who had adopted a policy of terrorism, and had assassinated the governor of Kharkov. He advocated removing the causes of popular discontent, and for this purpose he recommended to the emperor a large scheme of administrative and economic reforms. Alexander II. thereupon appointed Loris-Melikov minister of the interior with exceptional powers. The proposed scheme of reforms was never carried out. On the very day in March 1881 that the emperor signed an ukáz creating the necessary commissions, he was assassinated; and his successor, Alexander III., adopted a reactionary policy. Loris-Melikov resigned, and lived in retirement until his death (Dec. 22, 1888) at Nice.

LÖRRACH, a town in the *Land* of Baden, Germany, in the valley of the Wiese, 6 mi. N.E. of Basle. Pop. (1939) 20,306. Lörrach received market rights in 1403, but did not obtain municipal privileges until 1682. It is the seat of considerable industry, its manufactures including calico, cloth, silk, chocolate, cotton, ribbons, hardware and cigars and it has a trade in wine, fruit and timber. It is a centre for the transmission of the electric power generated from the Rhine near by. There is a fine view from the neighbouring Schützenhaus, 1,085 ft. high. In the neighbourhood also is the castle of Rötteln, formerly the residence of the counts of Hachberg and of the margraves of Baden; this was destroyed by the French in 1678, but was rebuilt in 1867.

LORRAINE, one of the former provinces of France. The original kingdom of Lorraine was the northern part of the territories allotted by the treaty of Verdun (Aug. 843) to the emperor Lothair I., and in 855 formed the inheritance of his second son, King Lothair, from whom the name Lotharingia is derived. This kingdom was situated between the realms of the East and the West Franks, and originally extended along the North sea between the mouths of the Rhine and the Ems, including the whole or part of Frisia and the cities on the right bank of the Rhine. From Bonn the frontier followed the Rhine as far as its confluence with the Aar, which then became the boundary, receding from the left bank in the neighbourhood of Bingen so as to leave the cities of Worms and Spires to Germany, and embracing the duchy of Alsace. After crossing the Jura, the frontier joined the Saône a little south of its confluence with the Doubs, and followed the Saône for some distance, and finally the valleys of the Meuse and the Scheldt. Thus the kingdom roughly comprised the region watered by the Moselle and the Meuse, together with the dioceses of Cologne, Trier, Metz, Toul, Verdun, Liége and Cambrai, Basel, Strasbourg and Besançon, and corresponded to what is now Holland and Belgium, parts of Rhenish Prussia, of Switzerland, and of the old province of Franche-Comté, and to the district known later as Upper Lorraine, or simply Lorraine. Though apparently of an absolutely artificial character, this kingdom corresponded essentially to the ancient Francia, the cradle of the Carolingian house, and long retained a certain unity.

The reign of King Lothair (*q.v.*), ended on Aug. 8, 869. His inheritance was divided by the treaty of Meersen (Aug. 8, 870), by which Charles the Bald received part of the province of Besançon and some land between the Moselle and the Meuse. Then for a time the emperor Charles the Fat united under his authority the whole of the kingdom of Lorraine with the rest of the Carolingian empire. After his deposition in 888 Rudolph, king of Burgundy, got himself recognized in Lorraine. He was unable to maintain himself there, and succeeded in detaching definitively no more than the province of Besançon. Lorraine remained in the power of the emperor Arnulf, who in 895 constituted it a distinct kingdom in favour of his son Zwentibold. Zwentibold quickly became embroiled with the nobles and the bishops, and especially with Bishop Radbod of Trier. After the death of Arnulf in 899, the Lotharingians appealed to his successor, Louis the Child, to replace Zwentibold, who, on Aug. 13, 900, was killed in battle. In spite of the dissensions which immediately arose between him and the Lotharingian lords, Louis retained the kingdom till his death. The Lotharingians, however, refused to recognize the new German king, Conrad I., and testified their attachment to the Carolingian house by electing as sovereign the king of the West Franks, Charles the Simple. The struggle which followed ended in the treaty of Bonn (921), by which apparently the rights of Charles over Lorraine were recognized. The revolt of the Frankish lords in 922 and the captivity of Charles finally settled the question. After an unsuccessful attack by Rudolph, king of France, the German king Henry I. became master of Lorraine in 925, thanks to the support of Giselbert, son of Regnier count of Hainault, whom he rewarded with the hand of his daughter Gerberga and the title of duke of Lorraine. Giselbert at first remained faithful to Henry's son, Otto the Great, but in 939 he declared open war against him and appealed to Louis d'Outremer, who penetrated into Lorraine and Alsace, but was soon called back to France by the revolt of the count of Vermandois. In the same year Giselbert was defeated and killed near Andernach, and Otto at once made himself recognized in the whole of Lorraine, securing it by a treaty with Louis d'Outremer, who married Giselbert's widow Gerberga, and entrusting the government of it to Count Otto, son of Ricuin, until Giselbert's son Henry should have attained his majority.

Henry and Count Otto died in 944. After attempting unsuccessfully to govern Lorraine through his son-in-law Conrad of Franconia, Otto the Great in 954 gave it to his brother Bruno, archbishop of Cologne. Bruno had to contend against the efforts of the last Carolingians of France to make good their claims on Lorraine, as well as against the spirit of independence exhibited by the Lotharingian nobles; and his attempts to raze certain castles built by brigand lords and to compel them to respect their oath of fidelity resulted in serious sedition. To obviate these difficulties Bruno divided the ducal authority, assigning Lower Lorraine to a certain Duke Godfrey, who was styled *dux Ripuariorum,* and Upper Lorraine to Frederick (d. 959), count of Bar, a member of the house of Ardenne and son-in-law of Hugh the Great, with the title of *dux Mosellanorum.* In 977 the emperor Otto II. gave the government of Lower Lorraine to Charles I., a younger son of Louis d'Outremer, on condition that that prince should acknowledge himself his vassal and should oppose any attempt of his brother Lothair on Lorraine. Charles left two sons, Otto, who succeeded him (*c.* 992) and died without issue, and Henry, who is sometimes regarded as the ancestor of the landgraves of Thuringia. The duchy was then given to Godfrey (d. 1023), son of Count Godfrey of Verdun, and for some time the history of Lorraine is the history of attempts made by his successors to seize Upper Lorraine. Gothelon (d. 1043), son of Duke Godfrey, obtained the whole of Lorraine at the death of Frederick II., duke of Upper Lorraine, in 1027, and victoriously repulsed the incursions of Odo, count of Champagne, who was defeated and killed in a battle near Bar (1037). At Gothelon's death in 1043, his son Godfrey the Bearded received from the emperor only Lower Lorraine, his brother Gothelon II. obtaining Upper Lorraine. Godfrey attempted to seize the upper duchy, but was defeated and imprisoned in 1045. On the death of Gothelon in 1046, Godfrey endeavoured to take Upper Lorraine from Albert of Alsace, to whom it had been granted by the emperor Henry III. The attempt, however, also failed; and Godfrey was for some time deprived of his own duchy of Lower Lorraine in favour of Frederick of Luxemburg. Godfrey took part in the struggles of Pope Leo IX. against the Normans in Italy, and in 1053 married Beatrice, daughter of Duke Frederick of Upper Lorraine and widow of Boniface, margrave of Tuscany. On the death of Frederick of Luxemburg in 1065 the emperor Henry IV. restored the duchy of Lower Lorraine to Godfrey, who retained it till his death in 1069, when he was succeeded by his son Godfrey the Hunchback (d. 1076), after whose death Henry IV. gave the duchy to Godfrey of Bouillon, the hero of the first crusade, son of Eustace, count of Boulogne, and Ida, sister of Godfrey the Hunchback. On his death in 1100 Lower Lorraine was given to Henry, count of Limburg. The new duke supported the emperor Henry IV. in his struggles with his sons, and in consequence was deposed by the emperor Henry V., who gave the duchy in 1106 to Godfrey, count of Louvain, a descendant of the Lotharingian dukes of the beginning of the 10th century. This Godfrey was the first hereditary duke of Brabant, as the dukes of Lower Lorraine came to be called.

Upper Lorraine.—The duchy of Upper Lorraine, or Lorraine *Mosellana,* to which the name of Lorraine was restricted from the 11th century, consisted of a tract of undulating country watered by the upper course of the Meuse and Moselle, and bounded N. by the Ardennes, S. by the table-land of Langres, E. by the Vosges and W. by Champagne. Its principal fiefs were the countship of Bar which Otto the Great gave in 951 to Count Frederick of Ardenne, and which passed in 1093 to the lords of Montbéliard; the countship of Chiny, formed at the end of the 10th century, of which, since the 13th, Montmédy was the capital; the lordship of Commercy, whose rulers bore the special title of *damoiseau,* and which passed in the 13th century to the house of Saarebrücken; and, finally, the three important episcopal lordships of Metz, Toul and Verdun. After having been the object of numerous attempts on the part of the dukes of Lower Lorraine, Upper Lorraine was given by the emperor Henry III. to Albert of Alsace, and passed in 1048 to Albert's brother Gerard, who died by poison in 1069. He was the ancestor of the hereditary house of Lorraine, of which the male line possessed the duchy continuously until the death of Duke Charles the Bold in 1431. By his will Lorraine was to pass to his daughter Isabella, who married René of Anjou, duke of Bar, in 1420. But Anthony of Vaudemont, Charles's nephew and heir male, disputed this succession with René, who was taken prisoner at the battle of Bulgnéville (July 2, 1431). It was not until 1436 that René obtained his liberty by paying a ransom of 200,000 crowns. In 1444 Charles VII. of France and the dauphin Louis went to Lorraine, accompanied by envoys from Henry VI. of England, and procured a treaty, by which Yolande, René's eldest daughter, married Anthony's son, Ferri of Vaudemont, and René's second daughter Margaret became the wife of Henry VI. of England. After his return to Lorraine in 1442, René was seldom in the duchy. Like his successor John, duke of Calabria, who died in 1470, he was continually occupied with expeditions in Italy or in Spain. John's son and successor, Nicholas (d. 1473), died without children, and his heir was René, son of Frederick of Vaudemont. He died in 1508, leaving by his second wife three sons—Anthony, called the Good, who succeeded him; Claude, the ancestor of the house of Guise; and John (d. 1550), known as the cardinal of Lorraine. Anthony had been brought up from the age of 12 at the French court, where he became the friend of Louis XII., whom he accompanied on his Italian expeditions. He succeeded in maintaining a neutral position in the struggle between Francis I. of France and the emperor Charles V. He died on June 14, 1544, and was succeeded by his son Francis I., who died of apoplexy (Aug. 1545) at the very moment when he was negotiating peace between the king of France and the emperor.

Lorraine in Modern Times.—Francis's son Charles, called the Great, succeeded under the tutelage of his mother and Nicholas of Vaudemont, bishop of Metz. Henry II. of France took this opportunity to invade Lorraine, and in 1552 seized the three bishoprics of Metz, Toul and Verdun. In the same year the emperor laid siege to Metz, but was forced to retreat with heavy loss before the energetic resistance of Duke Francis of Guise. On leaving Lorraine, Henry II. took Charles to France, brought him up at the court and married him to his daughter Claude. After the accession of Francis II., the young duke returned to Lorraine, and, while his cousins the Guises endeavoured to make good the claims of the house of Lorraine to the crown of France by virtue of its Carolingian descent, he devoted himself to improving the administration of his duchy. He reconstituted his domain by revoking the alienations irregularly granted by his predecessors, reorganized the working of the mines and saltworks, unified weights and measures and promulgated edicts against vagabonds. His duchy suffered considerably from the passage of German bands on their way to help the Protestants in France, and also from disturbances caused by the progress of Calvinism, especially in the neighbourhood of the three bishoprics. To combat Calvinism Charles established the Jesuits at Pont-à Mousson, and gave over to them the university he had founded in that town in 1572. To this foundation he soon added chairs of medicine and law, the first professor of civil law being the *maître des requêtes,* the Scotsman William Barclay, and the next Gregory of Toulouse, a pupil of the jurist Cujas. Charles died on May 14, 1608, and was succeeded by his eldest son Henry II., called the Good, who died in 1624 without issue.

Henry was succeeded by his brother Francis II., who abdicated on Nov. 26, 1624, in favour of his son Charles IV. or III. He died in 1675, after a life spent in continual, though rarely effective, opposition to the French monarchy. His nephew Charles was recognized as duke of Lorraine by all the Powers except France, but never obtained effective possession of the duchy. He died in 1690. Seven years later Leopold, his son, was restored to his estates by the treaty of Ryswick (1697), but had to dismantle all the fortresses in Lorraine and to disband his army with the exception of his guard. Under his rule Lorraine flourished. While diminishing the taxes, he succeeded in augmenting his revenues by wise economy. The population increased enormously during his reign—that of Nancy, for instance, almost trebling itself between the years 1699 and 1735. Leopold welcomed French immigrants, and devoted himself to the development of commerce and industry, particularly to the manufacture of stuffs and lace, glass and paper. He was responsible, too, for the compilation of a body of law which was known as the "Code Léopold." Some time after his death, which occurred on March 27, 1729, his heir Francis III. was betrothed to Maria Theresa of Austria, the daughter and heiress of the emperor Charles VI. France, however, could not admit the possibility of a union of Lorraine with the empire; and in 1735 Louis XV. negotiated an arrangement by which Francis received the duchy of Tuscany in exchange for Lorraine, and Stanislaus Leszczynski, the dethroned king of Poland and father-in-law of Louis XV., obtained Lorraine, which after his death would pass to his daughter—in other words to France. These arrangements were confirmed by the treaty of Vienna (Nov. 18, 1738). In 1736, by a secret agreement, Stanislaus had abandoned the financial administration of his estates to Louis XV. for a yearly subsidy. The intendant, Chaumont de la Galaizière, was instructed to apply the French system of taxation in Lorraine; but in spite of the severity of the administration Lorraine preserved a grateful memory of the good king Stanislaus, who held his brilliant little court at Lunéville, and founded an academy and several libraries and hospitals. At his death in Feb. 1766 the two duchies of Lorraine and Bar became definitively incorporated in the kingdom of France. The treaties of 1735 and 1736, however, guaranteed their legislation, the privileges enjoyed by the three orders, and their common law and customs tariffs, which they retained until the French Revolution. Lorraine and Barrois formed a large government corresponding, together with the little government of the three bishoprics, to the *intendance* of Lorraine and the *généralité* of Metz. For legal purposes, Metz had been the seat of a parlement since 1633, and the parlement of Nancy was created in 1776. There was, too, a *chambre des comptes* at Metz, and another at Bar-le-duc. (For the later history *see* ALSACE-LORRAINE.)

See Dom. A. Calmet, *Histoire ecclésiastique et civile de Lorraine* (2nd ed., Nancy, 1747–57); Comte D'Haussonville, *Histoire de la réunion de la Lorraine à la France* (2nd ed., 1860); E. Huhn, *Geschichte Lothringens* (1877); A. Digot, *Histoire de Lorraine* (1879–80); E. Bonvalot, *Histoire du droit et des institutions de la Lorraine et des Trois-Évêchés* (1895); R. Parisot, *Le Royaume de Lorraine sous les Carolingiens* (1899); E. Duvernoy, *Les États Généraux des duchés de Lorraine et de Bar jusqu'à la majorité de Charles III.* (1904).

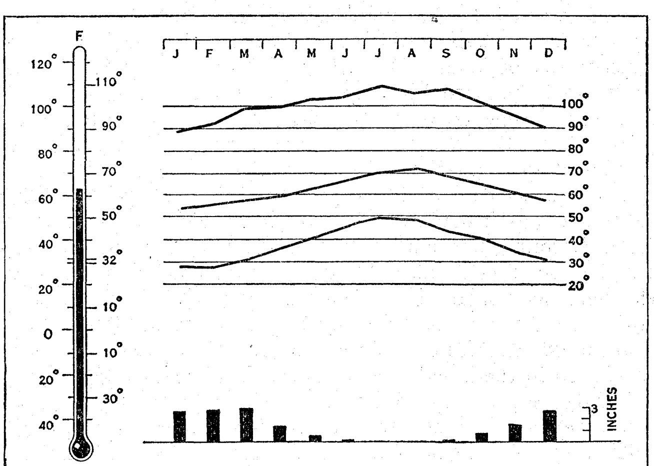
LORTZING, ALBERT (1801–1851), German composer, was born at Berlin on Oct. 23, 1801. His first opera *Ali Pascha von Jannina* appeared in 1824, but his fame rests chiefly upon the two operas *Der Wildschütz* (1842) and *Czar und Zimmermann* (1837). The latter, although now regarded as one of the masterpieces of German comic opera, was received with little enthusiasm on its first performance at Leipzig. It was translated into many European languages. Of his other operas it is only necessary to note *Der Pole und sein Kind,* produced shortly after the Polish insurrection of 1831, and *Undine* (1845). Lortzing died at Berlin on Jan. 21, 1851.

LORY, any of some 60 species of small (mostly 4.5 to 12 in.), brilliantly-coloured (many with bright red) parrots (*q.v.*), with beak less toothed and tongue brush-tipped, constituting the subfamily Loriinae. Some are called lorikeets. Lories are mostly from New Guinea and adjacent islands, though ranging to southeastern Australia, New Caledonia, the Philippines and Marquesas Islands. They fly swiftly in flocks, have shrill voices, and feed mostly on soft fruits and the nectar of flowers, gathered with the bushy tongue. The four or five white eggs are laid in holes in trees. There are about 15 genera, the best known being *Domicella, Trichoglossus, Chalcopsitta, Phigys, Vini* and *Eos*. (G. F. Ss.)

LOS ANDES, a former state of Venezuela under the redivision of 1881, which covered the extreme western part of the republic northwest of Zamora and south of Zulia. The territory is now cut up into three states—Mérida, Táchira and Trujillo.

LOS ANGELES (lōs ăń′gĕl ĕs or los ăng′ jĕ lĕz), a city and the county seat of Los Angeles county, in the southern part of the state of California, U.S.A., is situated in 34° 3′ N. and 118° 14′ W. The situation of the city between the mountains and the sea is attractive. The average altitude is about 275 ft., ranging from sea level to 1,692 ft. at Mt. Hollywood. The city had, on Jan. 1, 1941, an area of 442 square miles. The population within the city limits, according to the United States census bureau, increased from 319,198 in 1910 to 576,673 in 1920, to 1,238,048 in 1930 and to 1,504,277 in 1940, the 5th city in the union.

Geography.—The business section is 16 mi. northeast from the Pacific ocean, on level land, with foothills of the San Gabriel mountains on the north. Fresh water issuing from these hills led



WEATHER GRAPH OF LOS ANGELES. THE MERCURY STANDS AT THE ANNUAL MEAN TEMPERATURE. THE MIDDLE CURVE SHOWS THE NORMAL MONTHLY TEMPERATURE. THOSE ABOVE AND BELOW, THE HIGHEST AND LOWEST EVER RECORDED IN EACH MONTH. THE COLUMNS INDICATE THE NORMAL MONTHLY PRECIPITATION

to choice of the original site. The original town—the "pueblo" of "Our Lady, Queen of the Angels"—was built around a square, or plaza, near the Los Angeles river. With growth, after railways came, the city spread south, east and west over level land, assuming an irregular outline. In the region round about, separate municipalities grew up, of which Pasadena is largest. A high spur of the foothills on the west, which blocked growth in that direction for a time, has been pierced by tunnels and boulevards. On the south a narrow strip of annexed land, about 20 mi. long, known as the "shoestring strip," communicates with Los Angeles harbour. The city touches the ocean in annexed towns, San Pedro, Wilmington and Venice, and entirely surrounds separate municipalities, as Beverly Hills, Vernon and San Fernando.

The height of skyscrapers was limited to 150 ft. by city ordinance, with beneficial results in developing outlying centres. Hollywood, 8 mi. northwest of the business district, and part of Los Angeles municipally through annexation, is such a centre. It retains its original name and character, and is a distinct business and theatrical entity. A large area in the San Fernando valley, likewise annexed, has its distinctive communities.

Climate.—Even quality is the chief characteristic of the climate. Winter is a season of moderate rainfall, 15·23 in. yearly average. There is practically no rain from May to November. Winter days are sunny and warm; the nights are often cold, with occasional frost in December and January.

A 50-year average of the records of the U.S. weather bureau shows the mean temperature to be 62·4°; that there is a 72% possibility of sunshine; and 179 clear days. There are only 37 days per year with more than ·01 in. of rain. Average wind velocity was 6·1 mi. an hour; the highest wind ever recorded, 48 mi. an hour. During nearly half a century, Los Angeles has experienced a moderate earth tremor about once in five years. Since 1781, when the city was founded, there has never been a death or serious accident by earthquake.

Population.—The population of Los Angeles at the past five censuses was 102,479 (1900), 319,198 (1910), 576,673 (1920), 1,238,048 (1930), 1,504,277 (1940). About 1920 began an influx of population to southern California which surpassed even the movement of earlier years. The rapid increase of population, with a corresponding increase of capital and industry, and the discovery, at almost the same time, of rich new oil fields in the vicinity caused a "boom" which accounts for the city's phenomenal growth.

The Latin and Oriental population is about 17%. The census of 1930 showed the foreign-born whites to be 14·7% of the total population. Most of these were Mexicans, many Japanese, some Chinese, and the remainder chiefly Europeans and Canadians.

Natural Resources.—As coal was absent, petroleum and waterpower were the first resources developed by the Americans. Electricity generated in the mountains, for light and power, was brought over long transmission lines. Los Angeles pioneered long-distance transmission and the linking up of large electric networks. Within a radius of 300 mi. are deposits of metals and minerals, as copper, petroleum, soda, salt, potash, silica, infusorial earth, talc, graphite, limestone, building stone, marble and onyx.

Industries.—Manufacturing shows a striking increase since the World War of 1914–18—from $103,500,000 in 1914 to $654,-852,404 (U.S. census) in 1937. Manufacture was chiefly for local needs, as soap, confectionery, beverages and the like, until war made it necessary to meet certain shortages. This encouraged industrial enterprise. Peace brought building activity, increased population and new trade through the Panama canal and to the Orient. These further stimulated industry. The city and environs had during 1937, 4,504 factories. Motion pictures led in value with an output estimated at $171,943,349 yearly. Petroleum products were valued at $228,429,555, but this included recovery as well as refining. Meat packing ranked third with an output of $78,535,538. Other industries with products valued over $10,000,-000 were: printing and publishing, $36,964,886; bakery products, $42,199,182; tires, $65,000,000 (estimated); women's clothing, $34,122,832; machinery and machine shop products, $45,916,045; and furniture and fixtures, $22,805,363. Los Angeles ranks as a fashion centre for sportswear. At the harbour, canneries pack sardines (pilchard) and tuna, the latter a local innovation. Glass, chemicals, cement, paints and food preparations are leading products. Branch plants of eastern concerns are engaged in automobile assembling and the manufacture of rubber tires, furniture, metal articles, glass, tin cans, etc.

Motion Pictures.—Early motion pictures were made in sunlight. Constant sunshine and varied scenery brought this industry to Los Angeles. Hollywood, having at the outset (1910–15) ample land for studios, became famous as a centre; also Universal City and Burbank in the San Fernando valley, and Culver City. At least $95,320,051 were spent in 1940 in production, and 14,151 persons employed.

Agriculture.—Los Angeles county (4,155 sq.mi.) has for two dozen years led all other counties in the United States in value of soil products ($51,863,850 in 1940). The city is a financial and marketing centre for these products. The diversity is wide, including oranges, lemons, apricots, peaches, almonds, walnuts, summer and winter vegetables, figs, avocados, poultry, fur rabbits, grain, alfalfa, livestock, dairying and general farming. About 25,000 carloads of soil products are shipped from Los Angeles county annually. The first outstanding success in co-operative farm marketing was made in this section, by the California Fruit Growers' exchange, in orange distribution. The organization is now in Los Angeles. So is the California Walnut Growers' association.

Communication.—After American occupation (1847) sea trade was established between San Pedro harbour and San Francisco, and mail was carried fortnightly by land between the latter city and Los Angeles. The first freight wagon overland from the east arrived in 1851. In 1860, a ten-day pony express linked Los Angeles with the Missouri river. A railway from Los Angeles to San Pedro harbour was opened in 1869. The Southern Pacific railway from San Francisco to Los Angeles was completed in 1876, and the Santa Fe route connected the city with the east in 1885. Los Angeles by 1928 had three direct railways to the east—the Atchison, Topeka and Santa Fe via Kansas City, the Union Pacific via Ogden and Southern Pacific via New Orleans. The Southern Pacific to San Francisco gives access to other transcontinental routes from that city, and to the northwest. The railway to San Diego connects with still another route east. In a radius of 72 mi., the Pacific Electric railway system runs 3,000 trains daily over 1,106 mi. of track, carrying both passengers and freight. This system is linked to Los Angeles harbour. Los Angeles is a terminal for several national motor highways, and a centre for California highways. Over these roads a large motorbus and motor-truck traffic has developed. By sea, the city has shipping lines to all parts of the globe, as well as coast trade to both Pacific and Atlantic ports. Air service gives quick transportation and communication east and north. The national defence program (1941) made Los Angeles a centre for the aviation industry, with an estimated peak of 150,000 employees.

Harbour and Commerce.—San Pedro bay, in Spanish times, afforded an uncertain roadstead. It was chosen because accessible by a level land route from the city, 24 mi. away. The Americans established a stage route (1852) to the harbour and later a railroad (1869) but San Francisco enjoyed most of the sea trade. A long fight for Los Angeles harbour ended with annexation of two towns, San Pedro and Wilmington (1909), and the building of a breakwater by the U.S. government (1910) and an inner harbour by the city (1912–14). The Panama canal was opened at the same time, but the World War of 1914–18 temporarily disorganized foreign trade.

Growth was immediate when the war ended, rising from 752,513 short tons a year export and import to 5,624,000 short tons in 1940. On the Pacific coast, Los Angeles harbour stands next to that of the San Francisco bay area in water-borne commerce and ranks tenth among all U.S. ports. With 40 mi. water front, and capacity for large ocean vessels, harbour facilities were being enlarged in 1941 in co-operation with the city of Long Beach, which has a separate inner harbour. The chief imports in 1937 were raw silk, crude rubber, newsprint paper, sugar, fish, copra, coffee, tin, liquors, vegetable oil and fibres. Petroleum and petroleum products constituted 11,867,233 tons of the 16,481,646 tons exported, or 85%. The chief exports in 1937 were petroleum products, aircraft, raw cotton, citrus fruits, canned fish, iron and steel manufactures, copper, machinery, chemicals and automobile tires. Over $100,000,000 worth of aircraft flew away under its own power in 1940. Los Angeles harbour is the nearest Pacific terminus for the Panama canal. It is an operating centre for the U.S. navy.

As a Tourist Centre.—Los Angeles is a travel centre for the southwest. Several thousand visitors arrive in the city daily by train, automobile, motorbus, ship and aeroplane. The tourists by automobile (1940) were estimated at 1,580,500. Accommodation for visitors is on a large scale, 1,271 hotels and 5,000 apartment houses having facilities for 524,198 persons. Cottages, boarding and lodging houses, automobile camps, restaurants and cafeterias provide for visitors. At first, travel was limited chiefly to the winter season; but now summer travel slightly exceeds winter, a change brought about by better knowledge of the cool summers, and by activities of the All Year club of Southern California.

Streets and Traffic.—In the business district, streets run chiefly at right angles to diagonal compass points; elsewhere to direct compass points, with winding terraces where hills are built upon. Broad boulevards give access to the ocean, fruitful valleys and mountain wilderness. Motorbus lines operate in both urban and interurban traffic. Traffic congestion, formerly acute, has been relieved by automatic signals governing both vehicles and pedestrians. Steam railways skirt the eastern and northern boundaries of the city; the main area is served by electric street cars, which are operated over 412 mi. of track. With the development of hydroelectricity, Los Angeles became the centre of a network of electric interurban lines.

Water and Power.—Water is an important factor in the growth of a city in a semi-desert region. In 1904, this need was anticipated; William Mulholland, chief engineer of the city's water department, suggested an aqueduct to the east side of the Sierra Nevada mountain range, 250 mi. from the business district, through the Mohave desert. By 1908 bonds had been voted, and work begun. In 1913 the Los Angeles aqueduct was finished, 233 mi. in length, from intake to reservoir, the longest work of its kind in the world. The cost of construction was nearly $25,000,000. In the 233 mi. there are 142 tunnels; 97 mi. of covered conduit; 12 mi. of syphons; 37 mi. of lined canal; and 24 mi. of unlined canal. The capacity, about 280,000,000 gal. daily, is sufficient for 2,000,000 people; 250,000 ac. of land are irrigated with the surplus. For use in construction, 127 mi. of railroad and 215 mi. of highway were built. The giant Colorado river aqueduct, part of a $220,000,000 project which pierces 6 mountain ranges with 38 tunnels totalling 108 mi., will bring an ample water supply to 13 cities (including Los Angeles) in the metropolitan district and is of significance to all southern California. Power is supplied by a remarkable municipal system. The major portion of the electrical energy comes over a transmission line of 266 mi. from Boulder Dam. The four generators completed April 1937 supplied 115,000 horse power each. Five plants in San Francisquito canyon send 175,750 horsepower a distance of 50 miles and two steam plants supply 200,000 horsepower.

Finance.—Los Angeles is important in banking because capital is brought by newcomers, in addition to wealth produced locally. The surrounding country turns to it as the financial centre. Bank deposits grew from $118,000,000 in 1910 to $1,100,000,000 in 1927; yearly clearings increased from less than $1,000,000,000 in 1910 to $5,852,244,000 in 1935. Much capital is invested directly in land, buildings, oil and manufactures. There is also a large, growing investment in securities. The Los Angeles stock exchange transactions for the year 1940 represented a value of approximately $45,000,000.

Buildings.—Los Angeles is a somewhat hurriedly built city, now taking permanent form. Since the World War of 1914–18 (1920–35 inclusive) $1,390,000,000 has gone into building; the number of building permits in 1940 was 40,212, and their value, $74,300,510. This activity has made the city a centre of design and invention. Early builders adapted the bungalow, from India, as most suitable for the climate and the spacious sites then available. With more compact sites, the "California house" of Spanish design has replaced the bungalow. The city had almost no notable public buildings until 1925, but since that date a civic centre has been developed. Other buildings are the City hall, Hollywood police and fire stations, Lincoln Heights jail and Georgia Street hospital.

Theatres, Museums and Libraries.—With visitors seeking diversion, and many stage and screen players among its residents, Los Angeles is an important theatrical centre. Besides numerous theatres in the city and motion picture palaces, it has secondary theatrical centres like Hollywood, and an energetic "little theatre" activity. Grand opera is given in the Shrine Civic auditorium, seating 7,000 persons. Orchestra and other recitals are given in the Philharmonic auditorium. The Mission Play theatre, at San Gabriel, is one of the famous playhouses of the region. As climate makes outdoor entertainment attractive, the city has a number of gathering places like the Los Angeles coliseum, seating 105,000 persons, Hollywood bowl, seating 25,000, the adjoining Pilgrimage Play amphitheatre, and outlying auditoriums, as Pasadena Rose bowl, 84,000. The "symphony under the stars," in Hollywood bowl, during July and August, has become widely known. Easter morning is an occasion for outdoor services in various natural amphitheatres.

The Los Angeles museum of history, science and art has a spacious building in Exposition park. It exhibits mounted skeletons of sabre-toothed tigers, Imperial elephants, American mastodons, camels, wolves and small mammals recovered from La Brea asphalt pits, and has thousands of unmounted specimens. Its pictures, statuary, historical and scientific collections amply cover the field embraced in its title. The Southwest museum, in a building ornamented with cement casts from Mayan sculpture, specializes in the rich civilizations of the southwestern United States, Mexico and Central America, and also has collections of conchology, entomology and ornithology.

The Los Angeles public library, with 1,641,195 books, is housed in a building of monolithic concrete, and has 48 branches, mostly in special buildings. The city has various special libraries, belonging to colleges, professional associations and business concerns, devoted to law, medicine, architecture, mining, petroleum, minerals and industrial subjects. The Henry E. Huntington library and art gallery at San Marino, near Pasadena, is rich in rare books and manuscripts, mostly English and American, with the largest collection of *incunabula* in America. There also is an outstanding collection of the works of the great English painters of the so-called Golden age—Gainsborough, Reynolds, Lawrence, Romney. The Arabella Huntington Memorial, in the same place, includes rare art objects.

Parks.—Among the 130 parks, having an aggregate area of 5,412 ac., are: Griffith park, 3,761 ac. of natural foothill, with golf course; Exposition park, 114 ac., with Los Angeles museum; Elysian park, 599 ac., in natural state, with a motor camp; Sycamore Grove, 15 ac., a natural tract of dry river bed (arroyo); Barnsdall park, 10 ac., for children; Lincoln park, 46 ac., with a museum, zoo and exposition buildings; and Pershing Square, which is the only park in the business section, besides the old Spanish plaza. Many tourists visit Mt. Wilson and Mt. Lowe, northeast of the city, and Santa Catalina island, 23 mi. southwest from San Pedro.

Education.—More than 450,000 pupils were enrolled in 617 public schools in the fall of 1940; 10,283 teachers were giving instruction. Institutions for higher education, in order of the founding, are: (1) the coeducational University of Southern California (1879), Methodist, with students of all denominations. It is composed of 24 schools and colleges and is on large grounds in the central part of the city. Its enrolment in 1940 was 16,000. (2) Occidental college (1887), Presbyterian foundation, nonsectarian. It is coeducational, located on an attractive campus at Eagle Rock, at the northern border of Los Angeles. The college is devoted to the liberal arts; its enrolment in 1940 was about 750. (3) California Institute of Technology (1891), at Pasadena. Its work is confined to scientific and engineering subjects, notably for pure science and research. (4) Loyola university (1912), Catholic, near the beach, gives courses in science, art, engineering, commerce, finance, premedical studies and law. (5) University of California at Los Angeles (1919). It is on a 375 ac. campus at Westwood on the western border of the city. The institution has about 10,000 students, is coeducational and gives complete university training. (6) Other institutions include Chapman college and George Pepperdine college.

Churches and Charities.—The city's 979 churches, increased by about 50 yearly, are almost all new, and are varied in design and setting. Approximate church membership in 1940 was 338,911; of whom 91,046 were Protestant, 179,615 Roman Catholic and 68,250 Jewish. The 194 charitable and welfare organizations of the city secure funds through a yearly community chest solicitation. The contributions for 1940 totalled $2,500,450.

Government.—Los Angeles is governed under a charter adopted in 1924, in operation from July 1, 1925. It provides for the initiative, the referendum, the recall and an executive budget. The mayor (the chief executive, with wide powers of appointment), the city attorney, the controller and the seven members of the board of education are elected at large. The 15 members of the council (the legislative body) are elected by districts for a term of two years. The principal functions of government are entrusted to 16 commissions of 5 members each, appointed by the mayor, serving without salary, which appoint and fix the salary of general managers for their departments. There is also a municipal housing commission consisting of 12 members together with 4 judges and the president of the Chamber of Commerce.

History.—In 1769 an expedition under Gaspar de Portolá, which had been sent to San Diego, marched from that point in July and on Aug. 1 reached an Indian village called "Yang-na," on the present site of Los Angeles. The place was named on the following day, Aug. 2, the day of "Our Lady Queen of the Angels" (*Nuestra Señora la Reina de los Angeles*), by Father Juan Crespi. The pueblo, however, was not founded until Sept. 1781. The Franciscan mission of San Gabriel—still a famous landmark —had been established ten years earlier a few miles eastward. After Mexico's independence from Spain (1822) frequent political disturbances and revolts hampered the little town. In 1835 it was made a city by the Mexican congress, and declared the capital, but the last provision was not enforced and was soon repealed. In 1845–47 it was the actual capital of California. The city was rent by factional quarrels when war broke out between Mexico and the United States, and with the appearance of the United States troops under Commodore Robert F. Stockton and Capt. John C. Frémont, the defenders of Los Angeles fled; the American flag was raised over the city on Aug. 13, 1846. A garrison of 50 men, left in control, was compelled in October to withdraw on account of a revolt of the inhabitants, and Los Angeles was not retaken until Gen. S. W. Kearny and Commodore Stockton entered the city in January 1847. The city was incorporated in 1850, and in 1850 the first English school was opened and the first Protestant church established. Los Angeles continued to grow steadily thereafter until it attained railway connections with San Francisco in 1876, and with the east by the Santa Fe system in 1885. A carload of oranges was sent east by rail in 1877, and then began a new era of horticultural enterprise. A rate war between competing railways and a simultaneous land boom brought thousands of visitors to southern California. A large portion of these travellers became permanent settlers. It is also from this period (about 1890) that the "tourist era" dates. Each succeeding decade showed remarkable increases in population, industry and wealth. In 1914 the city's harbour (San Pedro) was opened, and with the Panama canal open, Los Angeles began to benefit by its position on a new world trade route. The discovery of rich new oil fields and the development of manufacturing enterprises made the decade 1920–30 momentous, and this has continued with the steady success of the cinema, continued public building, and the coming of cheap power.

LOS ISLANDS (Islas de los Idolos), a group of islands off the coast of French Guinea, West Africa, lying south of Sangarea Bay, between 9° 25′ and 9° 31′ N. and 13° 46′ and 13° 51′

W., and about 80 m. N.N.W. of Freetown, Sierra Leone. There are five principal islands: Tamara, Factory, Crawford, White (or Ruma) and Coral. The two largest islands are Tamara and Factory, Tamara, some 8 m. long by 1 to 2 m. broad, being the largest. These two islands lie parallel to each other, Tamara to the west; they form a sort of basin, in the centre of which is the islet of Crawford. The two other islands are to the south. The archipelago is of volcanic formation, Tamara and Factory islands forming part of a ruined crater, with Crawford Island as the cone. The highest point is a knoll, some 450 ft. above sea-level, in Tamara. All the islands are richly clothed with palm trees and flowering underwood. Tamara has a good harbour, and contains the principal settlement. The inhabitants, about 1,500, are immigrants of the Baga tribe of Senegambian negroes, whose home is the coast land between the Pongo and Nunez rivers. In 1818 Sir Charles McCarthy, governor of Sierra Leone, obtained the cession of the islands to Great Britain from the chiefs of the Baga country, and in 1882 France recognized them to be a British possession. They were then the headquarters of several Sierra Leone traders. By article 6 of the Anglo-French convention of the 8th of April 1904, the islands were ceded to France. They were desired by France because of their geographical position, Konakry, the capital of French Guinea, being built on an islet but 3 m. from Factory Island, and at the mercy of long range artillery planted thereon. The islands derive their name from the sacred images found on them by the early European navigators.

LOSSIEMOUTH, a small burgh, Moray, Scotland. Pop. (1938) 3,984. Area, .8 sq.mi. It embraces the villages of Lossiemouth, Branderburgh and Stotfield, at the mouth of the Lossie, 5½ mi. N.N.E. of Elgin, of which it is the port, by a branch line of the L.N.E. railway. The industries are boat-building and rope-making. Lossiemouth, or the Old Town, dates from 1700; Branderburgh, farther north, grew with the harbour and began about 1830; Stotfield is purely modern. There is a fine golf course and good bathing. The cliffs at Covesea, 2 mi. W., contain caves, one of which was used as a stable in the rebellion of 1745; prehistoric weapons were found in another, and the roof of a third is carved with early Celtic ornamentation. J. Ramsay MacDonald (1866–1937) was born in Lossiemouth.

Kinneddar castle, 1 m. W., was a seat of the bishops of Moray, and Old Duffus castle, 2½ m. S.W., was built in the reign of David II. Nearly midway between Lossiemouth and Elgin stand the massive ruins of the palace of Spynie, formerly a fortified residence of the bishops of Moray. The large tower, with walls 9 ft. thick, was built about 1470.

LOSSING, BENSON JOHN (1813–1891), American historical writer, was born in Beekman, N.Y., Feb. 12, 1813. After editing newspapers in Poughkeepsie he became an engraver on wood, and removed to New York in 1839 for the practice of his profession, to which he added that of drawing illustrations for books and periodicals. He likewise wrote or edited the text of numerous publications. His *Pictorial Field-Book of the Revolution* (first issued in 30 parts, 1850–52, and then in 2 vols.) was a pioneer work of value. Similar but less characteristic and less valuable undertakings were a *Pictorial Field-Book of the War of 1812* (1868), and a *Pictorial History of the Civil War in the United States of America* (1866–69). His other books were numerous: an *Outline History of the Fine Arts;* many illustrated histories, and biographical sketches of celebrated Americans, of which *The Life and Times of Major-General Philip Schuyler* (1860–73) was the most considerable. He died at Dover Plains, N.Y., June 3, 1891. *See* Nathaniel Paine, "A Biographical Notice of Benson John Lossing," *Worcester Society of Antiquity* (1892).

LOSSKI, NIKOLAI ONUFRIEVICH (1870–   ), Russian philosopher, was born at Kreslavka near Vitebsk. He was educated at Kreslavka and at the University of St. Petersburg (Leningrad) where he studied first science and then philology. From 1916 to 1921 he was professor of the same university, but in 1922 he was compelled to leave Russia and went to live in Prague. According to Losski's views, knowledge is immediate contemplation (intuition). His intuitionalism differs from Bergson's in so far as he considers the ideal-rational forms to be elements of realities, intuitively cognisable.

Losski assumes not only concrete real being, but concrete ideal being as well, *i.e.,* supra-temporal and supra-spatial substantial agents with creative force, which are the basis of spatio-temporal being. This doctrine leads Losski to his teaching of the freedom of the will.

Among Losski's most important books are *Die Grundlehre der Psychologie vom Standpunkte des Voluntarismus,* published in Russian (1903), in German (1905); *The Intuitive Bases of Knowledge* (1904; Eng. trans., 1919); and *Handbuch der Logik* (1922), in German (1926). The titles of his principal untranslated Russian works may be given in English as follows: *Introduction to Philosophy; The World as an Organic Whole; Principles of Epistemology; Matter and Life; Freedom of Will.*

LÖSSNITZ, a district in the *Land* of Saxony, Germany, extending for about 5 mi. along the right bank of the Elbe, immediately N.W. of Dresden. Pop. (1933) 7,762.

It lies in a sheltered position and its climate makes it suitable for market-gardening, the produce finding a ready market in Dresden.

LOSSO, a people closely related to the Kabre, inhabiting the Sokode district of Dahomey.

LOSTWITHIEL, a market town and municipal borough of Cornwall, England, on the river Fowey 30½ mi. W. of Plymouth by the G.W. railway. Pop. (1938) 1,925. Lostwithiel probably owed its existence to the neighbouring castle of Restormel, restored somewhat in 1930. The Pipe Rolls (1194–1203) show that Robert de Cardinan, lord of Restormel, paid ten marks yearly for having a market at Lostwithiel. He surrendered to the burgesses all the liberties given them by his predecessors (*anteces-sores*) when they founded the town. By Isolda, granddaughter of Robert de Cardinan, the town was given to Richard, king of the Romans, who granted to the burgesses a gild merchant sac and soc, toll, team and infangenethef, freedom from pontage, lastage, etc., throughout Cornwall, and exemption from the jurisdiction of the hundred and county courts, also a yearly fair and a weekly market. His son Edmund decreed that the coinage of tin should be at Lostwithiel only. In 1609 a charter of incorporation provided for courts of record and pie powder. From 1305 to 1832 two members represented Lostwithiel in parliament, but under the Reform act (1832) the borough became merged in the county. For the victory gained by Charles I. over the earl of Essex in 1644, *see* GREAT REBELLION. St. Bartholomew's church has a fine Early English tower and a Decorated spire. A bridge of the 14th century crosses the river.

The shire hall includes remains of a building, called the Stannary prison, dating from the 13th century. The G.W. railway has workshops here. The boundaries of the borough were further extended in 1934. Area 4·9 sq.mi.

LOT, in the Bible, the legendary ancestor of the two Palestinian peoples, Moab and Ammon (Gen. xix. 30–38; *cf.* Ps. lxxxiii. 8); he appears to have been represented as a Horite or Edomite (*cf.* the name Lotan, Gen. xxxvi. 20, 22). As the son of Haran and grandson of Terah, he was Abraham's nephew (Gen. xi. 31), and he accompanied his uncle in his migration from Haran to Canaan. Near Bethel Lot separated from Abraham, owing to disputes between their shepherds, and being offered the first choice, chose the rich fields of the Jordan valley which were as fertile and well irrigated as the "garden of Yahweh" (*i.e.,* Eden, Gen. xiii. 7 *sqq.*). It was in this district that the cities of Sodom and Gomorrah were situated. He was saved from their fate by two divine messengers who spent the night in his house, and next morning led Lot, his wife, and his two unmarried daughters out of the city. His wife looked back and was changed to a pillar of salt, but Lot with his two daughters escaped first to Zoar and then to the mountains east of the Dead Sea, where the daughters planned and executed an incest by which they became the mothers of Moab and Ben-Ammi (*i.e.,* Ammon; Gen. xix.). The account of Chedorlaomer's invasion and of Lot's rescue by Abraham belongs to an independent source (Gen. xiv.), the age and historical value of which has been much disputed. (*See* further ABRAHAM; MELCHIZEDEK.)

LOT, a department of south-western France, formed in 1790 from the district of Quercy, part of the old province of Guyenne. It is bounded N. by Corrèze, W. by Dordogne and Lot-et-Garonne, S. by Tarn-et-Garonne, and E. by Aveyron and Cantal. Area 2,018 sq.mi. Pop. (1936) 162,572. The department is that part of the south-western slope of the Massif Central which is drained by the river Lot, navigable with the help of locks, while its northern portion is crossed by the parallel Dordogne, both streams flowing west to the Garonne-Gironde. On its eastern side, towards the heights of Cantal, there are hills 2,560 ft. in height. The centre of the department is occupied by a calcareous Jurassic plateau called the Causses, 700–1,300 ft. (Causse de Martel north of the Dordogne, Causse de Gramat or de Rocamadour between Dordogne and Lot, and Causse de Cahors south of Lot). On the west, stream dissection has formed a series of hills fringing the plain of Aquitaine. Water soaks through the porous surface of the causses and vanishes down its many fissures (*igues*) and springs emerge lower down to form large streams in the narrow and beautiful valleys. Temperature varies greatly between the warm valleys and the highlands of impermeable rock in the east; rainfall is somewhat above the average for France. Wheat, oats, maize, buckwheat and rye are the chief cereals. Wines are well known. The north-east cantons produce large quantities of chestnuts, walnuts, truffles, plums, and potatoes are also grown. Sheep abound, but cattle, pigs, horses, mules and goats are also reared, as well as poultry and bees. Some iron and coal are mined, and a little zinc. Limestone is quarried. The three arrondissements are those of Cahors, the capital, Figeac and Gourdon; there are 29 cantons and 331 communes.

Lot belongs to the 17th military district (Toulouse), and to the *académie* of Toulouse, its court of appeal is at Agen, and it is in the province of the archbishop of Albi, bishopric of Cahors. It is served by the Orléans railway. Cahors, Figeac and Rocamadour are the principal places. The fine feudal fortress at Castelnau has an audience hall of the 12th century, the Romanesque abbey-church at Souillac has a finely sculptured entrance. The plateau of Puy d'Issolu, near Vayrac, is believed by most authorities to be the site of the ancient Uxcellodunum, the scene of the last stand of the Gauls against Julius Caesar in 51 B.C. Lot has many dolmens.

LOT, a river of southern France, about 300 m. long, rising in the Hercynian gneisses of the Cévennes on Mt. du Goulet, at a height of 4,918 feet. Its direction is westward through a deep gorge between the Causse of Mende and Aubrac mountains, and the tableland (*causses*) of Sauveterre, Sévérac and Comtal. It passes off the gneisses near Capdenac; hence its sinuous course crosses the plateau of Quercy, of Jurassic limestones, to enter a wider fertile plain, covered with Tertiary deposits and alluvium. Its largest tributary, the Truyère (right), joins it at Entraygues. Lower down it receives the Dourdou (left) and the Célé (right) above Cahors, below which is the town of Villeneuve-sur-Lot. The Lot is canalized and navigable between the Garonne and Bouquiès (160 miles).

LOT-ET-GARONNE, a department of south-western France, formed in 1790 of Agenais and Bazadais, two districts of the old province of Guienne, and of Condomois, Lomagne, Brullois and pays d'Albret, formerly portions of Gascony. It is bounded W. by Gironde, N. by Dordogne, E. by Lot and Tarn-et-Garonne, S. by Gers and S.W. by Landes. Area, 2,079 sq.mi. Pop. (1936) 252,761. The department is that part of the Garonne basin above and below the point at which the Lot joins it. The north-east and the south are hilly, and in the west are the borders of the Landes (*q.v.*). The Garonne, the Lot and the Drot, a right bank tributary of the Garonne, are navigable. The mean temperature of Agen is 56·6° F, or 5° above that of Paris; the annual rainfall, from 20 to 24 in., is nearly the least in France. Of cereals wheat is the chief, with oats and maize. Potatoes, vines and tobacco are important sources of wealth. The best wines are those of Clairac. Vegetables and fruit, especially plums, *prunes d'ente* and apricots, are grown. The chief trees are the pine and the oak; there is a good deal of forest and the cork-oak flourishes in the Landes. Horned cattle are the chief live stock. Poultry and pigs are also reared profitably. There are deposits of iron in the department. The forges, blast furnaces and foundries of Fumel are important; and agricultural implements and other machines are manufactured. The making of lime and cement, of tiles, bricks and pottery, of confectionery and dried plums (*pruneaux d'Agen*) and other delicacies are important. At Tonneins (pop. [1936] 4,506) there is a national tobacco manufactory. Cork cutting, of which the centre is Mézin, candle-making, tanning and paper making are other industries. The arrondissements are three, named from the towns of Agen, Marmande and Villeneuve-sur-Lot, and there are 35 cantons and 326 communes.

Agen, the capital, is the seat of a bishopric under Bordeaux and of the court of appeal. The department belongs to the region of the XVII. army corps (Toulouse), the *académie* of Bordeaux. Lot-et-Garonne is served by the lines of the Southern and the Orléans railways. The department possesses Roman remains at Mas d'Agenais and at Aiguillon. The churches of Layrac, Monsempron, Mas d'Agenais, Moirax, Mézin and Vianne are of interest, as also are the 13th century fortifications of Vianne, and the châteaux of Xaintrailles, Bonaguil, Gavaudun and of the industrial town of Casteljaloux.

LOTHAIR I. (795–855), Roman emperor, was the eldest son of the emperor Louis I., and his wife Irmengarde. Little is known of his early life, which was probably passed at the court of his grandfather Charlemagne, until 815, when he became ruler of Bavaria. When Louis in 817 divided the empire between his sons, Lothair was crowned joint emperor at Aix-la-Chapelle and given a certain superiority over his brothers. In 821 he married Irmengarde (d. 851), daughter of Hugo, count of Tours; in 822 undertook the government of Italy; and, on April 5, 823, was crowned emperor by Pope Paschal I. at Rome. In Nov. 824 he promulgated a statute which reserved the supreme power to the secular potentate, and he afterwards issued ordinances for the good government of Italy. On his return to his father's court his step-mother Judith persuaded him to secure a kingdom for her son Charles, a scheme which was carried out in 829. Lothair, however, soon changed his attitude, and spent the succeeding decade in constant strife over the division of the empire with his father. He was alternately master of the empire, and banished and confined to Italy; at one time taking up arms in alliance with his brothers and at another fighting against them; whilst the bounds of his appointed kingdom were in turn extended and reduced.

When Louis was dying in 840, he sent the imperial *insignia* to Lothair, who, disregarding the various partitions, claimed the whole of the empire. Negotiations with his brother Louis and his half-brother Charles, both of whom armed to resist this claim, were followed by an alliance of the younger brothers against Lothair. A decisive battle was fought at Fontenoy on June 25, 841, when, in spite of his personal gallantry, Lothair was defeated and fled to Aix. With fresh troops he entered upon a war of plunder, but he was compelled to surrender Aix to his brothers. In June 842 the brothers met on an island in the Saône, and agreed to an arrangement which eventually developed into the treaty of Verdun (843).

By this Lothair received Italy and the imperial title, together with a stretch of land between the North and Mediterranean seas lying along the valleys of the Rhine and the Rhône. He abandoned Italy to his eldest son, Louis, and remained in his new kingdom, engaged in alternate quarrels and reconciliations with his brothers, and in efforts to defend his lands from the attacks of the Normans and the Saracens. In 855 he fell ill, and divided his lands between his three sons. On Sept. 23 he entered the monastery of Prüm, where he died six days later.

LOTHAIR II. or **III.** (*c.* 1070–1137), surnamed the "Saxon," Roman emperor, son of Gebhard, count of Supplinburg, succeeded to extensive lands around Helmstadt in Saxony, on his father's death in 1075. Gebhard had been a leading opponent of the emperor Henry IV. in Saxony, and his son, taking the same attitude, assisted Egbert II., margrave of Meissen, in the rising of 1088. His position in Saxony was increased by his marriage (1100) with Richenza, daughter of Henry, count of Nordheim. Having assisted the German king, Henry V., against his father in 1104, Lothair was appointed duke of Saxony by Henry, when Duke Magnus, the last of the Billungs, died in 1106. His independent attitude brought him into collision with Henry V., to whom, however, he was forced to submit after an unsuccessful rising in 1112. In 1112 Lothair supported the claim of Siegfried, count of Ballenstädt to inherit the domains of Ulrich II., count of Weimar and Orlamünde, against the emperor, Henry V. The rebels were defeated, and Siegfried was killed at Warnstädt in 1113, but his son secured possession of the disputed counties. After the defeat by Lothair of Henry's forces at Welfesholz on Feb. 11, 1115, events called Henry to Italy; and Lothair appears to have been undisturbed in Saxony until 1123, when the death of Henry II., margrave of Meissen and Lusatia raised a dispute as to the right of appointment to the vacant margraviates. A struggle ensued, in which victory remained with the duke.

When Henry V. died in 1125, Lothair was chosen German king at Mainz on Aug. 30, 1125. His election was largely owing to the efforts of the papal party. The new king was crowned at Aix-la-Chapelle on Sept. 13, 1125. Lothair requested Frederick of Hohenstaufen to restore to the crown the estates bequeathed to him by the emperor Henry V. Frederick refused, and was placed under the ban. Lothair, unable to capture Nuremberg, gained the support of Henry the Proud, the new duke of Bavaria, by giving him his daughter, Gertrude, in marriage, and that of Conrad, count of Zähringen, by granting him the administration of the kingdom of Burgundy, or Arles. But Conrad of Hohenstaufen, the brother of Frederick, was chosen German king in December 1127, and was quickly recognized in northern Italy. But by the end of 1129 the Hohenstaufen strongholds, Nuremberg and Spires, were in Lothair's possession. This struggle was accompanied by disturbances in Lorraine, Saxony and Thuringia, but order was soon restored after the resistance of the Hohenstaufen had been beaten down. In 1131 the king led an expedition into Denmark; resistance was offered, and the Danish king, Niels, promised to pay tribute to Lothair.

The king's attention at the time was called to Italy where two popes, Innocent II. and Anacletus II., were clamouring for his support. At first Lothair remained heedless and neutral; but in March 1131 he was visited at Liége by Innocent, to whom he promised his assistance. Crossing the Alps with a small army in September 1132, he reached Rome in March 1133, accompanied by Innocent. As St. Peter's was held by Anacletus, Lothair's coronation as emperor took place June 4, 1133 in the church of the Lateran. He then received as papal fiefs the vast estates of Matilda, marchioness of Tuscany, thus securing for his daughter and her Welf husband lands which might otherwise have passed to the Hohenstaufen. He returned to Germany, where he restored order in Bavaria, and on the lower Rhine. Resuming the struggle against the Hohenstaufen, Lothair soon obtained the submission of the brothers, who retained their lands, and a general peace was sworn at Bamberg. The emperor's authority was now generally recognized, and the annalists speak highly of the peace and order of his later years. In 1135, Eric II., king of Denmark, acknowledged himself a vassal of Lothair; Boleslaus III., prince of the Poles, promised tribute and received Pomerania and Rügen as German fiefs; while the eastern emperor, John Comnenus, implored Lothair's aid against Roger II. of Sicily.

The emperor seconded the efforts of his vassals, Albert the Bear, margrave of the Saxon north mark, and Conrad I., margrave of Meissen and Lusatia, to extend the authority of the Germans in the districts east of the Elbe, and assisted Norbert, archbishop of Magdeburg, and Albert I., archbishop of Bremen, to spread Christianity. In Aug. 1136, attended by a large army, Lothair set out upon his second Italian journey. The Lombard cities were either terrified into submission or taken by storm; Roger II. was driven from Apulia; and the imperial power enforced over the whole of southern Italy. A mutiny among the German soldiers and a breach with Innocent concerning the overlordship of Apulia compelled the emperor to retrace his steps. An arrangement was made with regard to Apulia, after which Lothair, returning to Germany, died at Breitenwang, a village in the Tirol, on Dec. 3 or 4, 1137. Lothair has been described as the "imitator and heir of the first Otto." His reign was regarded, especially by Saxons and churchmen, as a golden age for Germany.

Bibliography.—The main authorities for the life and reign of Lothair are: "Vita Norberti archiepiscopi Magdeburgensis"; Otto von Freising, "Chronicon Annalista Saxo" and "Narratio de electione Lotharii" all in the *Monumenta Germaniae historica. Scriptores,* Bände vi., xii. and xx. (Hanover and Berlin, 1826–92). The best modern works are: L. von Ranke, *Weltgeschichte,* pt. viii. (Leipzig, 1887–88); W. von Giesebrecht, *Geschichte der Deutschen Kaiserzeit,* Band iv. (Brunswick, 1877), Band v. (Leipzig, 1888); Ph. Jaffe, *Geschichte des Deutschen Reiches unter Lothar* (1843); W. Bernhardi, *Lothar von Supplinburg* (Leipzig, 1879); O. von Heinemann, *Lothar der Sachse und Konrad III.* (Halle, 1869); and Ch. Volkmar, "Das Verhältniss Lothars III. zur Investiturfrage," in the *Forschungen zur Deutschen Geschichte,* Band xxvi. (Göttingen, 1862–86).

LOTHAIR (941–986), king of France, son of Louis IV., succeeded his father in 954, and was at first under the guardianship of Hugh the Great, duke of the Franks, and then under that of his maternal uncle Bruno, archbishop of Cologne. The beginning of his reign was occupied with wars against the vassals, particularly against the duke of Normandy. Lothair attempted to recover Lorraine by a sudden attack, and in the spring of 978 nearly captured the emperor Otto II. at Aix-la-Chapelle. In the autumn Otto invaded France, penetrating as far as Paris, but was forced to retreat with heavy loss. Peace was concluded in 980 at Margut-sur-Chiers, and in 983 Lothair was even chosen guardian to the young Otto III. Towards 980, however, Lothair quarrelled with Hugh the Great's son, Hugh Capet, who, at the instigation of Adalberon, archbishop of Reims, became reconciled with Otto III. Lothair died on March 2, 986. By his wife Emma, daughter of Lothair, king of Italy, he left a son who succeeded him as Louis V.

See F. Lot, *Les Derniers Carolingiens* (Paris, 1891); and the *Recueil des actes de Lothaire et de Louis V.,* edited by L. Halphen and F. Lot (1908).

LOTHAIR (825–869), king of the district called after him Lotharingia, or Lorraine, was the second son of the emperor Lothair I. On his father's death in 855, he received for his kingdom a district lying west of the Rhine, between the North Sea and the Jura mountains, which was called *Regnum Lotharii* and early in the 10th century became known as Lotharingia or Lorraine. On the death of his brother Charles in 863 he added some lands south of the Jura to this inheritance. The reign was chiefly occupied by efforts on the part of Lothair to obtain a divorce from his wife Teutberga, a sister of Hucbert, abbot of St. Maurice (d. 864); and his relations with his uncles, Charles the Bald and Louis the German, were influenced by his desire to obtain their support to this plan. Louis favoured the divorce, and Charles opposed it, while neither lost sight of the fact that Lothair was without male issue. Lothair put away Teutberga; but Hucbert took up arms on her behalf, and after she had submitted successfully to the ordeal of water, Lothair was compelled to restore her in 858. He then won the support of his brother, the emperor Louis II., by a cession of lands, and obtained the consent of the local clergy to the divorce and to his marriage with Waldrada, which was celebrated in 862. A synod of Frankish bishops confirmed this decision at Metz (863), but Teutberga fled to the court of Charles the Bald, and Pope Nicholas I. declared against the decision of the synod. An attack on Rome by the emperor failed, and in 865 Lothair again took back his wife. Teutberga, however, now expressed her desire for a divorce, and Lothair went to Italy to obtain the assent of the new pope Adrian II. On the return journey he died at Piacenza on Aug. 8, 869. He left, by Waldrada, a son Hugo who was declared illegitimate, and his kingdom was divided between Charles the Bald and Louis the German.

See Hincmar, "Opusculum de divortio Lotharii regis et Tetbergae reginae," in *Cursus completus patrologiae,* tome cxxv., edited by J. P. Migne (Paris, 1857–79); M. Sdralek, *Hinkmars von Rheims Kanonistisches Gutachten über die Ehescheidung des Königs Lothar II.* (Freiburg, 1881); E. Dümmler, *Geschichte des ostfränkischen Reiches* (Leipzig, 1887–88); and E. Mühlbacher, *Die Regenten des Kaiserreichs unter den Karolingern* (Innsbruck, 1881).

LOTHIAN, MARK KERR, First Earl of (d. 1609), the eldest son of Mark Kerr (d. 1584), abbot, and then commendator, of Newbattle, was a member of the famous border family of Ker of Cessford. Mark Kerr was an extraordinary lord of session under the Scottish king James VI; he became Lord Newbattle in 1587, and earl of Lothian in 1606. He died on April 8, 1609, having had, as report says, 31 children by his wife, Margaret (d. 1617), daughter of John Maxwell, 4th Lord Herries.

LOTHIAN, PHILIP HENRY KERR, 11TH MARQUESS OF (1882–1940), British ambassador to the United States, was born April 18, 1882. He was educated at the Oratory school, Birmingham, and at New college, Oxford university. In 1905 he was appointed assistant secretary of the Inter-Colonial Council of Transvaal and Orange River Colony and of the Railway Committee of Central South African Railways, and in those capacities he went to South Africa, where he remained until 1910. In South Africa he edited a magazine, *The State,* which favoured union of the South African colonies. After his return to England, he became editor of *The Round Table,* a journal of government and politics. Lloyd George made Kerr his secretary in 1916, in which capacity he assisted in preparing the Versailles treaty. He resigned in 1921 to direct the United Newspapers, Ltd.; served in the British cabinet as parliamentary under-secretary of the India office (1931–32); was chairman of the Indian Franchise committee (1932); and was secretary of the Rhodes trust, which administers the Rhodes scholarships (1925–39). In 1939 he was appointed British ambassador to the United States, a position he held until his death, Dec. 12, 1940, in Washington, D.C.

In the early 1930s, Kerr was an advocate of appeasing Germany but he abandoned that position after Hitler's seizure of Czechoslovakia. His chief effort as ambassador was to obtain war materials for Britain from the United States.

LOTHIAN. This name was formerly applied to a considerably larger extent of country than the three counties of Linlithgow, Edinburgh and Haddington Roxburghshire and Berwickshire at all events were included in it, probably also the upper part of Tweeddale (at least Selkirk). It would thus embrace the eastern part of the Lowlands from the Forth to the Cheviots, *i.e.,* all the English part of Scotland in the 11th century. This region formed from the 7th century onward part of the kingdoms of Bernicia and Northumbria. It cannot have come into English hands before the last decades of the previous century; for in the *Historia Brittonum* the Bernician king Theodoric, whose traditional date is 572–579, is said to have been engaged in war with four Welsh kings. One of these was Rhydderch Hên who, as we know from Adamnan, reigned at Dumbarton, while another named Urien is said to have besieged Theodoric in Lindisfarne. If this statement is to be believed it is hardly likely that the English had by this time obtained a firm footing beyond the Tweed. Most probably the greater part of Lothian was conquered by the Northumbrian king Aethelfrith, who, according to Bede, ravaged the territory of the Britons more often than any other English king, in some places reducing the natives to dependence, in others exterminating them.

In the time of Oswio the English element became predominant in northern Britain. His supremacy was acknowledged both by the Welsh in the western Lowlands and by the Scots in Argyllshire. On the death of the Pictish king Talorgan, the son of his brother Eanfrith, he seems to have obtained the sovereignty over a considerable part of that nation also. Early in Egfrith's reign an attempt at revolt on the part of the Picts proved unsuccessful. We hear at this time also of the establishment of an English bishopric at Abercorn, which, however, only lasted for a few years. By the disastrous overthrow of Egfrith in 685 the Picts, Scots and some of the Britons also recovered their independence. Yet we find a succession of English bishops at Whithorn from 730 to the 9th century, from which it may be inferred that the southwest coast had already by this time become English. The Northumbrian dominions were again enlarged by Eadberht, who in 750 is said to have annexed Kyle, the central part of Ayrshire, with other districts. In conjunction with Oengus mac Fergus, king of the Picts, he also reduced the whole of the Britons to submission in 756. But this subjugation was not lasting, and the British kingdom, though now reduced to the basin of the Clyde, whence its inhabitants are known as Strathclyde Britons, continued to exist for nearly three centuries. After Eadberht's time we hear little of events in the northern part of Northumbria, and there is some reason for suspecting that English influence in the southwest began to decline before long, as our list of bishops of Whithorn ceases early in the 9th century; the evidence on this point, however, is not so decisive as is commonly stated. About 844 an important revolution took place among the Picts. The throne was acquired by Kenneth mac Alpin, a prince of Scottish family, who soon became formidable to the Northumbrians. He is said to have invaded "Saxonia" six times, and to have burned Dunbar and Melrose. After the disastrous battle at York in 867 the Northumbrians were weakened by the loss of the southern part of their territories, and between 883 and 889 the whole country as far as Lindisfarne was ravaged by the Scots. During the next 50 years the influence of the Scottish kingdom seems to have increased in the south, and in 945 the English king Edmund gave Cumberland, *i.e.,* apparently the British kingdom of Strathclyde, to Malcolm I, king of the Scots, in consideration of his alliance with him. Malcolm's successor Indulph (954–962) succeeded in capturing Edinburgh, which thenceforth remained in possession of the Scots. His successors made repeated attempts to extend their territory southwards, and certain late chroniclers state that Kenneth II in 971–975 obtained a grant of the whole of Lothian from Edgar. Whatever truth this story may contain, the cession of the province was finally effected by Malcolm II by force of arms. At his first attempt in 1006 he seems to have suffered a great defeat from Uhtred, the son of earl Waltheof. Twelve years later, however, he succeeded in conjunction with Eugenius, king of Strathclyde, in annihilating the Northumbrian army at Carham on the Tweed, and Eadulf Cudel, the brother and successor of Uhtred, ceded all his territory to the north of that river as the price of peace. Henceforth in spite of an invasion by Aldred, the son of Uhtred, during the reign of Duncan, Lothian remained permanently in possession of the Scottish kings. (*See* SCOTLAND.)

LOTI, PIERRE (the pen name of Louis Marie Julien Viaud) (1850–1923), French author, was born at Rochefort on Jan. 14, 1850. His education began in Rochefort, but at the age of 17, following the tradition of his family, he entered the navy and began to attend the naval school, Le Borda. He gradually rose in his profession, attaining the rank of captain in 1906, and in 1910 was placed on the reserve list. His pseudonym is said to have been due to his extreme shyness and reserve in early life, which made his comrades call him after *le Loti,* an Indian flower which grows in unfrequented spots. He was never given to books or study, and it was not until 1876 that he was persuaded to write down and publish some curious experiences at Constantinople, in *Aziyadé,* a book which, like so many of Loti's, seems half a romance, half an autobiography. Thereafter he continued to write novels, which were mainly reminiscent of his travels. While taking part as a naval officer in the Tonking war, Loti exposed a series of scandals which followed on the capture of Hué (1883), and was suspended from the service for over a year. He continued silent for some time, but in 1886 published his most famous book, *Pêcheur d'Islande,* a novel of life among the Breton fisher-folk. In May 1891 he was elected a member of the French academy. He died at Hendaye (Basses Pyrénées), June 10, 1923.

Loti's greatest successes were gained in the species of confession, half-way between fact and fiction, of his earlier books. His later books of pure description were rather empty, for in spite of the beauty and melody and fragrance of his works, his mannerisms are likely to pall. With all his limitations, however, he was, in mechanism of style and cadence, one of the most original and talented French writers of the second half of the 19th century.

Among his most important works are: *Rarahu* (1880) republished as *Le Mariage de Loti; Le Roman d'un Spahi* (1881); *Mon frère Yves* (1883); *Propos d'exil* (1887); *Madame Chrysanthème* (1887); *Au Maroc* (1890); *Le Livre de la pitié et de la mort* (1891); *Fantôme d'orient* (1892); *Ramuntcho* (1897); *L'Inde (sans les Anglais)* (1903); *La troisième jeunesse de Mme. Prune* (1905); *Les Désenchantées* (1906; Eng. trans. by C. Bell); *La Mort de Philae* (1908); *Judith Renaudin* (Théâtre Antoine, 1904).

See also P. Loti, *Journal intime, 1878–1881* (1925); P. Loti, *Lettres à Mme. Juliette Adam, 1880–1922* (1924); N. Serban, *Pierre Loti, sa vie et son oeuvre* (1924).

LOTICHIUS or **LOTICH, PETRUS SECUNDUS** (1528–1560), German humanist, was born at Schlüchtern, Hesse-Cassel. He was educated at a number of schools including the one at Wittenberg, where he was a student of Melanchthon's. In 1547 he was a member of the army of the Protestant League of Schamlkalden which was defeated by the forces of the Holy Roman emperor, Charles V, at Mühlberg. He was made professor of medicine at Heidelberg in 1557 and he died in that city three years later. Lotichius is noted for his poems, particularly his elegies, of which he left several volumes. Stylistically they resemble the works of some of the classic Latin poets.

LÖTSCHEN PASS or **LÖTSCHBERG,** an easy glacier pass (8,842 ft.) leading from Kandersteg (Bernese Oberland) to the Lötschen valley (Valais). It is first mentioned in 1352, but was probably crossed earlier by the Valaisans who colonized various parts of the Bernese Oberland. In 1384 and in 1419 battles were fought on it between the Bernese and the Valaisans, while in 1698 a mule path (of which traces still exist) was contructed on the Bernese slope, though not continued beyond. The railway between Berne and Brig passes beneath the pass in the Lötschberg tunnel (9 mi. long and built in 1906–12). The tunnel starts above Kandersteg and enters the Lötschen valley at Goppenstein. This pass is to be distinguished from the Lötschenlücke (10,512 ft.), another glacier pass which leads from the head of the Lötschen valley to the Great Aletsch glacier.

LOTTERIES: *see* GAMING AND WAGERING.

LOTTI, ANTONIO (1667?–1740), Italian musical composer, was born at Venice, the son of Matteo Lotti, Kapellmeister to the court of Hanover. He entered the Doge's chapel as a boy, and in 1689 was engaged as an alto singer, succeeding later to the posts of deputy organist (1690), second organist (1692), first organist (1704), and, finally, in 1736, Maestro di Cappella at St. Mark's church. In 1717 he was invited to Dresden by the crown prince of Saxony. After producing three operas there he returned to his duties at Venice in 1719. He died on Jan. 5, 1740. Like many other Venetian composers he wrote operas for Vienna. Among his pupils were Alberti, Bassani, Galuppi, Gasparini and Marcello. Burney justly praises his church music, which is severe in style, but none the less modern in its grace and pathos. Lotti's greatest work is the *Crucifixus* (for six, eight or ten voices) printed in Rochlitz's collection. A fine setting of the *Dies Irae* is in the Imperial library at Vienna, and some of his masses have been printed in the collections of Proske and Lück.

See C. Spitz, *Antonio Lotti in seiner Bedeutung als opernkomponist* (1918).

LOTTO, LORENZO (*c.* 1480–1556), Italian painter, was born in Venice, but in the earlier years of his life lived at Treviso.

His two earliest authentic pictures, Sir Martin Conway's "Danaë" (about 1498) and the "St. Jerome" of the Louvre, as indeed all the works executed before 1509, have unmistakable quatrocentisque traits in the treatment of the drapery and landscape, and cool gray tonality. To this group belong the Madonnas at Bridgewater House, Villa Borghese, Naples and Sta. Cristina near Treviso, the Recanati altarpiece, the "Assumption of the Virgin" at Asolo, and the portrait of a young man at Hampton Court. He was in Rome between 1508 and 1512, when Raphael was painting in the Stanza della Signatura. A document in the Corsini library mentions that Lotto received 100 ducats as an advance payment for fresco-work in the upper floor of the Vatican, but there is no evidence that this work was ever executed. In the next dated works, the "Entombment" at Jesi (1512), and the "Transfiguration," "St. James" and "St. Vincent" at Recanati, Lotto has abandoned the dryness and cool colour of his earlier style, and adopted a fluid method and a blonde, joyful colouring.

In 1513 we find him at Bergamo, where he had entered into a contract to paint for 500 gold ducats an altarpiece for S. Stefano, completed in 1516, and now at S. Bartolommeo. From the next years, spent mostly at Bergamo, date the Dresden "Madonna," "Christ taking leave of his Mother" at the Berlin gallery, the "Bride and Bridegroom" at Madrid, the National gallery "Family Group" and portrait of the Protonothary Giuliano, several portraits in Berlin, Milan and Vienna, numerous altarpieces in and near Bergamo, the strangely misnamed "Triumph of Chastity" at the Rospigliosi palace in Rome, and the portrait of Andrea Odoni at Hampton Court. To this Bergamask period also belongs the fine series of frescoes in the Oratorio Guardi at Trescorre, near Bergamo (1524), free and original in design. In 1526 or 1527 Lotto returned to Venice, where Titian ruled supreme in the world of art; and it was only natural that the example of the great master should have fired him to emulation. However, even in the Carmine altarpiece, the "St. Nicholas of Bari," which is his nearest approach to Titian, he retained his individualized, as opposed to Titian's generalized, expression of emotion. But it was only a passing phase, and he soon returned to the cooler schemes of his earlier work.

Among his chief pictures executed in Venice between 1529 and 1540 are the "Christ and the Adulteress," now at the Louvre, the "Visitation" at the Jesi library, the "Crucifixion" at Monte S. Giusto, the "Madonna" at the Uffizi, the "Madonna and Saints" at Cingoli, and some portraits at the Berlin and Vienna museums, the Villa Borghese and Doria palace in Rome, and at the National gallery in London. He was at Treviso (1542–45), at Ancona in 1550, the year in which he entirely lost his voice; and in 1552 he "devoted his person and all his property to the Holy Virgin of Loreto" and took up his abode with the monks of that shrine. He died in 1556.

See Vasari (Milanesi ed.) *Vite;* G. Morelli, *Italian Masters in German Galleries* (1883); *Italian Painters in the Borghese and Doria Panfili Galleries* (1892–93); B. Berenson, *Lorenzo Lotto* (1901).

LOTTO (Ital. for "lot"), a gambling game often called *Keno* in America, played by any number of persons upon large boards or cards, each of which is divided into three horizontal rows of nine spaces, four spaces in each row being left blank and the other five marked with numbers up to 90. Each card is designated by a general number. The cards usually lie on the gaming-table, and a player may buy from the bank as many as he cares to use, each card being registered or *pegged* on an exposed table as soon as bought. Ninety small ivory markers, generally balls flattened on one side, numbered from 1 to 90, are placed in a bag and shaken out one by one, or, more usually, in a so-called *keno-goose,* a kind of urn with a spout through which the balls are allowed to roll by means of a spring. When a number falls out, the banker, or *keno-roller,* calls it out distinctly, and each player upon whose card that number occurs places a mark over it. This is repeated until one player has all the numbers in one row of his card covered, upon which he calls out "Keno!" and wins all the money staked excepting a percentage to the bank.

LOTUKO: *see* LOATUKO.

LOTUS, a popular name applied to several plants. The lotus fruits of the Greeks belonged to *Ziziphus lotus,* a bush native in south Europe with fruits as large as sloes, containing a mealy substance which can be used for making bread and also a fermented drink. In ancient times the fruits were an important article of food among the poor. A wine made from the fruit was thought to produce content and forgetfulness; hence the "lotophagi" or lotus-eaters. *Ziziphus* is a member of the family Rhamnaceae. The Egyptian lotus was a water-lily, *Nymphaea lotus;* also the sacred lotus of the Hindus, *Nelumbium nelumbo,* and the American lotus, *N. luteum.* The lotus tree, known to the Romans as the Libyan lotus, was probably *Celtis australis,* the nettle-tree (*q.v.*), a southern European tree, a native of the elm family, with fruits like small cherries, first red and then black. *Lotus* of botanists is a genus of the pea family (*Leguminosae*), containing a large number of species of herbs and undershrubs widely distributed in the temperate regions of the old world. It is represented in Britain by *L. corniculatus,* bird's foot trefoil, a low-growing herb, common in pastures and waste places, with clusters of small bright yellow pea-like flowers, which are often streaked with crimson; the popular name is derived from the pods which when ripe spread like the toes of a bird's foot. (X.)

In decoration, the lotus, through gradual conventionalization, became one of the most prolific ornamental forms. Its universal use in Egypt resulted from its symbolic association with the Nile, the giver of life. The flower itself is represented as a common votive offering and is frequently painted as though tied on to shrines or house pillars. The conventionalized form is not only the origin of the lotus bud capital, and the late lotus flower capital, but also serves in various ways as a basis for borders and all-over patterns. Two conventionalized varieties, the tri-lobe or three-leaved lotus, and the lotus palmette (in which the flower is combined with a semi-circle or semi-ellipse of radiating petals above it), were largely used by the Assyrians and all the peoples along the eastern shore of the Mediterranean. Thus the lotus is at the basis of such varying forms as the Assyrian sacred tree, and those Phoenician stele capitals which were the parents of the Ionic order. Lotus flower bud and palmette forms are also the origin of a great number of Greek, painted ceramic patterns and from them evolved into the egg and dart and into the anthemion (*q.v.*). The Romans not only borrowed and modified these Greek lotus derivatives, but also received further lotus forms from Etruscan art. Lotus derivatives, like many other Roman decorative motives, appear in modified form throughout Byzantine and Romanesque art. Lotus forms or derivatives are common even in the 20th century; thus their influence can be traced continuously back from modern times, through the Renaissance, mediaeval, Roman, Greek and western Asiatic work to its source in Egypt at least 5,000 years ago. For a complete, though not entirely sound discussion, *see* W. H. Goodyear, *Grammar of the Lotus.* (T. F. H.)

LOTUS-EATERS, a people encountered by Odysseus (*q.v.*) (Gr. Λωτοφάγοι); they lived on a plant called *lotos,* which they offered to his men; those who ate of it forgot home and friends and wanted only to remain there and eat of that food (Homer, *Od.* ix., 82 ff.). It should be plain enough that the Lotus-Eaters and their country are situated in fairy-land; but, besides allegorical interpretations, many ancient scholars amused themselves by trying to identify them with some people of Northern Africa, since that continent produces one or two edible plants called λωτὸς by the Greeks. This foolishness has been imitated by some moderns. The phrase "to eat lotus" is used metaphorically by numerous ancient writers to mean "to forget, to be unmindful."

See Roscher's *Lexikon,* art. "Lotophagen."

LOTZE, RUDOLF HERMANN (1817–1881), German philosopher, was born in Bautzen on May 21, 1817, the son of a physician. He studied in the gymnasium of Zittau, and in 1834 entered the university of Leipzig where, four years later, he gained his M.D. and also a doctorate in philosophy. Lotze's studies were governed by two distinct interests. The first was scientific, based upon mathematical and physical studies under the guidance of E. H. Weber, W. Volckmann and G. T. Fechner. The second was his aesthetical and artistic interest, which was developed under the care of C. H. Weisse. His scientific interests led him to condemn the form which Schelling's and Hegel's expositions had adopted, especially the dialectic method of the latter, whilst his love of art and beauty, and his appreciation of moral purposes, revealed to him the existence of a trans-phenomenal world of values into which no exact science could penetrate. His vocation then seemed to be the reconciliation of science with art, literature and religion; and hence the central point of his philosophy has been described as an analysis of the concept of the mechanism of nature with the object of proving that this concept necessarily leads to the assumption of an ideal principle of existence.

Lotze laid the foundation of his system in his *Metaphysik* (1841) and *Logik* (1843), short books published while he was still a junior lecturer at Leipzig, from which university he migrated to Göttingen in 1844, succeeding Herbart in the chair of philosophy. But he first became generally known through his *Allgemeine Pathologie und Therapie als mechanische Naturwissenschaften* (Leipzig, 1842, 2nd ed., 1848), his *Allgemeine Physiologie des Körperlichen Lebens* (Leipzig, 1851), and his *Medizinische Psychologie oder Physiologie der Seele* (Leipzig, 1852). In these he tried to show that the laws which govern particles of matter in the inorganic world govern them if they are joined into an organism. Final causes, vital and mental forces, and even the soul itself can only act through the inexorable mechanism of natural laws. But this mechanical view of nature is not identical with the materialistic. In the last of the above-mentioned works he asserts that mind must be considered as an immaterial principle, though its action on the body and vice versa is purely mechanical. In spite of the fact that Lotze declared that these writings were not intended to solve the origin and meaning of this all-pervading mechanism or to set forth the whole of his conception of Nature, they were counted among the opposition literature which destroyed the phantom of Hegelian wisdom and vindicated the independent position of empirical philosophy.

These misinterpretations induced Lotze to publish his *Streitschriften* (Leipzig, 1857), in which he protested against being counted either as a materialist or as a follower of Herbart. Lotze's next work, the *Mikrokosmos* (3 vols., 1856–64, Eng. trs. 2 vols., 1885) was intended to be a popular expression of his interests in science, aesthetics and religion, and a working out of his belief that the significance of the phenomena of life and mind would only unfold itself if by an exhaustive survey of the entire life of man, individually, socially and historically, we gain the necessary data for deciding what meaning attaches to the existence of this microcosm, or small world of human life, in the macrocosm of the universe. All separate channels of thought lead to the view that everywhere in the wide realm of observation we find three distinct regions—the region of facts, the region of laws and the region of standards of value. The world of facts is the field in which, and laws are the means by which, the higher standards of moral and aesthetical value are being realized; and such a union can again only become intelligible through the idea of a personal Deity, who in the creation and preservation of a world has voluntarily chosen certain forms and laws, through the natural operation of which the ends of His work are gained.

Having published his *Gesch. der Aesthetik in Deutschland* (1868), Lotze proposed to give a systematic exposition of his philosophy. His *Drei Bücher der Logik* appeared in 1874 (Eng. trs. 1888) and his *Drei Bücher der Metaphysik* in 1879 (Eng. trs. 1887), but the third volume which was to include aesthetics, ethics and the philosophy of religion was terminated by the death of Lotze at Berlin on July 1, 1881, three months after he had been called from Göttingen.

REALISTIC IDEALISM

In his exposition of logic he established two points, viz., the existence in our mind of certain laws and forms according to which we connect the material supplied by our senses, and, secondly, the fact that logical thought cannot be usefully employed without the assumption of a further set of connections, not logically necessary, but assumed to exist between the data of experience and observation. These connections handed to us by the sciences and by general culture are represented by such concepts as those of cause and effect, matter and force, end and means, freedom and necessity. It is the business of philosophy firstly to investigate these concepts and to discover the grounds on which the interconnection of phenomena rests, and secondly, to present the departments of knowledge in their true proportion. It follows, then, that any idealistic philosophy must have a realistic basis. Indeed, thought could not constitute reality because it is subjective and represents externals only inadequately, and because it is only one function among others upon which it is dependent *e.g.,* sensation, feeling and volition. All philosophical investigation falls into three parts, the first deals with those necessary forms in which we are obliged to think about things (metaphysics), the second is devoted to facts, and to the application of the results of metaphysics to these, especially to external and mental phenomena (cosmology and psychology), the third is concerned with those standards of value involved in our aesthetical or ethical judgments. We have already mentioned the final conception in which Lotze's speculation culminates, that of a personal Deity, Himself the essence of all that merits existence for its own sake, who in the creation and government of a world has voluntarily chosen certain laws through which His ends are to be realized. According to this view nothing is real but the living spirit of God and the world of living spirits which He has created; the things of this world have reality only in so far as they are the appearance of spiritual substance, which underlies everything.

In his metaphysical treatises, Lotze maintains that the course of things and their connection is only thinkable on the assumption of a plurality of existences, the reality of which can be conceived only as a multitude of relations. The nature of this reality cannot be represented as an unalterable something, but only as a fixed order of recurrence of continually changing events or impressions. Every attempt to think clearly what these relations are, what we really mean, if we talk of a fixed order of events, forces upon us the necessity of thinking also that the different things which stand in relations or the different phases which follow each other cannot be merely strung together or moved by some indefinable external power, in the form of some predestination or inexorable fate. The things themselves which exist and their changing phases must stand in some internal connection; they themselves must be capable of doing or suffering.

The simplest case of reciprocal action presupposes a universal substance, the essence of which we conceive as a system of laws underlying everything but known to us only through the impressions it produces on us, which we call things. Reflection teaches us that the nature of this universal substance can only be imagined as something analogous to our own mental life, where alone we experience the unity of a self preserved in the multitude of its (mental) states. Only where such mental life appears need we assign an independent existence; the purposes of everyday life as well as those of science are equally served if we deprive material things of an independence, and assign to them merely a connected existence through the universal substance by the action of which alone they appear to us.

The universal substance is at this stage of our investigations not endowed with the attributes of a personal Deity, and though Lotze's remarks on the subject are incomplete, in various passages he indicates that the absolute Being must be personal because personality alone possesses independence. In saying that the richness with which the working of the prime Being takes place determines the nature of existences. Lotze passes into his favourite realm of aesthetics.

Though Lotze disclaims being a follower of Herbart, his formal definition of philosophy and his conception of the object of metaphysics are similar to those of Herbart, and he forms with him an opposition to the philosophies of Fichte, Schelling and Hegel, which aimed at objective and absolute knowledge, and also to the criticism of Kant, which aimed at determining the validity of all human knowledge. But Lotze's spirit is more akin to the idealistic school than to the cold formalism of Herbart. What, however, with the idealists was an object of thought alone, the absolute, is to Lotze only inadequately definable in rigorous philosophical language; the aspirations of the human heart, the contents of our feelings and desires, the aims of art and the tenets of religious faith must be grasped in order to fill the empty idea of the absolute with meaning. This conviction of the emptiness of abstract notions, and of the fulness of individual life, has enabled Lotze to combine the two courses into which German philosophical thought had been moving since the death of Leibnitz.

LOUBET, ÉMILE FRANÇOIS (1838–1929), 7th president of the French republic, was born on Dec. 30, 1838, the son of a peasant proprietor at Marsanne (Drôme), who was more than once mayor of Marsanne. He was admitted to the Parisian bar in 1862, and began to practice at Montélimar, where he married in 1869 Marie Louis Picard. At the crisis of 1870 he became mayor of Montélimar, and thenceforward was a steady supporter of Gambetta's policy. Elected to the Chamber of Deputies in 1876 by Montélimar he was one of the 363 who in June 1877 passed the vote of want of confidence in the ministry of the duc de Broglie. In the Chamber he occupied himself especially with education, fighting the clerical system established by the Loi Falloux, and working for the establishment of free, obligatory and secular primary instruction. In 1880 he became president of the departmental council in Drôme. He had entered the Senate as a member of the moderate republican party in 1885, and he became minister of public works in the Tirard ministry (Dec. 1887 to March 1888). In 1892 President Carnot, who was his personal friend, asked him to form a cabinet. Loubet held the portfolio of the interior with the premiership, and had to deal with the anarchist crimes of that year and with the great strike of Carmaux, in which he acted as arbitrator, giving a decision regarded in many quarters as too favourable to the strikers. He was defeated in November on the question of the Panama scandals, but he retained the ministry of the interior in the next cabinet under Alexandre Ribot, though he resigned on its reconstruction in January. In 1896 he became president of the Senate, and in Feb. 1899 president of the republic in succession to Félix Faure by 483 votes as against 279 recorded by Jules Méline.

Loubet was marked out for fierce opposition and bitter insult as the representative of that section of the Republican party which sought the revision of the Dreyfus case. In June Loubet summoned Waldeck-Rousseau to form a cabinet, and at the same time entreated Republicans of all shades of opinion to rally to the defence of the State. By the reports of Loubet and Waldeck-Rousseau the Dreyfus affair was settled, when Loubet, acting on the advice of Galliffet, minister of war, remitted the ten years' imprisonment to which Dreyfus was condemned at Rennes. Loubet's presidency saw an acute stage of the clerical question, the separation of church and state; serious differences with England at the time of the South African War and the Dreyfus case respectively; and the formation of the Anglo-French *entente*. President Loubet was a typical example of the peasant-proprietor class, and had none of the aristocratic proclivities of President Faure.

His presidency came to an end in Jan. 1906, when he retired into private life, surviving until December 20, 1929, when he died at Montélimar.

LOUCHEUR, LOUIS (1872–1931), French politician, was born at Roubaix on Aug. 12, 1872. After studying at the École Polytechnique he began a highly successful career as an engineer and contractor. When, in Dec. 1916, Briand decided to give certain offices to non-political men of high technical ability, he called upon Loucheur to be an under-secretary of State. In the Clemenceau cabinet of 1917–20 he was minister of munitions, and remained at the head of the department, when it was converted at the end of the World War into a department of industrial reconstruction. In this capacity he was consulted in the drafting of the economic section of the Versailles Treaty. Loucheur entered the Chamber in Nov. 1919 as deputy for the Nord Department, and became minister for the liberated regions in the Briand cabinet in Jan. 1921. In that capacity he negotiated with the German minister of reconstruction, Walter Rathenau, the Wiesbaden Convention for facilitating payment in kind of part of the reparations. During the next two years Loucheur upheld before the Chamber, with great argumentative ingenuity, various schemes for remedying the financial situation. In the second Poincaré cabinet of 1924 he was minister of commerce. On Nov. 28, 1925, Briand appointed him minister of finance in his new cabinet. But he found every group in parliament violently hostile to the seven proposals which he submitted for alleviating the financial crisis, especially to the proposal for the forced consolidation of Government bonds. The finance commission of the Chamber twice rejected five of these proposals and he therefore resigned on Dec. 15, having held his portfolio exactly 17 days. He was one of the French delegates to the League of Nations Assembly in 1924 and 1925.

In the Herriot cabinet of 1926 Loucheur was minister of commerce. On the fall of the Herriot Government he again devoted himself to industry, and was a prime mover in the arrangements made for an international steel cartel. As one of the French delegates at the World Economic Conference at Geneva in 1927, he played an important part in the deliberations, and when Poincaré received a fresh mandate at the elections of 1928 he included Loucheur in his cabinet as minister of labour. Loucheur was proprietor of the *Petit Journal.* He died Nov. 23, 1931.

LOUDON, ERNST GIDEON, FREIHERR VON (1717–1790), Austrian soldier, was born on Feb. 2, 1717, at Tootzen, Livonia, where his family, of Scottish origin, had been settled since before 1400. His father had been in the Swedish service; the boy entered the Russian army as a cadet in 1732, saw service in 1734, 1735, and 1738–39, then resigned (1741), and after vainly applying for employment with Frederick the Great, became a captain in Trenck's corps in Vienna. Soon after the outbreak of the Seven Years' War he became colonel, in 1757 major-general of cavalry, and in 1758 forced Frederick to raise the siege of Olmütz. In 1760 he won a further victory at Kunersdorf, was promoted feldzeugmeister and made commander-in-chief in Bohemia, Moravia and Silesia.

He was successful at Landshut and Glatz, but was defeated by Frederick at Liegnitz (Aug. 15, 1760), which action led to bitter controversy with Daun and Lacy, the commanders of the main army, who, Loudon claimed, had left his corps unsupported. In 1761 he operated again in Silesia, but was hampered by the inactivity of his Russian allies. (*See* SEVEN YEARS' WAR.) His tireless activity continued to the end of the war, in conspicuous contrast with the temporizing strategy of Daun and Lacy, and led in the last three years of the war to ever-increasing friction between the "Fabius" and the "Marcellus," as they were called, of the Austrian army.

After the peace dissensions continued between Loudon and Lacy, and Loudon only remained in the army at the special request of Maria Theresa, acting as commander-in-chief in Bohemia and Moravia 1769–72. In 1776 he settled at Hadersdorf near Vienna, and was made a field-marshal in Feb. 1778.

In the same year he was reconciled with Joseph II. and Lacy and commanded one of the two armies in the field in the war of the Bavarian Succession, but this time with only moderate success. He then retired again to Hadersdorf; but recalled after the reverses of the other generals in the Turkish War, he was made commander-in-chief, and won a last brilliant success by capturing Belgrade in three weeks, 1789. He died on July 14 at Neu-Titschein in Moravia, still on duty. His last appointment was that of commander-in-chief of the armed forces of Austria, which had been created for him by the new emperor Leopold. Loudon was buried in the grounds of Hadersdorf.

See memoir by v. Arneth in *Allgemeine deutsche Biographie, s.v.* "Loudon," and life by G. B. Malleson.

LOUDOUN, JOHN CAMPBELL, 1ST EARL OF (1598–1663), Scottish politician, eldest son of Sir James Campbell of Lawers, became Baron Loudoun in right of his wife Margaret, granddaughter of Hugh Campbell, 1st Baron Loudoun (d. 1622). With John Leslie, 6th earl of Rothes, he took part in the promulgation of the Covenant and in the General Assembly at Glasgow in 1638. He served under Gen. Leslie, and was one of the Scottish commissioners at the Pacification of Berwick in June 1639. In November of that year and again in 1640 the Scottish estates sent Loudoun with Charles Seton, 2nd earl of Dunfermline, to London on an embassy to Charles I. Loudoun intrigued with the French ambassador, and was sent to the Tower. He was released in June, and two months later he re-entered England with the Scottish invading army, and was one of the commissioners at Ripon in October.

In the following August (1641) Loudoun was made lord chancellor of Scotland, and his title of earl of Loudoun (granted in 1633, but stopped in chancery), was allowed. He also became first commissioner of the treasury. He was constantly employed in negotiations in England, and in 1647 was sent to Charles at Carisbrooke castle, but the "engagement" to assist the king there made displeased the extreme Covenanters, and Loudoun was obliged to retract his support of it. He was now entirely on the side of the duke of Argyll and the preachers. He assisted in the capacity of lord chancellor at Charles II.'s coronation at Scone, and was present at Dunbar. He joined in the royalist rising of 1653, but eventually surrendered to Gen. Monk. His estates were forfeited by Cromwell, and a sum of money settled on the countess and her heirs. At the Restoration he was removed from the chancellorship. He died in Edinburgh on March 15, 1663.

LOUD SPEAKER, a device for converting electric energy into sound energy, the strength of sound produced being sufficient to be audible at a distance.

Loud speakers are generally used for the reproduction of speech and music in rooms, halls or the open air. Before 1918 the loud speaker consisted of a form of the ordinary electromagnetic telephone receiver, with a conical horn attached to it to concentrate the sound given out by the vibrating diaphragm.

Since that date considerable research work has been done on loud speakers, particularly in connection with broadcasting, public address work and talking pictures, and the most modern forms can reasonably be classed as musical instruments.

Requirements of a Good Loud Speaker.—Progress has been greatly assisted by the development of satisfactory methods of sound measurement. These have enabled the characteristics of loud speakers to be examined.

The results of such tests have demonstrated that in an electro-acoustic system such as is used in broadcasting from the studio to the listener, the loud speaker is the least satisfactory link in the chain. But these measurements also show the way to the evolution of the perfect loud speaker. Such an instrument from the practical point of view should have the essential characteristics of realism; which means that in listening to the perfect loud speaker connected to its appropriate amplifier and microphone, and reproducing music or speech picked up by that microphone, one would hear exactly the same as if one were placed in the position of the microphone, assuming, of course, that the microphone and amplifier are accurately converting sound pressure variations at the diaphragm of the microphone into similar voltage variations in the amplifier. Then the loud speaker would have to satisfy the following main requirements: (1) An even response for all frequencies. That is to say the sound pressure output for a given voltage input to the loud speaker or loud speaker amplifier must be the same for the whole musical range of frequencies, that is say from 25 to 12,000 cycles per second. Naturalness in reproduction, on the pressure basis, is synonymous with the treatment of all frequencies equally, which means that the frequency characteristic of the instrument is a straight line, having no resonance peaks to indicate that certain frequencies are favoured in comparison with others. (2) The relation between input and output must be linear within the limits of use; that is to say if the electrical input is increased in any proportion, the acoustic output must also be increased in the same proportion. (3) The loud speaker must deal faithfully with transient phenomena; in other words the response to sudden changes must be immediate. (4) The distribution of sound in various directions from the loud speaker must be equal for all frequencies. (5) The loud speaker must be reasonably efficient.

The majority of loud speakers fail to a certain extent on all these points; and a compromise is made in designing loud speakers for any particular purpose. The general uses for modern loud speakers are as follows: (1) For realistic and faithful reproduction of speech and music in a limited space; as for instance in the case of broadcast reception in the home. Frequency characteristic, linearity, and transient response must be good. Equal distribution and efficiency are not so important, but cost and maintenance must not be forgotten. (2) For public address work, efficiency and capability of handling great power are necessary. The remaining characteristics are not so important provided that complete intelligibility is maintained. (3) A purpose now coming into prominence, namely in connection with talking pictures, occupies a half way position between the two given above, and requires the fulfilment of all the above-mentioned points.

Development of the Loud Speaker.—The loud speaker essentially comprises a diaphragm which is set into motion by electrical forces and which by its movement generates sound waves in the neighbouring air. Its motion can be utilised in two ways. The diaphragm may be relatively small and transmit sound to the air by means of a horn; or it may be large and operate direct on the air.

The original electrical sound-producing instrument was the Bell telephone receiver. It consists of a thin iron diaphragm fixed in front of an electromagnetic system, the edges being firmly clamped for mechanical reasons. (*See* TELEPHONE.)

The diaphragm thus has very marked mechanical resonances; in other words it responds more to certain frequencies than to others; and in reproducing music these frequencies are particularly favoured, with a resulting loss of naturalness. The frequency response characteristic for an average telephone earpiece shows these resonance peaks; which are however considerably damped down when the telephone is applied to the ear.

The first loud speaker was developed from the telephone earpiece by placing a conical horn in front of the diaphragm. The air column of the horn acted as a damping on the diaphragm, reduced the effects of the resonance peaks and concentrated the energy of sound coming from the diaphragm. The conical horn however does not deal equally with all frequencies.

The next development was that of a horn which would deal equally with all frequencies. The exponential horn, in which the area of the section perpendicular to the axis varies exponentially with the distance along the axis, is capable of doing this provided that it is sufficiently long.

An exponential horn of medium length is good for high and middle frequencies but fails in the lower frequencies. The longer the horn the lower the cut off frequency. Such a horn acts essentially as an acoustic transformer between the confined area at the diaphragm and the open air condition at the flare of the horn. It is an ideal method of coupling a relatively small diaphragm to the open air to obtain the maximum output from the diaphragm. The subject has been dealt with fully by Hanna and Slepian.

A typical loud speaker exponential horn does not give, in actual practice, uniform characteristics when such a horn is used in conjunction with an electromagnetic unit of the telephone earpiece type. The resonance peaks are still present and there is a noticeable lack of response in the bass frequencies. These are due to the type of unit used where diaphragm resonances are so apparent, and also to the fact that this form of moving iron movement is constrained and asymmetrical, and unable to have the free motion necessary to produce the lower frequencies (the lower the frequency the greater the amplitude necessary for equal pressure radiation).

This restriction does not allow the condition of linearity to be satisfied, and results in the generation of harmonics for pure low frequency input.

These difficulties are overcome by the use of an electrodynamic or moving coil type of movement in the unit. This was developed in one form by Round in 1924, and in another by Wente and Thuras in 1927. In both these cases the diaphragm is non-magnetic, comparatively rigid in itself and flexibly mounted, and driven by a coil attached to it which is suspended in a strong magnetic field.

Such a loud speaker has very much more satisfactory frequency and linearity characteristics. In the Wente type the efficiency is also greatly increased to an average value of 30% which is a great advance beyond that for previous horn or large diaphragm types, the majority of which do not show an efficiency greater than 3%.

For the reproduction of broadcasting the horn type has been somewhat set aside and its place taken by the large diaphragm type, which, operated by some form of electrical movement, communicates the sound direct to the air. Such diaphragms are usually made in the form of paper or card cones, and in some cases these cones are designed to have particular resonances, introduced on purpose to remedy some defective part of the curve.

Where the electrical movements of these types of speakers embody moving iron armatures, lack of linearity exists just as it does for the earpiece type of movement, with consequent absence of pure low frequency reproduction. This fault has been remedied, as in the case of horn type speakers, by the electrodynamic drive. In this type a moving coil is attached to the apex of a lightly suspended paper cone diaphragm and moves in a constant strong magnetic field. The low frequency radiation is preserved by mounting the diaphragm in a baffle.

The baffle is an extension of the mounting, holding the edges of the diaphragm, which serves to lengthen the air path from one face of the diaphragm around to the other. Its function is to limit direct interaction between air pressure changes produced at the two faces of the diaphragm.

The relationship between sound pressure output and input current to the coil can be made more even for the frequency range. Although the acoustic theory for the radiation due to the motion of a circular diaphragm in a baffle was worked out by Rayleigh in 1878, and the moving coil principle was demonstrated by Oliver Lodge in 1898 to vibrate a wooden board to reproduce sounds, it was not until 1925 that the now familiar moving coil type of loud speaker was developed by Rice and Kellogg.

The basis of the design is that the mass of the movement is the controlling factor rather than the elasticity and the damping. On this basis moving coil loud speakers have, comparatively, extremely good frequency characteristics. There is no doubt that the good reproduction which can be obtained has been responsible for a considerable increase of interest by the musical public in broadcast transmission and reception.

The departure from the straight line in the frequency characteristic is due to two factors. A "breaking up" of the cone when vibrating at high frequency is responsible for one main and several subsidiary peaks in the range of frequencies above 1,000 cycles; and mechanical resonance in the suspension of the cone at very low frequency can result in a certain "boominess" in the reproduction. Careful design can however reduce very considerably these two defects.

Another form of electrodynamic large diaphragm type has been developed by Siemens and Halske. The electrical circuit consists of a zig zag metal strip mounted by its edge on a rectangular diaphragm. This is suspended over an electromagnet with parallel gaps, and poles alternately magnetised north and south; each portion of the strip fits into its own magnetic gap with the result that when current passes through the strip the diaphragm moves as a whole and does not tend to break up at certain frequencies. The reproduction is good, and a considerable amount of power can be radiated.

Another type of loud speaker which has not yet attained great success is made in the form of a condenser. One metallic plate is fixed, and the other is made of foil and held close to the fixed one, but insulated from it. The point of interest is that the electrical force is thus applied over the whole of the diaphragm, but the efficiency is not very great and the condenser loud speaker is comparatively insensitive.

Measurement of the Characteristics of Loud Speakers.—It is possible to obtain the frequency characteristic of loud speakers, and this forms a useful basis of comparison. (*See* MICROPHONE for methods used.) The same methods give the contour surfaces of distribution for various frequencies. It is also possible to measure on an oscillograph the degree of departure from linearity. These measurements have already received considerable attention from loud speaker designers.

The importance of response to transient phenomena however has not been fully realised and very little work on the subject has been carried out. There is no doubt however that this requirement is just as necessary for realistic musical reproduction as a good frequency characteristic. There is thus considerable room for improvement in loud speakers, particularly in regard to frequency characteristics, transient response and efficiency. *See* also RADIO; SOUND; TELEPHONE.

LOUDUN, a town of western France, capital of an arrondissement, in the department of Vienne, 45 mi. by rail S.W. of Tours. Pop. (1936) 4,687. Loudun (*Laudunum*) was a town of importance during the religious wars and gave its name in 1616 to a treaty favourable to the Protestants. Of the old walls a single gateway and two towers remain. A 12th century rectangular donjon of the castle of the counts of Anjou is preserved; at its base traces of Roman constructions have been found, with fragments of porphyry pavement, mosaics and mural paintings. There is a Carmelite convent; the old Romanesque church of Sainte Croix is now used as a market. The Gothic church of St. Pierre-du-Marché has a Renaissance portal and a high stone spire. There are several old houses in the town. The manufacture of farm implements is carried on, and there is a considerable trade in agricultural products, wine, etc.

LOUGHBOROUGH, ALEXANDER WEDDERBURN, 1ST BARON: *see* ROSSLYN, ALEXANDER WEDDERBURN, 1st earl of.

LOUGHBOROUGH (lŭf'brŭ), a town in Leicestershire, England, near the Soar, on the Loughborough canal. Pop. (1938) 30,370. The manor of Loughborough was granted by William the Conqueror to Hugh Lupus, from whom it passed to the Despensers. Edward II visited the manor several times. Among the subsequent lords were Henry, Lord Beaumont and Sir Edward Hastings. The market rights were purchased by the town in 1880. Lace-making was formerly the chief industry, but machines set up by John Heathcote were destroyed by the Luddites in 1816, and the manufacture lost its importance. It is 110 mi. N.N.W. of London by the L.M.S.R. and 113 mi. by the L.N.E.R. The neighbourhood is an agricultural district, and to the S.W. lies Charnwood forest. The grammar school, founded in 1495 by Thomas Burton, occupies modern buildings. The principal industry is hosiery making; there are also engineering, iron and dye works and bell foundries (introduced in 1840). The great bell for St. Paul's cathedral, London, largest in the United Kingdom, was cast here in 1881. Loughborough was incorporated in 1888, and was extended in 1935 and 1936. Area 14.4 sq.mi. Loughborough college is an important engineering school.

LOUGHREA, a picturesque market town of Co. Galway, Eire, on the N. shore of Lough Rea, 116 mi. W. from Dublin by rail. Pop. (1936) 2,891. There are slight remains of an Early English Carmelite friary dating *c.* 1300, which escaped the Dissolution. Loughrea is the seat of the Roman Catholic bishop of Clonfert, and has a cathedral built in 1900–1905. A part of the castle of Richard de Burgh, founder of the friary, still survives, and there are traces of the town fortifications. In the neighbourhood are a cromlech and two ruined towers, and crannogs, or ancient stockaded islands, have been discovered in the lough.

LOUGHTON (low'ton), a parish in the Chigwell urban district, Essex, England, near the Roding, 11½ mi. N.N.E. of Liverpool street station, London, by the L.N.E. railway. Pop. (1931) 7,390. The lordship of the manor was granted to Waltham abbey. In the vicinity are large earthworks, probably of British origin, known as Loughton camp. This is one of the villages near Epping forest, which has become the centre of an important residential district and a resort for Londoners.

LOUHANS, a town of east-central France in the department of Saône-et-Loire, 34 mi. N.N.E. of Mâcon by road. Pop. (1936) 2,781. Its church has a fine 15th-century tower with a carved balustrade. The main street is arcaded. The town is the central market of the agricultural plain of Bresse, with much trade in chickens and horses. It has a sub-prefecture and a tribunal of commerce.

LOUIS I. (778–840), surnamed the "Pious," Roman emperor, third son of the emperor Charlemagne and his wife Hildegarde, was born at Chasseneuil in central France, and crowned king of Aquitaine in 781. His tastes were ecclesiastical rather than military, the government of his kingdom was mainly conducted by his counsellors. In 794 or 795 he married Irmengarde, daughter of Ingram, count of Haspen. After the deaths of his two elder brothers, Louis, at his father's command, crowned himself co-emperor at Aix-la-Chapelle on Sept. 11, 813, and became sole ruler in the following January. He earned the surname of "Pious" by banishing his sisters and others of immoral life from court; by attempting to reform and purify monastic life; and by showing great liberality to the church.

In Oct. 816 he was crowned emperor at Reims by Pope Stephen IV.; and at Aix in July 817, he arranged for a division of his empire among his sons. This was followed by a revolt of his nephew, Bernard, king of Italy; but the rising was easily suppressed, and Bernard was killed, although in 818 Louis pardoned the followers of Bernard and restored their estates. In 819 he married Judith, daughter of Welf I., count of Bavaria, who in 823 bore him a son Charles, afterwards called the Bald. With the support of Judith's eldest step-son Lothair, a district was carved out for Charles in 829. Discontent at this arrangement led to a rebellion in the following year, provoked by Judith's intrigues with her favourite Bernard, count of Barcelona. Lothair and his brother Pippin joined the rebels, and after Judith had been sent into a convent and Bernard had fled to Spain, an assembly was held at Compiègne, when Louis was practically deposed and Lothair became the real ruler of the Empire. But at a second assembly held at Nimwegen in Oct. 830 he was restored to power.

Further trouble between Pippin and his father led to the nominal transfer of Aquitaine from Pippin to his brother Charles in 831. The emperor's plans for a division of his dominions then led to a revolt of his three sons. Louis met them in June 833 near Kolmar, but owing possibly to the influence of Pope Gregory IV., who took part in the negotiations, he found himself deserted by his supporters, and the treachery and falsehood which marked the proceedings gave to the place the name of *Lügenfeld,* or the "field of lies." Judith, charged with infidelity, was again banished; Louis was sent into the monastery of St. Medard at Soissons; and the government of the empire was assumed by his sons. But when the younger Louis had failed to induce Lothair to treat the emperor in a more becoming fashion, he and Pippin took up arms on behalf of their father. The result was that in March 834 Louis was restored to power at St. Denis; Judith returned and the kingdoms of Louis and Pippin were increased. The struggle with Lothair continued until the autumn, when he submitted to the emperor and was confined to Italy. An assembly at Diedenhofen declared the deposition of Louis to have been contrary to law, and a few days later he was publicly restored in the cathedral of Metz. In Dec. 838 Pippin died, and the Empire, except Bavaria, the kingdom of Louis, was now divided between Lothair, reconciled to his father, and Charles. The emperor was returning from suppressing a revolt on the part of his son Louis, when he died on June 20, 840 on an island in the Rhine near Ingelheim. He was buried in the church of St. Arnulf at Metz. Louis, who is also called *Le Débonnaire,* counts as Louis I., king of France.

LOUIS II. (825–875), Roman emperor, eldest son of the emperor Lothair I., was designated king of Italy in 839, and was crowned king at Rome by Pope Sergius II. on June 15, 844. In 850 he was crowned joint emperor at Rome by Pope Leo IV., and soon afterwards married his cousin, Engelberga, a daughter of King Louis the German, and undertook the independent government of Italy. On the death of his father in Sept. 855 he became sole emperor. In 857 he allied himself with Louis the German against his brother Lothair, king of Lorraine, and King Charles the Bald, but after he had secured the election of Nicholas I. as pope in 858, he became reconciled with his brother. In 863, on the death of his brother Charles, Louis received the kingdom of Provence. In 864 he quarrelled with Pope Nicholas I. over his brother's divorce, which the pope had declared invalid, and in February reached Rome with an army, but made peace with the pope and left the city.

In 866 he routed the Saracens, but could not follow up his successes owing to the want of a fleet. In 869, with the assistance of his ally, the eastern emperor, Basil I., he captured Bari, the headquarters of the Saracens. He had withdrawn into Benevento to prepare for a further campaign, when he was treacherously robbed and imprisoned by Adelchis, prince of Benevento, in Aug. 871, but was released a month later. Returning to Rome, he was crowned a second time as emperor by Pope Adrian II. on May 18, 872. After further successes against the Saracens, who were driven from Capua, he returned to northern Italy. He died, somewhere in the province of Brescia, on Aug. 12, 875, and was buried in the church of St. Ambrose at Milan, having named as his successor in Italy his cousin Carloman, son of Louis the German.

Mühlbacher, *Die Regesten des Kaiserreichs unter den Karolingern* (Innsbruck, 1881); Th. Sickel, *Acta regum et imperatorum Karolinorum, digesta et enarrata* (Vienna, 1867–68); and E. Dümmler, *Geschichte des ostfränkischen Reiches* (Leipzig, 1887–88).

LOUIS III. (*c.* 880–928), surnamed the "Blind," Roman emperor, was a son of Boso, king of Provence or Lower Burgundy and Irmengarde, daughter of the emperor Louis II. The emperor Charles the Fat took Louis under his protection on the death of Boso in 887; but Louis was not recognized as king of Provence until 890, when Irmengarde had secured the support of the Bavarian king Arnulf and of Pope Stephen V. In 900, after the death of the emperor Arnulf, he went to Italy to obtain the imperial crown. He was chosen king of the Lombards at Pavia, and crowned emperor at Rome in Feb. 901 by Pope Benedict IV. He gained a temporary authority in northern Italy, but was soon compelled by his rival Berengar, margrave of Friuli, to leave the country. In 904, however, he went again to Italy, where he secured the submission of Lombardy; but on July 21, 905, he was surprised at Verona by Berengar, who blinded him and sent him back to Provence, where he remained until his death, at Arles, in Sept. 928. He married Adelaide, possibly a daughter of Rudolph I., king of Upper Burgundy. His eldest son, Charles Constantine, succeeded only to the county of Vienne.

See *Forschungen zur deutschen Geschichte,* Bände ix. and x. (Göttingen, 1862–86); E. Dümmler, *Geschichte des ostfränkischen Reichs* (Leipzig, 1887–88); and *Gesta Berengarii imperatoris* (Halle, 1871); and F. de Gingins-la-Sarra, *Mémoires pour servir à l'histoire de Provence et de Bourgogne Jurane* (Zürich, 1851).

LOUIS IV., or **V.** (*c.* 1287–1347), surnamed the Bavarian, Roman emperor and duke of Upper Bavaria, was the second son of Louis II., duke of Upper Bavaria and count palatine of the Rhine, and Matilda, daughter of the German king Rudolph I. At his father's death in 1294 he inherited, jointly with his elder brother Rudolph, Upper Bavaria and the Palatinate, but passed his time mainly at the court of the Habsburgs in Vienna. In the quarrel with his brother over their joint possessions, Louis was supported by his uncle Albert I., the German king. Rudolph promised in 1301 to admit his brother to a share in the government of Bavaria and the Palatinate. When Albert was murdered in May 1308, Louis became a candidate for the German throne; but his claim was not strongly supported. The new king, Henry VII., was very friendly with Rudolph, and as the promise of 1301 had not been carried out, Louis demanded a partition of their lands, and received the north-western part of Upper Bavaria in 1310, but Rudolph refused to surrender any part of the Palatinate. In 1310, on the death of Stephen I., duke of Lower Bavaria, Louis undertook the guardianship of his two young sons. This led to a war between the brothers, which lasted till June 1313, when peace was made at Munich. Frederick III (the Fair), duke of Austria, called in by the nobles of Lower Bavaria, was defeated at Gammelsdorf on Nov. 9, 1313.

In Aug. 1313 the German throne had again become vacant, and Louis was chosen at Frankfort on Oct. 20, 1314, and crowned at Aix-la-Chapelle on Nov. 25. War followed between Louis and the rival candidate, Frederick of Austria. Louis's embarrassments were complicated by a new dispute with his brother; but in 1317 Rudolph renounced his claims on Upper Bavaria and the Palatinate in consideration of a yearly subsidy and Louis was able to give undivided attention to the war with Frederick. On Sept. 28, 1322, a battle was fought at Mühldorf, which ended in a complete victory for Louis, owing mainly to the timely aid of Frederick IV. of Hohenzollern, burgrave of Nüremburg. Frederick of Austria was taken prisoner, but the struggle was continued by his brother Leopold until the latter's death in 1326. Attempts to enable the two kings to rule Germany jointly failed, and about 1326 Frederick returned to Austria. Supported by Philip V. of France in his desire to free Italy entirely from German influence, Pope John XXII. refused to recognize either Frederick or Louis, and asserted his own right to administer the empire during a vacancy.

After the battle of Mühldorf Louis sent Berthold of Neifen, count of Marstetten, into Italy with an army, which soon compelled the papal troops to raise the siege at Milan. The pope threatened Louis with excommunication unless he resigned his kingdom within three months. The king thereupon appealed to a general council, and was placed under the papal ban on March 23, 1324, a sentence which he answered by publishing his charges against the pope. In the contest Louis was helped by the Minorites, who were upholding against John the principle of clerical poverty, and by the writings of Marsilius of Padua (who dedicated to Louis his *Defensor pacis*), William of Occam, John of Jandun and others. Taking the offensive, Louis met his Ghibelline supporters at Trent and reached Italy in March 1327; and in May he received the Lombard crown at Milan.

Louis compelled Pisa to surrender and on Jan. 17, 1328, he was crowned emperor in St. Peter's by Sciarra Colonna, a Roman noble; he answered the continued attacks of Pope John by pronouncing his deposition, and proclaiming Peter of Corvara pope as Nicholas V. He then undertook an expedition against John's ally, Robert, king of Naples, but, disunion among his troops and scarcity of money and provisions drove him again to Rome, where, finding that his exactions had diminished his popularity, he left the city, and after passing six months at Pisa, returned to Germany in Jan. 1330. The struggle with the pope was renewed in Germany, and a formidable league had been formed against Louis. He was prepared to assent to very humiliating terms, and agreed to abdicate; but negotiations were interrupted by the pope's death in Dec. 1334. John's successor, Benedict XII., was prevented from coming to terms by the influence of Philip VI. of France. Overtures for peace were made to Philip, but without success; and in July 1337 Louis concluded an alliance with Edward III., king of England, and made active preparations for war. During these years his attention was also occupied by a quarrel with John, king of Bohemia, over the possession of Tirol, by a campaign in Lower Bavaria, and a futile expedition against Nicholas I., bishop of Constance. His position was improved when the electors meeting at Rense in July 1338 banded themselves together to defend their elective rights, and when the diet at Frankfort confirmed a decree which declared that the German king did not need the papal approbation to make his election valid.

The heiress of Tirol, Margaret Maultasch, quarrelled with her husband, John Henry, margrave of Moravia, and fled to the protection of Louis, who seized the opportunity to declare her marriage void and to unite her in 1342 with his son Louis. The emperor also increased his possessions by his own marriage. In 1322 his first wife, Beatrice, daughter of Henry III., count of Glogau, had died and by his second marriage with Margaret, daughter of William III., count of Holland, he obtained, at the death of her brother, count William IV., in 1345, possession of Holland, Zealand and Friesland. In 1341 he recovered a portion of the Palatinate, and soon deserted Edward of England and came to terms with Philip of France. In the course of a war between Louis and the enemies made by his policy of acquisition which ensued in Germany he was forced to submit to humiliating terms, though he would not accept the election of Charles, margrave of Moravia (afterwards the emperor Charles IV.) as German king in July 1346. Charles consequently attacked Tirol; but Louis died suddenly at a bear-hunt near Munich on Oct. 11, 1347. He was buried in the Frauenkirche at Munich, where a statue was erected to his memory in 1622 by Maximilian I., elector of Bavaria, and where a second was unveiled in 1905. He had seven sons, three of whom were subsequently electors of Brandenburg, and ten daughters.

As a soldier Louis possessed skill as well as bravery, but he lacked perseverance and decision in his political relations; and the fact that he remained almost undisturbed in the possession of Germany in spite of the utmost efforts of the popes, is due rather to the political and intellectual tendencies of the time than to his good qualities. He encouraged trade and commerce and gave a new system of laws to the duchy.

Bibliography.—Many of the authorities for the life and reign of Louis are found in the *Fontes rerum Germanicarum,* Bände i. and iv., edited by J. F. Böhmer (Stuttgart, 1843–68). Among these is the *Vita Ludovici IV.*, by an unknown author. A number of important documents are found in the *Regesta imperii 1314–1347,* ed. J. F. Böhmer and J. Ficker (Innsbruck, 1865); *Acta imperii selecta,* ed. J. F. Böhmer and J. Ficker (Innsbruck, 1870); *Urkunden zur Geschichte des Römerzuges Königs Ludwigs des Bayern,* ed. J. Ficker (Innsbruck, 1865); *Urkundliche Beiträge zur Geschichte Kaisers Ludwigs IV.*, ed. C. Höfler (Munich, 1839); *Vatikanische Urkunden zur Geschichte Kaisers Ludwigs des Bayern,* Bände v. and vi. (Stuttgart, 1877–88); *Vatikanische Akten zur Deutschen Geschichte in der Zeit Kaisers Ludwigs des Bayern,* ed. S. Riezler (Innsbruck, 1891). In the *Forschungen zur Deutschen Geschichte* (Göttingen, 1862–86), Band. xx., is found *Urkunden zur Bairischen und Deutschen Geschichte 1256–1343,* ed. S. Riezler; and in Band xiii. is C. Häutle's *Beiträge zum Itinerar Kaiser Ludwigs.*

LOUIS I., king of Bavaria (1786–1868), son of the then prince, afterwards duke and elector, Max Joseph of Zweibrücken and his wife, Princess Augusta of Hesse-Darmstadt, was born at Strasbourg on Aug. 25, 1786. He was educated at home and at the universities of Landshut and Göttingen. Both the classics and contemporary classical poetry took hold upon his receptive mind (he visited Goethe in 1827). As a patron of the arts he proved himself as great as any who had ever occupied a German throne, and he was himself more than a mere dilettante.

The crown prince (his father had become elector in 1799 and king of Bavaria in 1805), became the leader of the small anti-French party in Bavaria. Napoleon sought in vain to win him over, and Louis fell more and more out of favour with him. Their relations continued to be strained, although in the campaigns of 1807 and 1809, in which Bavaria was among the allies of France, Louis won his laurels in the field. He married in 1810 Princess Therese of Saxe-Hildburghausen (1792–1854). Three daughters and four sons were born of this marriage, one of whom succeeded him as Maximilian II., while another, Luitpold, became prince regent of Bavaria on the death of Louis II. Louis resided chiefly at Innsbruck or Salzburg as governor of the circle of the Inn and Salzach. In 1815 he attended the congress of Vienna, where he sought to obtain the restoration of Alsace and Lorraine to Germany; and later in the year he was with the allies in Paris, using his influence to secure the return of the art treasures carried off by the French.

After 1815 also the crown prince maintained his anti-French attitude, and in 1817 his influence secured the fall of Comte Montgelas. Louis took great interest in the work of organizing the Bavarian constitution (1818) and defended it against Metternich and the Carlsbad Decrees (1819); he was also an ardent Philhellene. He succeeded to the crown of Bavaria on Oct. 12, 1825, and at once embarked upon a moderate constitutional policy, in which he found himself in general agreement with the parliament. Although a loyal Catholic he none the less opposed ultramontanism and the Jesuits. He improved the internal administration of the State, and especially that of the finances. He was a warm friend of learning, and in 1826 transferred the University of Landshut to Munich, where he placed it under his special protection. In the course of his visits to Italy he formed friendships with famous artists, notably with Thorwaldsen and Cornelius. He had the assistance of the painter Martin Wagner in procuring works of art for the great Munich collections.

Under the influence of the July revolution of 1830 he began to be drawn into the current of reaction; and though he never took up such a hostile attitude towards constitutional ideas as his brother-in-law, King Frederick William IV., he allowed the reactionary system of surveillance which commended itself to the German Confederation after 1830 to be introduced into Bavaria (*see* Bavaria: *History*). As a follower of the ideas of Friedrich List, he furthered the foundation of the Zollverein in the year 1833 and the making of canals. Of European importance was his enthusiasm for the liberation of Greece from the rule of Turkey, and his generous financial assistance. After his second son Otto (*q.v.*), had become king of Greece in 1832, Greek affairs became the central point of his foreign policy. In 1862 Otto was forced to abdicate. For this unfortunate issue Louis was not without blame; for he had totally misunderstood the national character of the Greeks and the problems involved in the attempts to govern them by bureaucratic methods. After Karl Abel became the head of the ministry in 1837 the strict Catholic party influenced affairs more and more decisively. For a while, indeed, this opposition did not impair the king's popularity, due to his amiable character, his extraordinary services in beautifying his capital at Munich, and to his lavish charity. But his disastrous *liaison,* beginning in 1846, with Lola Montez, the Spanish dancer, brought him into conflict with his people. She used her great influence against the clerical policy of Abel. The ministry protested against her proposed naturalization in the memorandum of Feb. 11, 1847. The king replaced Abel's Clerical ministry by a more accommodating Liberal one under Zu Rhein under which Lola Montez without more difficulty became Countess Landsberg. The revolutionary movement of 1848 and the pressure of the popular opposition compelled Louis to banish the countess. On March 20, 1848 he abdicated in favour of his son Maximilian.

In his retirement Louis continued to play the Maecenas magnificently. His popularity, shaken by the Montez affair, was partially recovered. To him Munich owes her finest art collections and most remarkable buildings, especially the acquisition of the famous Rhenish collection of the Boisserée brothers; also the Walhalla, the Glyptothek, the two Pinakotheken, the Odeon, the University, and many other magnificent buildings. The rôle of Munich as a great art centre would have been impossible without the splendid munificence of Louis I. He died on Feb. 28, 1868 at Nice, and was buried in Munich.

Kobell, *Unter den vier ersten Königen Bayerns* (1894); J. B. Sepp, *Louis I. Augustus, König von Bayern, und das Zeitalter der Wiedergeburt der Künste* (2nd ed., 1903).

LOUIS II., king of Bavaria (1845–1886), son of his predecessor Maximilian II. and Maria, daughter of Prince William of Prussia, was born at Nymphenburg on Aug. 25, 1845. With his brother Otto, Louis received a simple and serious education modelled on that of the German *Gymnasien.* Military instruction, physical exercises and sport, in spite of the crown prince's strong physique, received little attention. He developed a taste for solitude, which was combined with the romantic tendencies and musical and theatrical tastes traditional in his family.

Louis succeeded to the throne on March 10, 1864, at the age of eighteen. The early years of his reign were marked by a series of most serious political defeats for Bavaria. In the Schleswig-Holstein question, though he was opposed to Prussia and a friend of Duke Frederick VIII. of Augustenburg, he had not the material forces necessary effectively to resist Bismarck. Again, in the war of 1866, Louis and his minister, von der Pfordten, took the side of Austria, and at the conclusion of peace (Aug. 22) Bavaria had, in addition to the surrender of certain small portions of her territory, to agree to the foundation of the North German Confederation under the leadership of Prussia. The king's Bavarian patriotism, one of the few steadfast ideas underlying his policy, was deeply wounded, but he faced the inevitable, and wrote a letter of reconciliation (Aug. 10) to King William of Prussia. The defeat of Bavaria in 1866 showed the necessity of army reform. Under the new Liberal ministry of Hohenlohe (Dec. 29, 1866–Feb. 13, 1870) and under Prauckh as minister of war, a series of reforms were carried through which prepared for the victories of 1870. In his ecclesiastical policy Louis strove for a greater independence of the Vatican, and maintained friendly relations with Döllinger (*q.v*), but without extending his protection to the anti-Roman movement of the Old Catholics. Early in 1870 Louis formed a more Conservative cabinet under Count Bray-Steinburg. On the outbreak of the Franco-Prussian War he at once took the side of Prussia, and gave orders for mobilization. In 1871 it was he who offered the imperial crown to the king of Prussia; but not on his own initiative. Bismarck not only determined the king of Bavaria to take the decisive step which put an end to a serious diplomatic crisis, but actually drafted the letter to King William which Louis copied and despatched without changing a word.

In the early years of his reign Louis formed an intimate friendship with Richard Wagner, whom from May 1864 to Dec. 1865 he had constantly in his company. He paid 18,000 gulden of debts for him, and granted him a yearly income of 4,000 gulden (afterwards increased to 8,000). A series of performances of the Wagnerian music-dramas was instituted in Munich under the personal patronage of the king, and when the further plan of erecting a great festival theatre in Munich for the performance of Wagner's "music of the future" broke down in the face of the passive resistance of the local circles interested, Louis conceived the idea of building at Bayreuth, according to Wagner's new principles, a theatre worthy of the music-dramas. For a time Louis was entirely under Wagner's influence, and there is extant a series of emotional letters of the king to Wagner. Public opinion in Bavaria turned against Wagner. He was attacked for his foreign origin, his extravagance, his intrigues, his artistic utopias, and last but by no means least, for his unwholesome influence over the king. Louis had to give him up. But in 1866, in the midst of the preparation for war, the king hastened in May to Triebschen, near Lucerne, in order to see Wagner again. In 1868 they were seen together in public for the last time at the festival performances in Munich. In 1876 Wagner's *Ring des Nibelungen* was performed for the first time at Bayreuth in the presence of the king. Later, in 1881, the king formed a brief friendship with Joseph Kainz the actor. In Jan. 1867 he became betrothed to Duchess Sophie of Bavaria (afterwards Duchesse d'Alençon), daughter of Duke Max and sister of the empress of Austria; but the betrothal was dissolved in October of the same year.

Louis presently showed serious signs of an ill-balanced mind, and when ministers sought to check his wild extravagance, which included the building of many magnificent castles, he became violent. The unfortunate king was declared insane on June 8, 1886, and his uncle, Prince Luitpold, assumed the regency. Louis was placed under restraint. On June 13, 1886, he was drowned in the Starnberger See, together with his doctor, von Gudden, who had unwisely gone for a walk alone with his patient, whose physical strength was enormous. Louis's brother Otto, who succeeded him as king of Bavaria, was also incurably insane.

LOUIS III., king of Bavaria (1845–1921), was born on Jan. 7, 1845, and assumed the regency in succession to his father on Dec. 12, 1912. In accordance with the bill passed by the Bavarian diet he assumed the crown on Nov. 5, 1913. After the proclamation of the republic on Nov. 7, 1918, the king, with the queen and his daughters, left Munich. The royal family resided first at Berchtesgaden, and afterwards at a castle assigned to them on the shores of Chiem See. On Nov. 13 he formally signed his abdication, and relieved all Bavarian officials, officers and soldiers from their oath of allegiance. He died at Sarvar, Hungary, on Oct. 17, 1921.

LOUIS (804–876), surnamed "the German," king of the East Franks, was the third son of the emperor Louis I. When the emperor divided his dominions between his sons in 817, Louis received Bavaria and the neighbouring lands, but did not undertake the government until 825, when he began to fight the Slavs on his eastern frontier. In 827 he married Emma, daughter of Welf I., count of Bavaria, and sister of his stepmother Judith. He interfered in the quarrels arising from Judith's efforts to secure a kingdom for her own son Charles, and the consequent struggles of Louis and his brothers with the emperor Louis I. (*q.v.*). When the elder Louis died in 840 and his eldest son Lothair claimed the whole Empire, Louis in alliance with his half-brother, king Charles the Bald, defeated Lothair at Fontenoy on June 25, 841. By the Treaty of Verdun (August 843), Louis received the bulk of the lands of the Carolingian empire lying east of the Rhine, including a district around Speyer, Worms and Mainz, Bavaria, where he made Regensburg the centre of his government, Thuringia, Franconia and Saxony.

Louis may truly be called the founder of the German kingdom, though his attempts to maintain the unity of the Empire proved futile. In 842 he crushed a rising in Saxony, compelled the Abotrites to own his authority, and undertook campaigns against the Bohemians, the Moravians and other tribes. He did not succeed in freeing his shores from the ravages of Danish pirates. At his instance synods and assemblies were held where laws were decreed for the better government of church and state. From 853 onwards, he attempted to secure the throne of Aquitaine, offered to him by the oppressed subjects of Charles the Bald. But treachery and desertion in his army, and the loyalty of the Aquitanian bishops to Charles prevented success, and Louis renounced his claim by a treaty signed at Coblenz on June 7, 860.

In 855 the emperor Lothair died, and was succeeded in Italy by his eldest son Louis II., and in the northern part of his kingdom by his second son, Lothair. The weakness of these kingdoms afforded opportunities for intrigue by Louis and Charles the Bald, whose interest was increased by the fact that both their nephews were without male issue. Louis supported Lothair in his efforts to divorce his wife Teutberga, for which he received a promise of Alsace, but in 865 Louis and Charles renewed the peace of Coblenz, and doubtless discussed the possibility of dividing Lothair's kingdom. In 868 at Metz they agreed definitely to a partition; but when Lothair died in 869, Louis was ill, and his armies were engaged with the Moravians. Charles the Bald accordingly seized the whole kingdom; but Louis compelled him by a threat of war to agree to the Treaty of Mersen, which divided it between the claimants.

The later years of Louis were troubled by risings on the part of his sons, the eldest of whom, Carloman, revolted in 861 and in 863; an example followed by the second son Louis, who in a further rising was joined by his brother Charles. A report that Louis II. was dead led to peace between father and sons. The emperor, however, was not dead, but a prisoner; and as he was the nephew and son-in-law of Louis, that monarch hoped to secure both the imperial dignity and the Italian kingdom for his son Carloman. Meeting his daughter Engelberga, the wife of Louis II., at Trent in 872, Louis made an alliance with her against Charles the Bald, and in 874 visited Italy on the same errand. The emperor, having named Carloman as his successor, died in August 875, but Charles the Bald reached Italy before his rival, and by persuading Carloman to return, secured the imperial crown. Louis was preparing for war when he died on Sept. 28, 876 at Frankfort. He was in war and peace alike, the most competent of the descendants of Charlemagne. He obtained for his kingdom a certain degree of security against the Normans, Hungarians, Moravians and others. He lived in close alliance with the Church, to which he was very generous, and supported its missionary schemes.

Hist.* (vol. 3, 1922).

LOUIS (893–911), surnamed the "Child," king of the Franks, last of the German Carolingians, son of the emperor Arnulf, was born at Ottingen, designated by Arnulf as his successor in Germany in 897, and crowned on Feb. 4, 900. His chief adviser was Hatto I., archbishop of Mainz; and during his reign the kingdom was ravaged by Hungarians and torn with internal strife. He died in August or September 911 and was buried at Regensburg.

See O. Dietrich, *Beiträge zur Geschichte Arnolfs von Kärnthen und Ludwigs des Kindes* (1890).

LOUIS II. (846–879), king of France, called "le Bègue" or "the Stammerer," a son of Charles II. the Bald, Roman emperor and king of the West Franks, was born on Nov. 1, 846. After the death of his elder brother Charles in 866 he became king of Aquitaine, and in October 877 he succeeded his father as king of the West Franks, but not as emperor. He was crowned king by Hincmar, archbishop of Reims, on Dec. 8, following, and in Sept. 878 he was consecrated afresh by Pope John VIII. After an ineffectual reign of eighteen months Louis died at Compiègne on April 10 or 11, 879. By his first wife, Ansgarde, a Burgundian princess, he had two sons, his successors, Louis III. and Carloman; by his second wife, Adelaide, he had a posthumous son, Charles the Simple, who also became king of France.

The emperor Louis I. is counted as Louis I., king of France.

LOUIS III. (*c.* 863–882), king of France, was a son of Louis II. and with his brother Carloman succeeded his father as king in April 879. In consequence of the doubts cast upon the legitimacy of the young princes, it was proposed to offer the crown to the East Frankish ruler Louis, a son of Louis the German. But in September 879 the brothers were crowned at Ferrières by Ansègisus, archbishop of Sens. A few months later they divided their kingdom, Louis receiving the part of France north of the Loire. They acted together against the Northmen, over whom in August 881 they gained a memorable victory, and against Boso, who claimed sovereignty over Burgundy and Provence. On Aug. 5, 882 Louis died at St. Denis and Carloman became sole king.

LOUIS IV. (921–954), king of France, surnamed "d'Outremer" (*Transmarinus*), was the son of Charles III. the Simple. On his father's imprisonment in 922, his mother Odgiva (Eadgyfu), sister of the English king Aethelstan, fled with him to England—a circumstance to which he owes his surname. But after the death of the usurper Rudolph (Raoul), Ralph of Burgundy, Hugh the Great, count of Paris, and the other French nobles, chose Louis for their king, and the lad was consecrated at Laon on June 19, 936. His reign was marked by a series of rebellions of the French nobles who refused to recognize his authority, and by an irruption of the Hungarians into Burgundy and Aquitaine (937). Backed by the Pope, Louis showed great zeal in quelling these revolts, and by an alliance with Otto the Great, formerly one of his most determined enemies, he gained a temporary success. The powerful vassal, Hugh the Great, was in 948 forced to make submission and to restore Laon to his sovereign; but the last years of the reign were troubled by fresh difficulties with Hugh the Great and also by an irruption of the Hungarians into the south of France. Louis died on Sept. 10, 954, and was succeeded by his son Lothair.

The chief authority for the reign is the chronicler Flodoard. *See* also Ph. Lauer, *La Règne de Louis IV d'Outre-Mer* (1900); and A. Heil, *Die politischen Beziehungen zwischen Otto dem Grossen und Ludwig IV. von Frankreich* (1904).

LOUIS V. (967–987), "le Fainéant" king of France, succeeded his father Lothair in March 986, and finally embroiled the Carolingian dynasty with Hugh Capet and Adalberon, archbishop of Reims. Louis died in May 987, his mother Emma being accused of having poisoned him.

See F. Lot, *Les Derniers Carolingiens* (1891); and the *Recueil des actes de Lothaire et de Louis V.*, ed. L. Halphen and F. Lot (1908).

LOUIS VI. (1081–1137), king of France, surnamed "the Fat," "the Wideawake" or "the Bruiser," was the son of Philip I. and Bertha of Holland. He became associated with his father in the government about 1098, and by his victories over the English and the brigands, he won the support of the army against his step-mother, Bertrada, who tried to poison him. On the death of Philip I., in 1108, Louis was faced by powerful and rebellious barons, but after a hurried coronation at Orleans, he continued his policy of putting down feudal brigands and destroying their strongholds in the Île de France. So strong, however, were his enemies, that 24 years of continuous warfare were needed to root out the robber barons who lived on the plunder of the roads leading to Paris. In his opposition to the English, Louis was equally energetic. He supported William Clito, son of Robert of Normandy, against Henry I., and although worsted in the war which followed he continued to uphold the claims of his protegé. To oppose the forces of the emperor, Henry V., who had become the ally of the king of England, Louis even succeeded in gathering a national army under his flag, and thus temporarily consolidated his realm. Not only did he consolidate France, however, but he extended his power by acquiring control over Flanders.

In all his wars Louis fought in person, and for his prowess gained the reputation of a national hero, the protector of the poor, the Church, the peasants and the towns. He encouraged the communal movement on the fiefs of his vassals, and granted privileges to towns on his domains, but the title of "Father of the Communes," by which he is sometimes known, is not deserved. Neither was Louis the author of the movement for the emancipation of the serfs, his attitude being to favour emancipation only when it promised greater chance of profit. He was a great benefactor to the Church, aided the new, reformed monastic congregations of Cîteau, Prémontré and Fontevrault and chose his two chief ministers, Étienne de Garlande and Suger (*q.v.*) from the clergy. Louis died on Aug. 1, 1137.

See A. Luchaire, *Louis le Gros, annales de sa vie et son règne* (1890); and "Les Premiers Capétiens," in E. Lavisse's *Histoire de France;* Thomson, *Development of the French Monarchy under Louis VI. le Gros* (1895).

LOUIS VII. (*c.* 1121–1180), king of France, son of Louis VI. the Fat, was associated with his father and anointed by Innocent II. in 1131. In 1137 he succeeded his father, and in the same year married at Bordeaux Eleanor, heiress of William II., duke of Aquitaine. In the first part of his reign he was vigorous and jealous of his prerogatives, but after his crusade his religiosity developed to such an extent as to make him utterly inefficient. His accession was marked by no serious disturbances, save the risings of the burgesses of Orleans and of Poitiers, but he came into violent conflict with Pope Innocent II. The archbishopric of Bourges became vacant, and the king supported as candidate the chancellor Cadurc, against the pope's nominee Pierre de la

Châtre, swearing upon relics that so long as he lived Pierre should never enter Bourges. This brought the interdict upon the king's lands. He became involved in a war with Theobald, count of Champagne, which lasted two years (1142–44). The royal army occupied Champagne, and captured Vitry, where many persons perished in the burning of the church. Geoffrey the Handsome, count of Anjou, by his conquest of Normandy threatened the royal domains, and Louis VII. by a clever manoeuvre threw his army on the Norman frontier and gained Gisors, one of the keys of Normandy.

At his court which met in Bourges Louis declared on Christmas Day 1145 his intention of going on a crusade. St. Bernard preached the crusade at Vézelay (Easter 1146), and Louis set out from Metz in June 1147, on the overland route to Syria. The expedition was disastrous, and he regained France in 1149, overcome by humiliation. He caused a council at Beaugency (on the 21st of March 1152) to annul his marriage with Eleanor of Aquitaine, under pretext of kinship. Eleanor married Henry II. of England in the following May, and brought him the duchy of Aquitaine. Louis VII. led a half-hearted war against Henry; but in August 1154 gave up his rights over Aquitaine, and contented himself with an indemnity. In 1154 Louis married Constance, daughter of the king of Castile, and their daughter Marguerite he affianced imprudently by the treaty of Gisors (1158) to Henry, eldest son of the king of England, promising as dowry the Vexin and Gisors. After the death of Constance (1160), Louis VII. married Adèle of Champagne. Louis VII. gave little sign of understanding the danger of the growing Angevin power, though in 1159 he aided Raymond V., count of Toulouse, against Henry II. At the same time the emperor Frederick I. in the east was making good the imperial claims on Arles. When the schism broke out, Louis took the part of the pope Alexander III. He supported Henry's rebellious sons, but acted slowly and feebly, and so contributed to the break up of the coalition (1173–1174).

Finally in 1177 the pope intervened to bring the two kings to terms at Vitry. By his third wife, Adèle, Louis had an heir, the future Philip Augustus, born on the 21st of August 1165. He had him crowned at Reims in 1179, and died on the 18th of September 1180.

See R. Hirsch, *Studien zur Geschichte König Ludwigs VII. von Frankreich* (1892); A. Cartellieri, *Philipp II. August von Frankreich bis zum Tode seines Vaters, 1165–1180* (1891); A. Luchaire, *Études sur les actes de Louis VII.* (1885), and section in E. Lavisse's *Histoire de France,* tome iii. 1st part, pp. 1–81.

LOUIS VIII. (1187–1226), king of France, eldest son of Philip Augustus and of Isabella of Hainaut, was born in Paris on Sept. 5, 1187. Louis left the reputation of a saint, but was also a warrior prince. In 1213 he led the campaign against Ferrand, count of Flanders; in 1214, while Philip Augustus was winning the victory of Bouvines, he held John of England in check, and was victorious at La Roche-aux-Moines. In the autumn of 1215 Louis received from a group of English barons, headed by Geoffrey de Mandeville, a request to "pluck them out of the hand of this tyrant" (John). Louis himself prepared to invade England. The expedition was forbidden by the papal legate, but Louis landed at Stonor on May 22, 1216. (*See* ENGLISH HISTORY.) The pretexts on which he claimed the English crown were set down in a memorandum drawn up by French lawyers in 1215. These claims—that John had forfeited the crown by the murder of his nephew, Arthur of Brittany, and that the English barons had the right to dispose of the vacant throne—lost their plausibility on the death of King John and the accession of his infant son as Henry III. in October 1216. The papal legate, Gualo, arrived in England at the same time as Louis. He excommunicated the French troops and the English rebels, and, after the "Fair of Lincoln," in which his army was defeated, Louis resigned his pretensions, though by a secret article of the treaty of Lambeth (September 1217) he secured a small war indemnity.

Louis had assisted Simon de Montfort in his war against the Albigenses in 1215, and after his return to France he again joined the crusade. With Simon's son and successor, Amauri de Montfort, he directed the brutal massacre which followed the capture of Marmande. Philip Augustus dying on July 14, 1223, Louis VIII. was anointed at Reims on Aug. 6. He continued his father's policy. His reign was taken up with two great designs: to destroy the power of the Plantagenets, and to conquer the heretical south of France. An expedition conquered Poitou and Saintonge (1224); in 1226 he led the crusade against the Albigenses in the south, forced Avignon to capitulate and received the submission of Languedoc. While passing the Auvergne on his return to Paris, he died at Montpensier on Nov. 8, 1226. His reign, short as it was, brought gains both to the royal domains and to the power of the crown over the feudal lords. He had married in 1200 Blanche of Castile, daughter of Alphonso IX. of Castile and granddaughter of Henry II. of England, who bore him twelve children; his eldest surviving son was his successor, Louis IX.

See C. Petit-Dutaillis, *Étude sur la vie et le règne de Louis VIII.* (1894); and E. Lavisse, *Histoire de France,* tome iii. (1901).

LOUIS IX. (1214–1270), king of France, known as Saint Louis, was born on April 25, 1214. His father, Louis VIII., died in 1226, but his mother, Queen Blanche of Castile, secured her son's coronation at Reims on Nov. 29, 1226; and mainly by the aid of the papal legate, Romano Bonaventura, bishop of Porto (d. 1243), and of Thibaut IV., count of Champagne, was able to thwart the rebellious plans of Pierre Mauclerc, duke of Brittany, and Philippe Hurepel, a natural son of Philip Augustus. Mauclerc and Thibaut were both obliged to go on crusade. Louis IX. married Margaret, daughter of Raymond Berenger, count of Provence, in May 1234. The reign was comparatively uneventful. A rising of the nobles of the south-west reached threatening dimensions in 1242, but the king's armies easily overran the lands of the rebel Hugh de Saintonge, and defeated Henry III. of England, who had come to his aid, at Saintes. Raymond VII., count of Toulouse, yielded without resistance upon the advent of two royal armies, and accepted the peace of Lorris in January 1243. This was the last rising of the nobles in Louis's reign.

At the end of 1244, during an illness, Louis took the cross. He had already been much distressed by the plight of John of Brienne, emperor at Constantinople, and bought from him the crown of thorns, parts of the true cross, the holy lance and the holy sponge. The Sainte Chapelle in Paris still stands as a monument to the value of these relics to the saintly king. But the quarrel between the papacy and the emperor Frederick II., in which Louis maintained a watchful neutrality—only interfering to prevent the capture of Innocent IV., at Lyons—and the difficulties of preparation, delayed the embarkation until August 1248. His defeat and capture at Mansura, in February 1250, the next four years spent in Syria in captivity, in diplomatic intrigues, and finally in raising the fortifications of Caesarea and Joppa,—these events belong to the history of the crusades (*q.v.*). His return to France was urgently needed, as Blanche of Castile, whom he had left as regent, had died in November 1252, and upon the removal of her strong hand feudal turbulence had begun to show itself.

This period between his first and second crusades (1254–1269) is the real age of Saint Louis in the history of France. He imposed peace between warring factions of his nobility by mere moral force, backed up by something like an awakened public opinion. His nobles often chafed under his unrelenting justice but never dared rebel. The most famous of his settlements was the treaty of Paris, drawn up in May 1258 and ratified in December 1259, by which the claims of Henry III. of England were adjusted. Henry renounced absolutely Normandy, Anjou, Touraine, Maine and Poitou, and received, on condition of recognizing Louis as liege suzerain, all the fiefs and domains of the king of France in the diocese of Limoges, Cahors and Perigueux, and the expectation of Saintonge south of the Charente, and Agenais, if they should fall to the crown of France by the death of Alphonse of Poitiers. This treaty was unpopular, since the king surrendered a large part of France that Henry had not won; but Louis was satisfied that the absolute sovereignty over the northern provinces more than equalled the loss in the south.

Louis made a similar compromise with the king of Aragon in the treaty of Corbeil, 1258, whereby he gave up the claims of kings of France to Roussillon and Barcelona, which went back to the conquest of Charlemagne. The king of Aragon in his turn gave up his claims to part of Provence and Languedoc, with the exception of Narbonne. Louis's position was strikingly shown in 1264 when the English barons submitted their attempt to bind Henry III. by the Provisions of Oxford to his arbitration. His reply in the "Dit" or Mise of Amiens was a flat denial of all the claims of the barons and failed to avert the civil war. Upon the whole Louis maintained peace with his neighbours, although both Germany and England were torn with civil wars. He sanctioned the conquest of Naples by his brother, Charles, duke of Anjou.

On March 24, 1267, Louis proclaimed his purpose of going on a second crusade. Three years of preparation followed; then on July 1, 1270 they sailed from Aigues Mortes for Tunis, whither the expedition seems to have been directed by the machinations of Charles of Anjou, who, it is claimed, persuaded his brother that the key to Egypt and to Jerusalem was that part of Africa which was his own most dangerous neighbour. After seventeen days' voyage to Carthage, one month of the summer's heat and plague decimated the army, and when Charles of Anjou arrived he found that Louis himself had died of the plague on Aug. 25, 1270.

Saint Louis stands in history as the ideal king of the middle ages. An accomplished knight, physically strong in spite of his ascetic practices, fearless in battle, heroic in adversity, of imperious temperament, unyielding when sure of the justness of his cause, energetic and firm, he was indeed "every inch a king." Joinville says that he was taller by a head than any of his knights. His devotions would have worn out a less robust saint. He fasted much, loved sermons, regularly heard two masses a day and all the offices, dressing at midnight for matins in his chapel, and surrounded even when he travelled by priests on horseback chanting the hours. After his return from the first crusade, he wore only grey woollens in winter, dark silks in summer. He built hospitals, visited and tended the sick himself, gave charity to over a hundred beggars daily. Yet he safeguarded the royal dignity by bringing them in at the back door of the palace, and by a courtly display greater than ever before in France. His naturally cold temperament was somewhat relieved by a sense of humour, which, however, did not prevent his making presents of haircloth shirts to his friends. He had no favourite, nor prime minister. Louis was canonized in 1297.

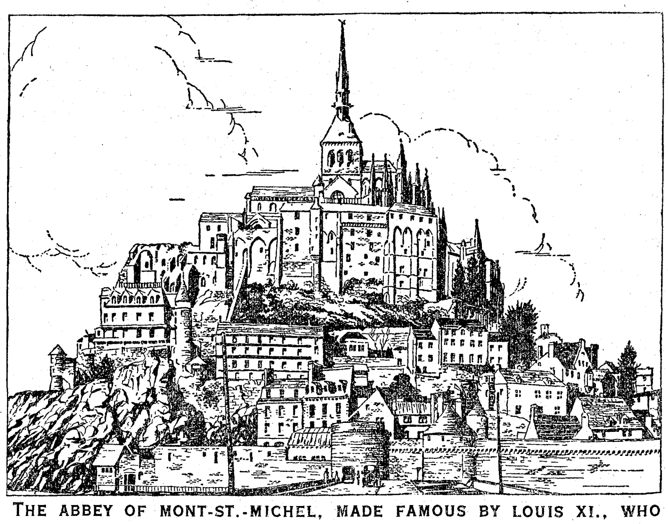
The best contemporary accounts of Louis IX. are the Memoirs of the Sire Jean de Joinville (*q.v.*), published by N. de Wailly for the *Soc. de l'Hist. de France,* under the title *Histoire de Saint Louis* (Paris, 1868), and again with translation (1874); English translation by J. Hutton (1868). *See* also C. V. Langlois in E. Lavisse's *Histoire de France,* tome iii., with references to literature; Frederick Perry, *Saint Louis, the Most Christian King* (New York, 1901); E. J. Davis, *The Invasion of Egypt by Louis IX. of France* (1898); H. A. Wallon, *Saint Louis et son temps* (1875); A. Lecoy de la Marche, *Saint Louis* (Tours, 1891); and E. Berger, *Saint Louis et Innocent IV.* (Paris, 1893), and *Histoire de Blanche de Castille* (1895). *See* also *The Court of a Saint,* by Winifred F. Knox (1909). (J. T. S.; X.)

LOUIS X. (1289–1316), king of France and Navarre, called *le Hutin* or "the Quarreller," was the son of Philip IV. and of Jeanne of Navarre. He was born at Paris on Oct. 4, 1289, took the title king of Navarre on the death of his mother, on April 2, 1305, and succeeded Philip IV. in France on Nov. 29, 1314, being crowned at Reims in August 1315. Louis X. granted to the nobility charters in which he made apparent concessions, but used evasive formulas which in reality ceded nothing. There was a charter to the Normans, one to the Burgundians, one to the Languedocians (1315). Robert de Béthune, count of Flanders, refused to do homage, and his French fiefs were declared confiscate by a court of his peers. Need of money inspired one famous ordinance of this reign; in 1315 the serfs of the royal domains were invited to buy their civil liberty,—an invitation which did not meet with great enthusiasm, as the freedman was merely freed for further exploitation, and Philip V. was obliged to renew it in 1318. Louis X. died suddenly on June 5, 1316. His first wife, Margaret, daughter of Robert II., duke of Burgundy, died a prisoner in the château Gaillard. By her he had one daughter, Jeanne, wife of Philip, count of Evreux and king of Navarre. By his second wife Clémence, daughter of Charles Martel, titular king of Hungary, he left a posthumous son, King John I.

See Ch. Dufayard, "La réaction feodale sous les fils de Philippe le Bel," in *Revue historique* (1894); Paul Lehugeur, *Histoire de Philippe le Long, roi de France* (1897); and Joseph Petit, *Charles de Valois* (1900).

LOUIS XI. (1423–1483), king of France, the son of Charles VII. and his queen, Marie of Anjou, was born on July 3, 1423, at Bourges, where his father, then nicknamed the "King of Bourges," had taken refuge from the English. At the birth of Louis XI. part of France was in English hands; when he was five years old, Joan of Arc appeared; he was just six when his father was crowned at Reims. But his boyhood was spent apart from these stirring events, in the castle of Loches, where he had as tutors Jean Majoris and Bernard of Armagnac. In June 1436, when scarcely thirteen, he was married to Margaret (*c.* 1425–1445), daughter of James I. of Scotland. Three years after this unhappy marriage Louis entered upon his stormy political career. Sent by his father in 1439 to direct the defence of Languedoc against the English, and to put down the brigandage in Poitou, he was induced by the rebellious nobles to place himself at the head of the Praguerie (*q.v.*). Charles VII. pardoned him this rebellion, and in 1440 he was fighting the English, and in 1443 aided his father to suppress the revolt of the count of Armagnac. In 1444 he led an army of from 15,000 to 20,000 mercenaries and brigands,—the product of the Hundred Years' War,—against the Swiss of the canton of Basle. After an ineffective siege, he made peace with the Swiss confederation, and led his robber soldiers into Alsace to ravage the country of the Habsburgs, who refused him the promised winter quarters. Meanwhile his father, making a parallel campaign in Lorraine, had assembled his first brilliant court at Nancy, and when Louis returned he found the king completely under the spell of Agnes Sorel. The death in 1445 of his wife Margaret, who was a great favourite of Charles VII., made the rupture complete. From that year until the death of the king, father and son were enemies. Louis prepared a plot to seize the king and his minister Pierre de Brézé. The plot was revealed to Charles, who banished his son to Dauphiné (1447). He never saw his father again.

Louis dismissed the governor; he determined the boundaries between his state and the territories of the duke of Savoy and of



THE ABBEY OF MONT-ST.-MICHEL, MADE FAMOUS BY LOUIS XI., WHO INSTITUTED THERE THE ORDER OF KNIGHTS OF ST. MICHEL

the papacy; and he enforced his authority over perhaps the most unruly nobility in western Europe, both lay and ecclesiastical. He made a secret treaty with the duke of Savoy which was to give him right of way to Genoa, and made arrangements for a partition of the duchy of Milan. The alliance with Savoy was sealed by the marriage of Louis with Charlotte, daughter of Duke Lodovico, in 1452, in spite of the formal prohibition of Charles VII. The king marched south, but withdrew again leaving his son unsubdued. Four years later, as Charles came to the Bourbonnais, Louis, fearing for his life, fled to Flanders to the court of Philip the Good, duke of Burgundy, leaving Dauphiné to be definitely annexed to the crown of France. The policy of the dauphin was reversed, his ten years' work was undone. Meanwhile he was installed in the castle of Genappe, in Brabant, where he waited impatiently for five years for the death of his father, keeping himself posted by spies on every stage of the king's illness, and thus laying himself open to the unsubstantiated accusation, believed by Charles himself, that he had hastened the end by poison.

On Aug. 15, 1461, Louis was anointed and crowned at Reims. His first act was to strike at the faithful ministers of Charles VII. Pierre de Brézé and Antoine de Chabannes were captured and imprisoned. But the more serviceable of the officers of Charles VII. were for the most part soon reinstated; Louis' advisers were mostly men of the middle class. He drew men of talent from England, Scotland, Italy, Spain and Portugal. Among the most prominent of these men in addition to Brézé, Chevalier and Chabannes, were Tristan Lermite, Jean de Daillon, Olivier le Dain (the barber), and after 1472, Philippe de Commines, drawn from the service of Charles the Bold of Burgundy, who became his most intimate adviser and his biographer. Surrounded by men like these Louis fought the last great battle of French royalty with feudalism.

THE STRUGGLE WITH CHARLES THE BOLD

Louis XI. began his reign with the same high-handed treatment of the nobles which had marked his rule in Dauphiné, going so far as to forbid them to hunt without his permission. He forced the clergy to pay long-neglected feudal dues, and intrigued against the great houses of Anjou and Orleans in Italy. The malcontent nobles soon began to plan revolt. Discharged officers of Charles VII., like Jean Dunois and John II. duke of Bourbon, stirred up hostility to the new men of the king, and Francis II. duke of Brittany was soon embroiled with Louis over an attempt to assert royal control over that practically independent duchy. The dissatisfied nobility found their greatest ally in Charles the Bold, afterwards duke of Burgundy, and in 1465 formed a "league of public welfare" and declared war on their king. The nominal head was the king's brother Charles, duke of Berry, then eighteen years old, a weak character, the tool of the rebels as he was later the dupe of the king. Every great noble in France was in the league, except Gaston de Foix—who kept the south of France for the king—and the counts of Vendôme and Eu.

The whole country seemed on the verge of anarchy. It was saved by the refusal of the lesser gentry to rise, and by the alliance of the king with the citizen class. After a successful campaign in the Bourbonnais, Louis fought an indecisive battle with Burgundians who had marched on Paris at Montlhéry, on July 16, 1465, and then stood a short siege in Paris. On Sept. 28, he made a truce with Charles the Bold, and in October the treaties of Conflans and Saint Maur-les-Fossés ended the war. The king yielded at all points; gave up the "Somme towns" in Picardy, for which he had paid 200,000 gold crowns, to Philip the Good, thus bringing the Burgundians close to Paris and to Normandy. Charles, the king's brother, was given Normandy as an apanage, thus joining the territories of the rebellious duke of Brittany with those of Charles the Bold. The kingdom was plundered both by royal tax gatherers and by unsubdued feudal lords.

Two months after he had granted Normandy to Charles, Louis took advantage of a quarrel between the duke of Brittany and his brother to take it again, sending the duke of Bourbon "to aid" Charles, while Dunois and Chabannes prepared for the struggle with Burgundy. The death of Duke Philip, on June 15, 1467, gave Charles the Bold a free hand. He gained over Edward IV. of England, whose sister Margaret he married; but while he was celebrating the wedding Louis invaded Brittany and detached Duke Francis from alliance with him. Normandy was completely reduced. The king's triumph was followed by his greatest mistake. After an interview between Charles and Louis at Péronne false news of Charles's death was spread, apparently at Louis' instigation. The king was humiliated and renewed intrigues followed. He attempted a diversion by assisting the Lancastrians in England. A new revolt was planned in 1471, but came to nothing. The country was saved a desperate civil war by the death of the king's brother, Charles, the nominal head of the coalition, on May 24, 1472. Charles the Bold, who had again invaded France, was obliged to make a lasting truce. Louis then forced the duke of Brittany to make peace, and turned against John V. count of Armagnac, whose death at the opening of March 1473 ended the power of one of the most dangerous houses of the south. The first period of Louis' reign was closed, and with it closed for ever the danger of dismemberment of France. John of Aragon continued the war in Roussillon and Cerdagne, where the struggle was protracted for two years. After the capture of Perpignan on March 10, 1475, the wise and temperate government of Imbert de Batarnay and Boffile de Juge slowly pacified the new provinces. The death of Gaston IV. count of Foix in 1472 opened up the long diplomatic struggle for Navarre, which was destined to pass to the loyal family of Albret shortly after the death of Louis. His policy had won the line of the Pyrenees for France.

The overthrow of Charles the Bold was the second great task of Louis XI. Charles's ally, Edward IV., invaded France in June 1475, but Louis bought him off on Aug. 29, at Picquigny. In September the invaders recrossed to England. The count of Saint Pol, who had continued to play his double part, was surrendered by Charles to Louis, and executed, as was also Jacques d'Armagnac, duke of Nemours. Louis subsidized the Swiss and René II. of Lorraine in their war upon Charles. The defeat and death of the duke of Burgundy at Nancy on Jan. 5, 1477, was the crowning triumph of Louis' diplomacy. But in his eagerness to seize the whole inheritance of his rival, definite peace was not established until after the death of Mary of Burgundy, Charles's daughter, who had married Maximilian of Austria; but by the treaty of Arras (1482) Louis received Picardy, Artois and the Boulonnais, as well as the duchy of Burgundy and Franche Comté. The Austrians were left in Flanders, a menace and a danger. The unification of France was completed (except for Brittany) and the frontiers enlarged by the acquisition, upon the death of René of Anjou in 1480, of the duchies of Anjou and Bar, and in 1481 of Maine and Provence upon the death of Charles II., count of Maine. Of the inheritance of the house of Anjou only Lorraine escaped the king.

Failure in Spain was compensated for in Italy. Without waging war Louis made himself virtual arbiter of the fate of the principalities in the north, and his court was always besieged by ambassadors from them. After the death of Charles the Bold, Yolande, duchess of Savoy, was obliged to accept the control of Louis, who was her brother. In Milan he helped to place Ludovico il Moro in power in 1479, but he reaped less from this supple tyrant than he had expected. Pope Sixtus IV., the enemy of the Medici, was also the enemy of the king of France. When Sixtus threatened Florence after the Pazzi conspiracy, 1478, Louis aided Lorenzo dei Medici to form an alliance with Naples, which forced the papacy to come to terms.

More than any other king of France, Louis XI. was a "bourgeois king." The upper bourgeois, the aristocracy of his "good cities," were his allies both against the nobles and against the artisan class, whenever they revolted, driven to desperation by the oppressive royal taxes which furnished the money for his wars or diplomacy. He ruled like a modern capitalist; placed his bribes like investments in the courts of his enemies; and, while draining the land of enormous sums, was pitiless toward the two productive portions of his realm, the country population and the artisans. His heartlessness toward the former provoked even an accomplice like Commines to protest. The latter were kept down by numerous edicts, tending to restrict to certain privileged families the rank of master workman in the gilds. There was the paternalism of a Frederick the Great in his encouragement of the silk industry,—"which all idle people ought to be made to work at,"—in his encouragement of commerce through the newly acquired port of Marseilles and opening market places.

Louis even dreamed of a great trading company "of two hundred thousand livres or more," to monopolize the trade of the Mediterranean, and planned to unify the various systems of weights and measures. In 1479 he called a meeting of two burgesses from each "good city" of his realm to consider means for preventing the influx of foreign coin. Impatient of all restraint upon his personal rule, he was continually in violent dispute with the parlement of Paris, and made "justice" another name for arbitrary government; yet he dreamed of a unification of the local customary laws (*coûtumes*) cf France. He was the perfect model of a tyrant. The states-general met but once in his reign, in 1468, and then no talk of grievances was allowed; his object was only to get them to declare Normandy inalienable from the crown. They were informed that the king could raise his revenue without consulting them. Yet his budgets were enormously greater than ever before. In 1481 the *taille* alone brought in 4,600,000 livres, and even at the peaceful close of his reign his whole budget was 4,655,000 livres—as against 1,800,000 livres at the close of his father's reign.

During the last two or three years of his life Louis lived in great isolation, "seeing no one, speaking with no one, except such as he commanded," in the château of Plessis-les-Tours, 2 m. S.W. of Tours, that "spider's nest" bristling with watch towers, and guarded only by the most trusty servitors. A swarm of astrologers and physicians preyed upon his fears—and his purse. But, however foolish in his credulity, he still made his strong hand felt both in France and in Italy, remaining to the last "the terrible king." His fervent prayers were interrupted by instructions for the regency which was to follow. He died on Aug. 30, 1483, and was buried in the church at Cléry, instead of at St. Denis. He left a son, his successor, Charles VIII., and two daughters.

See Charles Petit-Dutaillis in Lavisse's *Histoire de France,* tome iv. pt. ii. (1902), and bibliographical indications given there. Of the original sources for the reign the *Lettres de Louis XI.* (edited by Charavay and Vaesen, 8 vols., 1883–1902), the *Mémoires* of Philippe de Commines and the *Journal* of Jean de Royl come first. *See* further A. Molinier, *Sources de l'histoire de France* (tome v. pp. 1–146); C. Hare, *The Life of Louis XI.* (London, 1907).

LOUIS XII. (1462–1515), king of France, was grandson of Louis of Orleans, the brother of Charles VI., and son of the poet prince, Charles of Orleans, who, after the battle of Agincourt, spent twenty-five years of captivity in England. Louis was duke of Orleans until his accession to the throne. He married at fourteen, Joan, daughter of Louis XI. He revolted against Charles VIII., and for three years (1488–91) was a prisoner. In 1494 he held a command in the invasion of northern Italy. He succeeded Charles VIII. in 1499. He enjoyed a genuine popularity, and in 1506 the estates of Tours conferred on him the surname of *Père du Peuple.* He led in person several armies into Italy, and proved as severe and pitiless towards his enemies as he was gentle and clement towards his subjects. Louis had two daughters. After his accession he divorced Joan, and married, in 1499, Anne of Brittany, the widow of Charles VIII. On her death in January 1514, he married in 1514, for political reasons, Mary Tudor, sister of Henry VIII. of England. (*See* MARY, queen of France.) He died on Jan. 1, 1515.

See Henri Hauser, *Les Sources de l'histoire de France, XVI^e siècle,* vol. 1. (1906). The principal secondary authorities are De Maulde, *Histoire de Louis XII.* (1889–93); Le Roux de Lincy, *Vie de la reine Anne de Bretagne* (1860); H. Lemonnier, *Les Guerres d'Italie* (1903) in the *Histoire de France* by E. Lavisse.

LOUIS XIII. (1601–1643), king of France, was the son of Henry IV. and of Marie de' Medici. He became king on his father's assassination in 1610; but his mother at once seized the full powers of regent. She determined to bring France into alliance with Spain and the Austrian house. Louis was to marry Anne of Austria, daughter of the Spanish king, Philip III., and the Spanish prince, afterwards Philip IV., himself was to marry the Princess Elizabeth, the king's sister. The marriages were concluded in 1615. The next years were full of civil war and political intrigue, during which the queen relied upon the Marshal d'Ancre. Louis XIII. was attached to Charles d'Albert, sieur de Luynes; and with his help he arrested Marshal d'Ancre, and on his resistance had him assassinated. From this time to her death the relation between the king and his mother was one of concealed or open hostility. The article on FRANCE must be consulted for the intricate events of the following years.

The decisive incident for his private life as well as for his reign was the entrance of Cardinal Richelieu (*q.v.*) hitherto the queen's chief adviser, into the king's council in 1624. Henceforth the policy of France was directed by Richelieu, who returned to the policy of Henry IV. abroad, and asserted the power of the crown against all rivals at home. This policy brought Louis into unremitting conflict with the Protestants and the nobles of France, but also made him the enemy of his mother, of his brother Gaston of Orleans, who made himself the champion of the cause of the nobles, and sometimes even of his wife. It is not easy to define his relations to Richelieu. He was convinced of his loyalty and of his genius, and in the end always supported his policy. But he disliked the friction with his family circle which this policy produced. For the most part his share in the great events of the reign was a passive one. There were certain occasions when it seemed as if he would oppose Richelieu. The chief of these was what is known as the "Day of Dupes" (1630). Then the queen-mother and the king's brother passionately attacked the minister, and for a moment it was believed that Richelieu was dismissed and that the queen-mother and a Spanish policy had triumphed. But the minister regained his ascendancy over the king, punished his enemies and forced Marie de' Medici and Gaston of Orleans to sue for pardon. In 1631 Gaston fled to Lorraine and the queen-mother to Brussels. Gaston soon returned, to plot, to fail and to sue for pardon again and again; but Marie de' Medici ended her life in exile.

But the last great effort to overthrow Richelieu was the conspiracy of Cinq-Mars (*q.v.*), one of the king's personal favourites. Cinq-Mars believed himself secure of the king's favour. But Richelieu discovered his treasonous relations with Spain, and defeated his plot. Louis was reconciled to his minister. "We have lived too long together to be separated" he is reported to have said (September 1642). Yet when Richelieu died in December of the same year he allowed himself to speak of him in a jealous and satirical tone. He died himself a few months later (May 1643). (*See* also RICHELIEU, ARMAND JEAN DU PLESSIS DE.)

The chief source of information on Louis XIII.'s life is to be found in the contemporary memoirs, of which the chief are: Bassompierre, Fontenay-Mareuil, Gaston d'Orléans, Montrésor, Omer Talon. Richelieu's own Memoirs are chiefly concerned with politics and diplomacy. Of modern works those most directly bearing on the king's personal life are R. de Beauchamp, *Louis XIII. d'après sa correspondance avec le cardinal de Richelieu;* G. Hanotaux, *Histoire du cardinal de Richelieu* (1893–96); Rossignol, *Louis XIII. avant Richelieu;* M. Topin, *Louis XIII. et Richelieu* (1876). *See* too Professor R. Lodge, *Richelieu;* J. B. H. R. Capefigue, *Richelieu, Mazarin et la Fronde* (1835–36); and Dr. J. H. Bridges, *Richelieu, Mazarin and Colbert* (1866); Aymés, *La France sous Louis XIII.* (1909); *Lettres de la main de Louis XIII.* (2 pt. 1914).

For full bibliography *see* G. Monod, *Bibliographie de l'histoire de France; Cambridge Modern History,* vol. iv. ("The Thirty Years' War"); Lavisse et Rambaud, *Histoire générale,* vol. v. ("Guerres de religion").

LOUIS XIV. (1638–1715), king of France, was born at Saint-Germain-en-Laye on Sept. 5, 1638, the son of Louis XIII. and Anne of Austria. The death of his father made the child of five king on May 14, 1643. Power lay in the hands of the queen-mother and of her minister, Cardinal Mazarin, who had to face the domestic troubles of the Fronde and the last stages of the Thirty Years' War. Twice the court had to flee from Paris; once when there was a rumour of intended flight the populace was admitted to see the king in his bed. The memory of these humiliations played their part in developing later the autocratic ideas of Louis. Mazarin triumphed alike over his domestic and his foreign opponents. The Fronde was at an end by 1653; the peace of Westphalia (1648) and the peace of the Pyrenees (1659) marked the success of the arms and of the diplomacy of France. Louis XIV. was now twenty-one years of age. The peace of the Pyrenees was cemented by the marriage of Louis to his cousin, the Infanta Maria Theresa.

The marriage took place at once, and the king entered Paris in triumph in 1660. Mazarin died in the next year; and the king at once announced his intention of being his own first minister. He built up a thoroughly personal system of government, and presided constantly over the council and many of its committees.

Even the greatest of his ministers found themselves controlled by the king. Fouquet, the finance minister, was overthrown and condemned to perpetual imprisonment. Those who had most of the king's confidence afterwards were Colbert for home affairs; Lionne for diplomacy, Louvois for war; but as his reign proceeded he became more intolerant of independence of judgment in his ministers.

His court was brilliant. In art and in literature, the great period, which is usually called by the king's name, had in some respects passed its zenith when he began to reign. But France was unquestionably the first state in Europe both in arms and arts, and within France the authority of the king was practically undisputed. The nation, proud of its pre-eminence and weary of civil war, saw in the king its true representative and the guarantee of its unity and success. Louis played the rôle of *Grand Monarque* to perfection. His wife Maria Theresa bore him children but there was no community of tastes between them, and the chief influence at court is to be found not in the queen but in the succession of avowed mistresses: Louise de la Vallière, Madame de Montespan and Madame de Maintenon (*q.v.*), who ruled, however, not as mistress but as wife. Through her influence the king was reconciled to his wife, and, when Maria Theresa died in 1683, Madame de Maintenon shortly afterwards (in 1684) became the king's wife, though this was never officially declared. Under her influence the court lost most of its gaiety, and religion came to exercise much control over the life and the policy of the king.

The first years of the king's rule were marked by the great schemes of Colbert for the financial, commercial, industrial and naval reorganization of France, and in these schemes Louis took a deep interest. But in 1667 began the long series of wars, which lasted with little real intermission to the end of the reign. (*See* FRANCE.) The War of Devolution (or the Queen's War) in 1667–68 to enforce the queen's claim to certain districts in the Spanish Netherlands, led to the Dutch War (1672–78), and in both these wars the supremacy of the French armies was clearly apparent. The next decade (1678–88) was the real turning point in the history of the reign, and the strength of France was seriously diminished. The chief cause of this is to be found in the revocation of the Edict of Nantes. The French Huguenots found their privileges decreased, and then, in 1685, the edict was altogether withdrawn. The results were ruinous to France, which lost many thousands of her best citizens and, also, Protestant alliances in Europe which had been in the past her great diplomatic support. The English Revolution of 1688 changed England from a wavering ally into the most determined of the enemies of France.

The war with the Grand Alliance, of which King William III. was the heart and soul, lasted from 1688 to 1697; and the treaty of Ryswick, which brought it to an end, deprived France of certain territories on her frontier. But Louis saw in the Spanish question a chance of more than making up for this loss. The Spanish king Charles II. was dying, and the future of the possessions of Spain was doubtful. The astute diplomacy of Louis succeeded in winning the inheritance for his grandson Philip. But this involved France and Europe in an immense war (1700) and by the peace of Utrecht (1713), though the French prince retained the Spanish crown, France had again to make concessions of territory.

The peace found France burdened with debt; the reforms of Colbert were ruined; and opposition to the king's régime began to make itself felt. Peace brought some relief to France, but the last years of the king's life were gloomy in the extreme. His eldest son, the dauphin, died in April 1711; his eldest grandson the duke of Burgundy in Feb. 1712; and his great-grandson the duke of Brittany in March 1712. The heir to the throne was now the duke of Burgundy's son, the duke of Anjou, afterwards Louis XV. The king died on Sept. 1, 1715, after the longest recorded reign in European history. The judgment of posterity has not repeated the flattering verdict of his contemporaries; but he remains the model of a great king in all that concern the externals of kingship.

The reign Louis XIV. is particularly rich in memoirs describing the life of the court. The chief are Madame de Motteville's memoirs for the period of the Fronde, and the letters of Madame de Sévigné and the memoirs of Saint-Simon for the later period. The king's ideas are best seen in the *Mémoires de Louis XIV. pour l'instruction du dauphin* (edited by Dreyss, 2 vols.). His private life is revealed in the letters of Madame de Maintenon and in those of Madame, Duchesse d'Orléans. *See* also Voltaire, *Siècle de Louis XIV.*; P. Clément, *Histoire de la vie et de l'administration de Colbert;* Blennerhasset, *Louis and Madame de Maintenon* (1910); Martin and Besançon, *Hist. du crédit en France sous le règne de Louis XIV.* (1913); d'Angelo, *Luigi XIV. et la Santa Sede, 1689–93* (1914); M. L. E. Bertrand, *Louis XIV.* (1923); G. Mentz, *Ludwig XIV. Sein Reich und Seine Zeit* (Bonn, 1922), and bibliographies; G. Monod's *Bibliographie de l'histoire de France;* vol. v. ("The Age of Louis XIV.") of the *Cambridge Modern History;* and vol. vi. ("Louis XIV.") of the *Histoire générale* of Lavisse and Rambaud.

LOUIS XV. (1710–1774), king of France, was the great-grandson of Louis XIV. and the third son of Louis, duke of Burgundy, and Marie Adelaide, princess of Savoy. He was five years old when Louis XIV. died. With the help of the parlement of Paris the arrangement for a council of regency made by the late king was set aside, and the duke of Orleans was declared regent with full powers. Fleury, bishop of Fréjus, was appointed the king's tutor. He attained his legal majority at the age of thirteen, shortly before the death of the duke of Orleans. His first minister was the incapable duke of Bourbon, who in 1725 procured his marriage to Maria Leszczynska, daughter of the exiled king of Poland. In 1726 the duke of Bourbon was displaced by the king's tutor, Fleury, who exercised almost absolute power. His administration was successful and peaceful until the year 1734, when France intervened in Poland on behalf of the queen's father. The peace of Vienna (1735) secured to France the possession of Lorraine. In 1740 France drifted into the war of the Austrian Succession as an ally of Frederick of Prussia and the enemy of England, and of Maria Theresa of Austria.

On Fleury's death in 1743 Louis XV. determined to rule alone, but he was not strong enough in will or intellect to rule effectively. The queen for some time seems to have secured his affections, and she bore him seven children. But Louis entertained a series of mistresses. The first to acquire notoriety was the duchess of Châteauroux, the third sister of one family who held this position. He dismissed her in a fit of piety after an illness, but her place was taken in 1745 by Madame de Pompadour, whose influence on public affairs was a fatal one. She had many rivals during her lifetime and on her death in 1764 she was succeeded by Madame du Barry (*q.v.*). To the last Louis maintained the pretence of personal rule, but the machinery of government fell out of gear, and the disorder of the finances was never remedied before the revolution of 1789.

The peace of Aix-la-Chapelle (1748), which ended the war of the Austrian Succession, brought no gains to France in spite of her victories at Fontenoy and Raucoux; and the king was blamed for the diplomatic failure. The interval between this war and the Seven Years' War (1756) saw that great reversal of alliances which is sometimes called the "Diplomatic Revolution"; whereby France repudiated the alliance of Frederick the Great and joined hands with her old enemy Austria. The intrigues of Madame de Pompadour played in this change an important though not a decisive part. It was the cause of immense disasters to France; for after a promising beginning, both by land and sea, France suffered reverses which lost her both India and Canada and deprived her of the leading position which she had so long held in Europe. Her humiliation was declared by the peace of Paris (1763).

The article on the history of France (*q.v.*) shows how there arose during the last years of Louis XV.'s reign a strong reaction against the monarchy and its methods. In the parlements, provincial and Parisian; in religion and in literature, a note of opposition was struck which was never to die until the monarchy was overthrown. France annexed Corsica in 1768, but this was felt to be the work of the minister Chauvelin, and reflected no credit on the king. He died on May 10, 1774.

For the king's life generally *see* the memoirs of Saint-Simon, d'Argenson, Villars and Barbier, and for the details of his private life E. Boutaric, *Correspondance secrète de Louis XV.;* Madame de

Pompadour's *Correspondance* published by P. Malassi; Dietric, *Les Maîtresses de Louis XV.;* and Fleury, *Louis XV. intimes et les petites maîtresses* (1909).

For the system of secret diplomacy and organized espionage, *see* Albert duc de Broglie, *Le Secret du roi, Correspondance secrète de Louis XV. avec ses agents diplomatiques 1752–1774* (1878); Cahen, *Les querelles religieuses et parlementaires sous Louis XV.* (1913); and for a general account of the reign, H. Carré, *La France sous Louis XV.* (Paris, 1891); Mouffle d'Angerville, *The Private Life of Louis XV.* (1924); also C. Saint-André, *Louis XV.* (1921). For other works, general and special, *see* G. Monod, *Bibliographie de la France,* and the bibliography in the *Histoire générale* of Lavisse and Rambaud, vol. vii., and the *Cambridge Modern History,* vol. vi.

LOUIS XVI. (1754–1793), king of France, was the son of Louis, dauphin of France, the son of Louis XV., and of Marie Joseph of Saxony, and was born at Versailles on Aug. 23, 1754, being baptized as Louis Augustus. His father's death in 1765 made him heir to the throne, and in 1770 he married Marie Antoinette (*q.v.*) daughter of the empress Maria Theresa. He was twenty years old when the death of Louis XV. on May 10, 1774, placed him on the throne. He began his reign under good auspices, with Turgot, the greatest living French statesman, in charge of the disorganized finances; but in less than two years he dismissed him. Turgot's successor, Necker, however, continued the régime of reform until 1781, and it was only with Necker's dismissal that the period of reaction began. Marie Antoinette then obtained that ascendancy over her husband which was partly responsible for the extravagance of the ministry of Calonne.

The third part of his reign began with the meeting of the states-general on May 4, 1789, which marked the opening of the Revolution. The revolt of Paris and the taking of the Bastille on July 14 were its results. The suspicion, not without justification, of a second attempt at a *coup d'état* led on Oct. 6, to the "capture" of the king and royal family at Versailles by a mob from Paris, and their transference to the Tuileries. In spite of the growing radicalism of the clubs, however, loyalty to the king remained surprisingly strong. When he swore to maintain the constitution, then in progress of construction, at the festival of the federation on July 14, 1790, he was at the height of his popularity. Even his attempted flight on June 20, 1791, did not entirely turn the nation against him. Arrested at Varennes, he was maintained as a constitutional king, and took his oath on Sept. 13, 1791.

But already a party was forming in Paris which demanded his deposition. This first became noticeable in connection with the affair of the Champ de Mars on July 17, 1791. Crushed for a time the party gained strength through the winter of 1791–1792. The declaration of war against the emperor Francis II., nephew of Marie Antoinette, was forced upon the king by those who wished to discredit him by failure, or to compel him to declare himself openly an enemy to the Revolution. Their policy proved effective. The failure of the war, which intensified popular hatred of the Austrian queen, involved the king; and the invasion of the Tuileries on June 20, 1792, was but the prelude to the conspiracy which resulted on Aug. 10, in the capture of the palace and the "suspension" of royalty by the Legislative Assembly until the convocation of a national convention in September. On Sept. 21, 1792, the Convention declared royalty abolished, and in January it tried the king for his treason against the nation, and condemned him to death. He was executed on Jan. 21, 1793.

Louis XVI. was weak in character and mentally dull. His courage and dignity during his trial and on the scaffold has left him a better reputation than he deserves. His diary shows how little he understood, or cared for, the business of a king. Days on which he had not shot anything at the hunt were blank days for him. The greater part of his time was spent hunting. He also amused himself making locks, and a little at masonry. On one point only, he actively resisted the Revolution. A devoted and sincere Roman Catholic, he refused at first to sanction a constitution for the church in France without the pope's approval, and after he had been compelled to allow the constitution to become law he intrigued feebly against the Revolution. When he gave in, he delayed his acquiescence until it had the air of a surrender.

Having lost his elder son in 1789 Louis left two children, Louis Charles, usually known as Louis XVII. (*q.v.*), and Marie Thérèse Charlotte (1778–1851), duchess of Angoulême. The "orphan of the Temple," as the princess was called, was in prison for three years, during which time she remained ignorant of the fate which had befallen her parents. She died on Oct. 19, 1851. Her life by G. Lênotre has been translated into English by J. L. May (1908).

See the articles French Revolution and Marie Antoinette. F. X. J. Droz, *Histoire du règne de Louis XVI.* (3 vols., 1860), a sane and good history of the period; and Arsène Houssaye, *Louis XVI.* (1891). *See* also the numerous memoirs of the time, and the marquis de Ségur's *Au couchant de la monarchie, Louis XVI. et Turgot* (1910); de Baissière, *La mort du roi, 21 janvier 1793* (1909); Durfel, *La diplomatie de la France sous Louis XVI.* (1919).

LOUIS XVII., Charles (1785–1795?), titular king of France, second son of Louis XVI., and Marie Antoinette, was born at Versailles on March 27, 1785, and given the title of duke of Normandy, becoming dauphin on the death of his elder brother on June 4, 1789. In 1792 his parents and the rest of the royal party were imprisoned in the Temple—at first in the smaller tower; on Oct. 27 they were moved to the larger tower, and Louis was separated from his mother and aunt to be put in his father's charge, except for a few hours daily, but he was restored to the women when Louis was finally isolated at his trial.

On Jan. 21, 1793, Louis became, for the royalists, king of France, and the comte de Provence gave himself the title of regent. Plots were engineered for the escape of the prisoners by the Chevalier de Jarjayes, the baron de Batz (*q.v.*) and Lady Atkyns (*q.v.*). On July 3 the dauphin was given into the charge of Simon, a cobbler who had been named his guardian by the Committee of General Security. Although the Simons were unfit guardians there is little evidence that the child was actually ill-treated. On Oct. 6 Chaumette, Hébert and others visited him, and secured from him admissions of infamous accusations against his mother, and next day he met his sister, Marie Thérèse, for the last time. On Jan. 19 the Simons left the Temple.

Two days after their departure Louis is said by the Restoration historians to have been put in a dark room which was barricaded, while food was passed through the bars; and according to the legend nobody entered the room for six months, till Barras visited him after the 9th Thermidor (July 27, 1794). The child made no complaint to Barras, probably because he feared to do so. After this his condition improved; he was visited during the day by his new attendant, a creole named Jean Jacques Christophe Laurent (1770–1807), who had assistance from a man named Gomin after Nov. 8. From about this time the prisoner was inspected by representatives of the civil committee of the 48 sections of Paris, and on Dec. 19, 1794, he was visited by three commissioners from the Committee of General Security—J. B. Harmand de la Meuse, J. B. C. Mathieu, and J. Reverchon—who extracted no word from him. On Laurent's retirement Étienne Lasne was appointed on March 31, 1795, to be the child's guardian. In May 1795 Louis was seriously ill, and a doctor, P. J. Desault, who had visited him seven months earlier, was summoned. Desault died suddenly, not without suspicion of poison, on June 1, and it was some days before Doctors Pelletan and Dumangin were called. Then it was stated that on the 8th Louis Charles had died. Next day an autopsy was held, at which it was stated that a child apparently about ten years of age "which the commissioners told us was the late Louis Capet's son," had died of a scrofulous affection of long standing. He was buried on the 10th in the cemetery of Ste. Marguerite, but no stone was erected to mark the grave.

Immediately on the announcement of the dauphin's death there arose a rumour that he had escaped. Simien Despréaux, one of Louis XVIII.'s own authors, stated in 1814 that Louis XVII. was living, and Eckard left among his unpublished papers a statement that many members of "an assembly of our wise men" named Louis XVII. as the prince whom they wished to have. The royal family made no serious attempt to ascertain the truth, and the removal of Louis XVII. suited the comte de Provence (now Louis XVIII. for the émigrés) as well as it did the Revolutionary

Government.

The most important of some 40 pretenders under the Restoration were Karl Wilhelm Naundorff (*q.v.*) and the comte de Richemont. According to Naundorff, Barras determined to save the dauphin in order to please Joséphine Beauharnais, the future empress, having conceived the idea of using the dauphin's existence as a means of dominating the comte de Provence in the event of a restoration. The dauphin was concealed in the fourth storey of the Tower, a wooden figure being substituted for him. Laurent, to protect himself from the consequences of the substitution, replaced the wooden figure by a deaf mute, who was presently exchanged for the scrofulous child of the death certificate. The deaf mute was also concealed in the Temple. It was not the dead child but the dauphin who left the prison in the coffin, whence he was extracted by his friends on the way to the cemetery. Richemont's tale is that the woman Simon, who was genuinely attached to him, smuggled him out in a basket. Richemont was in prison in Milan for seven years and began to put forward his claims in Paris in 1828. In 1834, he was condemned to 12 years' imprisonment. He escaped after a few months and left the country, to return in 1840. He died at Gleize on Aug. 10, 1853.

If the dauphin did escape, it seems probable that he perished shortly afterwards or lived in a safe obscurity. The account of the substitution in the Temple is well substantiated, even to the names of the substituted. Lady Atkyns was trying by every possible means to get the dauphin out of his prison when he was apparently already in safe hands, if not outside the Temple walls. A child was in fact delivered to her agents, but he was found to be a deaf mute.

The official version of the dauphin's history as accepted under the Restoration was drawn up by Simien Despréaux in his uncritical *Louis XVII.* (1817), and is found, fortified by documents, in M. Eckard's *Mémoires historiques sur Louis XVII.* (1817) and in A. de Beauchesne's *Louis XVII., sa vie, son agonie, sa mort. Captivité de la famille royale au Temple* (2 vols., 1852, and many subsequent editions), contains copies of original documents. L. de la Sicotière, "Les faux Louis XVII.," in *Revue des questions Historiques* (vol. xxxii., 1882), deals with the pretenders Jean Marie Hervagault, Mathurin Bruneau and the rest; *see* also Dr. Cabanes, *Les Morts mystérieuses de l'histoire* (1901), and revised catalogue of the J. Sanford Saltus collection of Louis XVII. books (New York, 1908); also J. H. Hanson, *The Lost Prince* (1854); E. R. Buckley, *Monsieur Charles, The Tragedy of the True Dauphin* (1927).

For De Richemont see *Mémoires du duc de Normandie, fils de Louis XVI., écrits et publiés par lui-même* (1831), compiled, according to Quérard, by E. T. Bourg, called Saint Edme; Morin de Guérivière, *Quelques souvenirs . . .* (1832); and J. Suvigny, *La Restauration convaincue . . . ou preuves de l'existence du fils de Louis XVI.* (1851).

Since 1905 a monthly periodical has appeared in Paris on this subject, entitled *Revue historique de la question Louis XVII.*

LOUIS XVIII. (Louis le Désiré) (1755–1824). Louis-Stanislas-Xavier, comte de Provence, third son of the dauphin Louis, son of Louis XV. and Maria Josepha of Saxony, was born at Versailles on Nov. 17, 1755. His education was supervised by the devout duc de la Vauguyon, but his own taste was for the writings of Voltaire and the encyclopaedists. On May 14, 1771, took place his marriage with Louise-Marie-Joséphine of Savoy. During the long absence of heirs to Louis XVI., "Monsieur," as heir to the throne, courted popularity and took an active part in politics, but the birth of a dauphin (1781) was a blow to his ambitions. He opposed the revival of the *parlements,* wrote a number of political pamphlets, and at the Assembly of Notables presided, like the other princes of the blood, over a bureau, to which was given the name of the *Comité des sages;* he also advocated the double representation of the *tiers.* At the same time he cultivated literature, entertaining poets and writers both at the Luxembourg and at his château of Brunoy (*see* Dubois-Corneau, *Le Comte de Provence à Brunoy,* 1909), and gaining a reputation for wit by his verses and *mots* in the salon of the charming and witty comtesse de Balbi, one of Madame's ladies, who had become his mistress, and till 1793 exerted considerable influence over him. He did not emigrate after the taking of the Bastille, but, possibly from motives of ambition, remained in Paris. In June 1791, however, at the time of the flight to Varennes, he also fled by a different route, and, in company with the comte d'Avaray—who subsequently replaced Mme. de Balbi as his confidant, and largely influenced his policy—reached Brussels, where he joined the comte d'Artois and proceeded to Coblenz, now the headquarters of the emigration.

Here, living in royal state, he put himself at the head of the counter-revolutionary movement, appointing ambassadors, soliciting the aid of the European sovereigns, and especially of Catherine II. of Russia. Out of touch with affairs in France and surrounded by violent anti-revolutionists, headed by Calonne and the comte d'Artois, he followed an entirely selfish policy, flouting the National Assembly, issuing uncompromising manifestoes (Sept. 1791, Aug. 1792, etc.), and obstructing in every way the representatives of the king and queen. After Valmy he had to retire to Hamm in Westphalia, where, on the death of Louis XVI., he proclaimed himself regent; from here he went south, with the idea of encouraging the royalist feeling in the south of France, and settled at Verona, where on the death of Louis XVII. (June 8, 1795) he took the title of Louis XVIII. From this time onward his life is a record of constant wanderings, negotiations and conspiracies. In April 1796 he joined Condé's army on the German frontier, but was shortly requested to leave the country, and accepted the hospitality of the duke of Brunswick at Blanckenberg till 1797, when, this refuge being no longer open to him, the emperor Paul I. permitted him to settle at Mittau in Courland, where he stayed till 1801. All this time he was in close communication with the royalists in France, but was much embarrassed by the conflicting policy pursued by the comte d'Artois from England, and was largely at the mercy of corrupt and dishonest agents.[1] At Mittau was realized his cherished plan of marrying Madame Royale, daughter of Louis XVI., to the duc d'Angoulême, elder son of the comte d'Artois. From Mittau, too, was sent his well-known letter to Bonaparte (1799) calling upon him to play the part of Monk, a proposal contemptuously refused, though Louis in turn declined to accept a pension from Bonaparte, and later, in 1803, though his fortunes were at their lowest ebb, refused to abdicate at his suggestion and accept an indemnity.

Suddenly expelled from Mittau in 1801 by the capricious Paul I., Louis made his way, in the depth of winter, to Warsaw, where he stayed for three years. All this time he was trying to convert France to the royalist cause, and had a *conseil royal* in Paris, founded at the end of 1799 by Royer-Collard, Montesquiou, and Clermont-Gallerande, but after 1800, and still more after the assumption by Napoleon of the title of emperor (May 1804), the royalist cause appeared hopeless. In Sept. 1804 Louis met the comte d'Artois at Calmar in Sweden, whence they issued a protest against Napoleon's action. Warned that he must not return to Poland, he gained permission from Alexander I. again to retire to Mittau. After Tilsit, however (1807), he was again forced to depart, and took refuge in England, where he stayed first at Gosfield in Essex, and afterwards (1809 onwards) at Hartwell in Buckinghamshire. In 1810 his wife died, and in 1811 d'Avaray died, his place as favourite being taken by the comte de Blacas.[2] After Napoleon's defeats in 1813 the hopes of the royalists revived, and Louis issued a fresh manifesto, in which he promised to recognize the results of the Revolution. Negotiations were also opened with Bernadotte, who seemed willing to support his cause, but was really playing for his own hand.

In March 1814 the allies entered Paris, and thanks to Talleyrand's negotiations the restoration of the Bourbons was effected, Louis XVIII. entering Paris on May 2, 1814, after issuing the declaration of St. Ouen, in which he promised to grant the nation a constitution (*octroyer une charte*). He was now nearly 60, wearied by adversity, and a sufferer from gout and obesity. But though clear-sighted, widely read and a good diplomatist, his impressionable and sentimental nature made him too subject to personal and family influences. His concessions to the reactionary and clerical party of the *émigrés,* headed by the comte d'Artois and the duchess d'Angoulême, aroused suspicions of his loyalty to the constitution, the creation of his *Maison militaire,* alienated

[1]*See* E. Daudet, *La Conjuration de Pichegru* (Paris, 1901).

[2]Pierre-Louis-Casimir, comte (afterwards duc) de Blacas d'Aulps, was as rigidly royalist as d'Avaray, but more able.

the army, and the constant presence of Blacas made the formation of a united ministry impossible. After the Hundred Days, during which the king was forced to flee to Ghent, the dismissal of Blacas was made one of the conditions of his second restoration. On July 8 he again entered Paris, "in the baggage train of the allied armies," as his enemies said, but in spite of this was received with the greatest enthusiasm by a people weary of wars and looking for constitutional government. He was forced to retain Talleyrand and Fouché in his first ministry, but took the first opportunity of ridding himself of them when the elections of 1815 assured him of a strong royalist majority in the chamber (the *chambre introuvable,* a name given it by Louis himself). At this time he came into contact with the young Élie Decazes (*q.v.*), prefect of the police under Fouché, who now became his favourite and gained his entire confidence. Having obtained a ministry in which he could trust, with the duc de Richelieu at its head, and Decazes as minister of police, the king gave it his loyal support and did his best to shield his ministers from the attacks of the royal family. In Sept. 1816, alarmed at the violence of the *chambre introuvable,* he was persuaded by Decazes to dissolve it. An attempt on the part of the Ultras to regain their ascendancy over the king, by conniving at the sudden return of Blacas from Rome to Paris, ended in failure.

The king's policy throughout was one of prudence and common sense. While Decazes, who succeeded Richelieu as president of the council in Dec. 1818, was still in power, the king's policy to a large extent followed his, and was rather liberal and moderate, but after the assassination of the duc de Berry (1820), when he saw that Decazes could no longer carry on the government, he sorrowfully acquiesced in his departure, showered honours upon him, and transferred his support to Richelieu, the head of the new ministry. In the absence of Decazes a new favourite was found to amuse the king's old age, Madame du Cayla (Zoé Talon, comtesse du Cayla), a protégée of the vicomte Sosthène de la Rochefoucauld and consequently a creature of the Ultras. As the king became more and more infirm, his power of resistance to the intrigues of the Ultras became weaker. The birth of a posthumous son to the duc de Berry (Sept. 1820), the death of Napoleon (May 5, 1821) and the resignation of Richelieu, left him entirely in their hands, and after Villèle had formed a ministry of an ultra-royalist character, the comte d'Artois was associated with the government, which passed more and more out of the king's hands. He died on Sept. 16, 1824. Louis XVIII. had the Bourbon characteristics, their love of power, a certain nobility of demeanor, and a consciousness of dignity. But he was cold, unsympathetic and calculating. He had a talent for intrigue, to which was added an excellent memory and a ready wit. An interesting judgment of him is contained in Queen Victoria's *Letters,* vol. i., in a letter by Leopold I., king of the Belgians, dated Nov. 18, 1836, "Poor Charles X. is dead. . . . History will state that Louis XVIII. was a most liberal monarch, reigning with great mildness and justice to his end, but that his brother, from his despotic and harsh disposition, upset all the other had done and lost the throne. Louis XVIII. was a clever, hard-hearted man, shackled by no principle, very proud and false. Charles X. an honest man, a kind friend." As a personal, rather than a political estimate, this is just.

Bibliography.—There is no trustworthy or complete edition of the writings and correspondence of Louis XVIII. From his own hand are *Relation d'un voyage à Bruxelles et à Coblentz, 1791* (1823) and *Journal de Marie-Thérèse de France, duchesse d'Angoulême, corrigé, et annoté par Louis XVIII.,* edit. Imbert de St. Amand (1894). Some of his letters are contained in collections, such as *Lettres et instructions de Louis XVIII. au comte de Saint-Priest,* edit. P. B. de Barante (1845); *Lettres d'Artwel: correspondance politique et privée de Louis XVIII.,* addressed to d'Avaray (1880); *Talleyrand et Louis XVIII. corr. pendant le congrès de Vienne, 1814–1815,* edit. G. Pallain (1881, Eng. trans. 2 vols., 1881); *see* also the correspondence of Castlereagh, Metternich, J. de Maistre, the Wellington Despatches, etc., *Corr. diplomatique de Pozzo di Borgo avec le comte de Nesselrode* (2 vols., 1890–97), the correspondence of C. de Rémusat, Villèle, etc. *See* also E. Capefigue, *La Comtesse du Cayla* (1866), J. Turquan, *Souveraines et grandes dames: les favorites de Louis XVIII.* (1900), Vicomte de Reiset, "Anne de Caumont-Laforce, comtesse de Balbe" in *Les Reines de l'émigration,* vol. ii. (1908). *See* also the chief memoires of the period, such as those of Talleyrand, Chateaubriand, Guizot, duc de Broglie, Villèle, Vitrolles, Pasquier, L. F. S. de la Rochefoucauld (15 vols., 1861–64), and of the comtesse de Boigne, edit. C. Nicoullaud (1907).

LOUIS II. (1506–26), king of Hungary and Bohemia, was the only son of Wladislaus II., king of Hungary and Bohemia, and the French princess Anne of Candale. Prematurely born at Buda on July 1, 1506, it required all the resources of medical science to keep the sickly child alive, yet he developed so precociously that at the age of 13 he was well bearded and moustached, while at 18 his hair was silvery white. His parts were good and he could speak and write six languages at a very early age, but the zeal of his guardians and tutors to make a man of him betimes nearly ruined his feeble constitution, while the riotous life led by him and his young consort, Maria of Austria, whom he wedded on Jan. 13, 1522, speedily disqualified him for affairs, so that at last he became an object of ridicule at his own court. He was crowned king of Hungary on June 4, 1508, and king of Bohemia on May 11, 1509, and was declared of age when he succeeded his father on Dec. 11, 1521. But during most of his reign he was the puppet of the magnates and kept in such penury that he was often obliged to pawn his jewels to get proper food and clothing, while his guardians and the Hungarian nobles rent the kingdom with their factions. In the last struggle with the Turks, which was brought on partly by Louis's own folly, the young king was deserted by the nobles who should have helped him. His army was utterly defeated at Mohács, Aug. 29, 1526, and he himself is said to have been drowned in his flight from the field (*see* Hungary: *History*). After his death the Crowns of Hungary and Bohemia passed to the Habsburg dynasty.

See *Rerum Hungaricarum libri* (vol. ii., ed. Ferencz Toldy, Budapest, 1867); and József Podhradczky, *King Louis* (Hung.) (1860).

LOUIS I. (1326–82), called "the great," king of Hungary and Poland, was the third son of Charles Robert, king of Hungary, and Elizabeth, daughter of the Polish king, Ladislaus Lokietek. On July 21, 1362, he was crowned king of Hungary in succession to his father. He engaged in a prolonged struggle against Venice for the Adriatic sea-board. On July 1, 1346, he was defeated by the Venetians at Zara, which had placed itself under the protection of Hungary. The battle has been immortalized by Tintoretto. In 1357, however, Louis formed a league of all the enemies of Venice, including the emperor, the Habsburgs, Genoa and other Italian towns, and forced her to cede most of the Dalmatian towns and renounce the title of duke of Dalmatia and Croatia, hitherto borne by the doge. (Treaty of Zara, Feb. 18, 1358.) In the same year the republic of Ragusa voluntarily submitted to him, Louis undertaking its defence against an annual tribute. The third Venetian War (1378–81), where Louis was again helped by Genoa, was ended by the congress of Turin (1381), Venice virtually surrendering Dalmatia to Louis and undertaking to pay him an annual tribute of 7,000 ducats. The persistent hostility of Venice is partially attributable to her constant fear lest Louis should inherit the crown of Naples and thus threaten her trade and her sea-power from two sides.

Louis's younger brother Andrew had wedded Joanna, granddaughter and heiress of old King Robert of Naples, on whose death, in 1343, she reigned in her own right, and is strongly suspected of having secured her consort's assassination in 1345. Although Louis claimed the throne, and twice occupied Naples, he could never secure the crown. At last in 1378 Joanna, having made the mistake of recognizing the antipope Clement VII., was promptly deposed and excommunicated in favour of Prince Charles of Durazzo, who had been brought up at the Hungarian court. With the Habsburgs, Louis generally maintained friendly relations, and his differences with Rudolph of Habsburg were composed without war at the peace congresses of Nagyszombat (1360) and of Pressburg (1360). On the death of his uncle, the childless Casimir the Great of Poland, who had been Louis's lifelong friend, and had appointed him his successor, Louis was crowned king of Poland (Nov. 17, 1370). This personal union of the two countries was more glorious than profitable. Louis was never able to establish real authority over his Polish subjects although in 1374 he compelled them by force to recognize his daughter Maria and her affianced husband, Count Sigismund of Brandenburg, as their future king and queen. Against the Turks, who were now beginning to threaten Europe, Louis took little or no action. He died suddenly at Nagyszombat, Sept. 10, 1382. He left two daughters Maria and Jadwiga (the latter he destined for the throne of Hungary) under the guardianship of his widow. She was the daughter of the valiant ban of Bosnia, Stephen Kotromanic, and she was married in 1353.

(Agram, 1903); Antal Pór, *Life of Louis the Great* (Hung.) (Budapest, 1892); and *History of the Hungarian Nation* (Hung.) (vol. iii., Budapest, 1895).

LOUIS, the name of three kings of Naples.

Louis I., duke of Anjou and count of Maine (1339–1384), was the second son of John II., king of France, and was born at Vincennes on July 23, 1339. As duke of Anjou he led a wing of the French army at the battle of Poitiers. He was a hostage for the treaty of Brétigny in 1360, but he broke his parole in 1363 and so brought about King John's return into captivity. He took part in the war against England which was renewed in 1369, uniting the rival houses of Foix and Armagnac in the common cause, and in other ways rendering good service to his brother, King Charles V. Anjou's entrance into the troubled politics of Italy was one result of the papal schism which opened in 1378. Anxious to secure the support of France, the antipope Clement VII. persuaded the queen of Naples, Joanna I. (*q.v.*), to name Louis as her heir, and about the same time the death of Charles V. (Sept. 1380) placed the duke in the position of regent of France. Neglecting France to prosecute his ambitions in Italy, he collected money and marched on Naples; but although helped by Amadeus VI., count of Savoy, he was unable to drive his rival, Charles, duke of Durazzo, from Naples. His army destroyed by disease, Louis died at Biseglia, near Bari, on Sept. 20, 1384, leaving two sons, his successor, Louis II., and Charles, duke of Calabria.

Louis II., duke of Anjou (1377–1417), born at Toulon on Oct. 7, 1377, took up the struggle for Naples after his father's death and was crowned king by Clement VII. in 1389. After carrying on the contest for some years he took refuge in France. He made other attempts to secure the kingdom of Naples, which was now in the possession of Ladislas, a son of Charles of Durazzo, and he gained a victory at Roccoserra in May 1411. He was again driven back to France, and he died at Angers on April 29, 1417. He married Yolande, a daughter of John I., king of Aragon.

Louis III., duke of Anjou (1403–1434), born on Sept. 25, 1403, son of Louis II., attempted to conquer Naples in 1420; he died at Cosenza on Nov. 15, 1434. In 1424 Louis received from King Charles VII. the duchy of Touraine.

Another titular king of Naples of this name was Louis, a son of Philip, prince of Taranto. In 1346 he became the husband of Joanna I., queen of Naples, and in 1352 he was crowned king. After attempting to conquer Sicily he died on May 26, 1362.

LOUIS or **LEWIS,** a masculine proper name derived from Frankish *Chlodowîch,* Latinized as *Lodhuvicus,* whence O.Fr. *Lodhuwigs, Loys,* and later *Louis; cf.* Ger. *Ludwig.* It means "famous in fight" and was borne by many sovereigns.

The "Louis" or "Louis d'or" was a term applied to the gold coins of France prior to the Revolution. The franc and livre (*qq.v.*) were silver coins which had shrunk in value to such an extent that larger coins were needed, and just as England adopted the guinea so did the French kings have gold coins struck and called after their name. After the Revolution Napoleon continued the practice, but called the coins "Napoleons."

LOUISBURG or Louisbourg, a town and port of entry of Cape Breton, Nova Scotia, Canada, the terminus of the Sydney & Louisburg railway, 39 mi. from Sydney. Pop. (1941) 1,012. Under the French *régime,* Louisburg was second only to Quebec. A fortress was erected at enormous expense, and the city was the centre of the cod-fisheries. The fortress was, however, captured in 1745 by the American colonists, under Sir William Pepperell (1696–1759), assisted by the British fleet, and again in 1758 by a British land and sea force under General Jeffrey Amherst (1717–1797) and Admiral Boscawen. The jealousy of the British settlement of Halifax led to its almost utter destruction, and only a few casemates now remain. Under English rule a fishing village grew up on the other side of the harbour. This harbour is deep, and open save for occasional drift ice in the spring. The site of the fortifications is now the Louisburg National Historic park.

LOUIS OF NASSAU (1538–1574), son of William, count of Nassau, and Juliana von Stolberg, and younger brother of William the Silent, was one of the leaders of the league of nobles who signed the document known as "the Compromise" in 1566, and was a member of the deputation who presented the petition of grievances called "the Request" to the regent, Margaret of Parma. On the arrival of Alva at Brussels, Count Louis, with his brother William, withdrew from the Netherlands and raised a body of troops in defence of the patriot cause. In the spring of 1568 Louis invaded Friesland, and at Heiligerlee, on May 23, completely defeated a Spanish force under Count Aremberg, who was killed. Alva annihilated the levies of Louis at Jemmnigen (July 21), Louis himself escaping by swimming across an arm of the Ems. He now joined William, who had in October to beat a hasty retreat before Alva's superior skill. The brothers then made their way to the camp of Admiral Coligny.

Louis took an active part in the Huguenot campaign, and fought heroically at Jarnac and Moncontour. In 1572 Louis raised a small force in France, and, suddenly entering Hainaut, captured Mons (May 23). Here he was besieged by Don Frederick of Toledo, Alva's natural son, who blockaded all approach to the town. William made an attempt to relieve his brother, but failed, and Mons surrendered (September 17). Louis withdrew to his home, Dillenburg, to raise money and troops for another invasion of the Netherlands. In the hope of diverting the Spaniards from the siege of Leiden, Louis with his brothers John and Henry, at the head of a mixed force, crossed the frontier near Maastricht, and advanced to the Mookerheide near Nijmwegen. Here he was attacked by Sancho d'Avila, and routed. Both Louis and his younger brother Henry were killed.

Van der Aa, *Biographisch woordenboek der Nederlanden* (22 vols., Haarlem, 1852–78); and Ledderhose, *Graf Ludwig von Nassau* (1877).

LOUIS PHILIPPE I., king of the French (1773–1850), was the eldest son of Louis Philippe Joseph, duke of Orleans (known during the Revolution as Philippe Egalité) and of Louise Marie Adelaide de Bourbon, daughter of the duc de Penthièvre, and was born at the Palais Royal in Paris on Oct. 6, 1773. The legend that he was a supposititious child is dealt with elsewhere. (*See* Maria Stella, countess of Newborough.) The god-parents of the duke of Valois, as he was entitled till 1785, were Louis XVI. and Queen Marie Antoinette; his governess was the famous Madame de Genlis, to whose influence he doubtless owed his wide, if superficial knowledge, his orderliness, and perhaps his parsimony. Known since 1785 as the duc de Chartres, he was 16 at the outbreak of the Revolution, with which, like his father, he at first identified himself. In 1790 he joined the Jacobin club, in which the moderate elements still predominated, and attended the debates of the National Assembly. He thus became a *persona grata* with the party in power; he was already a colonel of dragoons, and in 1792 he was given a command in the army of the north. As a lieutenant-general, at the age of 18, he was present at Valmy (Sept. 20) and Jemappes (Nov. 6).

The republic had meanwhile been proclaimed, and the duc de Chartres, now like his father surnamed *Egalité,* posed as its zealous adherent. Fortunately for him, he was too young to be elected to the Convention, and while his father was voting for the death of Louis XVI. he was serving under Dumouriez in Holland. He shared in the defeat of Neerwinden (March 18, 1793); was implicated with Dumouriez in the plot to overthrow the republic, and on April 5 escaped with him into the Austrian lines. He went first, with his sister Madame Adelaide, to Switzerland where he obtained a situation as professor in the college of Reichenau under the assumed name of M. Chabaud de la Tour, mainly in order to escape from the fury of the *émigrés*. The execution of his father in Nov. 1793 had made him duke of Orleans, and he now became the centre of the intrigues of the Orleanist party. In 1795 he was at Hamburg with Dumouriez, who still hoped to make him king. With characteristic caution Louis Philippe refused to commit himself, and announced his intention of going to America; but in the hope that something might happen in France to his advantage, he postponed his departure, travelling instead through the Scandinavian countries. But in 1796, the Directory having offered to release his mother and his two brothers, who had been kept in prison since the Terror, on condition that he went to America, he set sail for the United States, and in October settled in Philadelphia, where in Feb. 1797 he was joined by his brothers the duc de Montpensier and the comte de Beaujolais. The news of the *coup d'état* of 18 Brumaire decided them to return to Europe. They returned in 1800, only to find Napoleon Bonaparte's power firmly established. Immediately on his arrival, in Feb. 1800, the duke of Orleans, at the suggestion of Dumouriez, sought an interview with the comte d'Artois, through whose instrumentality he was reconciled with the exiled king, Louis XVIII. The duke, however, refused to join the army of Condé and to fight against France, an attitude in which he persisted, while maintaining his loyalty to the king. He settled with his brothers at Twickenham.

On May 18, 1807, the duc de Montpensier died at Christchurch in Hampshire of consumption. The comte de Beaujolais was ill of the same disease and in 1808 the duke took him to Malta, where he died on May 29th. The duke now, in response to an invitation from King Ferdinand IV., visited Palermo where, on Nov. 25, 1809, he married Princess Maria Amelia, the king's daughter. He remained in Sicily until the news of Napoleon's abdication recalled him to France. He was cordially received by Louis XVIII.; his military rank was confirmed, he was named colonel-general of hussars, and such of the vast Orleans estates as had not been sold were restored to him by royal ordinance. This made him enormously rich.

Meanwhile, his sympathy with the Liberal opposition brought him again under suspicion. His attitude in the House of Peers in the autumn of 1815 cost him a two years' exile to Twickenham; he courted popularity by having his children educated *en bourgeois* at the public schools; and the Palais Royal was the rendezvous of that middle-class by which he was to be raised to the throne.

His opportunity came with the revolution of 1830. During the three "July days" the duke kept himself discreetly in the background, retiring first to Neuilly, then to Raincy. Meanwhile, Thiers issued a proclamation pointing out that a Republic would embroil France with all Europe, while the duke of Orleans who was "a prince devoted to the principles of the Revolution" and had "carried the tricolour under fire" would be a "citizen king" such as the country desired. This view was that of the rump of the chamber still sitting at the Palais Bourbon, and a deputation headed by Thiers and Laffitte waited upon the duke to invite him to place himself at the head of affairs. He returned with them to Paris on the 30th, and was elected by the deputies lieutenant-general of the realm. The next day, wrapped in a tricolour scarf, he went on foot to the Hôtel de Ville—the headquarters of the republican party—where he was publicly embraced by Lafayette as a symbol that the republicans acknowledged the impossibility of realizing their own ideals and were prepared to accept a monarchy based on the popular will. Hitherto, in letters to Charles X., he had protested the loyalty of his intentions, and the king now nominated him lieutenant-general and, abdicating in favour of his grandson the comte de Chambord, appointed him regent. On Aug. 7, however, the Chamber by a large majority declared Charles X. deposed, and proclaimed Louis Philippe "king of the French, by the grace of God and the will of the people."

For the trappings of authority he cared little. To conciliate the revolutionary passion for equality he was content to veil his kingship for a while under a middle-class disguise. He erased the royal lilies from the panels of his carriages; and the Palais Royal, like the White House at Washington, stood open to all and sundry who cared to come and shake hands with the head of the State. This pose served to keep the democrats of the capital in a good temper, and so leave him free to consolidate the somewhat unstable foundation of his throne and to persuade his European fellow-sovereigns to acknowledge in him not a revolutionary but a conservative force. But when once his position had been established, it became clear that he possessed all the Bourbon tenaciousness of personal power. When a "party of resistance" came into office with Casimir-Pèrier in March 1831, the speech from the throne proclaimed that "France has desired that the monarchy should become national, it does not desire that it should be powerless"; and the migration of the royal family to the Tuileries symbolized the right of the king not only to reign but to rule. Republican and Socialist agitation, culminating in a series of dangerous risings, strengthened the position of the king as defender of middle-class interests; and since the middle classes alone were represented in Parliament, he came to regard his position as unassailable. Little by little his policy became more purely dynastic. His position in France seeming assured, he sought to strengthen it in Europe by family alliances. The fact that his daughter Louise was the consort of Leopold I., king of the Belgians, had brought him into intimate relations with the English court. Broken in 1840 during the affair of Mohammed Ali, the *entente* with Great Britain was patched up in 1841 by the Straits Convention, and re-cemented by visits paid by Queen Victoria and Prince Albert to the Château d'Eu in 1843 and 1845 and of Louis Philippe to Windsor in 1844, only to be irretrievably wrecked by the affair of the "Spanish marriages," a deliberate attempt to revive the traditional Bourbon policy of French predominance in Spain. If in this matter Louis Philippe had seemed to sacrifice the international position of France to dynastic interests, his attempt to re-establish it by allying himself with the reactionary monarchies against the Liberals of Switzerland finally alienated from him the French Liberal opinion on which his authority was based. When, in Feb. 1848, Paris rose against him, he found that he was isolated.

Charles X., after abdicating, had made a dignified exit from France. Louis Philippe was less happily situated. Escaping with the queen from the Tuileries by a back entrance, he made his way with her in disguise to Honfleur, where the royal couple found refuge in a gardener's cottage. They were smuggled out of the country by the British consul at Havre as Mr. and Mrs. Smith, arriving at Newhaven "unprovided with anything but the clothes they wore." They settled at Claremont, placed at their disposal by Queen Victoria, under the *incognito* of count and countess of Neuilly. Here on Aug. 26, 1850, Louis Philippe died.

Louis Philippe had eight children. His eldest son, the popular Ferdinand Philippe, duke of Orleans (b. 1810), who had married Princess Helena of Mecklenburg, was killed in a carriage accident on July 13, 1842, leaving two sons, the comte de Paris and the duc de Chartres. The other children were Louise, consort of Leopold I., king of the Belgians; Marie, who married Prince Alexander of Württemberg and died in 1839; Louis Charles, duc de Nemours; Clementine, married to the duke of Coburg-Kohary; François Ferdinand, prince de Joinville; Henri Eugène, duc d'Aumale (*q.v.*); Antoine Philippe, duc de Montpensier, who married the younger sister of Queen Isabella of Spain.

LOUISE [Auguste Wilhelmine Amalie Luise] (1776–1810), queen of Prussia, was born on March 10, 1776, in Hanover, where her father, Prince Charles of Mecklenburg-Strelitz, was field-marshal of the household brigade. Her mother was a princess of Hesse-Darmstadt. In 1793 Louise met at Frankfort the crown prince of Prussia, afterwards King Frederick William III., whom she married on Dec. 4. As queen of Prussia she commanded universal respect and affection, and won a great name by the dignity and unflinching courage with which she bore the sufferings inflicted on her and her family during the Napoleonic wars. After the battle of Jena she went with her husband to Königsberg, and when the battles of Eylau and Friedland placed Prussia at the mercy of France, she made a personal appeal to Napoleon at his headquarters in Tilsit, but without success. Early in 1808 she accompanied the king from Memel to Königsberg, whence, towards the end of the year, she visited St. Petersburg (Leningrad), returning to Berlin on Dec. 23, 1809. During the war Napoleon attempted to destroy the queen's reputation, but the only effect of his charges in Prussia was to make her more deeply beloved. She died on July 19, 1810, at Strelitz, and was buried in the garden of the palace at Charlottenburg. The Louise Foundation (Luisenstift) for the education of girls was established in her honour, and in 1814 Frederick William III. instituted the Order of Louise (Luisenorden). In 1880 a statue of Queen Louise was erected in the Thiergarten at Berlin.

LOUISE OF SAVOY (1476–1531), duchess of Angoulême, mother of Francis I. of France, was daughter of a cadet of the house of Savoy, Philip, count of Bresse, afterwards duke of Savoy, and of Marguerite de Bourbon. At the age of 12 she was married to Charles of Valois, count of Angoulême, great-grandson of King Charles V. The count died in 1496, leaving her the mother of two children, Marguerite (b. 1492) and Francis (b. 1494). The accession of Louis XII., who was childless, made Francis of Angoulême the heir-presumptive to the throne of France. Louise brought her children to the court, and received Amboise as her residence. Finally, her son became king on Jan. 1, 1515, by the death of Louis XII. From 1515 to her death, she took the chief share in the Government. The part she played has been variously judged, and is not yet completely elucidated. It is certain that Louise had a clear head, practical good sense and tenacity. In the critical situation after the battle of Pavia (1525) she maintained order in the kingdom, and manoeuvred very skilfully to detach Henry VIII. of England from the imperial alliance. She died in 1531, and Francis reunited to the crown her domains, which comprised the Bourbonnais, Beaujolais, Auvergne, la Marche, Angoumois, Maine and Anjou.

There is extant a *Journal* of Louise of Savoy, edited by Guichenon in his *Histoire généalogique de la maison de Savoie* (1778–80, vol. iv.).

Jacqueton, *La Politique extérieure de Louise de Savoie . . .* (1892); H. Hauser, "Étude critique sur le Journal de Louise de Savoie," in the *Revue historique*, vol. 86 (1904).

LOUISIADE ARCHIPELAGO, a chain of islands in the Pacific Ocean, extending south-eastward from the easternmost promontory of New Guinea, and included in the Australian territory of Papua (British New Guinea). The islands number over eighty, and are interspersed with reefs. They are rich in tropical forest products, while gold is also obtained. The islands were probably observed by Torres in 1606, but were named by L. A. de Bougainville in 1768 after Louis XV.

LOUISIANA, popularly known as the "Pelican State," is one of the west South Central States of the United States of America, lying on the north coast of the Gulf of Mexico. It is bounded north by Arkansas along the parallel of 33° N.; east by the Mississippi river to 31°, which separates it in part from the State of Mississippi, eastward on the parallel of 31° to the Pearl river and thence to the Gulf, still with the state of Mississippi on the east; south by the Gulf of Mexico; west by the Sabine river, from the Gulf to 32° N. and thence to the parallel of 33° by a line a little west of (and parallel to) the meridian of 94° W., which separates Louisiana from Texas. The state has an area of 48,523 sq.m., of which 3,346 are water surface (including 1,060 sq.m. of landlocked bays called "lakes"). The length of the coast of the mainland and islands is about 1,700 miles.

Physical Features.—Geologically Louisiana is a very recent creation, and belongs to the "coastal plain province." Most of

MAP OF THE MAIN ROADS IN LOUISIANA

the rocks or soils composing its surface were formed as submarine deposits; the easternmost and southernmost parts are true river deposits. These facts are the key to the State's chorography. The average elevation of the State above the sea is only about 100 ft., and the only parts reaching 400 ft. high are hills in Claiborne parish. The physiographic features are few and very simple. The essential elements are five: "pine-hills," "bluffs," prairies, coastal marshes and alluvial plains. These were successive stages in the geologic process which has created and is still actively modifying the State. They are all seen, spread from north to south, west of the Mississippi, and also, save only the prairies, in the so-called "Florida parishes" east of the Mississippi.

These different elements in the region west of the Mississippi are arranged from north to south in the order of decreasing geologic age and maturity. Beginning with elevations of about 400 ft. near the Arkansas line, there is a gentle slope toward the south-east. The northern part can best be regarded as a low plateau (once marine sediments) sloping southward, traversed by the large diluvial valleys of the Mississippi, Red and Ouachita rivers, and recut by smaller tributaries into smaller plateaus and rather uniform flat-topped hills. The "bluffs" (remnants of an eroded plain formed of alluvion deposits over an old, mature and drowned topography) run through the second tier of parishes west of the Mississippi above the Red river. Below this river prairie areas become increasingly common, constituting the entire southwest corner of the State. They are usually only 20 to 30 ft. above the sea in this district, never above 70, and are generally treeless except for marginal timber along the sluggish, meandering streams. The prairies shade off into the coast marshes. This fringe of wooded swamp and sea marsh is generally 20 to 30 m., but in places even 50 to 60 m. wide. Where the marsh is open and grassy, flooded only at high tide or in rainy seasons, and the ground firm enough to bear cattle, it is used as range. Considerable tracts have also been diked and reclaimed for cotton, sugar and especially for rice culture. The tidal action of the gulf is so slight and the marshes are so low that perfect drainage cannot be obtained through tide gates, which must therefore be supplemented by pumping machinery when rains are heavy or landward winds long prevail. "Trembling prairies"—land that trembles under the tread of man or beast—are common near the coast. The marshes encroach most upon the parishes of St. Charles, Orleans and Plaquemines. In Orleans the city of New Orleans occupies nearly all the high ground and encroaches on the reclaimed swamps. The alluvial lands include the river flood plains.

Each of the larger streams, as well as a large proportion of the smaller ones, is accompanied by a belt of bottom land, of greater or less width, lying low as regards the stream, and liable to overflow at times of high water. These flood plains form collectively what is known as the alluvial region, which extends in a broad belt down the Mississippi, and up the Ouachita and its branches and the Red river to and beyond the limits of the state. Its breadth along the Mississippi within Louisiana ranges from 10 to 50 or 60 mi., and that along the Red river and the Ouachita has an average breadth of 10 miles. Through its great flood plain the Mississippi river winds upon the summit of a ridge formed by its own deposits. In each direction the country falls away in a succession of minor undulations, the summits of the ridges being occupied by the streams and bayous. Nearly all of this vast flood plain lies below the level of high water in the Mississippi, and, but for the protection afforded by the levees, every considerable rise of its waters would inundate vast areas of fertile and cultivated land. The low regions of Louisiana, including the alluvial lands and the coast swamps, comprise about 20,000 sq.mi., or nearly one-half the area of the state. The swamp fringe and much of the swampland proper are reclaimable.

The principal rivers are the Mississippi, which flows nearly 600 mi. through and along the border of the state, the Red river, the Ouachita, Sabine and Pearl; all except the last are navigable at all stages of the water. There are many bayous, several of which are of great importance for navigation, for drainage and for scenic beauty. They may be characterized as secondary outlets of the rivers or flood distributaries. Among them are Bayou Teche, Bayou Plaquemines, Atchafalaya bayou, Bayou Lafourche and Bayou Boeuf. Almost all secondary watercourses, particularly if they have sluggish currents, are known as bayous. The alluvial portion of the state, especially below the mouth of the Red river, is an intricate network of these bayous, which, before their closure by a levee system, served partially, in time of flood, to carry off the escaping surplus of river waters.

The alluvial region of the state is mainly protected against overflow from the Mississippi river by 706 mi. of levee on that river within the state, and by levees on the Mississippi river, Cypress and Amos bayous in Arkansas, forming part of the general system which extends up the Mississippi to the highlands above the junction of the Ohio river. The state and federal government co-operated in the construction and maintenance of this system, but the latter did not give national aid (except the grant of swamplands in 1850) until 1879, when it began acting through a board of engineers, known as the Mississippi River commission. For about a century and a half before that time, levee building had been undertaken in a more or less spasmodic and tentative way, first by riparian interests, and finally by the state, acting through levee districts, advised by a board of engineers. The system of Mississippi river levees, within the state, was built almost entirely after 1866 and represents an expenditure of over $60,000,000 for primary construction alone. Some of the levees, especially those in swampy regions where outlet bayous were closed, are of extraordinary solidity and dimensions, being 30 to 50 ft. high, or even more, across former streams or bayous, with bases of 10 ft. or more to one of height. Levee systems on the interior rivers and bayous, aggregating hundreds of miles, are built and maintained exclusively by the state.

The unprecedented heights of the flood in 1922 led the Mississippi River commission to recommend the raising of the levees along that stream an additional three feet. To carry out this policy congress authorized the expenditure of $60,000,000 on the entire Mississippi system. More than half of this sum had been expended when the deluge of April and May 1927 demonstrated that even the three-ft. margin contemplated would not be sufficient. In 1928 President Coolidge approved the Mississippi Valley Flood Control act, appropriating $325,000,000. Spillways, sluices to relieve the pressure of high water, were built. The Bonnet Carré spillway, in St. Charles parish about 20 mi. above New Orleans, built with federal flood control appropriations, connects the Mississippi river and Lake Pontchartrain. At high stages a vast volume of the waters of the Mississippi is diverted to Lake Pontchartrain through this spillway, thus substantially reducing the river level at New Orleans and its environs, and, in the opinion of engineering experts, making the city practically floodproof under extreme conditions of high water.

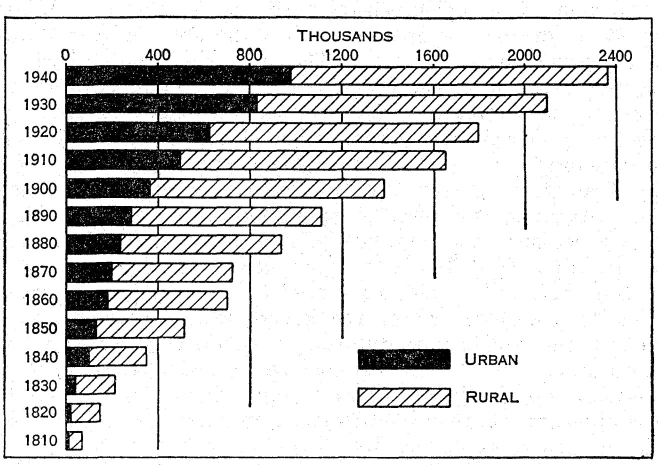
The lakes are mainly in three classes. First come the coast lagoons, many of which are merely landlocked salt-water bays, the waters of which rise and fall with the tides. Of this class are Pontchartrain, Borgne, Maurepas and Sabine. These are simply parts of the sea which have escaped the filling-in process carried on by the great river and the lesser streams. A second class, called "oxbow" lakes, large in number but small in area, includes ordinary cutoff meanders along the Mississippi and Red rivers. A third class, those upon the Red river and its branches, are caused mainly by the partial stoppage of the water above Shreveport by the "raft," a mass of drift such as frequently gathers in western rivers, which for a distance of 45 mi. almost completely closed the channel until it was broken up by government engineers. These lakes are much larger at flood season than at other times and have been much reduced in size by the cutting of a channel through the raft.

Climate.—The climate is semitropical and exceptionally equable over large areas. In the south and southeast the equable temperature is largely the effect of the network of bays, bayous and lakes, and throughout the state the climate is materially influenced by the prevailing southerly winds from the Gulf of Mexico. Some daily variation in the temperature of adjoining localities is caused by a dark soil in the one and a light soil in the other, but the differences of mean annual temperature are almost wholly due to differences of latitude and elevation. The mean annual temperature ranges from 70° F. at Port Eads, in the extreme southeast, to 65° F. at Lake Providence, in the northeast. The mean temperature of July, the hottest month, is comparatively uniform over the state, varying only from 81° to 83°; the mean for January, the coldest month, varies from 46° in the extreme north to 56° in the extreme south. Even in the coldest localities eight or nine months are wholly free from frost, and in the coast parishes frost occurs only a few days in each year. Rainfall is usually heavy in the southeast, but it decreases toward the northwest. As much as 85·6 in. have fallen within a year at New Orleans, but in this locality the average for a year is about 57·4 in.; at Shreveport the average is 46 in., and for the entire state it is 55 inches. Summer is usually the season of heaviest rainfall.

Population.—The population of Louisiana in 1810 was 76,556; in 1830 it was 215,739; in 1850, 517,762; in 1880, 939,946; in 1910, 1,656,388; and in 1940, 2,363,880. This last figure represents an increase of 12·5% over the population in 1930. The population per square mile was 52·3, as compared with 44·2 for the United States as a whole. Of the 1940 population, 980,439, or 41·5%, lived in urban places, that is, in cities and villages of 2,500 or more. The rural population, occupying the remainder of the state, thus constituted 58·5% of the total. The population of the state and of its principal cities is summarized below:

Area	Population			Percent of increase	
	1940	1930	1920	1930–40	1920–30
The State	2,363,880	2,101,593	1,798,509	12·5	16·9
Urban	980,439	833,532	628,163	17·6	32·7
Rural	1,383,441	1,268,061	1,170,346	9·1	8·3
Percent urban	41·5	39·7	34·9	..	..
Principal cities:					
New Orleans	494,537	458,762	387,219	7·8	18·5
Shreveport	98,167	76,655	43,874	28·1	74·7
Baton Rouge	34,719	30,729	21,782	13·0	41·1
Monroe	28,309	26,028	12,675	8·8	105·3
Alexandria	27,066	23,025	17,510	17·6	31·5

The number of occupied dwelling units returned in the housing census of 1940 was 592,595, which is approximately the same as the number of families. The average population per family (occupied dwelling unit) declined from 4·3 in 1930 to 4·0 in 1940. The white population of Louisiana formed 64·0% of the total in 1940, as compared with 62·9% in 1930, practically all the non-white population being Negro. The number of males per 100 females in the entire population of the state was only 98·4, though there was a slight excess of males in the white population, the sex ratio being 100·8 for the white and only 94·3 for the non-white population.



BY COURTESY OF THE U.S. BUREAU OF THE CENSUS

URBAN AND RURAL POPULATION OF LOUISIANA, 1810–1940

HISTORY

Exploration and Settlement.—The early history of Louisiana belongs to the romance of American history. It is possible that the mouth of the Mississippi was discovered in 1519 by Alonso Alvarez de Piñeda, but this interpretation of his vague manuscript remains conjectural; and that it was discovered by the expedition of Panfilo de Narvaez cannot be established. That Hernando de Soto entered the borders of the present state of Louisiana and that his burial place in the Mississippi was where that river takes the waters of the Red, are probable enough, but incapable of conclusive proof. Survivors of de Soto's expedition, however, descended the Mississippi to its mouth in 1542. Spain set up no claim to the region, and when Robert Cavelier, Sieur de la Salle, came down the river in 1682 from the French possessions to the north, he took possession in the name of France, which thereby gained her first title to the vast drainage basin of the Mississippi. In honour of Louis XIV, the new possession was named "Louisiana"—a name then and until 1812 applied to a much larger area than that of the present state. La Salle attempted to settle a colony in 1684, but missed the Mississippi's mouth and landed in Texas, where he was murdered in 1687 by some of his followers. In 1697, after Ryswick, Pierre Le Moyne d'Iberville (1661–1706) was chosen to lead another colony, which reached the Gulf coast early in 1699. Soon after d'Iberville had built Fort Maurepas (near the present city of Biloxi, Mississippi) in 1699, a fort was erected on the Mississippi river about 40 mi. above the mouth. This was the earliest settlement in what is now the state of Louisiana. It was unhealthy and unprosperous. From 1712 to 1717 "Louisiana," or the French possessions of the Mississippi valley, was held by Antoine Crozat (1655–1738) as a private grant from the king. It proved as great a drain upon his purse as it had proved to the crown, and he willingly parted with it to the so-called "Western Company," afterward incorporated with the great Company of the Indies (*see* LAW, JOHN). The company accomplished much for the colony of Louisiana. Jean Baptiste Le Moyne, Sieur de Bienville (1680–1768), a brother of d'Iberville, was sent out as governor. For 40 years he was the life of the colony. New Orleans was founded in 1717. De Bienville was the founder of the city. In 1718 seven vessels were sent from France with stores and immigrants; eleven followed during the next year. Five hundred Negroes from the Guinea coast were imported in 1719, and many hundreds more soon followed. The Law company eventually came to an end fatal to its creditors in France, but its misfortunes did not check the prosperity of "Louisiana." The company retained its grant of the colony until 1731, when it reverted to the crown. Cotton culture began in 1740, and sugar cane was successfully introduced from Santo Domingo by the Jesuits in 1751. Tafia rum and a waxy, sticky sugar syrup subsequently became important products; but not until the end of the century were the means found to crystallize sugar and so give real prosperity to the industry. Under the French regime 11 governors ruled the province of Louisiana during 14 administrations.

The Spanish Period.—By a secret treaty of Nov. 3, 1762, "Louisiana" was transferred from France to Spain. This treaty was not made known to the people of Louisiana until d'Abbadie, director of Louisiana, issued his proclamation (1764), which was the first example of printing in the province of Louisiana. Spain did not take full possession of the colony until 1769. By a treaty between Spain and France on the one hand and Great Britain and Portugal on the other, signed at Paris in Feb. 1763, all that portion lying east of the Mississippi river, the Iberville river, and lakes Maurepas and Pontchartrain was ceded to Great Britain. The international interests thus created, and others that sprang from them, heavily burdened the diplomacy, and even threatened the safety of the United States after they were placed in possession of the eastern bank of the Mississippi down to 31° in 1783.

The news of the cession of the colony to Spain roused strong discontent among the colonists. Antonio de Ulloa (1716–95), a distinguished Spanish naval officer and scholar, came to New Orleans in 1766 to take possession for his king. An official census taken the same year showed a total population of 5,552. The merchants and civil and military officers refused to support Ulloa who was compelled to continue in an ambiguous and anomalous position—which his lack of military force probably first compelled him to assume—ruling the colony through the French governor, Philippe Aubry, without publicly exhibiting his powers. When the colonists found protests at Paris unavailing, they turned to the idea of independence, but sought in vain the armed support of the British at Pensacola. Nevertheless they compelled Ulloa to leave the colony in Nov. 1768. There is no doubt that the men who led the Creole opposition contemplated independence, and this gives the incident peculiar interest. In the summer of 1769 Alexandro O'Reilly went to New Orleans with a strong military force (3,600 troops). Beginning his rule with an affability that allayed suspicions and securing from Aubry proofs against the popular leaders, he invited them to a reception and arrested them while they were his guests. Five were put to death, one having been previously murdered, and others were imprisoned at Havana. Thus O'Reilly put down the revolution of 1768 with determination and in accord with the instructions of his king. He was, however, liberal and enlightened in his general rule. Among the incidents of these troubled years was the arrival in Louisiana (after 1765) of some hundreds of French exiles from Acadia, who made their homes in the Attakapas country. There their descendants live today, still speaking their soft patois, with somewhat of the glamour thrown over land and people by the "Evangeline" of Longfellow.

On Aug. 18, 1769, Louisiana was formally transferred to Spain. Spanish law and language replaced the French officially, but the colony remained essentially French. Many French Creoles were appointed to office, intermarriages of French and Spanish and even English were encouraged by the highest officials, and in general a liberal and conciliatory policy was followed, which made Louisiana under Spanish rule quiet and prosperous. Bernardo de Galvez (1746–86), a brilliant young officer of twenty-one, when he became the governor of the colony, was one of the most liberal of the Spanish rulers and of all the most popular. During the American Revolution he gave valuable aid to the United States; and when Spain finally joined in the war against Great Britain, Galvez, in a series of energetic and brilliant campaigns (1779–81), captured all the important posts in the British colony of West Florida. The chief interest of the Spanish period lies in the advance of settlement in the western territories of the United States, the international intrigues—British, French and Spanish—involving the future of the valley, the demand of the United States for free navigation on the Mississippi and the growing consciousness of the supreme importance of the river and New Orleans to the union.

In 1794 Spain, hard pressed by Great Britain and France, turned to the United States, and by the treaty of 1794 the Mississippi river was recognized by Spain as the western boundary of the United States, separating it from Louisiana, and free navigation of the Mississippi was granted to citizens of the United States, to whom was granted for three years the right "to deposit their merchandise and effects in the port of New Orleans, and to export them from thence without paying any other duty than a fair price for the hire of the stores." At the expiration of the three years the Spanish governor refused the use of New Orleans as a place of deposit, and contrary to the treaty named no other port in its place. Spanish rule, however, came unexpectedly to an end by the retrocession of Louisiana to France in 1800. Under the Spanish regime 11 governors ruled the province of Louisiana during 10 administrations. French dominion gave way in turn in 1803—as the result of a chain of events even more unexpected, and for the United States fortunate—to the rule of the last-named country. On Nov. 30, 1803, the representatives of the French republic received formal possession from the Spanish governor, and on Dec. 20, lower Louisiana was transferred to the U.S. (*See* LOUISIANA PURCHASE.)

American Control and Statehood.—By an act of Congress, of March 25, 1804, that portion of the Louisiana purchase south of 33° was organized as the territory of Orleans, and was given a government less democratic than might otherwise have been the case, because it was intended to prepare gradually for self-government the French and Spanish inhabitants of the territory, who desired immediate statehood. The foreign slave trade was forbidden by this organic act. English was made the official language. In Nov. 1811 a convention met at New Orleans and framed a constitution under which, on April 30, 1812, the territory of Orleans became the state of Louisiana. A few days later the portion of West Florida between the Mississippi and Pearl rivers (the present "Florida Parishes") was included in its boundaries, making them as they are today. In this same year the first steamboat reached New Orleans. It descended the Ohio and Mississippi from Pittsburgh, whence there had already been a thriving river trade to New Orleans for about 30 years. During the War of 1812 a decisive victory was won by the American forces at Chalmette, near New Orleans, on Jan. 8, 1815. (*See* NEW ORLEANS: *Battle of New Orleans.*) Up to 1860 the development of the state in population, agriculture and commerce was very rapid. Donaldsonville was the (nominal) capital in 1825–31, Baton Rouge in 1849–64 and again after 1882. At other times New Orleans has been the capital, and there too have always been various state offices which, in other states, ordinarily are in the capital.

The Civil War Period.—By an ordinance of secession passed Jan. 26, 1861, Louisiana joined the Confederate states. In the first year there was very little military activity in the state, but in April 1862 Admiral D. G. Farragut, with a powerful fleet, ascended the Mississippi past forts Jackson and St. Philip, which defended the approach to New Orleans, and a military force under Gen. B. F. Butler occupied that city. His administration became a byword for infamy in Louisiana. He was replaced by Gen. N. P. Banks in Dec. 1862. The navigation of the river being secured by this success and by later operations in the north ending in July 1863 with the capture of Vicksburg and Port Hudson, the state was wholly at the mercy of the union armies. Later, in April 1864, the Confederates under Gen. Richard Taylor won a success against the Unionists under Gen. N. P. Banks at Sabine Cross Roads near Mansfield and were themselves repulsed at Pleasant Hill, these battles being incidental to a campaign undertaken by the union forces to crush opposition in western Louisiana.

Reconstruction.—As early as Dec. 1862 the union military government, at President Lincoln's direction, had ordered elections for congress, and the men chosen were admitted in Feb. 1863. In March 1864 also a state government to supersede the military rule was established under the president's auspices. The radicals among the loyal element demanded the calling of a constitutional convention and the abolition of slavery. By a convention that assembled in April 1864 a constitution was framed closely following that of 1852 but repudiating the debt incurred by Louisiana as one of the Confederate states and abolishing slavery. The legislature was ordered to establish free schools for the Negroes and was empowered to give them the suffrage: neither of these provisions, however, was carried out. The extent of the union control is shown by the fact that the legislature of 1864 represented half of the area and two-thirds of the population of the state. The army stood at the back of the new government, and by the end of 1864 Louisiana was apparently "reconstructed." But in 1864 the opposition of congress to presidential reconstruction had clearly developed, so that the electoral votes of Louisiana (like those of Tennessee) for president were not counted. By the spring of 1866 the ex-Confederates had succeeded in gaining possession of most of the local government and most of the state offices, although not of the governorship. The Republican party naturally became extremely radical. The radicals wished to have Negro suffrage in order to get possession of the government. They, therefore, wanted still another constitutional convention. A clause in the constitution of 1864 provided for the reconvening of the convention in certain circumstances, but this clause referred only to necessities prior to the establishment of a government. The radicals, because it was impossible to call a convention through the medium of the state government, took advantage of this clause to reconvoke the old convention at New Orleans. The ex-Confederate party determined to prevent the gathering, but the idea of interference by force seems to have been abandoned. A street riot was precipitated, however, incidental to a procession of armed Negroes; the metropolitan police fired upon the assembled convention; and altogether some 200 persons, mostly Negroes, were killed. This incident raised the crucial question of national politics in 1866: namely, whether the states reconstructed by the president should not again be reconstructed.

This being settled affirmatively, Louisiana was reconstructed with vigour. A constitution of 1868 gave suffrage to the Negroes and disfranchised all whites made ineligible to office under the proposed 14th amendment to the national constitution, and also (practically) those who had by word, pen or vote defended secession. Then the state ratified the 14th amendment and was declared readmitted to the union in July 1868. Probably no other southern state suffered equally with Louisiana from the corruption of "carpetbag," "scalawag," Negro legislatures. For four years (1868–72) the government expenses increased to ten times their normal volume, taxation was enormously increased, and about $57,000,000 of debt was created. But a quarrel broke out among the Republicans (1872), the result of which was the installation of two governors and legislatures, one supported by the Democrats and Liberal Republicans and the other by the radical Republicans, the former being certainly elected by the people. The rivalry of these two state governments, clashes of arms, the recognition by the federal authorities of the radical Republican government (Pinchback and Kellogg, successively governors) followed. One historic clash in New Orleans (Sept. 14, 1874) between the "White League" and the Republican police is commemorated by a monument, and the day is regarded by Louisianans as a sort of state independence day. Finally, in the year 1876, Francis T. Nicholls, a Democrat, was chosen governor, but the Republican candidate, S. B. Packard, claimed the election and with a Republican legislature for a time occupied the state house. In the national election of 1876 there were double returns (Republican: 75,315 for Hayes and 70,508 for Tilden; and Democratic: 83,723 for Tilden and 77,174 for Hayes) from Louisiana, which, as was the case with the double electoral returns from Florida, Oregon and South Carolina, were adjudicated by the electoral commission in favour of the Republican electors voting for Hayes. Civil war being threatened within the state President Hayes sent to Louisiana a commission, composed of Wayne McVeagh, Gen. J. R. Hawley, Charles B. Lawrence, J. M. Harlan and John C. Brown, ex-governor of Tennessee, which was instructed to promote "an acknowledgment of one government within the state." The rival legislatures united, organizing under the Nicholls government, which the commission found was upheld by public opinion. The president ordered the withdrawal of federal troops from the capital on April 20, 1877, and the white party was thus left in control.

Politics and Events.—After 1877 the state prospered in material respects except when floods or the boll weevil destroyed the crops, or some distant factor brought prices down; the fortunate presence of two major crops—cotton and cane sugar—moderated many catastrophes. The most devastating flood of the period occurred in the spring of 1927, inundating 1,300,000 ac., driving 300,000 people from their homes and destroying millions of dollars worth of property. The catastrophe prompted congress to pass its $325,000,000 Mississippi Valley Flood Control act in 1928.

Among early political developments the progressive disfranchisement of the Negro was most significant, but the fight against the Louisiana State Lottery company (1868–93) attracted more attention. Louisiana has been overwhelmingly Democratic since 1877. One section or another has shown a readiness to revolt against specific grievances, as when the sugar-cane area turned against the Democratic low tariff in 1913.

Local politics entered upon a tumultuous era in 1928 with the election of Huey Pierce Long as governor. Leader of the back country, Long soon came into violent conflict with the older party leaders centred in the city. His determination to increase the state expenditures for education under the compulsory education law of 1914 and to build roads and bridges throughout the state frustrated the hopes of many for government economy. The attempts of the opposition to secure Long's impeachment failed in 1929 and his grip on the state became more secure. After his election to the U.S. senate Long refused to vacate the governor's office until the senate convened a year later. In the succeeding election Long's candidate, O. K. Allen, was chosen governor. The Roosevelt campaign of late 1932 and the rigours of the bank crisis of the following year brought a brief lull to the political struggle, but Gov. Allen was soon invoking martial law against the opposition dominant in New Orleans. Four legislative sessions were convened in 1934 and an unprecedented quantity of legislation was rubber-stamped, concentrating in the hands of the governor control over state and local functions.

Continued activity of special sessions during the following year roused local and national concern over the future course of the dictatorship, but in 1935 Long was assassinated by Dr. Carl A. Weiss, Jr., ending a serious third party threat. The political machine abandoned the "Share the Wealth" campaign, returned to the Democratic fold, and carried the state for Roosevelt in 1936. At the death of Gov. O. K. Allen, James A. Noe became governor for 3½ months. Richard Webster Leche was elected to the governorship in 1936 and under him and the "successors" of the Long dynasty serious political and financial scandals resulted in the resignation and trial and conviction in the federal courts of Governor Leche and some of his intimates. Lt. Gov. Earl K. Long became governor on the resignation of Leche. In the gubernatorial contest of 1940 between Earl K. Long and Sam Houston Jones, Jones was elected on a reform ticket. In the 1940 national election Louisiana gave Roosevelt 319,751 votes and Willkie 52,446.

Government.—The "parishes" date from 1807; they were based on an earlier Spanish division for religious purposes—whence the names of saints in parish nomenclature. Since the admission of the state to the union in 1812 there have been 10 state constitutions; the present constitution was adopted June 18, 1921. Under this organic act, sessions of the legislature are biennial (meeting on the second Monday in May in even-numbered years) and are limited to 60 days. The number of senators is fixed by the constitution at 39; the number of representatives is 100. Members of the legislature are elected for four years. Contingent appropriations are forbidden, and the constitution contains a long list of subjects on which special laws may not be passed.

The executive department consists of a governor, lieutenant governor, auditor, treasurer, secretary of state, register of land office, commissioner of agriculture and immigration and commissioner of conservation. The chief executive officers have four-year terms, neither the governor nor the treasurer being eligible for immediate re-election. The attorney general is elected by the voters of the state for a four-year term. The superintendent of public education is similarly elected by the voters of the state and, also, has a four-year term. The governor's power of veto extends to all measures and to individual items in appropriation bills, and any measure so vetoed becomes a law only if passed by a two-thirds vote in each house of the general assembly. In 1940 a reorganization bill was passed co-ordinating all governmental agencies and bureaus under 20 departments.

The judicial powers of the state are vested in a supreme court, courts of appeal, district courts, juvenile courts, justice of the peace court and certain special courts. The supreme court is composed of a chief justice and six associate justices, four of whom shall concur to render a judgment when the court is sitting *en banc.* They are elected for a term of 14 years and receive an annual salary of $12,000. There are three courts of appeal each composed of three judges elected for a term of 12 years. These courts hold terms in Baton Rouge, Shreveport, Alexandria, Monroe, New Iberia, Opelousas and New Orleans, respectively.

Louisiana, outside the parish of Orleans, is divided into 28 judicial districts, each having one or more judges elected for a term of six years. The district courts of the parish of Orleans have both civil and criminal divisions presided over by five judges each; their term of office is 12 years. The New Orleans city court has three judges elected for terms of eight years. The constitution provides that each parish, the parish of Orleans excepted, shall be divided into not less than three nor more than six justice of the peace wards.

Suffrage is granted to every citizen of the state and of the United States not less than 21 years of age, who possesses the following qualifications: (1) Residence in the state two years, in the parish one year and in the precinct three months next preceding the election at which he (or she) offers to vote; (2) legally enrolled as a registered voter on his own personal application; (3) should be of good character, able to understand the duties of citizenship and able to read and write; or if illiterate, of good character and able to interpret the constitution of the state or nation. A general primary election law for the selection by the voters of candidates for state office was in effect after 1906 and was re-enacted in 1940.

Law.—Louisiana has been peculiar among the states of the union in the history of the development of its legal system. In Louisiana alone (as the state is known today), out of all the territory acquired from France as the Louisiana purchase in 1803, was the civil law so established under French and Spanish rule that it persisted under American dominion. In all the other states formed from the purchase, the civil law, never existent practically, was early expressly abrogated, and the common law of England established in its place. After O'Reilly established his power in 1769 (see *History,* above), the Spanish law was supreme. All the old codes of the peninsula, as well as the law of the Indies and special royal decrees and schedules, were in force in the colony. The United States left the task of altering the laws to the people, as far as there was no conflict between them and the constitution of the United States and fundamental American legal customs. In its present form the law shows plainly the Latin and English elements. English law has largely moulded, for example, criminal, commercial law and the law of evidence; the development of the law of corporations, damages, prohibitions and such extraordinary remedies as the mandamus has been very similar to that in other states; while in the fusion of law and equity, and the law of successions, family relations and in the domain of private law generally, the civil law sources of France and Spain, especially much of the text and principles of the Code Napoleon, still prevail.

Finances.—The total assessed valuation of all taxable property in Louisiana for 1940 was $1,370,060,292. The state shared in the Agricultural Adjustment administration crop benefits. The state's chief source of revenue in 1940 was the gasoline taxes, which amounted to $18,151,102. Other important sources of revenue were property taxes, district levee taxes, motor vehicle and business licences, revenue from the port of New Orleans dock board, an inheritance tax, an income tax and a severance tax on natural resources. The total receipts of and disbursements by the state treasury for the year ending Dec. 31, 1940, were $107,-930,488 and $109,495,452, respectively. The chief expenditures were from the following funds: general highway bonds, $10,696,-090; operating, $5,212,069; public schools, $9,152,528; general, $11,879,504. The state debt on Dec. 31, 1940, was $187,970,416, consisting of bonded debt, $183,915,020; notes payable, $3,977,-467; interest accrued, $77,928. The state also acted as guarantor for port improvement, highway and penitentiary bonds.

Education.—Schooling was very scant before the creation of the public schools in 1845. Very little was done for education in the French and Spanish period, although the Spanish governors made commendable efforts in this regard; the first American territorial legislature began the incorporation of feeble "colleges" and "academies." To some of these the state gave financial aid ($1,613,898) before 1845. The public schools were flourishing at the outbreak of the Civil War. War and reconstruction threw upon them the new burden of the Negro children. The constitution of 1879 was illiberal in this respect, but a healthier public opinion soon prevailed. The money given by the state to the public schools is distributed among the parishes according to their school population. The state's part of the public-school fund comes chiefly from a tax of 2½ mills on all properties assessed; sale of public lands granted by the United States; the residue of the severance tax fund; net avails of a ½ cent tax per gallon on motor fuel and appropriations of the legislature. The public-school receipts from all sources, both state and local, for the session 1939–40 were $29,545,533. The public-school expenditures for the same period amounted to $38,042,887. The per caput cost of the public elementary and high schools in 1939–40, based on registration, was white, $61.21; Negro, $14.21. The per caput cost for the total population was $16.10. The total number of pupils enrolled in the public and elementary schools of Louisiana in 1938 was 460,946; there were 60,866 pupils in private and parochial schools, excluding kindergartens. The number of teachers in public schools in 1938 was 14,001; their average annual salary was $982. The total pupil enrolment was divided as follows: white, 294,192; Negro, 166,754. The average attendance per pupil enrolled was 152 days for the white pupils and 124 days for the Negro pupils. According to federal census of 1930, 7·3% of the native white population over ten years of age was illiterate, and 23·3% of the Negro population was illiterate.

State institutions of higher education include: (public) Louisiana state university, Baton Rouge; Louisiana State Normal college, Natchitoches; Southwestern Louisiana institute, Lafayette; Louisiana Polytechnic institute, Ruston; Southeastern Louisiana college, Hammond; Southern university (Negro) Scotlandville. Private institutions are: Tulane university, New Orleans; Loyola university of the South, New Orleans; Centenary college, Shreveport; Louisiana college, Pineville; Mount Carmel college, New Orleans; Normal College of Sacred Heart, Grand Coteau; St. Vincent's academy, Shreveport; Dodd college, Shreveport; De La Salle Normal college, New Orleans; Holy Cross Normal college, New Orleans; Dillard university (Negro), New Orleans; Xavier university (Negro), New Orleans; Leland college (Negro), Baker. The state-approved institutions of higher education with a registration exceeding 500 in 1940–41 were 10 in number.

Agriculture.—Agriculture has always been one of the chief industries of Louisiana. The year 1940 was one of the poorest crop years. Cotton, which is the chief field crop in Louisiana, in 1940 produced 455,000 bales, whereas the output of 1939 was 745,000 bales and in 1937 more than 1,000,000 bales. Indian corn, rice and sugar were similarly affected. In 1940, 9,996,108 ac. were in farms. Of this amount, 4,051,670 ac. of the farm area were classified as cropland. The farm population in 1940 was 857,475 or 36·3% of the total population, as compared with 830,606 or 39·5% of the total population in 1930. In 1940 there were 150,007 farm operators in the state, the farm population being indeterminate. During the years 1935–40 the number of farms decreased from 170,216 to 150,007, and the size of the average farm increased from 61·4 ac. to 66·6. The value of land and buildings increased during the period 1935–40 from $295,-515,197 to $353,873,506. Tenantry decreased during the same period from 63·7% to 59·4%. Of the total number of farmers, 90,423 were white and 59,584 nonwhite. The value of all livestock on farms Jan. 1, 1941, was $61,622,000. The value of farm products in 1940, a poor crop year, was estimated to be $86,227,-000, a figure below the previous five years' average.

Cotton, Indian corn, rice, sugar cane and sweet potatoes, in the order named, constituted the most important field crops. From the 1,126,000 ac. planted in cotton in 1940, 455,000 bales of lint cotton and 203,000 tons of cotton-seed were produced. The total farm value of the cotton crop, lint cotton and seed combined, was $25,733,000 for 1940, a value which gave Louisiana the rank of sixth among the states. The yield of Indian corn, which reached the maximum of 35,022,000 bu. in 1921, was 27,-676,000 bu. in 1935 and had a value of $19,373,000; in 1940 the yield was 24,128,000 bu. valued at $15,924,000. In the production of rice, Louisiana leads all other states, the yield over a period of years averaging nearly one-half the total raised in the United States. The crop in 1940 amounted to 18,040,000 bu., with a value of $12,989,000. Practically all the cane sugar produced in the United States, except for some tonnage from Florida, comes from Louisiana. In 1940, 259,000 ac. yielded 3,335,000 tons of cane for sugar and seed with a value of $9,171,000. From this were produced 242,000 tons of sugar and 21,999,000 gal. of molasses, including blackstrap. About 29,000 ac. were planted in sugar cane for syrup, producing 6,380,000 gal. valued at $2,-424,000. Louisiana ranked fourth among the states of the union in 1939 in the production of sweet potatoes, but first among states producing them as a money crop. The 86,000 ac. devoted to this crop in 1940 yielded 4,988,000 bu. valued at $3,741,000. Rice and sugar cane are the only field crops with restricted areas of production. The sugar-cane region is confined, almost exclusively, to the Mississippi delta and Bayou Teche regions, while the chief area of rice production is the prairie region of the southwest. Irrigation is almost entirely confined to rice farms. The principal sources of water supply are the streams flowing to the Gulf, and wells, from both of which water is pumped. The production of vegetables has not been developed to the extent that the state's climate would warrant; however, the industry has acquired considerable importance in the vicinity of New Orleans. Commercial truck farming, using 30,000 ac., produced crops valued at $2,196,000 in 1940. In addition, 40,000 ac. planted in Irish potatoes yielded 2,280,000 bu. valued at $1,824,000; 4,700 ac. in shallots yielded 596,000 bu. valued at $390,000; and 4,500 ac. in watermelons yielded 1,260,000 melons valued at $156,000. The raising of strawberries has proved profitable on the cutover pine lands of Livingston and Tangipahoa parishes. In 1941 Louisiana stood first among the states of the United States in the production of strawberries with a crop covering 23,000 ac., producing 1,934,000 pt. crates, valued at $3,500,-000. Citrus fruits are grown in considerable quantities along the Mississippi river below New Orleans. In 1940, 224,000 boxes of oranges, valued at $224,000 were produced. Among the nuts the native pecan is exceptionally abundant and is commercially important; the yield for 1940, both improved and wild pecans, was 4,514,000 lb. valued at $423,000. About 10,000,000 lb. of peanuts and 1,500,000 lb. of figs are average crops.

Minerals.—In the value of its mineral products ($168,900,-000) Louisiana, in 1939, ranked seventh among the states of the union. Petroleum, natural gas, natural gasoline, sulphur, sand and gravel and salt, in the order named were the principal products. At first, most of the petroleum produced came from the parishes of Caddo, Red River, De Soto and Claiborne. Now the fields extend throughout various parts of the state to the Gulf of Mexico. The state's output of petroleum in 1940 was 102,037,245 bbl., valued at approximately $100,000,000—a production which gave Louisiana the rank of fourth among the states. In the production of natural gas the state ranked second in 1940, with an output of 325,013,162,000 cu.ft. An important product of natural gas is natural gas gasoline extracted from it, which (1940) amounted to 2,701,858 bbl. Until 1924 Louisiana led all other states in the production of sulphur, but late in that year production in Calcasieu parish was suspended because of the exhaustion of the deposit, after 25 years of production with a total yield of about 10,000,000 tons of sulphur. It was this deposit which made the United States the chief sulphur-producing country in the world, and the product virtually displaced Sicilian sulphur, which at one time held first place in the world's market. The state's sulphur output in 1940 was 512,935 long tons, valued at about $5,500,000, and Louisiana was second only to Texas. In 1940 with 601,935 tons, valued at about $2,000,000, Louisiana ranked fourth among the states of the union as a producer of salt. Sand and gravel (1940) amounting to 4,666,703 tons were dug from the pits, valued at $2,500,000. Limestone, of less importance, is the principal stone product.

Manufactures.—The manufacturing industries of the state are for the most part closely related to the products of the soil, about two-thirds of the value of all manufactures in 1939 being represented by petroleum refining, sugar and molasses refining, food preparations, lumber and timber products, chemicals, paper and pulp mills and rice polishing. The value of all manufactured products in 1939 was $565,265,273, as compared with $674,259,000 in 1929. There were 71,218 wage earners employed in 1,861 establishments. In the production of lumber in 1937, Louisiana ranked fourth in quantity among the states of the union. Petroleum refining, which came first in 1939 in value among the state's products, gave Louisiana the rank of fifth among the states. New Orleans, with industries giving employment to 19,707 wage earners and having an output valued at $126,551,895, was the principal industrial centre in 1939. Second in importance was Shreveport with 2,304 wage earners and products valued at $26,552,090.

The table below shows the chief industries of Louisiana, ranked according to value of product in 1939, and the number of wage earners engaged in each industry.

Industry	Wage Earners	Value of Products
Petroleum refining	2,629	$109,627,341
Sugar refining, cane	3,247	66,673,546
Food and kindred products	4,627	51,985,065
Saw mills, veneer and cooperage mills	16,947	33,319,261
Chemicals	1,269	32,506,506
Paper and paperboard mills	2,536	25,650,456
Rice cleaning and polishing	1,158	17,296,826
Pulp mills	1,787	13,816,560
Bread and bakery products	2,537	12,170,338
Nonalcoholic beverages	614	11,013,503
Textile bags	928	10,741,090
Malt liquors	661	10,662,514
Cotton-seed oil, cake and meal	732	7,823,552
Total	39,672	$403,286,558

Forest Products.—The forests of Louisiana are among the finest in the United States. With a total land area of 28,913,280 ac., the forest area in 1934–35 was 16,211,200 ac. or 56%. In 1937 there were 645 establishments in primary forest industries (*i.e.*, saw mills, pulp mills, veneer and cooperage plants). These gave employment to 29,641 persons and had a product value of $116,472,338. The 1,361,637,000 bd.ft. cut in 1937 ranked Louisiana as fourth among the 48 states. Of this production there were, of softwoods: 738,148,000 bd.ft. of pine and 89,416,000 bd.ft. of cypress; of hardwoods, 534,073,000 bd.ft., making Louisiana the first state as producer of hardwood lumber. Oak, red gum and tupelo constituted 82% of the hardwoods. The state ranked first in the production of oak, red gum, tupelo, ash and magnolia, second in the production of cypress and hickory and third in the production of elm. The work of reforestation proceeded very rapidly during the decade 1931–41. Exclusive of the plantings by the forest service, approximately 10,000,000 trees are planted each year on private lands.

Fisheries and Wild Life.—The coastal fisheries of Louisiana in 1939, according to the U.S. bureau of fisheries, employed 5,362 persons and used vessels and other fishing boats totalling 1,404. The total production of the fisheries amounted to 127,725,200 lb. valued at $4,341,777. The more important species were shrimp, 100,612,500 lb., valued at $3,280,121; oysters, 13,586,400 lb., valued at $719,901; squeteagues or "sea trout," 716,000 lb., valued at $76,294; red drum or redfish, 694,100 lb., valued at $69,056; red snapper, 90,900 lb., valued at $7,863; and sheepshead, 80,400 lb., valued at $4,764. Fish canning and the manufacture of by-products were carried on by 31 establishments, employing 4,934 persons. The total output of these industries was valued at $3,198,560; of this amount canned shrimp represented $2,867,476. Production of dried shrimp was 2,592,997 lb. valued at $453,106. Louisiana ranks first in shrimp production.

Louisiana is a paradise for birds and fowl of infinite variety, with its Russell Sage and Rockefeller game refuge and other sanctuaries in Cameron and Iberia parishes.

The original French settler came to Louisiana for the fur trade. In 1940–41, Louisiana, with a fur crop of $6,084,510, was the greatest fur-producing state, producing more pelts than Canada and Alaska combined. Its yield was 6,235,097 pelts. The muskrat was by far the largest in yield and value, followed in value by mink, raccoons, mice (small muskrats), opossums, otters, foxes and skunks.

Transportation and Commerce.—The steam railway mileage in the state as of Jan. 1941 was 5,020.56; the total in 1915 was 5,729 mi. Electric railways operate only in the cities. There are 34 bus lines, 12 truck lines operated by subsidiaries of railroads and one by the Railway Express agency. Louisiana is showing much progress in the construction of improved highways. On Jan. 1, 1941, there were 19,490 mi. of road in the state highway system, and of this amount 2,579 mi. were concrete, 1,709 asphalt and 12,533 gravel roads. The highway system had 5,925 bridges.

Inland waterways have always been an important factor in Louisiana's transportation system. There are systems of improved bayous, lakes and canals, which, in conjunction with the Mississippi river, afford a total navigable length of waterways amounting to approximately 1,800 mi. Chief among the artificial waterways is the industrial canal (opened Feb. 6, 1923) which connects the Mississippi river at New Orleans with Lake Pontchartrain, thus giving shipping a more direct access to the sea. There is a large, growing and important commerce down the Mississippi to New Orleans. Petroleum and its products comprise its chief item. In 1939 the total of all water-borne imports and exports for the state was 6,780,107 tons; coastwise receipts and shipments 12,059,172 tons; internal (domestic) receipts and shipments 9,936,893 tons; making a total of 28,776,172 tons of water-borne commerce.

In 1940 the port of New Orleans had imports of 2,896,269 tons valued at $101,267,893 and exports of 3,351,177 tons valued at $223,414,336. The grand total of all water-borne traffic through the port of New Orleans including imports and exports and coastwise shipments and receipts (*i.e.*, ocean-going) was 11,613,772 tons; this tonnage, with the internal receipts and shipments, amounted to $19,795,599. The total valuation of imports and exports for 1940 marked a gain of $45,456,889 over 1939. New Orleans is the largest banana port with 11,423,603 bunches, in 1940, valued at $6,167,791. Coffee import in 1940 was 443,838,000 lb., with higher figures shown for 1941. Of sugar 1,267,674 lb. were imported. New Orleans is the second port of the United States. Other ports of entry in the state are Baton Rouge, with foreign imports and exports of 558,005 tons and coastwise receipts and shipments of 3,634,829 tons in 1940, and Lake Charles (in the Sabine customs district).

Three modern steel bridges for railroad, vehicular and pedestrian use span the Mississippi. One is just above New Orleans; the others are at Baton Rouge and Vidalia. All are built to permit the passage of warships.

Bibliography.—For general description: *The Geology and Agriculture of Louisiana* (Baton Rouge, agric. exper. station, pts. 1–6, 1892–1902); also publications of U.S. geological survey; *e.g.*, "Underground Waters of Southern Louisiana," *Water Supply and Irrigation Papers*, No. 101. For fauna and flora: publications of U.S. biological survey (department of agriculture, bibliographies). For soil and agriculture: the above state geological report and material on irrigation in publications of the U.S. geological survey and in the U.S. census publications; also the *Reports* of the state board of agriculture and immigration and various publications of the U.S. department of agriculture. For manufactures and other industries: primarily the publications of the national census. For commerce and communications: U.S. interstate commerce commission, *Statistics of Railways*. On river navigation and river improvements, especially of the Mississippi, an enormous mass of material in the *Annual Reports* of the chief of engineers, U.S. army (consult *Index to Reports* of same). For administration: *see* reports of the various executive officers of the state (Baton Rouge); a special account of the government of the territorial period is found in D. Y. Thomas, *History of Military Government in Newly Acquired Territory of the United States* (Columbia University Studies in History, Economics and Public Law, vol. xx., No. 2, 1904); for the Civil War and reconstruction period compare below also American Historical Association, *Annual Report* (1892); on education, in addition to the *Biennial Report* of the board of education, consult annual reports of the U.S. commissioner of education.

For history: the standard work is that of Charles Gayarré, coming down to the Civil War, based on deep and scholarly research, and greatly altered in successive editions (1846–1903). The style is that of the classic school, that of Prescott and Motley, full of colour, characterization and spirit. *See* especially *The French Domination* (1854), *The Spanish Domination* (1854) and *The American Domination* (1867). More important for the later period are Alcée Fortier, *A History of Louisiana* (1904), devoting 2 vol. to American dominations; G. E. King and J. R. Ficklen, *A History of Louisiana* (1902); and H. E. Chambers, *A History of Louisiana* (vol. ii. and iii. biography, 1925); Wm. O. Scroggs, *The Story of Louisiana* (1924), the best textbook; Judge F. X. Martin, *History of Louisiana* (New Orleans 1827–28, later edited by J. F. Condon, continued to 1861, New Orleans, 1882) is also valuable and supplements Gayarré. Baron Marc de Villiers, *Histoire de la Fondation de la Nouvelle-Orléans,* (1717–22) (Paris, 1917) (English tr., New Orleans, 1920) is authoritative. Le Page du Pratz, author of *Histoire de la Louisiane* (Paris, 1758; London, 1763), was the first historian of Louisiana. For the reconstruction period *see* E. Lonn, *Reconstruction in Louisiana after 1868* (1918). The rarest and most valuable of early memoirs and much archive material are embodied in B. F. French's *Historical Collections of Louisiana* (1846–53) and *Historical Collections of Louisiana and Florida* (1869, 1875). Documentary materials on the greater "Louisiana" between the Gulf of Mexico and Canada will be found in the *Jesuit Relations,* edit. by R. G. Thwaites (1896 *et seq.*); and on early voyages in Pierre Margry, *Découvertes et éstablissements des Français* (Paris, 1879–88). *See* also the publications of The Louisiana Historical Society (New Orleans), especially its *Louisiana Historical Quarterly* (1918–41), a mine for the historical researcher; *Reports* of U.S. bureau of the census. (E. A. Ps.)

LOUISIANA, a city of Pike county, Missouri, U.S.A., on the Mississippi river, 94 mi. above St. Louis, at the mouth of the Salt river. It is on federal highway 54 and state highway 79 and is served by the Burlington and the Alton railways, and by river steamers and barges. Pop. (1940), 4,669. Wooded hills and rocky bluffs add charm to the river shores along this stretch. A $1,000,000 highway bridge across the Mississippi was completed in 1928. The city ships large quantities of grain, pork and apples, nursery stock, cotton gloves, pearl buttons, and has various manufacturing industries. It is the home of the largest nursery in the country, which in 1927 took over all of Luther Burbank's experimental farms and all rights in his experiments and in his horticultural creations not yet marketed. From 1818, when the town was laid out, until 1825, Louisiana was the county seat. It was incorporated as a town in 1845 and as a city in 1849.

LOUISIANA PURCHASE, a large portion of the area of the west central section of the United States of America, purchased from the French Republic in 1803. The "Louisiana," to which France held explorer's title, originally included the entire valley of the Mississippi (*see* LOUISIANA); but that part of the territory which was ceded by her to Spain in 1763 (England refusing it, preferring the Floridas), retroceded to France in 1800, and ceded by Napoleon to the United States—in violation of his pledge to Spain that he would not alienate the province—embraced only the portion west of the river and the island of New Orleans on the east (and, as might be claimed with some show of argument, West Florida to the Perdido river).

With the rapid increase of American settlement in the trans-Allegheny region, the freedom of the Mississippi had become of vital importance to the western people, and Spain had recognized these interests in her treaty with the United States of 1794, by guaranteeing freedom of navigation and the privilege of deposit at New Orleans. The transfer of Louisiana from a weak neighbour to so powerful and ambitious a State as France was naturally unwelcome to the United States, and Robert R. Livingston, the American minister in Paris, was instructed by Secretary of State Madison to endeavour to prevent the consummation of the retrocession; or, should that be irrevocable, to endeavour to buy the Floridas (either from France, if they had passed with Louisiana, or through her goodwill from Spain)—or at least West Florida—and if possible New Orleans, so as to give the United States a secure position on the Mississippi, and ensure her commerce.

In his preliminary propositions Livingston lightly suggested to Talleyrand a cession of Louisiana to satisfy certain claims of American merchants for spoliations by French cruisers; following it with the more serious demand that France should pledge observance of the Spanish concession to the Mississippi trade. This pledge Napoleon readily gave. But during these negotiations a suspension by the Spanish governor of the right of deposit aroused extreme apprehension in America and resulted in warlike votes in Congress. Of these, and of London reports of a British expedition against New Orleans preparing in anticipation of the imminent rupture of the peace of Amiens, Livingston made most capable use; and pressed for a cession of West Florida, New Orleans and Louisiana north of the Arkansas river. But without New Orleans Louisiana was of little present worth, and Napoleon—the collapse of whose American colonial schemes seemed involved in his failure in Santo Domingo, and who was persuaded he could not hold Louisiana against Great Britain—suddenly offered to Livingston the whole of the province. Livingston disclaimed wanting the part below the Arkansas. In even mentioning Louisiana he had gone outside his instructions.

At this stage James Monroe became associated with him in the negotiations. They were quickly closed, Barbé-Marbois acting for Napoleon. By three conventions signed on April 30, 1803, the American ministers, without instructions, boldly accepted for their country a territory approximately 1,000,000 sq.m. in area—about five times the area of continental France. For this imperial domain, perhaps the richest agricultural region of the world, the United States paid 60,000,000 francs ($11,250,000) outright, and assumed the claims of her citizens against France to the extent of 20,000,000 francs ($3,750,000) additional; the interest payments incidental to the final settlement raising the total eventually to $27,267,622, or about four cents an acre.

The exact limits of the acquisition were not definitely drawn. The French archives show that Napoleon regarded the Rio Grande as the western boundary of the territory of which he was to take possession, and the United States up to 1819 ably maintained the same claim. She also claimed all West Florida as part of Louisiana—which, in the usage of the second half of the 18th century, it apparently was not. When she acquired the Floridas in 1819–21, the claim to Texas was abandoned. The line then adopted between the American and Spanish possessions on the west followed the Sabine river from the Gulf of Mexico to the parallel of 32° N., ran thence due north to the Red river, followed this to the meridian of 100° W. and this line north to the Arkansas river, thence along this to its source, thence north to the parallel of 42°, and along this line to the Pacific. Such is the accepted description of the western boundary of the Louisiana Purchase—waiving Texas—thus retrospectively determined, except that the original boundary ran with the crest of the Rocky mountains north of its intersection with the parallel of 42°. No portion of the purchase lay west of the mountains, although for some years after 1870 the official maps of the U.S. Government included Oregon as so acquired—an error finally abandoned by 1900.

On Dec. 20, 1803, at New Orleans, the United States took possession of the lower part of the province, and on March 9, 1804, at St. Louis, of the upper. The entire region then contained possibly 80,000 residents. The treaty of cession required the incorporation of Louisiana in the Union, and the admission of its inhabitants, "as soon as possible, according to the principles of the Federal Constitution, to the enjoyment of all the rights, advantages and immunities of citizens of the United States." By act of March 26, 1804, the region below 33° N. was organized as the Territory of Orleans (*see* LOUISIANA), and that above as the District of Louisiana. The region above 33°, renamed in 1805 the Territory of Louisiana, and in 1812 the Territory of Missouri, was divided as time went on into many Indian reservations, Territories and States. Thus were carved from the great domain of the purchase Louisiana, Missouri, Arkansas, Iowa, North and South Dakota, Nebraska and Oklahoma in their entirety and most of Kansas, Colorado, Wyoming, Montana and Minnesota.

The gain of so vast a territory made it possible for the United States to hold a more independent and more dignified position between France and England during the Napoleonic wars; it established for ever in practice the doctrine of implied powers in the interpretation of the Federal Constitution; it gave the new republic a grand basis for material greatness; assured its dominance in North America; afforded the field for a magnificent experiment in expansion and new doctrines of colonization; fed the national land hunger; and accentuated the slavery issue.

BIBLIOGRAPHY.—The official literature is in the *American State Papers, Foreign Relations,* vol. ii., and *Public Lands,* vol. ii.; diplomatic papers reprinted in *House Document 431, 57th Congress, 2nd Session* (1903); to which add the *Histoire de la Louisiane et de la cession* (Paris, 1829; Eng. trans., Philadelphia, 1830), by François Barbé-Marbois. This book abounds in supposed "speeches" of Napoleon, and "sayings" by Napoleon and Livingston that would have been highly prophetic in 1803, though no longer so in 1829. They have been used liberally and indiscriminatingly by the most prominent American historians. *See* also T. Donaldson, *The Public Domain, House Miscellaneous Document 45, pt. 4, 47th Congress, 2nd Session.* For the boundary discussions by J. Q. Adams and Don L. de Onis, 1818–19, *American State Papers, Foreign Relations,* vol. iv.; also in Onis's *Official Correspondence between Don Luis de Onis . . . and John Quincy Adams,* etc. (London, 1818), or *Memoria sobre las negociaciones entre España y los Estados Unidos que dieron motivo al tratado de 1819* (Madrid, 1820). *See* also discussion and map in *U.S. Census, 1900, Bulletin 74;* and the letters of Thomas Jefferson, James Madison, Rufus King and other statesmen of the time. The best general accounts of the diplomacy are in Henry Adams's *History of the United States,* vols. i. and ii., and J. B. McMaster's *History of the People of the United States,* vol. ii., iii. Consult also various valuable periodical articles, especially in the *American Historical Review,* by F. J. Turner and others. B. Hermann, *The Louisiana Purchase* (1898), and Theodore Roosevelt's *Winning of the West,* vol. iv., are of value. Of the various special but popular accounts (by J. K. Hosmer, Ripley Hitchcock, R. Blanchard, K. E. Winship, etc.), not one is worthy of its subject, and all contain various inaccuracies. Much information pertaining to the early government and politics of the Territory is contained in the *Official Letter Books of W. C. C. Claiborne, 1801–16,* edit. by Dunbar Rowland (1917).

LOUIS STYLES, the French decorative and architectural styles generally current during the reigns of Louis XIII., XIV., XV. and XVI. In all a vacillation between the ideals of classic grandeur and fantastic, imaginative lavishness is observable.

Louis XIII. (1610–1643), a period noteworthy for the gradual change from the extreme Baroque of the Henry IV. style to the classic grandeur of that of Louis XIV. and for the beginning of the use of various scroll and shell-like forms which were used in varying forms throughout the Louis styles. The influence of the contemporary Italian Baroque style was very strong, but in interior work many painted panels, often with curved ends, gave promise of later development.

Louis XIV. (1643–1715).—Classic formality dominated the early years of this period. More and more, as the period progressed, the wish for the most lavish possible decoration led to modifications of the earlier classicism, which, however, continued to dominate exterior design. In interior work, curved headed panels were common, often decorated at the top with shells and complicated, interlaced, rather thin acanthus scrolls. Panel moulds were reduplicated and complex. The fire-place frames were scrolled and bowed, and the use of enormous mirrors was frequent. Classic orders continued to be used, although a growing desire for softness of form led to the imposition of a wide, curved, sweep or cove, usually decorated with a network pattern between the cornice of the order and the ceiling proper. During the end of the period, sometimes differentiated as the Régence (1715–1773) style, a growing love for curves overwhelmed the last remnants of classic dignity. Panel corners were cut off and the custom became universal of surrounding each panel with at least three sets of mouldings and of painting all interiors white, with lavish gilding upon mouldings and carvings. The classic orders gradually disappeared from interior use.

Louis XV. (1750–1774), merely a logical development of the love of fantastic curves which had grown up during the Régence. Exteriors, however, were little affected, except in minor details, and as interiors became richer and more bizarre, exteriors became colder and more restrained. In interior work, the love of curves dominated everything. Panels not only had universally curved tops, but were frequently asymmetrical. The carving at panel heads and bases became continuously richer, more naturalistic, and more involuted, and panel moulds frequently died into, or were combined with, this carving. Definite cornice lines were avoided and wall decoration carried up into the ceiling. Fantasy, combined richness and delicacy, and unbridled imagination were the aims of the developed period.

Louis XVI. (1774–1793), the reaction against the excessive and bizarre fancies of the Louis XV. style. The classic ideal which had been banished to exterior architecture returned and controlled design inside as well as out. Rectangular panels again became universal, although the triple panel mould remained. Cornices came back into use; pilasters occasionally framed mirrors and doors and simple semi-circular or oval arches replaced the broken curves. At times, early Louis XVI. work strongly resembled the early work of the Louis XIV. period, but as the style developed, it attained a new delicacy entirely alien to the taste of the time of the "Sun King." The romanticism which coloured the literature of the period, and fostered a false pastoral sentimentality among the upper classes, found expression in the decorative painting of panels and over doors. *See* PERIODS OF ART.

PAINTING AND SCULPTURE

The same conflict between classic formality and playful fantasy that characterized the architecture dominates the other arts. During the reign of Louis XIII. and the early part of the reign of Louis XIV. a formal and dry classicism was almost universal. Nicholas Poussin (1594–1665) was characteristic; a man of brilliant and basically unconventional genius, he was yet forced by the spirit of the times to paint largely scenes from classic history and mythology.

This dominating classic and academic ideal produced acres of stupid historical, Biblical and classic canvases whose only virtue was their size and a certain soundness in drawing. Two influences were, however, at work, to mitigate this dearth of vitality. The first was a strain of pure naturalism, coming down from an earlier tradition; its master was the great portraitist Philippe de Champaigne (1602–1674), and an allied genius, the landscape painter Claude Lorrain (1600–1682). (*See* PAINTING.)

Similarly, in sculpture, it is the realistic work of Girardon (1628–1715), as in the tomb of Richelieu in the church of the Sorbonne, which seems vital; the fashionable classicisms of the Versailles gardens by Coysevox (1640–1720) are either dry or tortured into over-baroque theatricalness of posture.

To all of this combination of realism, classicism and baroque contortion the close of the reign of Louis XIV. put a definite end; and the development in general from 1715 on was towards graciousness, delicacy, fanciful invention and a continual ever-more facile technique. In the work of Watteau (1684–1721) the transition is already made, and his later pictures show all the freedom and the daintiness of the new style without the superficial prettinesses that occasionally disfigured it.

In sculpture, the demands of the material prevented any such complete debacle. Yet if the architectural sculpture of the period is of a universally high level, the little statuettes which were the most common forms which sculpture took, those of Clodion (1738–1814), for example, paralleled as far as possible the soft nudes the painters loved. Across this movement, and with little relation to it lies the work of the one great sculptor of the period, J. A. Houdon (1741–1828), who profited by the technical advances of his time, and used them to create sculpture, mostly portraiture, which is magnificent in its combination of realistic vision and sculptural sense. (*See* SCULPTURE.)

THE DECORATIVE ARTS

During the reign of Louis XIII., furniture was in a state of transition from the stiff heaviness of the early Renaissance to more free and gracious forms; furniture was taking its modern generic shapes and types. This movement reached the first climax in the lavish and gorgeous period of Louis XIV., who was as generous a patron of the decorators as of the architects. The work of the time is distinguished by solidity, dignity, surface richness. Toward the end of the reign lacquer began to be introduced in imitation of the Chinese and Japanese furniture that was occasionally imported. (*See* INTERIOR DECORATION, *European.*)

Under Louis XV., the rococo style, which dominated interior architecture, was supreme in furniture as well. The heavy richness of Louis XIV. work yielded to the graceful curves, the delicate carving, and suave lines of that of Caffieri (1725–1792) and Slodtz (1655–1726). (*See* ROCOCO.) The reaction to delicate straight-lined classicism during the period of Louis XVI was as marked in furniture as in all interior woodwork. The structural simplicity of the best Louis XIV work returned, and with it there came an additional refinement and delicacy of every line.

In textiles a similar progress is evident. The age of Louis XIV found ample expression for its love of the grandiose in tapestry design, the establishment at the Gobelins in Paris under the direction of Le Brun being especially famous for its large works, and that at Beauvais for smaller pieces. More and more they were reserved for ecclesiastical use; in domestic work brocades and brocatelles usurped their place. Under Louis XVI printed cloths began to assume importance, especially that type of printed cotton known as *toile de Jouy,* which was to gain such importance in the early 19th century. (*See* TEXTILES AND EMBROIDERIES: *Europe and the Near East.*)

In ceramics, the period was distinguished by the founding in 1738 at Vincennes of a great porcelain manufactory, which in 1756 was moved to Sèvres and became the property of the government in 1759. Here, first soft porcelain, and after 1769 hard porcelain resembling Dresden ware was produced, in designs which followed the rococo spirit of the Louis XV period, and then, like the interior architecture and the furniture, reacted to classicism and restraint under Louis XVI. (*See* also POTTERY AND PORCELAIN.)

Throughout the arts there thus runs through the reigns of these four Louis' a continual struggle between academic classicism and the rococo, between restraint and licence, between monumentality and fantastic invention. Richness and luxury dominate all the manifestations. A semiofficial court-supported art could go no further; it was almost as if in the arts, as well as elsewhere, a revolution was inevitable; the last shreds of the Renaissance tradition were thus unravelled, and the old texture of the arts perished along with the *ancien régime.* (T. F. H.)

LOUISVILLE (lo͞o'ĭ-vĭl), the largest city of Kentucky, U.S.A., on the Ohio river, 90 mi. in a beeline S.W. of Cincinnati; a port of entry and the county seat of Jefferson county. It is on federal highways 31E, 31W, 42, 60 and 150; has two airports; and is served by the Baltimore and Ohio, the New York Central, the Chesapeake and Ohio, the Chicago, Indianapolis, and Louisville, the Illinois Central, the Kentucky and Indiana Terminal, the Louisville and Nashville, the Southern and the Pennsylvania railways, by river packets, barge lines and numerous motor truck and bus lines. The population in 1930 was 307,745 (of whom 47,354 were Negroes) and in 1940 it was 319,077.

The city occupies 37.9 sq.mi., in part in a level plain, and in part in the surrounding hills. It has 8 mi. of water front, around a wide curve of the river, which falls in a series of rapids 26 ft. in 2 miles. Canalization of the Ohio was completed from Pittsburgh to Cairo in 1929, providing an all-year 9-foot stage. Highway bridges, one municipally owned, lead to New Albany and Jeffersonville, Indiana, on the north bank of the river. One of these carries railway traffic, and there are two other railway bridges. A hydroelectric power station at the falls (completed in 1927) has a capacity of 108,000 h.p.

The valuation of property for tax purposes in Jefferson county including Louisville in 1940 was $618,502,000. The 34 parks and playgrounds cover 2,177 ac., with 4 municipal golf courses, 33 baseball diamonds and 84 tennis courts. Iroquois amphitheatre in Iroquois park provides a sylvan setting for alfresco musical shows, concerts and pageants. The University of Louisville, said to be the oldest municipal university in the country (founded 1837), occupies a campus of 55 ac. in the southern section of the city. The Southern Baptist theological seminary (established 1859), newly located in a setting known as the Beeches, has a modern well-equipped group of buildings. The Baptist Women's Missionary Union training school adjoins the seminary. The Presbyterian theological seminary of Kentucky (formed in 1901 by the consolidation of two older institutions, dating from 1853 and 1893) has a quadrangle, designed after Balliol college, Oxford. Other higher educational institutions are Nazareth college (for women), Simmons university for Negroes (Baptist), the Jefferson School of Law, the Louisville College of Pharmacy and the Kentucky school for the blind. The public-school system includes 76 schools (1941), with an enrolment of 47,614 pupils. There are 58 parochial schools, with an enrolment of 15,638, and some 16 other private educational institutions of various types, including 7 business colleges. The public library contains 329,965 volumes and maintains 16 branches. There are two newspapers. The *Courier-Journal* (formed in 1868 by the consolidation of three papers and edited from 1868 to 1918 by Henry Watterson) has long been influential.

The United States government maintains at Louisville a marine hospital, a fish hatchery and a coast guard station, the only one in the interior of the country. Bowman field, a municipal airport and an air corps flying field, is on the outskirts of the city to the southeast, and Fort Knox is 33 mi. southwest. The Kentucky state fair, held in the city annually in September on its own spacious grounds, drew an attendance of 168,000 in 1940. At the famous old Churchill Downs, which has 29 days of racing every year, the Kentucky derby, America's foremost horse-racing classic and held annually since 1875, is run in May. It pays $62,575 to the winners and attracts 60,000 people.

Louisville is one of the largest commercial and industrial centres of the south. It is the seat of branches of the federal reserve bank and the farm credit administration. Bank debits to individual accounts in 1940 amounted to $2,057,875,847. The output of the manufacturing establishments within the city in 1937 was valued at $294,210,000, and there are important plants just outside the corporate limits. Widely diversified in character, the 11 leading industries in the order of value of output are: distilled and malt liquors; tobacco products, including cigarettes; food products, including meat packing; railroad repair shops; rolled and extruded aluminium products; lumber and timber products, including furniture; motor vehicles, including motor vehicle parts; printing and publishing, including newspapers and periodicals; textile products, including clothing; chemicals, including petroleum products; paints, varnishes and lacquers.

Wholesale trade in 1939 amounted to $215,936,000, while retail trade grossed $131,004,000 in the same year. As the foremost livestock market of the south, 805,003 of all kinds of stock were received in 1940.

National defence preparations brought an extraordinary stimulus to the Louisville metropolitan district in 1940 and 1941. At Fort Knox, Kentucky, at Bowman field, Louisville's municipal airport, and at the U.S. quartermaster depot at Jeffersonville, Ind., there was an expansion of military forces to more than 40,000 men. Plants for the production of smokeless powder and powder bags sprang up at suburban Charlestown, Ind., a naval gun mounting plant and a carbide plant in Louisville. These national defence industries gave regular employment to around 20,000, increasing the industrial workers in metropolitan Louisville by more than 50%.

In the centre of Fort Knox is the gold vault where the major portion of Uncle Sam's gold supply is stored.

History.—The site of Louisville was probably visited by La Salle in 1669 or 1670. In July 1773, Captain Thomas Bullitt, acting under a commission from the College of William and Mary, surveyed a tract of 2,000 ac. opposite the falls of the Ohio, and laid out a town site. Though the county surveyor refused to approve this survey, Lord Dunmore, the governor of Virginia, conveyed it, in Dec. 1773, to his friend, Dr. John Connolly. There may have been a settlement on Corn island (which has now practically disappeared) at the falls of the Ohio, as early as 1775. In May 1778, Gen. George Rogers Clark, on his way to the Illinois country, landed on this island and built blockhouses for his stores and cabins for some of the colonists who had come with him. Most of these settlers moved to the mainland the following winter and established themselves in a fort within the present limits of Louisville. They organized a town government in April 1779; and on May 14, 1780, the legislature of Virginia, on their petition, declared that Dr. Connolly had forfeited his title (he had been actively pro-British during the Revolution) and incorporated the settlement under the name of Louisville, in recognition of the assistance given by Louis XVI of France to the colonies in the Revolutionary War. In 1828 the town was chartered as a city; in 1851 it received a second charter; in 1870, a third; in 1893, a fourth, and in 1926, a fifth, under which it still operates. The city's growth was greatly stimulated by the introduction of successful steam navigation on the Ohio in 1811, and by the construction (1825–30) of the canal around the falls of the Ohio. The first railway reached it in 1851. In 1922 an area (11,000 ac.) was annexed to the city. On Aug. 6, 1855 ("Bloody Monday"), a riot incited by members of the Know Nothing party resulted in the loss of several lives and considerable damage to property. In March, 1890, a tornado caused great loss of life and property. The city suffered severely during the record Ohio floods of January 1937. Gen. Clark lived in the city after 1779. It was the home of the actress Mary Anderson in her early years, and of J. J. Audubon from 1808 to 1812. Louis Philippe of France, during his American exile, lived for a time a few miles from the city. Five miles east are the homestead and the tomb of Zachary Taylor. At Camp Zachary Taylor, two miles distant, 75,000 men were trained during the war of 1914–18.

LOUISVILLE AND NASHVILLE RAILROAD COMPANY was incorporated in the State of Kentucky on March 5, 1850. Almost from the beginning its undertakings were profitable and with but few reverses it has steadily grown until at the end of 1939 this line operated 4,871·30mi. of road in 13 States of the South, providing service in the territory from Cincinnati to Louisville, Nashville, Birmingham, Montgomery, Pensacola, Mobile and New Orleans on the South; Knoxville and Atlanta on the South-east and to Memphis, St. Louis and Evansville on the West. It also owns a majority of the capital stock of, or is interested jointly with other lines in, other property, including the Nashville, Chattanooga and St. Louis railway; Clinchfield railroad; Chicago, Indianapolis and Louisville railway, and Georgia railroad and Dependencies, aggregating 2,487·24mi., making the total for the L. and N. system 7,358·54 miles. It is itself controlled by the Atlantic Coast Line Railroad Company and is known as one of the Walters Group.

The L. and N. operates through a rich section of the central South-east noted for the production of cotton, although recently this region has been characterized by a marked diversity in agricultural development. The road serves the important iron and steel district near Birmingham, Ala., but its chief source of traffic —about 57%—is bituminous coal, mined from the coal fields of eastern and western Kentucky, Virginia, Tennessee, Alabama and Illinois. About 84% of its traffic originates on its own lines.

The L. and N., at the end of 1939, had a capital stock of $117,000,000 and a funded debt of $221,881,530. Its gross earnings in 1939 approximated $88,300,000 per annum. (J. B. H.)

LOULÉ, a town of southern Portugal, beautifully situated in an inland hilly district, 10 m. N.N.W. of the seaport of Faro and 5 m. from São João da Venda on the Lisbon-Faro railway. Pop. (1940), 7,535. It is surrounded by walls and towers dating from the Moorish period. Basket-making is the principal industry; leather, porcelain and various products of the palm, agave and esparto grass are also manufactured.

LOUNSBURY, THOMAS RAYNESFORD (1838–1915), American scholar, was born at Ovid, N.Y., on Jan. 1, 1838, and educated at Yale university (A.B., 1859; A.M., 1877). He was on the editorial staff of the *American Encyclopaedia* 1860–62, and then enlisted in the 126th N.Y. Volunteers to serve through the Civil War. In 1870 he became instructor and in 1871 professor of English language and literature in the Sheffield Scientific school of Yale university. In 1906 he was retired as professor emeritus. He was also librarian of the Sheffield Scientific school 1873–1906. He won recognition as a scholar in both branches of his subject: study of the English language and study of its literature. His *History of the English Language* (1879) is characterized by Prof. Brander Matthews as "a little masterpiece of carefully controlled information, and of marvellously lucid exposition." He followed this with later studies of pronunciation, usage and spelling no less authoritative: *The Standard of Pronunciation in English* (1904); *The Standard of Usage in English* (1908); *English Spelling and Spelling Reform* (1909). He was one of the most influential of those who advocated spelling reform and was one of the organizers, and later president, of the simplified spelling board. His studies in literature show him a master of his successive subjects. His first was a *Life of James Fenimore Cooper* (1882). *Studies in Chaucer* in three impressive volumes (1891) remains an enduring work. His *Shakespeare as a Dramatic Artist* (1901), *Shakespeare and Voltaire* (1902), and *The Text of Shakespeare* (1906) marked him as one of the foremost writers on Shakespearian subjects. He also wrote *The Early Literary Career of Robert Browning* (1910) and edited the complete works of Charles Dudley Warner. He died on Apr. 9, 1915.

LOURDES, a town of south-western France in the department of Hautes-Pyrénées, at the foot of the Pyrénées, 12 mi. S.S.W. of Tarbes on main line of Southern railway between that town and Pau. Pop. (1936) 10,155. The origin of Lourdes is uncertain. From the 9th century onwards it was the most important place in Bigorre, largely owing to its famous fortress. In 1360 it passed by the treaty of Brétigny from the French to the English, who lost it to the French in 1406. During the religious wars the castle held out successfully against the Protestant troops. From the reign of Louis XIV. to the beginning of the 19th century the castle was used as a state prison. After the visions of Bernadette Soubirous, a peasant girl, in 1858, their authentication by a commission of enquiry appointed by the bishop of Tarbes, and the authorization by the pope of the cult of Our Lady of Lourdes, the quarter on the left bank of the Gave sprang up, and about 600,000 pilgrims annually visit the town, August being the favorite month.

Several religious communities have been named after Our Lady of Lourdes. Of these one, consisting of sisters of the third order of St. Francis, called the Congregation of Our Lady of Lourdes (founded 1877), has its headquarters in Rochester, Minnesota. Another, the Order of Our Lady of Lourdes, was founded in 1883 for work in the archdiocese of New Orleans. Lourdes is divided into an old and a new town by the Gave de Pau, which at this point leaves the valley of Argelès and turns abruptly to the west. The old quarter on the right bank surrounds a scarped rock, on which stands the fortress with its large square 14th century keep. A tower of the 13th or 14th century, surmounting a gateway known as the Tour de Garnabie is part of the old fortifications. The old quarter is united with the new by a bridge which is continued in an esplanade leading to the basilica, the church of the Rosary and the Grotto, with its spring of healing water, where the Virgin Mary is believed in the Roman Catholic world to have revealed herself repeatedly to Bernadette Soubirous. A statue of the Virgin stands on a rock projecting above the grotto, the walls of which are covered with crutches and other votive offerings; the spot is marked by a basilica built in 1876 above the grotto. The Byzantine church of the Rosary was built in front of and below the basilica from 1884 to 1889. Near the grotto are other caves, where prehistoric remains have been found.

Lourdes is the seat of the tribunal of first instance of the arrondissement of Argelès. There are slate quarries and the pastures support a breed of valuable Aquitaine cattle.

LOURENÇO MARQUES, capital of Portuguese East Africa or Mozambique, on the north bank of the Espirito Santo or English river, Delagoa bay, and 396 m. by rail via Pretoria from Johannesburg. A census completed in 1936 gives the population of city and suburbs as 47,392, including 9,000 Europeans, an increase in the European population of 71·88% since 1912. The large majority of non-Europeans are Africans, but there are also 1,364 British Indians. Foreigners numbering 1,588 are employed in the town, which is close to the mouth of the river in 25° 53′ S. and 32° 30′ E., and is built upon a low-lying spit of sand, formerly surrounded by swamps which have now been filled in, providing a large area for business and other occupation, and on the hills behind it. The streets are regularly laid out, and most of them are tar-surfaced; the town and suburbs are lighted by electricity, and adorned by several fine buildings, among which are the railway station, municipal market, post and telegraph offices, the treasury, the residency, the British consulate, offices of the attorney general and the palatial Polana hotel. There are Roman Catholic, Anglican and Wesleyan Methodist churches, and the large church of the Mission Suisse Romande. There are three theatres and many good shops. The handsome Avenida Aguiar, in which are situated the fine municipal gardens, adjacent to which is the municipal museum, leads to the upper town. The electric tram system has been replaced by a municipal bus service, and motor buses ply between the lower and the upper town.

At Ponta Vermelha (Reuben point), which marks the spot where the river enters the bay, are cavalry barracks, the wireless station and many private residences of the wealthier citizens. The town is healthy. The climate is almost ideal in the winter months while sea breezes temper somewhat the summer heat. The mean annual temperature (14 years) was 72° F. There is a large military and civil hospital in the town and also several nursing homes. Water, brought from the Umbeluzi river 18 mi. away, is of excellent quality. Pop. est. (1931) 42,779.

Trade.—There is safe entrance to the harbour, the minimum depth in the Cockburn channel being 29 ft. At its mouth, the river is about 2 mi. across. Lourenço Marques is the nearest port to the Rand gold mines. It is 7,308 mi. from London via Capetown, and 8,460 mi. via the Suez canal. The wharf (cost £500,000), of reinforced concrete, is about a mile long, and can accommodate 12 large steamers at once. There are 11 large warehouses, in addition to the transit shed and national warehouse. Telegraph, telephone and railway booking offices are on the wharf; and a clock gives the official time, a three-hour signalling device giving the time to shipping.

The whole wharf area is enclosed and electrically lighted. There are 38 electric cranes, one 80 ton; and three tugs, one for use on the high seas. There are two docks for small craft, and a dry dock which admits vessels up to 1,400 tons (cost £30,000). In 1936, 1,025 vessels entered the port, unloading 741,858 tons of cargo and loading 588,461 tons of goods and coal. There are regular services of British, Portuguese, German, American, Norwegian and Italian lines. The great bulk of the traffic of the port is that in transit to the Union of South Africa. Over 50% of the import trade of Johannesburg is with Lourenço Marques. (For convention regulating this traffic, *see* PORTUGUESE EAST AFRICA.) Union duties can be paid in Lourenço Marques. The port possesses two coaling plants, capable of handling respectively 400 and 600 tons an hour. The bunkering trade is growing in importance. Great Britain, Portugal and Germany, in this order, have the bulk of the import trade. Most of the imports, being forwarded to the Transvaal, figure also as exports.

A great proportion of the trade of the town, the forwarding trade especially, is in the hands of British firms. The retail trade and the native trade is very largely in the hands of Indians. The chief articles imported are foodstuffs and liquors, iron, mineral oils, inks and dyes, timber and livestock. These all form part of the transit trade. There is little export trade by sea except in coal, chiefly from the collieries at Middelburg, Transvaal. The chief import for local consumption is wine.

History.—In the latter part of 1925 the depreciation of Portuguese currency, and the abolition of the use of sterling currency caused serious difficulties to importers, and led to strikes and other disturbances. The position began to improve in 1926, and by 1928 was stable. For the early history of the town *see* DELAGOA BAY. The existing town dates from about 1850, the previous settlement having been entirely destroyed by natives. In 1871 the town was described as a poor place, with narrow streets, fairly good flat-roofed houses, grass huts, decayed forts and rusty cannon, enclosed by a wall 6 ft. high then recently erected and protected by bastions at intervals. The growing importance of the Transvaal led, however, to greater interest being taken in Portugal in the port. A commission was sent by the Portuguese Government in 1876 to drain the marshy land near the settlement, to plant the blue gum tree, and to build a hospital and a church. It was not, however, until the end of the 19th century that any marked development took place in the town, and up to 1903 cargo had to be discharged in tugs and lighters. Later, a wooden wharf preceded the present reinforced concrete one. The settlement was declared a village in 1876, a corporate town in 1887, and in 1907 became the capital of the Province.

In 1873–77 Mr. Burgers, president of the Transvaal, endeavoured, unsuccessfully, to get a railway built from Pretoria to Delagoa bay. Later, Col. McMurdo organized a company which built a line from the coast to the frontier as marked on maps of 1883, and this railway was opened in 1888. The Portuguese government insisted that the line must be continued another 5 mi. to the frontier as fixed after 1883. This led to disputes, seizure of the line, etc., and a long arbitration. Meantime, however, the railway had been completed and was opened for through traffic to Pretoria on July 8, 1895. In 1906–10 another railway (47 mi. long) was built from Lourenço Marques due west to the Swaziland frontier, being a link in a new line to shorten the distance by rail between the Rand and the sea by some 60 mi.

See also DELAGOA BAY and the authorities there cited. The text of the railway arbitration award was published in French at Berne in 1900. Annual reports on the trade of Lourenço Marques are issued by the British Foreign Office.

LOUSE, a name commonly applied to small wingless insects parasitic upon birds and mammals and belonging to the order Mallophaga and Anoplura. They are dorso-ventrally flattened creatures with short, 3- to 5-segmented antennae, the eyes may be reduced or wanting and the tarsi are 1- or 2-segmented with strongly developed claws for clinging to their hosts. The eggs are attached to the hairs, feathers or clothing, and the young lice are active as soon as they emerge. In structure and habits the immature lice resemble the adults, but they pass through several moults before reaching sexual maturity. When lice are numerous they cause great irritation to the hosts, upon whose bodies their whole life is passed.

The Mallophaga or biting-lice (*see* BIRD-LOUSE) constitute a separate order of insects although they were previously classed as a suborder of the Anoplura. The order Anoplura, also known as the Siphunculata, is restricted to the sucking lice. The sucking lice have extrusible mouth-parts adapted for piercing and sucking, and they live by imbibing the blood or tissue fluids of mammals. None are parasitic on birds or reptiles.

Sucking lice show very distinct host specificity; that is, one species of louse is restricted to a species or a small group of species of hosts, usually within a single genus. Genera of lice are characteristic of certain families or related families of mammals. The louse family Pediculidae is peculiar to the primates, the Echinopthiriidae to the marine carnivores and the Haematopinidae to the rodents, rabbits and ungulates with very few exceptions. Vernon L. Kellogg has suggested that the presence of related lice on related groups of hosts is evidence of parallel evolution of parasites and hosts.

In addition to man and his domestic mammals a wide variety of wild mammals are infested by these insects, each host, genus or species having its own characteristic parasites. A few hosts such as man, the domestic cow and some rodents have two characteristic species of sucking lice, but usually only one species is found on a host. Sucking lice are largely restricted to old world primates, marine carnivores (seals, sea lions and walrus), rodents, rabbits and ungulates. Several species are known from insectivores. The domestic dog is one of the few land carnivores parasitized by sucking lice. No species are known from monotremes, Australian marsupials, bats, elephants or cetaceans. The elephant louse, *Haematomyzus,* is an anomalous insect with a long proboscis and biting mouthparts. It is questionably referred to the order Mallophaga.

The best known species of louse is *Pediculus humanus,* the common louse of man, which infests the human race wherever lousiness has not been eliminated by modern hygiene. Its distribution is almost coextensive with that of the human race and the antiquity of this association is demonstrated by the presence of lice on ancient mummies from Egypt and the southwestern United States. This species has apparently been inherited by man from his remote primate ancestors. There are two varieties of the common human louse, viz., *Pediculus humanus* var. *capitis,* the head louse, and *P. humanus* var. *corporis,* the body louse. The human louse is recognized as the carrier from man to man of the pathogenic agents of epidemic typhus fever, trench fever of World War I and louse-borne relapsing fever (in contrast to tick-borne relapsing fever). The terrible role of these diseases in the history of man is related by Hans Zinsser in *Rats, Lice and History.* Epidemic typhus fever has been a scourge whenever populations have been disrupted or concentrated by war, famine or floods and the attendant insanitary conditions.

The only other louse which infests man is the pubic or crab louse, *Phthirus pubis,* which is occasionally found in the axillae, eyebrows and beard as well as in the pubic regions. It is not known to be an important disease vector.

Related species of lice are *Pediculus schäffi,* of the chimpanzee, and *Phthirus gorillae* of the gorilla. The other lice from old world primates are included in the genus *Pedicinus. Pediculus mjöbergi,* which is almost indistinguishable from the human louse, is recorded from several species of new world monkeys. It is generally considered that these monkeys have acquired the parasite by contact with man, although it may be established on wild monkeys.

Some of the common lice of domestic animals are *Haematopinus suis* of the pig, *H. asini* of the horse, *H. eurysternus* and *Linognathus vituli* of the cow and *L. setosus* of the dog.

Extensive museum collections of lice have been accumulated at Stanford university, United States National museum and the British museum. The Anoplura of the world have been monographed by Gordon F. Ferris of Stanford university in a series of publications entitled *Contributions Toward a Monograph of the Sucking Lice.*

The word louse is also applied in a popular sense to many animals other than the true lice, *e.g.,* wood louse, fish louse (*see* CRUSTACEA), book louse of the insect order Corrodentia, plant louse (*see* APHIDS) and bark louse (*see* SCALE INSECTS). It is also used as a mild epithet indicating small, mean or disgusting.

(W. L. J.)

LOUTH, a maritime county in the province of Leinster, Eire, bounded northeast by Carlingford bay and Co. Down, east by the Irish sea, southwest by Meath, and northwest by Monaghan and Armagh. It is the smallest county in Ireland, its area being 202,814 ac. or about 317 sq.mi. Pop. (1936) 64,339.

Much of the county is occupied by an undulating lowland of much-folded Silurian shales and fine-grained sandstones; but carboniferous limestone overlies these rocks north and east of Dundalk. Igneous rocks form a mountainous promontory, approaching 2,000 ft. in height on the border of Carlingford lough. A raised beach provides a flat terrace at Greenore. As in the adjacent parts of Armagh and Monaghan, lead is worked.

Apart from the promontory of Clogher head, which rises abruptly to 180 ft., the coast is mostly low and sandy. Carlingford lough is navigable beyond the limits of the county, and Carlingford and Greenore are watering places on the Co. Louth shore. The Bay of Dundalk stretches to the town of that name and affords convenient shelter.

The principal rivers, the Fane, the Lagan, the Glyde and the Dee, flow eastward. The Boyne is navigable for large vessels as far as Drogheda.

The territory which afterward became Co. Louth was included in the principality of Uriel, Orgial or Argial, which embraced also the greater part of Meath, Monaghan and Armagh. The chieftain of the district was conquered by John de Courcy in 1183, and Louth or Uriel was among the shires generally considered to have been created by King John, and peopled by English settlers. Until the time of Elizabeth it was included in the province of Ulster. The cromlech of Ballymascanlan lies between Dundalk and Greenore. Danish raths and other forts are numerous. The most interesting monastic ruins are at Monasterboice and Mellifont, both near Drogheda. At the former site are two churches, the larger dating probably from the 9th century, the smaller from the 13th; a round tower, 110 ft. high, and three crosses, two decorated. Ardee, incorporated in 1376, has a 13th century castle. At Dunbar a charter of Charles II (1679) granted the right to elect a sovereign. Louth, $5\frac{1}{2}$ mi. S.W. from Dundalk, gave its name to the county, and contains ruins of an abbey to which was attached one of the most noted early schools in Ireland.

In the lower regions the soil is a rich deep mould, adapted for cereals and green crops. Agriculture generally is in an advanced condition, and the farms are well drained. Oats, barley, flax, potatoes and turnips are cultivated. Cattle, sheep, pigs and poultry represent the bulk of the live stock. Linen manufactures are of some importance. The deep-sea and coast fishery has its headquarters at Dundalk, and the salmon fisheries at Dundalk (Castletown river) and Drogheda (River Boyne). The county is traversed by the Great Northern railway; while Dundalk is connected with Greenore by the L.M.S. railway. From Greenore passenger steamers run regularly to Holyhead. Ardee is served by a branch from the Great Northern line at Dromin. Louth returns three members to Dáil Eireann.

LOUTH, a market town and municipal borough in the Parts of Lindsey and the Louth parliamentary division of Lincolnshire, England, on the River Lud, $141\frac{1}{2}$ mi. N. of London by the L.N.E. Ry. Pop. (1938) 9,747. Area, 4.39 sq.mi. Louth is first mentioned in the Domesday record as a borough held, as it had been in Saxon times, by the bishop of Lincoln who had a market there. The see surrendered the manor to Henry VIII, who granted it to Edward, earl of Lincoln; it was recovered by the crown before 1562. Louth owed its early prosperity to the adjacent Cistercian abbey, founded in 1139 by Alexander, bishop of Lincoln. A manor court under the presidency of the bishop's high steward governed the town, the custom being for the reeve to be elected by 18 exreeves. During the 13th and 14th centuries nine religious guilds were founded in the town. Louth has never been a parliamentary borough. The markets said to have been held from ancient times and the three fairs on the third Sunday after Easter and the feasts of St. Martin and St. James were confirmed in 1551. Louth was a seat of the wool trade as early as 1297. The Perpendicular church of St. James was completed about 1515. The grammar school was refounded and endowed by Edward VI in 1551. The industries include the manufacture of agricultural implements, malting, bone crushing and lime burning.

LOUVAIN (Flem. *Leuven*), a town of Belgium in the province of Brabant, of which it was the capital in the 14th century before the rise of Brussels. Pop. (est. 1939) 36,971. Local tradition attributes the establishment of a camp here to Julius Caesar, but Louvain only became important in the 11th century as a residence for the dukes of Brabant. In 1356 Louvain was the scene of the famous *Joyeuse Entrée* of Wenceslas, the principal charter of Brabant. At that time it had a population of at least 50,000 and was the centre of the wool trade in central Belgium. The guild of weavers numbered 2,400 members. The old walls of Louvain, $4\frac{1}{2}$ mi. in circumference, have been replaced by boulevards, but within them is much cultivated ground. Soon after the *Joyeuse Entrée* a feud began between citizens and patricians, and eventually the duke threw in his lot with the latter. After a struggle of over twenty years' duration the White Hoods, as the citizens called themselves, were crushed. In 1379 they massacred seventeen nobles in the town hall, but this brought the vengeance of the duke, to whom in 1383 they made the most abject surrender. Many weavers fled to Holland and England, the duke took up residence in the strong castle of Vilvorde, and Brussels prospered at the expense of Louvain. What it lost in trade it partially recovered as a seat of learning, for in 1426, Duke John IV of Brabant founded there a university, and ever since Louvain university has enjoyed the first place in Belgium. It has always prided itself most on its theological teaching. In 1432 the university was established in the old Cloth Workers' Hall, a building dating from 1317, with long arcades and graceful pillars supporting the upper stories. In the 16th century there were 6,000 students, and four residential colleges are attached to the university. The aula and the university library were burnt in the German invasion of 1914. A new library was built (1921–28) by gifts from citizens of the United States, and books and fittings came from many nations. The library had more than 600,000 volumes. It was again destroyed by fire during the German attack in May 1940. The town hall is one of the richest examples of pointed Gothic. Mathieu de Layens, master mason, built it (1448 to 1463) in three stories, each with ten pointed windows facing the square.

The church of St. Peter (1425–97), damaged in 1914, was restored. It has seven chapels, in two of which are fine pictures by Dierik Bouts formerly attributed to Memling. Much of the iron and brass work is by Jan Matsys. There are other interesting churches in Louvain, viz., Ste. Gertrude, St. Quentin, St. Michael and St. Jacques, the last with a fine De Crayer (St. Hubert).

LOUVER, LOUVRE or **LUFFER,** in architecture, originally a lantern or cupola built on the ridge of the roof of the great hall of a mediaeval house to let out the smoke; now generally applied to a system of slanting boards, sheets of metal or glass, or other material, so arranged in an opening as to permit the entrance or egress of air without admitting rain. Louvers, usually of copper, are almost universal at exterior vents and intakes of modern ventilating systems; on a much larger scale, and in wood, they are frequent in the arched openings of church belfries.

LOUVET DE COUVRAI, JEAN BAPTISTE (1760–1797), French writer and politician, was born in Paris on June 12, 1760. He became a bookseller's clerk, and published two novels, *Les Amours du chevalier de Faublas* (1787–89), and *Emilie de Varmont,* which attracted some attention. *Paris justifié,* a reply to Mounier's proposal that the court should be established elsewhere (Oct. 1789), led to Louvet's election to the Jacobin club, and he energetically opposed the moderate constitutional royalty advocated by Lafayette and others. On Dec. 25, 1791 he presented at the bar of the assembly his *Pétition contre les princes.*

Louvet was elected deputy to the assembly, and attached himself to the Girondists, publishing, at Roland's expense, a biweekly *journal-affiche* called *La Sentinelle* (March-Nov. 1792). On Aug. 10 he became editor of the *Journal des Débats,* in which he violently attacked Robespierre, Marat and the other Montagnards. His violent invective, coupled with his courageous attitude at the trial of Louis XVI, discredited the Girondists, and he fled after the crisis of May 31, 1793. (*See* GIRONDISTS.)

After Robespierre's fall, Louvet was recalled to the convention and elected a member of the committee of the constitution, president of the assembly, and a member of the committee of public safety. He advocated union among republicans in *La Sentinelle,* which he revived. Under the directory (1795) he was elected member and secretary of the Council of Five Hundred. The bookseller's shop which he had again set up in the Palais Royal was attacked, and Louvet and his wife again fled from Paris. He was appointed consul at Palermo, but died on Aug. 25, 1797, before taking up his post.

Louvet published a part of his memoirs in 1795 under the title *Quelques notices pour l'histoire et le récit de mes périls depuis le 31 mai 1793,* giving a vivid picture of the sufferings of the proscribed Girondists. The first complete edition was published in 1889, ed. F. A. Aulard, *Mémoires de Louvet de Couvrai.*

LOUVIERS, a town of France, in the department of Eure, 17½ mi. S.S.E. of Rouen. Pop. (1936) 9,744. Louviers was originally a *villa* of the dukes of Normandy and in the middle ages belonged to the archbishops of Rouen; its cloth-making industry arose in the beginning of the 13th century. It changed hands many times during the Hundred Years' War, and from Charles VII it received extensive privileges, and the title of Louviers le Franc for the bravery of its inhabitants in driving the English from Pont de l'Arche, Verneuil and Harcourt. It passed through various troubles successively at the period of the League of the Public Weal under Louis XI, in the religious wars (when the parlement of Rouen sat for a time at Louviers) and in the wars of the Fronde. Louviers lies on the Eure. The old part of the town is built of wood; the more modern portions, in brick and hewn stone. The Gothic church of Notre-Dame has a south portal of the 15th century; it contains stained glass of the 15th and 16th centuries. The chief industries are cloth, fancy goods and flannel, leather-work, metal and bell founding.

LOUVOIS, FRANÇOIS MICHEL LE TELLIER, MARQUIS DE (1641–1691), French statesman, war minister of Louis XIV, was born at Paris on Jan. 18, 1641. He was the son of Michel le Tellier, whom he succeeded as war minister in 1666. His talents were perceived by Turenne in the war of Devolution (1667–68), who gave him instruction in the art of providing armies. After the peace of Aix-la-Chapelle, Louvois organized the French army. The work of Louvois in the years 1668–72 is bound up with the historical development of the French army and of armies in general. (*See* ARMY.) Louvois reorganized the military orders of merit, founded the Hôtel des Invalides, and enrolled the nobility and gentry of France for service in the army or at court. The success of his measures is to be seen in the victories of the great war of 1672–78. After the peace of Nijmwegen Louvois was high in favour, his father had been made chancellor, and the influence of Colbert was waning. The surprise of Strassburg in 1681 in time of peace was planned and executed by Louvois and Monclar.

A saving clause in the revocation of the Edict of Nantes, which provided for some liberty of conscience, if not of worship, Louvois sharply annulled. He claimed the credit of inventing the dragonnades, and mitigated their rigour only in so far as licence was prejudicial to discipline. Colbert died in 1683, and Louvois took the ministry for public buildings. Louvois died suddenly on July 16, 1691. Louvois was a war minister only equalled by Carnot. Both organized old armies on a new system, both were admirable contrivers of campaigns, and both devoted themselves to the material well-being of the soldiers. In private life and in the means employed for gaining his ends, Louvois was unscrupulous. His sudden death caused a suspicion of poisoning.

The principal authority for Louvois's life and times is Camille Rousset's *Histoire de Louvois* (1872), a great work founded on the 900 volumes of his despatches at the Depôt de la Guerre. Saint-Simon from his class prejudices is hardly to be trusted, but Madame de Sévigné throws many side lights on his times. *Testament politique de Louvois* (1695) is spurious; L. André, *M. Le Tellier de Louvois et l'organisation de l'armée monarchique* (1906).

LOUYS, PIERRE (1870–1925), French novelist and poet, was born at Paris on Dec. 10, 1870. When he was 19 he founded a review, *La Conque,* which brought him into contact with the leaders of the Parnassians, and counted Swinburne, Maeterlinck, Mallarmé and others among its contributors. He won notoriety by his novel *Aphrodite* (1896), which gave a vivid picture of Alexandrian morals at the beginning of the Christian era. His *Chansons de Bilitis, roman lyrique* (1894), which purported to be a translation from the Greek, is a glorification of Sapphic love, whose delicate decadent prose is typical of a modern French literary school. Some of the "songs" were set to music by Debussy and others. Later books are: *La Femme et le pantin* (1898); *Les Aventures du roi Pausole* (1900); *Sanguines* (1903); *Archipel* (1906). He died on June 4, 1925.

See Gaubert, *Pierre Louys* (1904).

LOVAT, SIMON FRASER, 12TH BARON (*c.* 1667–1747), Scottish chief and Jacobite intriguer, was born about 1667 and was the second son of Thomas Fraser, third son of the 8th Lord Lovat. Young Simon was educated at King's College, Aberdeen, and one of his first acts on leaving college was to recruit 300 men from his clan to form part of a regiment in the service of William and Mary, in which he himself was to hold a command. Among other outrages in which he was engaged about this time was a rape and forced marriage committed on the widow of the 10th Lord Lovat with the view apparently of securing his own succession to the estates. A prosecution having been instituted against him by Lady Lovat's family, Simon retired first to the Highlands, and afterward (1702) to the court of St. Germain.

He planned to land 5,000 French troops at Dundee, where they might reach the northeastern passes of the Highlands in a day's march, and divert the British troops till the Highlands should have time to rise. Immediately afterward 500 men were to land on the west coast, seize Fort William or Inverlóchy, and thus prevent the access of any military force from the south to the central Highlands. His plan was continuously kept in view in all future attempts of the Jacobites, and finally acted on in the outbreak of 1745. Lovat was despatched (1703) on a secret mission to ascertain what forces the chiefs might bring into the field. He found little disposition to rebellion, and he then decided to reveal all that he knew to the government of Queen Anne. He persuaded the duke of Queensberry that his rival, the duke of Atholl, was in the Jacobite plot, and that if Queensberry supported him he could obtain evidence of this at St. Germain. Queensberry foolishly entered into the intrigue with him against Atholl, but when Lovat had gone to France with a pass from Queensberry the affair was betrayed to Atholl by Robert Ferguson, and resulted in Queensberry's discomfiture. The story is obscure, and is complicated by partisanship on either side; but Lovat was certainly playing a double game. Suspicions got afloat as to Lovat's proceedings, and on his return to France he was imprisoned in the castle of Angoulême. He remained nearly ten years under supervision, until in Nov. 1714 he made his escape to England.

For about 25 years after this he was chiefly occupied in lawsuits for the recovery of his estates and the re-establishment of his fortune. The intervals were filled by Jacobite and Anti-Jacobite intrigues, in which he betrayed both parties. When the rebellion of 1745 broke out, Lovat represented to the Jacobites that his weak health and advanced years prevented him from joining the standard of the prince in person, while to the Lord President Forbes he professed his cordial attachment to the house of Hanover, and expressed regret that his son had joined the Pretender and taken with him a strong force from the clan of the Frasers. The truth was that the lad was unwilling to go, but was compelled by his father. After the battle of Culloden he was obliged to retreat to the Highlands. Lovat, after enduring extreme hardships in his wanderings, was at last arrested on an island in Loch Morar. He was conveyed in a litter to London, and after a trial of five days sentence of death was pronounced on March 19, 1747. He was beheaded on April 9.

His son SIMON FRASER, Master of Lovat (1726–1782) (not to be confused with another Simon Fraser who saw somewhat similar service and was killed in 1777 at the battle of Saratoga), was a soldier, who at the beginning of the Seven Years' War raised a corps of Fraser Highlanders for the English service, and at the outbreak of the U.S. War of Independence raised another regiment which took a prominent part in it. He fought under Wolfe in Canada, and also in Portugal, and rose to be a British major-general. The family estates were restored to him, but the title was not revived until 1837.

See *Memoirs of Lord Lovat* (1746 and 1767); J. Hill Burton, *Life of Simon, Lord Lovat* (1847); J. Anderson, *Account of the Family of Frizell or Fraser* (Edinburgh, 1825); A. Mackenzie, *History of the Frasers of Lovat* (Inverness, 1896); Mrs. A. T. Thomson, *Memoirs of the Jacobites* (1845–46); and W. C. Mackenzie, *Simon Fraser, Lord Lovat* (1908); *Papers relating to Simon, Lord Lovat* edited by J. R. N. Macphail (1924).

LOVEBIRD, a name bestowed, chiefly by dealers and their customers, on some of the smaller short-tailed parrots, from the affection which examples of opposite sexes exhibit towards each other. They belong to the genera *Forpus* (5 spp.) and *Agapornis* (9 spp.), the former being South American, the latter African. One of the birds most commonly called lovebird, which, however, bears no near relationship to the above, but is a small, long-tailed parrot, is the budgerigar (*Melopsittacus undulatus*) now familiar throughout the world, being bred by hundreds in aviaries. Its native country is Australia. (*See* BUDGERIGAR.)

LOVEDALE, a mission station in the Victoria East division of the Cape province, South Africa. It lies 1,720 ft. above the sea on the banks of the Tyumie (Chumie) tributary of the Keiskama river, some 2 mi. N. of Alice, a town 88 mi. N.W. by rail of East London. The station was founded in 1824 by the Glasgow Missionary Society and was named after Dr. John Love, one of the leading members of the society.

Until 1841 the missionaries devoted themselves almost entirely to evangelistic work; in that year the Lovedale Missionary Institute was founded by the Rev. W. Govan, who, save for brief intervals, continued at its head until 1870. He was then succeeded by the Rev. James Stewart (1831–1905), who had joined the mission in 1867, having previously (1861–63), and partly in company with David Livingstone, explored the Zambezi regions. To Stewart, who remained at the head of the institute till his death, is due the existing organization at Lovedale. The institute, in addition to its purely church work—in which no sectarian tests are allowed—provides for the education of natives of both sexes in nearly all branches of learning (Stewart discontinued the teaching of Greek and Latin, adopting English as the classic); it also takes European scholars, no colour distinction being allowed in any department of the work.

The institute gives technical training in many subjects and maintains various industries, including such diverse enterprises as farming and printing-works. It also maintains a hospital. The school buildings rival in accommodation and completeness those of the schools in large English cities. The educational and industrial methods initiated at Lovedale have been widely adopted by other missionary bodies. Lovedale is now a branch of the work of the United Free Church of Scotland. The institute had approximately 900 students in 1938.

See R. Young, *African Wastes Reclaimed and Illustrated in the Story of the Lovedale Mission* (1902); J. Stewart, *Lovedale, Past and Present* (1884), and *Dawn in the Dark Continent* (1903); J. Wells, *Stewart of Lovedale* (1908).

LOVEJOY, ELIJAH (1802–1837), U.S. abolitionist, was born at Albion, Me., on Nov. 9, 1802, and graduated at Waterville college in 1826. The following year he moved to St. Louis, Mo., where he established a school and entered journalism. Later he began to publish a religious paper called *The Observer* in which he strongly condemned slavery and recommended gradual emancipation. A letter in 1835 signed by a number of the important men of St. Louis requested him to moderate the tone of his editorials. He replied in an editorial reiterating his views and his right to publish them. Threats of mob violence forced him to move his press across the Mississippi river to Alton, Ill. There his press was destroyed by mobs several times in one year, and on the night of Nov. 7, 1837, when a mob attacked the building, Lovejoy was killed in its defense. The news of his death stirred the people of the north profoundly and led greatly to the strengthening of abolitionist sentiment.
